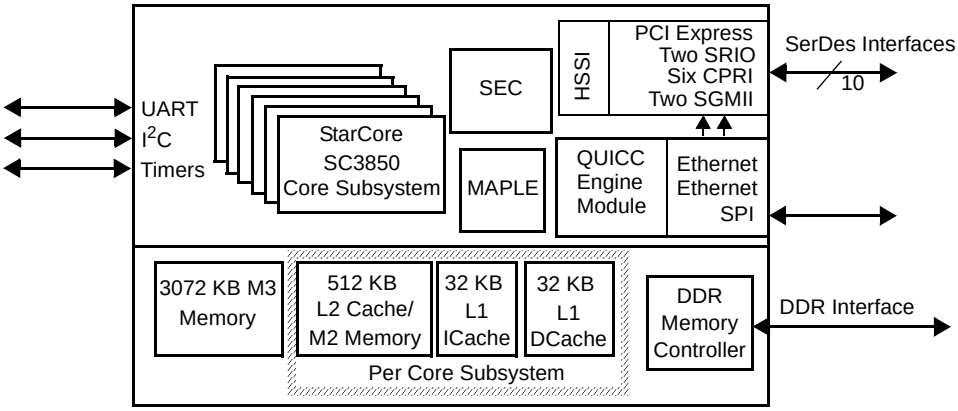
16 Serial RapidIO Controller and Enhanced Message Complex

17 PCI Express Controller

About This Book

The MSC8157E device is the fourth generation of Freescale high-end multicore DSP devices. It builds upon the proven success of the previous multicore DSPs and is designed to support the 3G-LTE (FDD and TDD), HSPA+, LTE-Advanced, and WiMAX markets. Its tool suite provides a full-featured development environment for C/C++ and assembly languages as well as ease of integration with third-party software, such as off-the-shelf libraries and a real-time operating system. The MSC8157E device includes six DSP core subsystems, a large internal memory subsystem and DDR memory controller for external memory, and a variety of communication processors and interfaces.



Six DSP Core Subsystems

Each DSP core subsystem includes an SC3850 DSP core, a 32 KB 8-way level 1 ICache, a 32 KB 8-way level 1 DCache, 512 KB level 2 cache configurable as M2 memory, a memory management unit, an embedded programmable interrupt controller (EPIC) with up to 256 interrupts and 32 priority levels, two general-purpose 32-bit timers, an on-chip emulator (OCE), a debug and profiling unit (DPU), a JTAG test access port (TAP), and two low-power operating modes (Wait and Stop). Interface from the cores to the memories and external interfaces is through a chip-level arbitration and switching system (CLASS).

Memory Subsystem

The memory subsystem includes 3072 KB of shared M3 memory, one DDR-SDRAM controller to access up to 2 GB of DDR3/3L external memory, and a 32-channel direct memory access (DMA) controller optimized for DDR-SDRAM.

MAPLE-B2

The second-generation multi-accelerator platform engine (MAPLE-B2) provides Turbo or Viterbi decoding, Turbo encoding and rate matching, MIMO MMSE, IRC and ML equalization schemes, matrix operations, CRC insertion and check, DFT/iDFT and FFT/iFFT calculations, and Chip Rate acceleration.

Communications Processors and Interfaces

Includes a PCI Express interface, two serial RapidIO interfaces, six CPRI lanes, a UART interface, an I^2C interface, eight timer input/outputs, and a QUICC Engine module with two 1000Base-T Ethernet controllers and an SPI. In addition, the global interrupt controller (GIC) consolidates all chip-maskable and non-maskable interrupts and routes them to $\overline{\text{NMI\_OUT}}$, $\overline{\text{INT\_OUT}}$, and to the cores. The hardware semaphores allow initiators to protect and reserve the system hardware resources.

Security Engine (SEC)

The optional SEC has an internal bus controller, 4 data channels, 6 execution units, and a shared random number generator for communications security applications encryption/ decryption

Before Using This Manual—Important Note

This manual describes the structure and function of the MSC8157E device. The information in this manual is subject to change without notice, as described in the disclaimers on the title page of this manual. As with any technical documentation, it is your responsibility as the reader to ensure that you are using the most recent version of the documentation. For more information, contact your sales representative.

Before using this manual, determine whether it is the latest revision and whether there are errata or addenda. To locate any published errata or updates associated with this manual or this product, refer to the Freescale web site. The address for the web site is listed on the back cover of this manual.

Audience and Helpful Hints

This manual is intended for software and hardware developers and applications programmers who want to develop products with the MSC8157E. It is assumed that you have a working knowledge of DSP technology and that you may be familiar with Freescale products based on StarCore technology.

For your convenience, the chapters of this manual are organized to make the information flow as predictably as possible. When feasible, the information in each chapter follows this general sequence:

- General description, block diagram, features, and architecture
- Functional description with operating modes and example applications and programming
- Programming Model (registers)

In chapters that include a Programming Model section, this section is the last one in the chapter, or module subsection for those chapters that include multiple modules, and describes all registers for the module discussed. The Programming Model section begins with a bulleted overview of the registers that includes the page number where the description of each register begins.

Notational Conventions and Definitions

This manual uses the following notational conventions:

mnemonics	Instruction mnemonics appear in lowercase bold.
COMMAND names	Command names are set in small caps, as follows: GRACEFUL STOP TRANSMIT or ENTER HUNT MODE.
italics	Book titles in text are set in italics, as are cross-referenced section titles. Also, italics are used for emphasis and to highlight the main items in bulleted lists.
0x	Prefix to denote a hexadecimal number.
0b	Prefix to denote a binary number.
REG[FIELD]	Abbreviations or acronyms for registers or buffer descriptors appear in uppercase text. Specific bits, fields, or numeric ranges appear in brackets. For example, ICR[INIT] refers to the Force Initialization bit in the host Interface Control Register.
ACTIVE HIGH SIGNALS	Names of active high signals appear in sans serif capital letters, as follows: TT[04], TSIZ[0–3], and DP[0–7].
$\overline{\text{ACTIVE LOW SIGNALS}}$	Signal names of active low signals appear in sans serif capital letters with an overbar, as follows: $\overline{\text{DBG}}$, $\overline{\text{AACK}}$, and $\overline{\text{EXT\_BG[2]}}$.
x	A lowercase italicized x in a register or signal name indicates that there are multiple registers or signals with this name. For example, BRCG*x* refers to BRCG[1–8], and M*x*MR refers to the MAMR/MBMR/MCMR registers.

On the MSC8157E device, the SC3850 cores are 16-bit DSP processors. The following table shows the SC3850 assembly language data types. For details, see the *StarCore SC3850 DSP Core Reference Manual*.

Name	SC3850
Byte/Octet	8 bits
Half Word	8 bits
Word	16 bits
Long/Long Word/2 Words	32 bits
Quad Word/4 Words	64 bits

The following table lists the SC3850 C language data types recognized by the StarCore C compiler. For details, see the *StarCore SC100 C Compiler User's Manual (MNSC100CC/D)*.

Name	Size
char/unsigned char	8 bits
short/unsigned short	16 bits
int/unsigned int	16 bits

Name	Size
fractional short	16 bits
long/unsigned long	32 bits
fractional long	32 bits
pointer	32 bits

Conventions for Registers

The Programming Model section of each chapter includes a register bit table for each register in that module, as well as a table describing each bit in the register. The register bit table not only shows the names and positions of the bits/bit fields but also their reset value, value after boot, and their type (Read/Write). For registers that are not changed by the system boot, no boot line is listed. The register address is shown with the register name and mnemonic. Reserved bits/fields are indicated with a long dash (—). In the RSR shown below, all of the bits are read/write (R/W). Other registers may include read-only (R) and write-only (W) bits. Notice that the least significant bit (LSB) is 0, or big-endian order.

RSR Reset Status Register Offset 0x10

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCWSRC			—					SW0	SW1	SW2	SW3	SW4	SW5	SW6	SW7
Type	R/W															
Reset	RCW_SRC[0–2]			1	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	BSF	—	SWHR	RM	JPO	JH	—					RIO2	RIO1	RS	—
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Organization

Following is a summary and a brief description of the chapters of this manual:

- **Chapter 1, *Overview***. Features, descriptive overview of main modules, configurations, and application examples.
- **Chapter 2, *SC3850 Core Overview***. Target markets, features, overview of development tools, descriptive overview of main modules.
- **Chapter 3, *External Signals***. Identifies the external signals, lists signal groupings, including the number of signal connections in each group, and describes each signal within a functional group.
- **Chapter 4, *Chip-Level Arbitration and Switching System (CLASS)***. Describes the system switch fabric that allows multi-initiator access to the internal memory and devices and enables high-bandwidth internal data transfers with few bottlenecks.

- **Chapter 5, *Reset***. Covers reset sources, causes, and configurations; gives examples of different reset configuration scenarios, including systems with multiple MSC8157E devices.
- **Chapter 6, *Boot Program***. Describes the bootloader program that loads and executes source code to initialize the MSC8157E after it completes a reset sequence and programs its registers for the required mode of operation. This chapter covers selection of bootloader modes, normal sequence of events for bootloading a source program, and booting in a multi-processor environment.
- **Chapter 7, *Clocks***. Contains an overview of the MSC8157E clock modules.
- **Chapter 8, *General Configuration Registers***. Contains a detailed description of the general configuration registers.
- **Chapter 9, *Memory Map***. Defines the address spaces for all MSC8157E modules; includes cross references to all registers discussed.
- **Chapter 10, *SC3850 DSP Subsystem***. Describes the structure of the DSP core subsystem, which includes the SC3850 core, the instruction cache (ICache), the data cache (DCache), L2/M2 memory, memory management unit (MMU), two 32-bit timers, the embedded programmable interrupt controller (EPIC), and the on-chip emulator (OCE).
- **Chapter 11, *Internal Memory Subsystem***. Describes the structure and operation of the L1 ICache, L1 DCache, L2/M2 memory, and M3 memory.
- **Chapter 12, *DDR SDRAM Memory Controller***. Describes the how the memory controller interface works and how to program it. This interface increases the efficiency of accesses through the DDR memory controller to external DDR memory.
- **Chapter 13, *Interrupt Handling***. Discusses the interrupt controllers that provide maximum flexibility in handling MSC8157E interrupts, enabling interrupts to be handled by the SC3850 cores internally, by an external host, or by a combination of the two; also discusses source priority schemes.
- **Chapter 14, *Direct Memory Access (DMA) Controller***. Describes the different DMA operating modes, transfer types, and buffer types. The chapter also gives procedures for programming different types of transfers. The multi-channel DMA controller includes hardware support for up to 16 time-multiplexed channels including buffer alignment. The DMA controller supports flyby transactions on either bus. and enables hot swaps between channels, by using time-multiplexed channels that impose no cost in clock cycles.
- **Chapter 15, *High Speed Serial Interface (HSSI) Subsystem***. Describes subsystem that supports and multiplexes the Serial RapidIO, PCI Express, and SGMII signals across the dual SerDes PHY ports and how the dedicated DMA controllers support the serial RapidIO interfaces and PCI Express interface and how to program them.
- **Chapter 16, *Serial RapidIO Controller and Enhanced Message Complex***. Describes the how the serial RapidIO interfaces and eMSG complex work and how to program them.

- **Chapter 17, *PCI Express Controller***. Describes the how the PCI Express interface works and how to program it.
- **Chapter 18, *Common Public Radio Interface (CPRI) Complex***. Describes how the CPRI complex works and how to program it.
- **Chapter 19, *QUICC Engine Subsystem***. Describes the QUICC Engine module, the Ethernet controllers, and the serial peripheral interface (SPI). Detailed information is referenced in the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM).
- **Chapter 20, *UART***. Describes the UART interface, which is a full-duplex serial port used to communicate with other devices.
- **Chapter 21, *Timers***. Discusses the 32 identical 16-bit general-purpose timers residing in four timer modules, 16 identical 32-bit general purpose timers residing in two timer modules, and the 8 system watchdog timers and their sets of configuration registers.
- **Chapter 22, *GPIO***. Discusses the thirty-two GPIO signals. Sixteen of the signals can be configured as external interrupt inputs. Each pin is multiplexed with other signals and can be configured as a general-purpose input, general-purpose output, or a dedicated peripheral pin.
- **Chapter 23, *Hardware Semaphores***. Describes the function and programming of the hardware semaphores, which control resource sharing.
- **Chapter 24, *I2C***. Describes the I^2C interface. which allows the MSC8157E to boot from a serial EEPROM device.
- **Chapter 25, *Debugging, Profiling, and Performance Monitoring***. Includes aspects of the JTAG implementation that are specific to the SC3850 core and should be used with the supporting **IEEE** Std. 1149.6 documentation. The discussion covers the items that the standard requires to be defined and provides additional information specific to the MSC8157E implementation. Also includes debugging resources available in the SC3850 DSP core subsystem, including the OCE modules, and L2 ICache module.
- **Chapter 26, *Multi Accelerator Platform Engine, Baseband 2 (MAPLE-B2)***. Describes the architecture, function, and register and memory structures used by the second-generation multi-accelerator platform engine (MAPLE-B2) for Channel Decoding/Encoding, Fourier Transforms, UMTS chip rate processing, OFDMA and SC-FDMA equalization and CRC algorithms. The MAPLE-B2 includes a quad-RISC programmable control processor, a second generation Programmable-System-Interface (PSIF2) that is a programmable controller with DMA capabilities, and ten accelerators.
- **Chapter 27, *Security Engine (SEC)***. Describes the architecture, function, and register and memory structures used for security algorithm processing.

Other MSC8157E Documentation

You can find the following documents on the Freescale Semiconductor web site listed on the back cover of this manual.

- *MSC8157E Data Sheet (*MSC8157E*)*. Details the signals, AC/DC characteristics, clock signal characteristics, package and pinout, and electrical design considerations of the MSC8157E device.
- *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM). Describes all functional blocks supported by the QUICC Engine technology, provides detailed programming registers and guidelines, and indicates which QUICC Engine blocks and functionality are supported by specified Freescale products.
- *MSC8157/8 Design Checklist* (AN4110). Identifies resources and provides guidance for developing applications using the MSC8157/8 DSP devices. It includes a check list for design phases of projects that incorporate the MSC8157/8 DSPs.
- *Differences Between the MSC8156 and the MSC8157 DSPs* (EB720). Indicates functional differences between the earlier generation MSC8156 and the MSC8157 DSPs.
- *Differences Between the MSC8157 and the MSC8158 DSPs* (EB723). Indicates functional differences between the devices in the MSC8157 DSP family.
- *Other documents.* Application Notes and Engineering Bulletins that cover various board layout and programming topics related to the StarCore DSP core and the MSC8157E device.

Further Reading

The following documents are available with a signed non-disclosure agreement (see your Freescale representative or distributor for details):

- *SC3850 DSP Core Reference Manual*. Covers the SC3850 core architecture, control registers, clock registers, program control, on-chip emulator (OCE), and instruction set.
- *SC3850 DSP Core Subsystem Reference Manual*. Covers the SC3850 DSP core subsystem which includes an SC3850 DSP core, a memory management unit (MMU), and instruction channel with L1 ICache, a data channel with L1 DCache, an embedded programmable interrupt controller (EPIC), real-time debug support with the core OCE and a JTAG interface and a debug and profiling unit (DPU), and a dual timer.

Revision	Date	Change Description
2	Jan 2012	• **Chapter 5, *Reset*** – Updated rows for bit 17 and bit 16 in **Table 5-5**, **Table 5-7**, and **Table 5-9**. • **Chapter 8, *General Configuration Registers*** – Updated SerDes PLL designators in the descriptions for bits 19 and 18 in **Table 8-7**. • **Chapter 15, *High Speed Serial Interface (HSSI) Subsystem*** – Add EATTR settings in **Table 15-29**. – Updated the description of the LA[2–1] row in **Table 15-37**. – Split old **Section 15.10.52** into two: **Section 15.10.52** and **Section 15.10.53** to describe SRDB1RSTCTL and SRDB2RSTCTL individually. – Updated FRATE_SEL settings description in **Table 15-62**. • **Chapter 21, *Timers*** – Added an updated version of **Section 21.1.8**, *Special CPRI Support* which had been removed in Rev. 1.

1 Overview

The MSC8157E device is the fourth generation of Freescale high-end multicore DSP devices that target the communications infrastructure and delivers the industry's highest level of performance and integration. It builds upon the proven success of the previous multicore DSPs and is designed to support the rapidly changing and expanding broadband wireless markets, with support for 3G-LTE (FDD and TDD), HSPA+, LTE-Advanced, and WiMAX processing. The MSC8157E is carefully optimized for minimal cost, power, and area per channel. The highly flexible, fully-programmable and powerful MSC8157E broadband wireless access DSP offers tremendous processing power while maintaining a competitive price and high performance.

The highly integrated MSC8157E DSP device includes the following:

- Six StarCore SC3850 DSP subsystems each running at up to 1 GHz with an architecture optimized for wireless applications.
- One high-speed industry-standard DDR3 memory interface.
- Multi-Accelerator Platform Engine for Baseband 2 (MAPLE-B2) supports hardware acceleration for Turbo or Viterbi decoding, Turbo encoding and rate matching, MIMO MMSE, IRC and ML equalization schemes, matrix operations, CRC insertion and check, DFT/iDFT and FFT/iFFT calculations, and Chip Rate acceleration.
- High-Speed Serial Interface (HSSI) subsystem (10-lane) that supports
  - Two serial RapidIO interfaces
  - Two Gigabit serial Ethernet interfaces
  - Six CPRI channels
  - One PCI-Express controller
- QUICC Engine dual RISC-based subsystem to guarantee reliable data transport over packet networks while significantly off loading such processing from the DSP cores that supports:
  - Two gigabit Ethernet controllers with RGMII and SGMII support
  - One SPI
- 16 bidirectional channels DMA controller
- UART interface
- I^2C interface

- Security Engine Core (SEC) to support multiple security algorithms and networking protocols, including IPSec and accelerates data plane encryption/decryption and code protection with minimal DSP cores intervention.

1.1 Features

The MSC8157E includes the following features:

- StarCore DSP subsystem. The DSP subsystem includes:
  - StarCore SC3850 core
    - Running at up to 1 GHz
    - Up to 8000 16-bit MMACS. A MAC operation includes a multiply-accumulate command with the associated data moves and a pointer update.
    - Backwards binary compatible with the SC140 and SC3400 architectures.
    - Data Arithmetic and Logic Unit (DALU) containing 4 ALUs, each capable of performing 2 16 × 16 multiply accumulate operations, effectively doubling the performance of convolution-based kernels relative to the SC3400 core
    - New instructions double the performance of complex and extended precision multiplication.
    - Address Generating Unit (AGU) containing 2 Address Arithmetic Units (AAU)
    - Up to six instructions executed in a single clock cycle: 4 DALU and 2 AGU instructions
    - Variable-length Execution Set (VLES) execution model.
    - 16 data registers, 40 bits each; 27 address registers, 32 bits each.
    - Hardware support for fractional and integer data types.
    - Four hardware loops with near-zero cycle overhead
    - Very rich 16-bit wide orthogonal instruction set.
    - Application specific instructions for Viterbi and Multimedia.
    - Special SIMD (Single instruction, multiple data) instructions working on 2-word or 4-byte operands packed in a register, enabling to perform 2 to 4 operations per instruction (8 to 16 operations per VLES)
    - New dedicated instructions accelerate FFTs enabling a 40% cycle count reduction and improved SNR
    - User and Supervisor privilege levels, supporting a protected SW model
    - New instructions and features to improve control code performance
    - Precise exceptions for memory accesses enabling good RTOS support and Soft Error corrections
    - Branch Target Buffer (BTB) for acceleration of change of flow operations

— L1 ICache:
  - 32 Kbytes
  - 8 ways with 16 lines of 256 bytes per line
  - Multi-task support
  - Real-time support through locking flexible boundaries
  - Line pre-fetch capability
  - Software coherency support
  - Software pre-fetch support by core instructions
— L1 DCache:
  - 32 Kbytes
  - 8 ways with 16 lines of 256 bytes per line
  - Capable of serving two data accesses in parallel (XA, XB)
  - Multi-task support
  - Real-time support through locking flexible boundaries
  - Software coherency support
  - Writing policy programmable per memory segment as either write-back or write-through
  - 0.25 Kbytes Write-back Buffer (WBB)
  - Six 64-bit entry WTB
  - Line pre-fetch capability
  - Software pre-fetch, synchronize, and flush support by core instructions
— Unified L2 Cache/M2 Memory:
  - 512 Kbyte
  - 8 ways with 1024 indexes and a 64 byte line
  - Physically addressed
  - Dynamically configured as a DMA accessible M2 Memory
  - Maximum user flexibility for real time support through address partitioning of the cache
  - Support various write policies and methods to reduce cache inclusiveness
  - Multi-channel, two dimensional software pre-fetch support
  - Software coherency support with seamless transition from L1 cache coherency operation.
— Memory management unit (MMU):
  - Highly flexible memory mapping capability
  - Provides virtual to physical address translation
  - Provides task protection

- Supports multi-tasking
- Supports precise interrupts. Enabling to have an open RTOS.

— Debug and Profiling Unit (DPU) block:
- Supports the debugging and profiling of the platform in cooperation with the OCE Block
- Supports various breakpoint and event counting options
- Supports real-time tracing to the main memory with the Trace Write Buffer (TWB)

— Extended programmable interrupt controller (EPIC)
- 256 interrupts
- 32 priority levels with NMI support

— Two general-purpose 32-bit timers
— Low-power design with the following modes of operation:
- Wait processing state for peripheral operation
- Stop processing state

— ECC/EDC support.

■ Multi Accelerator Platform Engine for Baseband 2 (MAPLE-B2)
— Two operating modes: 3G mode (3GLTE and UMTS standards) and WiMAX mode (**IEEE** 802.16e and 802.16m standards).
— Second Generation Programmable System Interface (PSIF2)
- Software friendly buffer descriptor based handshake and task assignment.
- Support for high priority and low priority tasks via multiple descriptor rings.
- Processing elements management and scheduling.
- Four 128-bit master buses for data transfers from/to the system memory.
- Two 128-bit slave buses for the following purposes:
  — General purpose connection to CLASS, allowing any host or peripheral to access the MAPLE-B2 internal memories for placing job-descriptors in the PSIF2 internal memories or read/write data from/into PEs internal memories. This port is a read/write port and is referred to as MBus Slave0 port.
  — .Direct connection to CPRI for direct data transfer between the Antenna interface and MAPLE-B2. This port is a write only port and is referred to as MBus Slave1 port.
- Interrupt or RapidIO Door Bell generation and/or status bit indication on job or multiple jobs completion.
- System memory utilized only for input/output data, all the internal calculations are performed using MAPLE-B memories.

— Turbo decoding for WiMAX, UMTS and 3GLTE systems using an eTVPE module:
- Turbo decoder, rate-dematcher and HARQ combining acceleration

- Each decoder scalable with 1, 2, or 4 Radix 4 dual-recursion engines
- Binary and duo-binary codes
- Trellis termination and tail biting
- Various rate de-matching functions support for rate 1/3 code including sub-block de-interleaving and de-interlacing
- Max Log Map or Linear Log Map (MAX*)
- Non Linear Dynamics extrinsic factorization
- Programmable number of iterations
- Multiple stop conditions: CRC check, hard output compare and a-posteriori quality indication
- SIMD type of operation utilizing high level of hardware parallelism to provide high throughput and low latency channel decoding capabilities

— Turbo encoding for WiMAX OFDMA, 3GLTE DL/UL-SCH and UMTS systems using DEPE module:
- Information bits encoding and rate matching up to 1.8 Gbps for 3GLTE and WiMAX
- Code block CRC attachment and filler bits insertion for 3GLTE
- Bit randomization for WiMAX
- Transport block CRC attachment in 3GLTE in case of single code block.
- Information bits encoding and rate matching up to 900 Mbps for UMTS
- HS-DSCH and E-DCH (TDD and FDD) Turbo encoding and rate matching.
- CRC attachment for Transport Block $\leq$ 5090.
- Optional bit scrambling for Transport Block $\leq$ 5090 (FDD only).
- Transport Block generation assist in system memory using bit write granularity
- Transport Block segmentation assist using bit read granularity.

— Viterbi decoding for various technologies using eTVPE[1] module:
- Supports K =5,7,9
- Fully programmable polynomials
- Various rates/puncturing cases

— DFT/iDFT and FFT/iFFT processing using three eFTPE modules:
- Variable length FFT/iFFT processing of 128, 256, 512, 1024, 1536 and 2048 points.
- Variable length DFT/iDFT processing of the form, up to 1200 points: 12, 24, 36, 48, 60, 72, 96, 108, 120, 144, 180, 192, 216, 240, 288, 300, 324, 360, 384, 432, 480, 540, 576, 600, 648, 720, 768, 864, 900, 960, 972, 1080, 1152 and 1200 points

1.Viterbi and Turbo decoding share memories and share throughput; 100% throughput of Viterbi and 100% throughput of Turbo cannot be achieved simultaneously.

- Variable input data size, supporting 16 bit {8I,8Q} or 32 bit {16I,16Q}
- Programmable guard band insertion and removal for iFFT and FFT processing.

– Programmable Cyclic Prefix insertion and removal.

- Pre-Multiplication (“array multiplication”) support by programmable complex values vector.
- Post-Multiplication support of all samples by programmable complex values vector.
- Phase rotation of input samples.
- Input data complex conjugate and re-ordering (1 to N samples reversed to N to 1)
- Zero padding of input data
- UMTS scrambled pilot samples generation in frequency domain
- Programmable scaling method, supporting one of the following methods:
- Automatic adaptive scaling using overflow detection between transform stages, and optional programmable overall scaling factor for the output data
- User defined scaling between transform stages
- Automatic or programmable input scale up for input data with small values, to increase calculation precision.

— CRC check and insertion using CRCPE:

- CRC check & report for UL processing
- CRC insertion for DL processing
- Up to 10 Gbps, supporting the following polynomials:
  - CRC24 with polynomial $D^{24} + D^{23} + D^6 + D^5 + D + 1$
  - CRC24 with polynomial $D^{24} + D^{23} + D^{18} + D^{17} + D^{14} + D^{11} + D^{10} + D^7 + D^6 + D^5 + D^4 + D^3 + D + 1$
  - CRC16 with polynomial $D^{16} + D^{12} + D^5 + 1$
  - CRC16 with polynomial $D^{16} + D^{15} + D^2 + 1$
  - CRC32 with polynomial $D^{32} + D^{26} + D^{23} + D^{22} + D^{16} + D^{12} + D^{11} + D^{10} + D^8 + D^7 + D^5 + D^4 + D^2 + D + 1$
  - CRC18 with polynomial $D^{18} + D^{17} + D^{14} + D^{13} + D^{11} + D^{10} + D^8 + D^7 + D^6 + D^3 + D^2 + 1$
  - CRC12 with polynomial $D^{12} + D^{11} + D^{10} + D^8 + D^5 + D^4 + 1$
  - CRC6 with polynomial $D^6 + D^5 + D^3 + D^2 + D + 1$

— MMSE (Minimum Mean Square Error) / ZF (Zero Forcing)/ IRC (Interference Rejection Combining) Equalization

- Estimation of signal by MMSE/ZF/IRC equalizer using following inputs:

- Observations, channel estimation, noise and transmitted layers covariance matrices and previously detected layer (for cancellation)
- Inputs precision 32 bit {16I,16Q} with block floating point 8 bit scaling factor.
- Supporting various Rx Antenna (1,2,4,8) and MIMO layers (1,2,3,4) configurations
- Optional Channel Estimation interpolation with user defined weights.
- Embedded support for advanced receivers with iterative interference cancellation schemes with internal single layer cancellation, rank reduction, layer discarding and MIMO layers covariance matrix.
- Optional support for full noise & interference covariance matrix, with variable granularity, up to different matrix per sub-carrier (RE).
- Flexible output format supporting 32 bit {16I,16Q} with optional block floating point representation using 8 bit scaling factor per element or per group of elements.

— Maximum Likelihood estimation implemented with QRD-M tree search

- Estimation of signal by QRD-M equalizer using following inputs:
- observations, channel estimation, noise variance.
- Supporting various Rx Antenna (1,2,4,8[1]) and MIMO layers (1,2,3,4) configurations.
- Optional Channel Estimation interpolation with user defined weights.
- Configurable search width, with M up to 64[2], providing performance-latency trade-off.
- LLR output generation.

— Matrix Inversion

- Support for up to 4×4 matrix inversion.
- Programming model optimized for batch job of multiple matrix inversions.
- High precision floating-point arithmetic
- Input samples are received in 32 bit {16I,16Q} block floating point (BLF) with 8-bit scale factor.
- Internal calculations performed using custom floating-point (FLP) format: 40 bit {20I,20Q} mantissa and 8-bit exponent.

— Downlink Chip Rate Processing:

- Capacity of up to 512 Physical Channels including MIMO, STTD, TSTD and Closed Loop Mode 1 operation per channel.
- Input data precision of 16 bit {8I,8Q} complex symbols.

1. In case of 8 Rx antenna system, QR decomposition is executed by DSP cores externally to MAPLE-B2 and QR matrices are input to MLD equalization and detection.
2. M=64 supported for up to 2 layers, M=32 for higher number of layers

- Spreading with SF 4,8,16,32,64,128, and 256 using internally generated channelization codes.
- Scrambling using internally generated, up to 32 independent codes, including support for compressed mode codes.
- Supporting SF 1 special channels with spreading, scrambling bypass
- Programmable complex gains per Physical Channel, with differentiation between data and control information, supporting various slot formats.
- Physical channels combining and flexible assignment to up to 16 virtual antenna's.
- Optional Beam Forming operation on combined Physical Channels.
- Output data precision of 32 bit {16I,16Q} complex chips.

— Uplink Batch Processing - for data and control channels with variable spreading factors

- Capacity of up to 384 Physical Channels with up to 2144 total fingers from up to 24 antenna streams with max 512 chips delay spread.
- Optional pre-de-spreading support with up to 80 Physical Channels with SF 4
- Input data precision of 16 bit {8I,8Q} complex chips.
- Optional Internal interpolation of x2 oversampled input stream, up to x16 resolution using programmable 8 tap polyphase filter.
- Despreading with SF 2,4,8,16,32,64,128,256 using internally generated channelization codes.
- Descrambling by short or long codes, with up to 384 different, internally generated, scrambling codes.
- Optional fingers combining using programmable weights.
- Optional frequency correction functionality using programmable correction factor.
- Multiple output formats:
  - 16 bit fixed point or custom 22 bit (16-bit mantissa and 6-bit exponent) floating point formats for fingers combining option.
  - complex 32 bit {16I,16Q} for fingers combining bypass option.

— Uplink Fast Processing - for (E)DPCCH processing

- Capacity of up to 400 Physical channels with up to 3200 total fingers from up to 24 antenna streams.
- Input data precision of 16 bit {8I,8Q} complex chips.
- Optional Internal interpolation of x2 oversampled input stream, up to x16 resolution using programmable 8 tap polyphase filter.
- Descrambling by short or long codes with internally generated scrambling codes.
- Despreading using SF 256 for DPCCH and E-DPCCH channels.
- Optional correlation with pilot sequence.

- Programmable slot format and early/on-time/late processing for various fields of control channels.
- Output 16 bit I and 16 bit Q.
- Internal commands FIFO for flexible updates of fingers and channels association.
- Latency of 68 chips including processing and write back of results to system memory

— PN code generator
- Short or Long codes generation based on programmable init values
- Generates scrambling code or scrambling code multiplied by Hadamard code with programmable spreading factor and OVSF.
- Two output formats:
- 16 bit {8I,8Q} format, with throughput of up to 4 Gsamples/s
- 2 bit {1I, 1Q} format, with throughput of up to 32 Gsamples/s

— Easily initialized and configured with minimal intervention:
- Software-friendly buffer descriptor handshake mechanism and task assignment
- Externally accessible memories and registers for debug purposes
- Internal, high throughput, DMA capabilities to fetch the input data and output the results to system memory
- Internal memory used for all module processing

— Multi-core support: Multiple configurable descriptor rings with support for high and low priority tasks
— System notification can generate RapidIO doorbells or interrupts on task completion
— Programmable customization including processing management and scheduling: Second Generation of Programmable System Interface (PSIF2)
— When it is not required, the MAPLE-B power can be disabled internally to reduce overall device power consumption.

■ The Security Engine (SEC) includes 8 different execution units (EUs). For EUs for which data flows in and out, each EU has buffer FIFOs of at least 256 bytes. EU types and features include the following:

— Advanced Encryption Standard Unit (AESU)
- Implements the Rijndael symmetric key cipher per U.S. National Institute of Standards and Technology FIPS 197.
- Modes providing data confidentiality: ECB, CBC, CCM, Counter, GCM, XTS, CBC-RBP, OFB-128, and CFB-128.
- Modes providing data authentication: CCM, GCM, CMAC (OMAC1), and XCBC-MAC.
- 128, 192, 256 bit key lengths (only 128 bit keys in XCBC-MAC)
- ICV checking in CCM, GCM, CMAC (OMAC1), and XCBC-MAC mode

- XOR operations on 2–6 sources for RAID applications

— ARC Four Execution Unit (AFEU)
- Implements a stream cipher compatible with the RC4 algorithm
- 8-bit to 128-bit programmable key

— Cyclic Redundancy Check Unit (CRCU)
- Implements CRC32C as required for iSCSI header and payload checksums, CRC32 as required for **IEEE** Standard 802 packets, as well as for programmable 32 bit CRC polynomials
- ICV checking

— Data Encryption Standard Execution Unit (DEU)
- DES, 3DES
- Two key (K1, K2, K1) or Three Key (K1, K2, K3)
- ECB, CBC, CFB-64 and OFB-64 modes for both DES and 3DES

— Kasumi Execution Unit (KEU)
- Implements cipher and authentication modes F8 and F9 used in 3G, A5/3 for GSM and EDGE, and GEA3 for GPRS
- 128-bit confidentiality key and 128-bit integrity key
- ICV checking for F9

— SNOW3G Execution Unit (STEU)
- Implements cipher and authentication modes UEA2 (F8) and UIA2 (F9)
- 128-bit confidentiality key and 128-bit integrity key
- ICV checking for F9

— Message Digest Execution Unit (MDEU)
- Implements SHA with 160-bit, 224-bit, 256-bit, 384-bit, and 512-bit message digest (as specified by the FIPS 180-2 standard)
- Implements MD5 with 128-bit message digest (as specified by RFC 1321)
- Implements HMAC computation with either message digest algorithm (as specified in RFC 2104 and FIPS-198)
- Implements SSL MAC computation
- ICV checking

— Public Key Execution Unit (PKEU)
- RSA and Diffie-Hellman with programmable field size up to 4096 bits
- Elliptic curve cryptography
  - — F_2m and F_p modes
  - — Programmable field size up to 1023 bits
- Run time equalization to protect against timing and power attacks

- Random Number Generator (RNGU). Combines a True Random Number Generator (TRNG) and a NIST-approved Pseudo-Random Number Generator (PRNG) (as described in Annex C of FIPS140-2 and ANSI X9.62).

- Chip-level arbitration and switching system (CLASS)
  - A full fabric that arbitrates between the DSP cores and other CLASS masters to the core M2 memory, shared M3 memory, DDR SDRAM controller, MAPLE-B2, and the device configuration control and status registers (CCSRs).
  - High bandwidth.
  - Non-blocking allows parallel accesses from multiple initiators to multiple targets.
  - Fully pipelined.
  - Low latency.
  - Per target arbitration highly optimized to the target characteristics using prioritized round-robin arbitration.
  - Reduces data flow bottlenecks and enables high-bandwidth internal data transfers.
- Internal memory. The 4608 Kbyte internal memory space includes:
  - 32 Kbyte L1 ICache per core.
  - 32 Kbyte L1 DCache per core.
  - 512 Kbyte unified L2 Cache/M2 Memory per core.
  - 3072 Kbyte shared triple-bank, triple-port M3 memory. Power supply of two banks (2048 Kbyte) can be turned off to reduce power dissipation.
  - 96 Kbyte boot ROM accessible from the cores.
- Clocks
  - Four input clocks:
    - Global input clock.
    - Two differential input clocks (one per each SerDes PLL).
    - Optional DDR clock
  - Six PLLs:
    - Three system PLLs
    - Two SerDes PLLs
    - DDR Controller PLL
  - Clock ratios selected during reset via reset configuration pins.
  - Clock modes user-configurable after reset.
- One DDR Controller supporting:
  - Up to 667 MHz clock rate (1333 MHz data rate).
  - Supports DDR3 devices
  - Programmable timing
  - Support for a 64-bit data interface (72 bits including ECC), up to 1333 MHz data rate
  - Support for a 32-bit data interface (40 bits including ECC), up to 1333 MHz data rate

- Full ECC support for single-bit error correction and multi-bit error detection up to the maximum specified data rates
- Two banks of memory via two chip selects. Each chip select supports up to 2 Gbytes, but memory total cannot exceed 2 Gbytes.
- DRAM chip configurations from 64 Mbits to 4 Gbits with x8/x16 data ports
- Support burst lengths of 4 (burst chop) and On the Fly
- Sleep mode support for self-refresh SDRAM
- On-die termination support
- Supports auto refreshing
- Support for SODIMMs

■ DMA Controller

- 32 unidirectional channels, providing up to 16 memory-to-memory channels.
- Buffer descriptor programing model.
- Up to 1024 buffer descriptors per channel direction provide a total of 32 Kbyte buffer descriptors. Buffer descriptors can reside in M2 or DDR memories.
- Priority-based time-multiplexing between channels, using four internal priority groups with round-robin arbitration between channels on equal priority group.
- Earliest deadline first (EDF) priority scheme that assures task completion on time.
- Flexible channel configuration with all channels supporting all features.
- A flexible buffer configuration, including:
  - Simple buffers
  - Cyclic buffers
  - Single address buffers (I/O device).
  - Incremental address buffers
  - Chained buffers
  - 1D to 4D buffers, optimized for video applications
  - 1D or 2–4D complex buffers, a combination of buffer types
- Two external DMA request (DREQ) and two $\overline{\text{DONE}}$ signal lines that allow an external device to trigger DMA transfers.
- High bandwidth
- Optimized for DDR SDRAM

■ High-Speed Serial Interface (HSSI)

- Ten multiplexed SerDes lanes
- Serial RapidIO Subsystem
  - Two Serial RapidIO ports supporting x1/x2/x4 operation up to 5 Gbaud with a RapidIO enhanced messaging unit (eMSG) and two RapidIO DMA units.
  - Each x1/x2/x4 Serial RapidIO endpoint operates at 1.25/2.5/3.125/5 Gbaud and complies with the following parts of Specification 2.1 of the RapidIO trade association interconnect specification:

- Part I (input and output logical specifications)
- Part II (message passing logical specification)
- Part III (common transport specification)
- Part VI (physical layer 1x LP-serial specification)
- Part VIII (error management extension specification)

- Each Serial RapidIO port supports read, write, messages, doorbells, data streaming and maintenance accesses:
  - Small and large transport information field only
  - All priorities flow
  - Pass-through between the two ports that allows cascading devices using the Serial RapidIO and enabling message/data path between the two Serial RapidIO ports without core intervention. A message/data that is not designated for the specific device passes through it to the next device.
- RapidIO Enhanced Messaging Unit supports:
  - RapidIO Interconnect Specification 1.3, Part 2: Message Passing Logical Specification.
  - RapidIO Interconnect Specification 1.3, Part 10: Data Streaming Logical Specification.
  - RapidIO Interconnect Specification 2.1, Part 10: Stream Management Flow Control. Basic stream management flow control (XON/XOFF) using extended header message format.
  - 64 outbound queues allowing multi-core environment.
  - 16 concurrent inbound reassembly operations. One additional reserved reassembly for inbound unit 0 to carry session management protocol.
  - Multi unicast.
- Each RapidIO DMA unit supports:
  - Four high-speed/high-bandwidth channels accessible by local and remote masters
  - Basic DMA operation modes (direct, simple chaining)
  - Extended DMA operation modes (advanced chaining and stride capability)
  - Programmable bandwidth control between channels
  - Up to 256 bytes for DMA sub-block transfers to maximize performance over the RapidIO interface
  - Three priority levels supported for source and destination transactions

- Common Public Radio Interface (CPRI) Controller

- Supports v4.1 of the CPRI standard
- Up to 6 lanes
- Supports 1.2288 Gbaud, 2.4576 Gbaud, 3.072 Gbaud, 4.9152 Gbaud and 6.144 Gbaud
- Supports scrambling
- Daisy-chain capability that allows cascading devices according to pre-determined user configuration. Chaining can be done for each lane using the CPRI controller. Chaining lanes does not require core intervention or internal device bandwidth overhead.
- Input power can be disabled for system power reduction if CPRI is not required.

— PCI-Express Controller

- Complies with the *PCI Express Base Specification, Revision 2.0*
- Supports root complex (RC) and endpoint (EP) configurations
- 32- and 64-bit address support
- x4, x2, and x1 link support
- Supports 2.5 Gbaud, 5.0 Gbaud.
- Supports accesses to all PCI Express memory and I/O address spaces (requestor only)
- Supports posting of processor-to-PCI Express and PCI Express-to-memory write
- Supports strong and relaxed transaction ordering rules
- PCI Express configuration registers (type 0 in EP mode, type 1 in RC mode)
- Baseline and advanced error reporting support
- One virtual channel (VC0)
- 256-byte maximum payload size (MAX_PAYLOAD_SIZE)
- Supports three inbound general-purpose translation windows and one configuration window
- Supports four outbound translation windows and one default window
- Supports eight non-posted and four posted PCI Express transactions
- Supports up to six priority 0 internal platform reads and eight priority 0 to 2 internal platform writes. (The maximum number of outstanding transactions at any given time is eight.)
- Credit-based flow control management
- Supports PCI Express messages and interrupts

■ The QUICC Engine subsystem includes dual RISC processors and 48-Kbyte multi-master RAM to handle the Ethernet and SPI interfaces, thus off loading the tasks from the cores. The three communication controllers support:

— Two Ethernet Controllers

- Two Ethernet physical interfaces:
  - 1000 Mbps SGMII protocol using a 4-pin SerDes interface multiplexed through the HSSI SerDes port.
  - 1000 Mbps RGMII protocol
- MAC-to-MAC connection in all modes
- Full-duplex operations
- Full-duplex flow control feature (**IEEE** Std. 802.3x)
- Receive flow control frames
- Detection of all erroneous frames as defined by **IEEE** Std. 802.3-2002
- Multi-buffer data structure
- Diagnostic modes: Internal and external loopback mode and echo mode
- Serial management interface MDC/MDIO
- Transmitter network management and diagnostics
- Receiver network management and diagnostics
- VLAN Support
- **IEEE** Std. 802.1p/Q QoS
- Eight Tx/Rx queues
- Queuing decision for IP/MAC/UDP filtering based on MAC destination addresses, IP destination address, and UDP destination port
- Programmable maximum frame length
- Enhanced MIB statistics
- Optional shift of data buffer by two bytes for L3 header alignments
- Extended features
  - IP header checksum verification and calculation
  - Parsing of frame headers and adding a frame control block at the frame head, containing L3 and L4 information for CPU acceleration

— Serial peripheral interface (SPI)

- Four-signal interface (SPI_MOSI, SPI_MISO, SPI_CK and SPI_SL)
- Full-duplex operation
- Works with 32-bit data characters, or with a range from 4-bit to 16-bit data characters•Supports back-to-back character transmission and reception
- Supports master or slave SPI mode
- Supports multiple-master environment
- Continuous transfer mode for automatic scanning of a peripheral
- Maximum clock rate is (QUICC Engine clock)/8 in master mode and (QUICC Engine clock)/4 in slave mode (not in back-to-back operation)

- Independent programmable baud rate generator
- Programmable clock phase and polarity
- Local loopback capability for testing
- Open-drain outputs support multimaster configuration
- Communication with Ethernet PHY for configuration and status (MIIMCOM-MII management communication protocol)
- Multi-MIIMCOM environment with up to 32 PHYs
- Programmable clock gap between two characters in master mode
- Controlled by the DSP cores and the QUICC Engine RISC processors according to user configuration.

- I/O Interrupt Concentrator consolidates all chip maskable interrupt and non-maskable interrupt sources and routes them to $\overline{\text{INT\_OUT}}$, $\overline{\text{NMI\_OUT}}$, and the cores.
- UART
  - Bit rate up to 6.25 Mbps
  - Two signals for transmit data and receive data
  - Full-duplex operation
  - Standard mark/space non-return-to-zero (NRZ) format
  - 13-bit baud rate selection
  - Programmable 8-bit or 9-bit data format
  - Separately enabled transmitter and receiver
  - Programmable transmitter output polarity
  - Separate receiver and transmitter interrupt requests
  - Receiver framing error detection
  - Hardware parity checking
  - 1/16 bit-time noise detection
  - Single-wire and loop operations
- Timers
  - Two general-purpose 32-bit timers for RTOS support per SC3850 core
  - Four TMR modules, each with four 16-bit timers; cascadable timers; count up/down; programmable count modulo; count once or repeatedly; counters are preloadable; compare registers can be preloaded; counters can share available inputs; separate prescaler for each counter; each counter has capture and compare capability; any of the following clock sources: system clock or external clock input
  - Two TIMER_32B modules, each with four 32-bit timers; cascadable timers; count up/down; programmable count modulo; count once or repeatedly; counters are preloadable; compare registers can be preloaded; counters can share available inputs; separate prescaler for each counter; each counter has capture and compare capability; any of the following clock sources: system clock or external clock input.
  - Eight software watchdog timer (SWT) modules

- Eight programmable hardware semaphores, locked by simple write access without need for read-modify-write operation by the DSP core.
- Virtual interrupts
  - Generation of 32 virtual interrupts by a simple write access
  - Generation of virtual $\overline{\text{NMI}}$ by a simple write access
- I^2C interface
  - Two-wire interface
  - Multi-master operational
  - Calling address identification interrupt
  - START and STOP signal generation/detection
  - Acknowledge bit generation/detection
  - Bus busy detection
  - Programmable clock frequency
  - On-chip filtering for spikes on the bus
- General-purpose input/output (GPIO) ports:
  - 32 GPIO ports
  - Each GPIO port can either serve the on-device peripherals or act as a programmable I/O pin
  - Sixteen GPIO pins can be configured as external interrupt inputs
  - All ports are bidirectional
  - All ports are set as GPIO inputs at system reset
  - All port values can be read while the pin is connected to an internal peripheral
  - All ports have open-drain output capability
- Boot interface options:
  - Ethernet
  - Serial RapidIO interface
  - I^2C
  - SPI
- JTAG. Test Access Port (TAP) and Boundary Scan Architecture designed to comply with **IEEE** Std. 1149.6.
- Reduced power dissipation
  - Very low power CMOS design
  - Low-power standby modes
  - Optimized power management circuitry (instruction-dependent, peripheral-dependent, and mode-dependent)
- Technology: The MSC8157E device is manufactured using CMOS 45 nm SOI technology.
- Flip Chip-Plastic Ball Grid Array (FC-PBGA), 783-ball, 1 mm pitch, 29 mm × 29 mm

1.2 Block Diagram

A block diagram of the MSC8157E is shown in **Figure 1-1**.

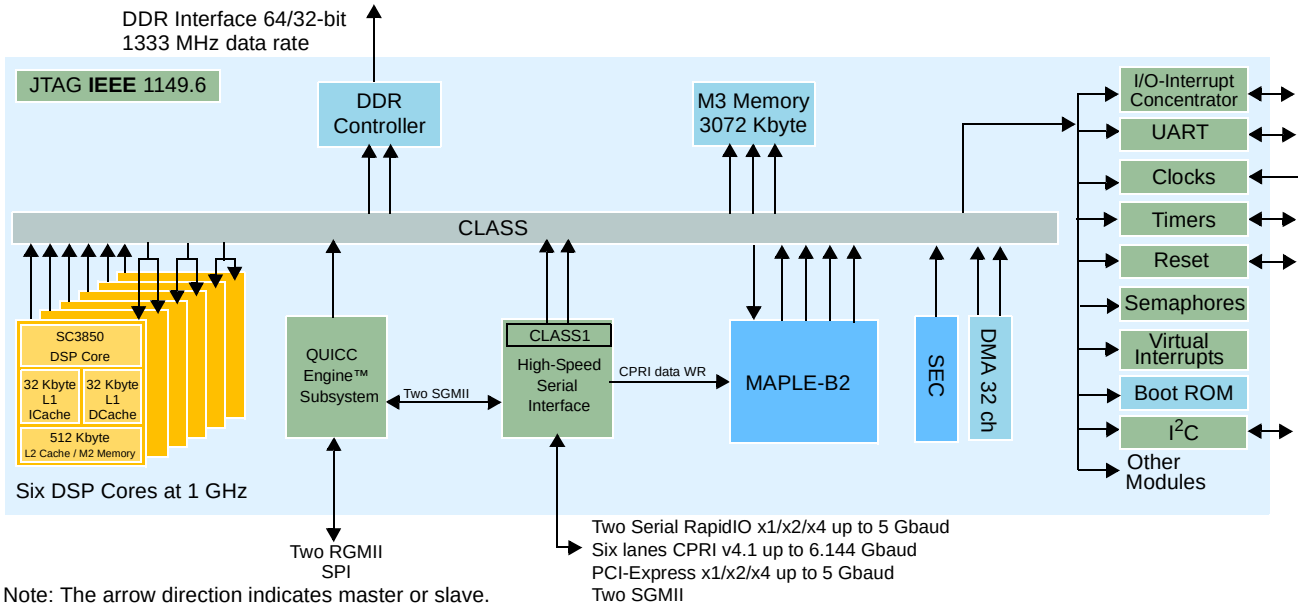

Figure 1-1. MSC8157E Block Diagram

1.3 Architecture

The MSC8157E architecture is carefully optimized to achieve the maximum channel density for a given device area, power, and cost. Also, the MSC8157E is a derivative of the same system internal platform Freescale uses to implement new DSPs. Therefore, Freescale can swiftly spin off DSP devices from the same platform and provide the customer with familiar modules and programming models.

1.4 StarCore SC3850 DSP Subsystem

Figure 1-2 shows the block diagram of the StarCore SC3850 DSP subsystem, which contains the SC3850 core, the ICache, the DCache, the MMU for task and memory protection and address translation and two write buffers. In addition, there is an interrupt controller, two timers, a debug and profiling unit, and a trace write buffer. The SC3850 core fetches instructions through a 128-bit wide program bus (P-bus), and it fetches data through two 64-bit wide data buses (Xa-bus and Xb-bus). After a brief overview of the DSP platform, this section presents a subsection on each part of the platform.

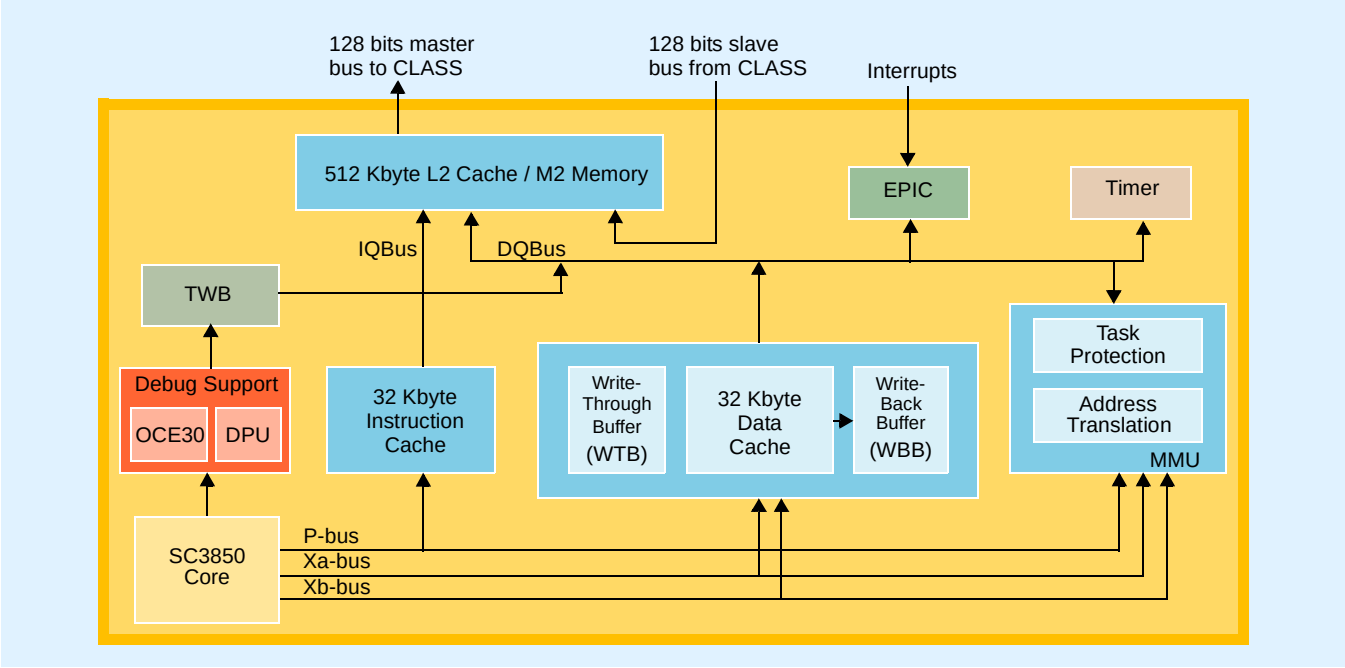

Figure 1-2. StarCore SC3850 DSP Subsystem Block Diagram

Instruction/data read accesses are performed as follows:

- Non-cacheable instructions/data are read from the target memory (for example, M2 memory).
- Cacheable instructions/data are read from the ICache/DCache. If they do not reside in the cache (a miss), they are first fetched directly from the target memory.

There are three write policies when writing data outside the core:

- *Cacheable write-back*. Information is written only to the cache. The modified cache lines are written to main memory only when they are replaced. The subsequent write-back buffer is combined with the write-allocate write-miss policy in which the required lines are loaded to the cache whenever a write-miss occurs.
- *Cacheable write-through*. Both the cache and the higher-level memory are updated during every write operation. In the StarCore SC3850 DSP subsystem, the write-through buffer is

a non-write allocate buffer. Therefore, a cacheable write-through access does not update the cache unless there is a hit.

- *Non-cacheable*. The write is direct to memory and is not written to the cache. A hazard mechanism ensures that read accesses read updated data.

The DSP subsystem supports a Real-Time Operating System (RTOS) as follows:

- Virtual-to-physical address translation in the MMU.
- Two privilege levels: user and supervisor.
- Memory protection.
- Precise exceptions upon an MMU violation enabling dynamic memory management.

The embedded programmable interrupt controller (EPIC) handles up to 256 interrupts with 32 priorities, 222 of which are external platform inputs.

1.4.1 StarCore SC3850 DSP Core

The SC3850 core is a flexible, programmable DSP core that handles compute-intensive communications applications, providing high performance, low power, and high code density. It is fully binary-backward compatible with the MSC8101, MSC8102, MSC8103, MSC8112, MSC8113, MSC8122, MSC8126, MSC8144, and MSC8144E DSPs, and it introduces many new features and enhancements.

The SC3850 core includes a data arithmetic logic unit (DALU) that contains four arithmetic logic units (ALUs). The core also includes an address generation unit (AGU) that contains two address arithmetic units. The SC3850 efficiently deploys the variable-length execution set (VLES) execution model, allowing grouping of up to 4 DALU and 2 AGU instructions in a single clock cycle without sacrificing code size for unused execution slots.

Each ALU has two 16-bit × 16-bit multipliers and a 40-bit accumulation capability, a 40-bit parallel barrel shifter and a 40-bit adder/subtractor. Each ALU performs one MAC operation per clock cycle, so a single core running at 1 GHz can perform up to 8 GMACS. Each AAU in the AGU can perform one address calculation and drive one data memory access per cycle. Data access widths are flexible from 8 to 64 bits. The AGU can support a throughput of up to 128 Gbps between the core and the memory.

Arithmetic operations use both fractional and integer data types, enabling the user to choose an individual style of code development or to use coding techniques derived from an application-specific standard. Parts of many algorithms use data with reduced width such as 8 or 16 bits. For better efficiency, the SC3850 core also supports single-instruction multiple-data (SIMD) instructions working on 2-word or 4-byte operands packed in a register. This packing allows the core to perform 2 to 4 operations per instruction (a maximum of 10 to 18 operation per VLES including AGU operations).

A new dual 20-bit packed data format enables you to accumulate two multiplication results from the dual multiply ALU into a single register with guard bits. Alternatively, accumulation of both multiplies can be combined into a single 40-bit accumulator (dot product). In addition, the SC3850 supports special instructions to support special operations, such as Viterbi and video applications.

Although the SC3850 is a DSP, the rich instruction set also gives special attention to control code, making the SC3850 core ideal for applications that embed DSP and communications operations as general control code. Among the features that support control code are the interlocked pipeline that solves dependency hazards. The powerful SC3850 compiler translates code written in C/C++ into parallel fetch sets and maintains high code density and/or high performance by taking advantage of these features and the compiler-friendly instruction set. Even compiled pure control code yields results with high code density.

The SC3850 core supports general micro-controller capabilities, making it a suitable target for advanced operating systems. These capabilities include support for user and supervisor privilege levels that enable (with the off-core MMU) a protected software model implementation. Precise exceptions for memory accesses allow implementation of advanced memory management schemes and soft error correction.

The SC3850 core includes a dynamic branch prediction mechanism that contains a 48-entry branch target buffer (BTB) to improve performance by reducing the change of flow latency.

1.4.2 L1 Instruction Cache

The instruction channel, which comprises the instruction cache (ICache) and the instruction fetch unit (IFU), provides the core with instructions that are stored in higher-level memory. The ICache operates at core speed and stores recently accessed instructions. Whenever an addressed instruction (from the cacheable memory area) is found in the array, it is immediately made available to the core (ICache hit). When the required address is not found in the array, it is loaded to the ICache from the external (off-subsystem) memory by the IFU (ICache miss). The IFU operates in parallel with the core to implement a HW line prefetching algorithm that loads the ICache with information that has a high probability of being needed soon. This action reduces the number of cache misses. When an instruction is addressed from a non-cacheable area, the IFU fetches it directly to the XP bus of the core without writing it to the cache.

1.4.3 L1 Data Cache

The data channel comprises the data cache (DCache), the data fetch unit (DFU), the data control unit (DCU), the write-back buffer (WBB), and the write-through buffer (WTB). This two-way channel reads and writes information from the core to/from higher-level memory (M2 or L2) and control memory (internal blocks and external peripherals) spaces.

The DCache, which operates at core speed, keeps the recently accessed data. When addressed data (from a cacheable memory area) is found in the array, it is immediately made available to the core (DCache hit) in a read and updated if written to. When the required address is not found in the array, a DCache miss occurs, and the DFU loads the data to the DCache from the external (off-subsystem) memory and drives it to the core. The DFU operates in parallel with the core and implements a HW line prefetch algorithm that loads the DCache with information that has a high probability of being needed soon, thus reducing the number of data cache misses.

The channel differentiates between cacheable and non-cacheable addresses. For cacheable addresses, it supports the write-back allocate and write-through writing policies. The selection is made on an address segment basis, as programmed in the MMU. The data channel supports the arrangement of data in big-endian formats. Core data types can be byte, word, long (4 bytes), or 2 long (8 bytes) wide.

1.4.4 L2 Unified Cache/M2 Memory

The L2 cache processes data and program accesses to the external M3/DDR memory. Caching the accesses requested by the L1 subsystem reduces the average penalty of accessing the high latency M3. The L2 cache includes a slave arbitration and tag unit, cache logic and arrays, along with a write buffer for write back and write through accesses, fetch logic to fetch data from the off platform memory upon a miss or a non-cacheable access, and a master arbiter that arbitrates between the different internal units.

1.4.5 Memory Management Unit (MMU)

The MMU performs three main functions:

- Memory hardware protection for instruction and data access with two privilege levels (user and supervisor).
- High-speed address translation from virtual to physical address to support memory relocation.
- Cache and bus controls for advanced memory management

Memory protection increases the reliability of the system so that errant tasks cannot ruin the privileged state and the state of other tasks. Program and data accesses from the core can occur at either the user or supervisor level. The MMU checks each access to determine whether it matches the permissions defined for this task in the memory attributes and translation table (MATT). If it does not, the access is killed and a memory exception is generated.

1.4.6 Debug and Profiling Unit (DPU)

The on-chip emulator (OCE) and the debug and profiling unit (DPU) are hardware blocks for debugging and profiling. The OCE performs the following tasks:

- Communicates with the host debugger through the SoC JTAG test access port (TAP) controller
- Enables the SC3850 core to enter the debug processing state upon a varied set of conditions to:
  - Single step
  - Execute core commands inserted from the host debugger to upload and download memory and core registers.
- Sets up to six address-related breakpoints on either PC or a data address
- Sets a data breakpoint on a data value, optionally combined with a data address
- Generates the PC tracing flow, optionally filtered to a subset of events such as only jumps/returns from subroutine, interrupts, and so on.

The DPU has the following characteristics:

- Enables parallel counting of subsystem events in six dedicated counters, from more than 40 events
- Filters, processes, and adds task ID and profiling information on the OCE PC trace information

1.4.7 Extended Programmable Interrupt Controller

The internal extended programmable interrupt controller (EPIC) manages internal and external interrupts. The EPIC handles up to 256 interrupts, 222 of which are external subsystem inputs. The rest of the interrupts serve internal subsystem conditions. The external interrupts can be configured as either maskable interrupts or non-maskable interrupts (NMIs). The EPIC can handle 33 levels of interrupt priorities, of which 32 levels are maskable at the core and 1 level is NMI.

1.4.8 Timer

The timer block includes two 32-bit general-purpose counters with pre-loading capability. It counts clocks at the core frequency. It is intended mainly for operating system use.

1.5 MAPLE-B2

Decoding/Encoding, Fourier Transforms, UMTS chip rate processing, OFDMA and SC-FDMA equalization and CRC algorithms. The MAPLE-B2 consists of second generation Programmable-System-Interface (PSIF2), a programmable controller with DMA capabilities. Eight accelerators are attached to it:

- eTVPE (Enhanced Turbo/Viterbi Processing-Element). Accelerates Turbo Decoding, Rate-De-Matching and HARQ combining.
- Three eFTPE (enhanced FFT/DFT Processing-Element). Accelerates various sizes of Fourier transforms and various pre/post transform processing.
- DEPE (Turbo Encoder Processing-Element). Accelerates Turbo Encoding and Rate Matching.
- EQPE (Equalization Processing-Element). Accelerates MMSE and MLD types of equalization algorithms and Matrix Inversion.
- CRPE (Chip Rate Processing-Element). Accelerates Downlink and Uplink UMTS chip rate processing
- CRCPE (CRC Processing-Element). Accelerates CRC attachment or check.

In addition to the eight accelerators, MAPLE-B2 provides virtual processing elements which enable chained functionality of multiple processing elements:

- Convolution or Filtering functionality utilized by combination of eFTPE and EQPE.
- Turbo Decoding and Re-encoding including rate matching using combination of eTVPE and DEPE.
- MMSE equalization combined with DFT and/or IDFT functions utilizing eFTPE and EQPE.

1.6 Security Engine (SEC)

The Security Coprocessor version 3.1.0 (SEC) performs computationally intensive security functions including the following:

- Key generation and exchange
- Authentication
- Bulk encryption.

It is optimized to process all the algorithms associated with internet protocol security (IPSec), internet key exchange (IKE), secure sockets layer/transport layer security (SSL/TLS), internet small computer system interface (iSCSI), secure real-time transport protocol (SRTP), the **IEEE** 802.11i security standard, worldwide interoperability for microwave access (WiMAX), third generation (G3) A3/5 for global system for mobile communication (GSM) and Enhanced Data Rates for GSM evolution (EDGE), and GEA3 for general packet radio service (GPRS). For

applications requiring security protection for sensitive data, the SEC provides encryption/decryption capability without imposing process loading on the device core processors. The SEC includes a controller, four data channels, and eight execution units (EUs) including a shared random number generator (RNGU) that use a common interface to the controller. The EUs perform the specific mathematical manipulations required by protocols used in cryptographic processing.

1.7 Chip-Level Arbitration and Switching System (CLASS)

The Chip Level Arbitration and Switching System (CLASS) is the central internal interconnect system for the MSC8157E device. The CLASS is a non-blocking, full-fabric interconnect that allows any initiator to access any target in parallel with another initiator-target couple. The CLASS uses a fully pipelined low latency design. The CLASS demonstrates per-target prioritized round-robin arbitration, highly optimized to the target characteristics. The CLASS operates at 667 MHz, and is separate from the SC3850 core frequency to provide an optimized trade-off between power dissipation, memory technology, and miss latency. Controlling the intradevice data flow, the CLASS reduces bottle necks and permits high bandwidth fully pipe-lined traffic. The CLASS system is ready for use and does not require any special configuration to perform non-blocking pipelined transactions from any initiator to any memory. The configurable arbitration features described in this chapter are for fine-tuning the system for specific application requirements.

The fifteen CLASS initiators are:

- Six SC3850 core subsystems (initiator ports 0–5)
- Four MAPLE bridges (initiator ports 6–7 and ports 13–14)
- Two HSSI ports shared by two Serial RapidIO controllers, the PCI Express controller, six CPRI controllers, and two SGMIIs (initiator ports 8 and 12)
- Peripherals bridge shared by the SEC, SPI, RGMII, SGMII, and JTAG interface (initiator port 9)
- Two DMA ports (initiator ports 10–11)

The ten CLASS targets are:

- Configuration Control and Status Registers (CCSR) (target port 0)
- Two DDR ports (target ports 1 for writes and 2 for reads)
- MAPLE module (target port 3)
- Three core subsystem bridges (two core subsystems per bridge) (target ports 4–6)
- Three M3 memory ports (target ports 7–9)

1.8 M3 Memory

The 3072 KB M3 memory can be used for both program and data and eliminates the need for an external memory in a variety of applications, thus reducing board space, power dissipation, and cost. The memory is divided into three 1 MB blocks. One block is always on when the chip is powered up; the other two blocks can be powered down. The M3 memory has three 128-bit wide ports and runs at 667 MHz using dense memory technology. The M3 memory supports partial, full, and burst accesses. The M3 memory includes hidden refresh with a low probability of conflict with core accesses, and it supports burstable accesses. If the full M3 memory is not required, power can be turned off to the upper 2048 MB to reduce power consumption.

1.9 Clocks

The MSC8157E device has four input clocks:

- A global input clock.
- Two differential input clocks (one per SerDes PLL).
- MCLKIN (optional) input for the DDR memory

The MSC8157E device includes six PLLs:

- Three system PLLs to support the different internal system clock requirements required by the peripherals and interfaces.
- Two SerDes PLLs.
- DDR Controller PLL

The ratios between the system clocks are selected during reset via reset configuration pins. The clock ratios are selected from a fixed table called clock modes table. The clock modes can be changed by the user after reset.

1.10 DDR Controller (DDRC)

The DDR SDRAM interface is useful when the channel storage size is relatively big and also when more channels are required to supplement the internal memory. When the MSC8157E device works with channel data stored in the DDR SDRAM, the DMA controller can swap the data to and from the M2 memory, thus enabling the L1 DCache to fetch from M2 memory instead of accessing the DDR SDRAM memory directly. Fetch latency is thus reduced, significantly improving the average clock cycles required per task. The M2 and M3 memories are large enough to accommodate the number of channels processed by the DSP subsystems for a variety of applications. However, it is not large enough for memory intensive application, especially when high channel densities are required. For such applications, the MSC8157E can interface with JEDEC-compliant DDR3 SDRAM devices. A DDR SDRAM can be used not only as an extension for the M2 and M3 memories but also to store code. In a typical application,

infrequently used code is either swapped into M2/M3 memory when needed or executed directly from an external DDR SDRAM. The DDR SDRAM interface frequency is decoupled from the DSP subsystem frequency, and it has a separate PLL to deliver the required frequency according to the bandwidth requirements It has a separate strobe per byte. Two logical banks (chip select) are supported, each with logical programmable bank start and end addresses. Programmable parameters allow for a variety of SDRAM organizations and timings. Using data mask bits, the SDRAM controller enables partial write operations to bytes in a word or words in a burst. Optional ECC protection is provided for the DDR SDRAM data bus. Using ECC, the memory controller detects all two-bit errors and corrects all single-bit errors within the 32-bit data bus. For ECC, an additional ECC DDR SDRAM device is usually needed. Both the data DDR SDRAM and the ECC DDR SDRAM should have the same CAS latency. There is page retention for up to four simultaneous open pages, and the number of clocks for which the pages are kept open is programmable. Pages are replaced using a pseudo-LRU replacement algorithm.

1.11 DMA Controller

The DMA controller enables data movement and rearrangement while the DSP cores work independently. The DMA controller transfers blocks of data to and from the M2 memory, M3 memory, and the DDR SDRAM controller. It has 16 high-speed bidirectional channels and can be commanded from each of the DSP subsystems, as well as from an off-device initiator through the RapidIO or PCI using BDs. All channels are capable of complex data movement and advanced transaction chaining. Operations such as descriptor fetches and block transfers are initiated by each of the sixteen channels. Full duplex operation allows the DMA controller to read data from one target and store it in its internal memory while concurrently writing another buffer to another a target. This capability can be used extensively when data is read from the M3 memory and written into the M2 memory. The bidirectional DMA controller reads from one of the CLASS target ports while writing to the second one. The DMA controller supports smart arbitration algorithms such as round robin, bandwidth control, and a timer-based mechanism using an earliest deadline first (EDF) algorithm.

1.12 High Speed System Interface

The High Speed Serial Interface (HSSI) is a 10-port serial communications subsystem that supports multiplexing of the following serial interfaces:

- Two x1/x2/x4 Serial RapidIO ports
- One x1/x2/x4 PCI Express port
- Two SGMII ports
- Six x1 CPRI ports

To support these interfaces, the HSSI includes the following blocks:

- One CLASS1 non-blocking fabric to interface between the HSSI and the system CLASS module.
- One 8-port OCN fabric with two dedicated DMA controllers and two OCN to MBus bridges to provide high-speed memory access with no core intervention for the two Serial RapidIO port controllers and the PCI Express controller. The bridges connect to the CLASS 1 module.
- Two Serial RapidIO port controllers (port 1 and 0) with enhanced messaging unit (eMSG). The RapidIO complex includes an AXI bridge to MBus to connect to the CLASS1 fabric and an eMSG MBus expander and normalizer to connect to the two Serial RapidIO port controllers. The RapidIO complex and eMSG details are provided in **Chapter 16**, *Serial RapidIO Controller and Enhanced Message Complex*.
- One PCI Express controller with a bridge to the OCN fabric. The PCI Express controller details are provided in **Chapter 17**, *PCI Express Controller*
- Six CPRI controllers, described in detail in **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.
- One Protocol Converter module to link the two Serial RapidIO ports, one PCI Express port, six CPRI ports and the two SGMII ports to the SerDes PHY.
- One 10-channel SerDes PHY that multiplexes the RapidIO, PCI Express, CPRI and SGMII signals for external connection.

These communication interfaces allow the cores to execute the data processing code and be relieved from the data transfer and handling overhead for processing serial data flow.

1.12.1 CLASS1

Based on the same design as the system CLASS fabric, CLASS1 uses a fully pipelined low latency design and is the interconnect between the HSSI complex and the system CLASS. Like the CLASS, CLASS1 is a non-blocking, full-fabric interconnect that allows any initiator to access any target in parallel with another initiator-target couple. CLASS1 uses per-target prioritized round-robin arbitration, highly optimized to the target characteristics. CLASS1 is

ready for use and does not require any special configuration to perform non-blocking pipelined transactions from any initiator to any memory. The configurable arbitration features described in this chapter are for fine-tuning the system for specific application requirements.

The Six CLASS1 initiators are:

- OCN-to-MBus bridge 0 (initiator port 0)
- OCN-to-MBus bridge 1 (initiator port 3)
- AXI-to-MBus bridge 0 (initiator port 5)
- AXI-to-MBus bridge 1 (initiator port 2)
- CPRI MBus port 0 (initiator port 4)
- CPRI MBus port 1 (initiator port 1)

The two CLASS1 targets are:

- HSSI port 0 (target port 0). Connects to CLASS initiator port 8.
- HSSI port 1 (target port 1). Connects to CLASS initiator port 12.

1.12.2 OCN Fabric

The On-Chip Network (OCN) fabric is a non-blocking high speed interconnect used for embedded system devices. The MSC8155E DSP HSSI uses an 8-port OCN to connect between the Serial RapidIO Controllers, PCI Express Controller, the two OCN-to-MBus bridges (O2M[0–1]) that connect to the CLASS1 module, and the two supporting dedicated DMA controllers. The OCN requires no programming and provides a seamless interface for the HSSI.

1.12.3 OCN-to-MBus (O2M) Bridges

The O2M bridges provide an interface between the OCN fabric and the CLASS1 module that connects to the system CLASS. The bridges support all mandatory MBus and OCN interface protocol procedures. The bridges provide initiator interfaces to access the target CLASS ports, formats OCN packets, negotiates with the OCN arbiter, and transmits/receives associated transactions.

1.12.4 DMA Controllers

The MSC8157E includes two dedicated DMA controllers that transfer blocks of data between the serial RapidIO controller/PEX Controller and the local address space independent from the DSP cores.

1.12.5 Serial RapidIO Complex

The Serial RapidIO complex includes two ports (SRIO0 and SRIO1) that perform the serial data transfers between the SerDes PHY and the DSP system, an enhanced messaging unit (eMSG),

and the interface bridges that connect between SRIO0 and SRIO1, the eMSG module, and the CLASS1 module. Configuration and functional details for this complex are provided in **Chapter 16**, *Serial RapidIO Controller and Enhanced Message Complex*. Transfers through the SRIO modules can be tracked by the performance monitor. See **Section 25.3**, *Performance Monitor*, on page 25-27 for details.

1.12.6 PCI Express Controller

HSSI includes one PCI Express controller that supports 1x/2x/4x link configuration. It is interfaced to the SerDes Phy through Protocol converter module and connects to the OCN fabric through PEX to OCN bridge. The functional and configuration details are provided in **Chapter 17**, *PCI Express Controller***.**

1.12.7 Protocol Converter

The protocol converter interfaces the Serial RapidIO, PCI Express, CPRI and SGMII signals to the SerDes PHY. It is programmed internally by selections make in the General Configuration Registers and the power-on reset configuration (see **Section 15.10**, *SerDes PHY Interfaces*, on page 15-30).

1.12.8 SerDes PHY Interfaces

The HSSI includes one 10-port SerDes interface that multiplexes the two Serial RapidIO ports, the PCI Express port, six CPRI lanes, and the two SGMII ports from the QUICC Engine subsystem. Multiplexing configuration is determined by the reset configuration word settings (see **Chapter 5**, *Reset* for details).

1.13 QUICC Engine Subsystem

The MSC8157E QUICC Engine module is a versatile communications engine based on a subset of the MPC83XX QUICC Engine subsystem that integrates several communications peripheral controllers. The QUICC Engine module combines interface hardware and RISC firmware to support multimedia packet operations. The QUICC Engine module includes control registers and an interrupt controller to allow the DSP cores to control and monitor operations. These registers configure certain global options and create specific commands related to the communication protocols. The cores issue commands by writing to the QUICC Engine module Command Register (QECMDR). These commands are used to initialize the RISC processors and each specific communications controller while the RISC engines are running. The QUICC Engine module includes various blocks to provide the system with an efficient way to handle data communication tasks, including:

- Two RISC processors, each of which provide:

  - One instruction per clock
  - Code execution from internal ROM or multi-port RAM
  - 32-bit RISC architecture
  - Up to sixteen internal software timers maintained in the multi-port RAM
  - Interface with the core processors through a 48-KB dual-port RAM and virtual DMA channels for each interface controller
  - Ability to handle serial protocols and virtual DMA
- Multi-initiator 48-KB multi-port RAM
- 48-KB instruction RAM (IRAM)
- Serial DMA channel
- Three full-duplex communications controllers:
  - Communications controllers 1 and 3 support IEEE 802.3/Fast Ethernet controllers
- Interrupt controller
- Multiplexer and timers logic
- Baud-rate generators

The internal clocks (RCLK/TCLK) for each communications controller can be programmed to use either an external or internal source. The rate of these clocks can be up to one-half of the QUICC Engine module clock frequency. However, the ability of an interface to support a sustained bit stream depends on the protocol settings and other factors.

1.13.1 Ethernet Controllers

The two identical gigabit Ethernet controllers are based on the enhanced PowerQUICC II Ethernet controller with network statistics. The Ethernet controllers support two standard MAC-PHY interfaces to connect to an external Ethernet transceiver:

- 1000 Mbps SGMII with SerDes support
- 1000 Mbps RGMII (full duplex only)

The Ethernet transmitter requires little core intervention. After the software driver initializes the system, the Ethernet controller activates its transmit scheduler. As a result, the controller starts polling the first transmit buffer descriptor (TxBD) in one of the eight transmit queues as chosen by the scheduler. The TxBD ring is polled every 512 transmit clocks. If TxBD[R] bit is set, the Ethernet controller begins moving transmit buffers from memory to the Tx virtual FIFO. The Ethernet MAC transmitter takes data from Tx virtual FIFO and transmits the data through the appropriate interface (RGMII/SGMII) to the physical media. The transmitter, once initialized, runs until the end-of-frame (EOF) condition is detected, unless a collision within the collision window occurs (in half-duplex mode) or an abort condition is encountered. The Ethernet

Controller receiver can perform pattern matching, data extraction, Ethernet type recognition, CRC checking, VLAN detection, short frame checking, and maximum frame-length checking.

1.13.2 Serial Peripheral Interface (SPI)

The serial peripheral interface (SPI) allows the exchange of data with other devices containing an SPI. The SPI also communicates with peripheral devices such as EEPROMs, real-time clocks, A/D converters, and ISDN devices. The SPI is a full-duplex, synchronous, character-oriented channel that supports a four-wire interface (receive, transmit, clock, and slave select). The SPI block consists of transmitter and receiver sections, an independent baud-rate generator, and a control unit. The transmitter and receiver sections use the same clock, which is derived from the SPI baud rate generator in master mode and generated externally in slave mode. During an SPI transfer, data is sent and received simultaneously.

1.14 Global Interrupt Controller (GIC)

The GIC receives the external and internal $\overline{\text{NMI}}$ and maskable interrupt sources and routes them to the SC3850 cores, to the $\overline{\text{INT\_OUT}}$ lines, or to the $\overline{\text{NMI\_OUT}}$ lines.

1.15 UART

The UART is used mainly for debugging. It provides a full-duplex port for serial communications by transmit data (TXD) and receive data (RXD) lines. During reception, the UART generates an interrupt request when a new character is available to the UART data register. During transmission, the UART generates an interrupt request when its data register can be written with new character. When accepting an interrupt request, an SC3850 core or external host should read the UART status register to identify the interrupt source and service it accordingly.

1.16 Timers

The MSC8157E device contains 16 identical 16-bit timers divided into four groups and 8 identical 32-bit timers divided into two groups. Each of the 16-bit groups (TMR) contains four identical 16-bit timers, each with a prescaler, a counter, a load register, a hold register, a capture register, two compare registers, two status registers, and a control register. Each of the 32-bit groups (TMR_32b) contains four identical 32-bit timers, each with a prescaler, a counter, a load register, a hold register, a capture register, two compare registers, two status registers, and a control register. In addition, each SC3850 subsystem includes eight general purpose 32-bit timers divided into two groups. each with the same basic registers supported by the 16-bit timers. The MSC8157E device also includes 8 software watchdog timers. Each of the software watchdog timers can be used by any of the cores within MSC8157E as well as by an external host.

1.17 Hardware Semaphores

There are eight coded hardware semaphores. Each semaphore is an 8-bit register with a selective write protection mechanism. When the register value is zero, it is writable to any new value. When the register value is not zero, it is writable only to zero. Each SC3850 core/host/task has a unique predefined lock number (8-bit code). When trying to lock the semaphore, the SC3850 core writes its lock number to the semaphore and then reads it. If the read value equals its lock number, the semaphore belongs to that host and is essentially locked. An SC3850 core/host/task releases the semaphore by writing a 0 to it.

1.18 Virtual Interrupts

The global interrupt controller generates 26 virtual interrupts including 16 maskable interrupts, 8 VNMIs, and 2 interrupts for external interrupt and NMI outputs ($\overline{\text{INT\_OUT}}$ and $\overline{\text{NMI\_OUT}}$, respectively). A virtual interrupt/VNMI is generated via a write access to the Virtual Interrupt Generation Register (VIGR) by one of the SC3850 cores or an external host CPU.

1.19 I^2C Interface

The inter-integrated circuit (I^2C) controller enables the MSC8157E to exchange data with other I^2C devices, such as microcontrollers, EEPROMs, real-time clock devices, A/D converters, and LCD displays. The I^2C controller uses a synchronous, multi-initiator bus that can connect several integrated circuits on a board. Two signals, serial data (I2C_SDA) and serial clock (I2C_SCL), carry information between the integrated circuits connected to it.

1.20 GPIOs

The MSC8157E has 32 general-purpose I/O (GPIO) ports that are multiplexed as either GPIO ports or dedicated peripheral interface ports. As GPIOs, each port is configured as an input or output (with a register for data output that is read or written at any time). Sixteen of the GPIs can also be configured as IRQ inputs. If configured as output, the GPIO ports can also be configured as open-drain (that is, configured in an active low wired-OR configuration on the board). In this mode, an output drives a zero voltage but goes to tri-state when driving a high voltage. GPIO ports do not have internal pull-up resistors. The dedicated MSC8157E peripheral functions multiplexed with the GPIO ports are grouped to maximize the usefulness of the ports in the greatest number of MSC8157E applications.

1.21 Boot Options

The boot program in the internal boot ROM initializes the MSC8157E after it completes a reset sequence. The MSC8157E device can boot from an external host through the serial RapidIO interface or download a user boot program through the I^2C, SPI, or Ethernet ports.

1.22 JTAG

The dedicated user-accessible test access port (TAP) is fully compatible with **IEEE** Std. 1149.6. The MSC8157E device supports circuit-board test strategies based on this standard. For details on the standard, refer to the standard documentation.

1.23 Developer Environment

Freescale supplies a complete set of DSP development tools for the MSC8157E device. The tools provide easier and more robust ways for designers to develop optimized DSP systems. Whether the application targets a 3G-LTE, TD-SCDMA, or WiMAX system, the development environment gives the designers everything they need to exploit the advanced capabilities of the MSC8157E architecture.

1.23.1 Tools

The MSC8157E tool components include the following:

- *Integrated development environment (IDE).* Easy-to-use graphical user interface and project manager for configuring and managing multiple build configurations.
- *C compiler with in-line assembly*. The developer can generate highly optimized DSP code by exploiting the StarCore multiple-ALU architecture, with parallel fetch sets and high code density.
- *Librarian*. The developer can create application-specific DSP libraries for modularity.
- *Linker*. The developer can efficiently produce executables from object code and partition memory according to the application architecture; the linker supports code overlay.
- *Multi-Core Debugger*. Seamlessly integrated real-time, non-intrusive, multi-mode, multi-core, and multi-DSP debugger handles highly optimized DSP algorithms. The developer can choose to debug in source code, assembly code, or mixed mode. Supports RTOS-aware debugger.
- *Royalty-free RTOS*. Included with package and includes a graphical user interface (GUI) called Kernel Aware that shows task information, interrupts, and other processing elements.
- *Software Simulator*. Full chip simulation (FCS) that allows the developer to design an application and run it on the simulator before running it on the silicon. FCS is integrated under integrator developer environment (IDE), the simulator provides customers with tools to create projects and debug them as they would on silicon (high speed simultaneous transfers). In addition, there is an SC3850 subsystem performance accurate (PACC) simulator that is approximately 95% cycle accurate.
- *Profiler*. The developer can analyze and identify program design inefficiencies.

- *High Speed Run Control*. USB TAP high speed host-target interface allows users to program in Flash memory, ROM, and cache.
- *Host Platform Support*. Microsoft Windows and Solaris.
- *Development Board*. The application development system (ADS).
- *Kit for MSC8157*. A complete system for developing and debugging real-time hardware and software.

1.23.2 Application Software

Freescale offers a broad range of DSP applications through its third-party application software partners; these applications target IP telephony, telephony modem, wireless and multimedia transcoding, and wireless base stations. Applications and software modules are listed in **Table 1-1**.

Table 1-1. Application Software Modules

Application	Modules
Baseband	3G-LTE evolving kernels library.
	Optimized FFT kernels, MMSE, QR Decomposition and other matrix multiplication operations.
	WCDMA including symbol rate and chiprate library.
	WiMAX solution supporting Wave 1 features with future extension to Wave 2 and beyond.
Device Drivers and Example Code	MAPLE-B2 driver, DMA driver, Serial RapidIO driver, PCI-Express, CPRI, Ethernet driver, UART driver, security engine, memory allocation, and interrupt handling.
StarCore Libraries	Rich set of StarCore software libraries, including: Math (Part 1 and 2), Signal, Complex vector, Control function, Frequency domain, Filter, Common, Image Processing, Communication, and Matrix.

2 SC3850 Core Overview

The SC3850 digital signal processing (DSP) core features an innovative architecture that addresses the key market needs of DSP applications, especially in the fields of wireline and wireless infrastructure, subscriber communication, and multimedia packet transfer. This flexible DSP core supports compute-intensive applications by providing high performance, low power, efficient compile, and high code density. Each high-performance core is binary compatible with the SC140 core used in the MSC81xx DSP family, the SC1400 core, and the SC3400 core used in the MSC8144 family and delivers up to 8000 16-bit MMACS using an internal 1 GHz clock at 1 V. A MAC operation includes a multiply-accumulate command with the associated data moves and a pointer update.

The StarCore SC3850 DSP core and subsystem is an evolution of the StarCore SC3400 DSP core and subsystem that enhances many of the original core and subsystem components and optimizes overall performance and memory hierarchy to target future application needs. Optimizations target:

- Improved control/compiled code performance
- Better operation of DSP intensive kernels
- Minimizing memory system stalls to increase core use.

Note: See the *SC3850 DSP Core Reference Manual* for a detailed description of core functionality and instruction set. The manual is only available with a signed non-disclosure agreement. Contact your local Freescale sales office or representative for details.

2.1 Core Architecture Features

Key features of the SC3850 DSP core include the following:

- Main core resources
  - 4 Data ALU execution units
  - 2 integer and address generation units
  - Sixteen 40-bit data registers with 8 guard bits, freely accessible by Data ALU instructions
  - Sixteen 32-bit address registers, freely accessible by Address generation instructions
- Instruction set
  - 16-bit instruction set, expandable to 32 and 48 instructions
  - High orthogonality of operands
  - Rich instruction set for DSP and control features
  - A very good compiler target
- Very high execution parallelism
  - Up to six instructions executed in a single clock cycle, statically scheduled
  - Variable Length Execution Set (VLES) execution model
  - Up to 4 Data ALU instructions and 2 Memory access/integer instructions per cycle
- Data type support
  - Byte (8-bit), word (16-bit) and long (32-bit) data widths, supported by instructions and memory moves
  - Both Integer (signed and unsigned) and fractional data types
  - Packed fractional complex data type
  - Several packed data types (2 to 4 objects on the same register) for SIMD operations
- Very high numerical throughput for DSP operations
  - Each Data ALU can perform two 16x16 multiplications per cycle (total of 8 multiplications for all ALUs), which can be used for:
    - Dot product acceleration (40 + (16x16) + (16x16))
    - SIMD2 multiplication and accumulation into two 20-bit register portions
    - Acceleration of Complex multiplication
    - Acceleration of extended precision multiplication
  - Some performance summary metrics are listed in **Table 2-1**:

Table 2-1. Multiplication Throughput Summary Figures for the SC3850

Operation	Precision	Instructions per Operation	Result Throughput (4 ALUs)
Real multiply	16 × 16	0.5	8
	16 × 32	1	4
	32 × 32	2	2
Complex multiply	16 × 16	2	2
	16 × 32	4	1

- Application specific instructions for acceleration the following algorithms
  - FFT
  - Video processing
  - Viterbi
  - Baseband operations
- High throughput memory interface
  - Unified, 32-bit byte addressable memory space
  - Dual Harvard architecture that permits one 128-bit program access and two 64-bit data accesses per cycle
  - Core to data memory throughput of up to 16 Giga Bytes per second, at 1 GHz core frequency
- Powerful address generation model
  - Zero overhead modulo arithmetic support for address pointers
  - Several
- Advanced pipeline
  - 12 stage, fully interlocked pipeline
  - No stalls for memory load to register, MAC operation, and result storage to memory
  - Speculation of conditionally executed instructions and change of flow execution paths
- Control features
  - Zero-overhead hardware loops with up to four levels of nesting
  - A Branch Target Buffer (BTB) for accelerating execution of change of flow instructions
- OS support
  - Precise memory exception support, for advanced OS
  - User and Supervisor privilege levels, supporting a protected, task oriented execution model
  - Full support for memory protection and address translation in the off-core MMU
  - Exception and Normal stack pointer for software stack support
  - Low task switch overhead using wide stack save and restore instructions
- Rich set of real-time debug capabilities through an On-Chip Emulator (OCE)
  - Real-time PC, data address and data breakpoint capabilities
  - Up to six hardware breakpoint channels, and unlimited debugger-enabled SW breakpoints
  - Single stepping
  - Externally forced instructions in debug mode by the host processor
  - Precise detection of PC breakpoints
  - PC tracing with filtering and compression options
- Low Power Design
  - Low-power Wait and Stop instructions
  - A very low power design
  - Fully static logic

2.2 StarCore SC3850 Core Architecture

The SC3850 core contains a Data Arithmetic and Logic Unit (DALU) with four ALUs, and an Address Generation Unit (AGU) that includes two Address Arithmetic Units (AAU). The SC3850 efficiently deploys the variable-length execution set (VLES) execution model, allowing to group up to 4 DALU and 2 AGU instructions in a single clock cycle without sacrificing code size for execution slots that are not used. **Figure 2-1** shows a block diagram of the SC3850 DSP core.

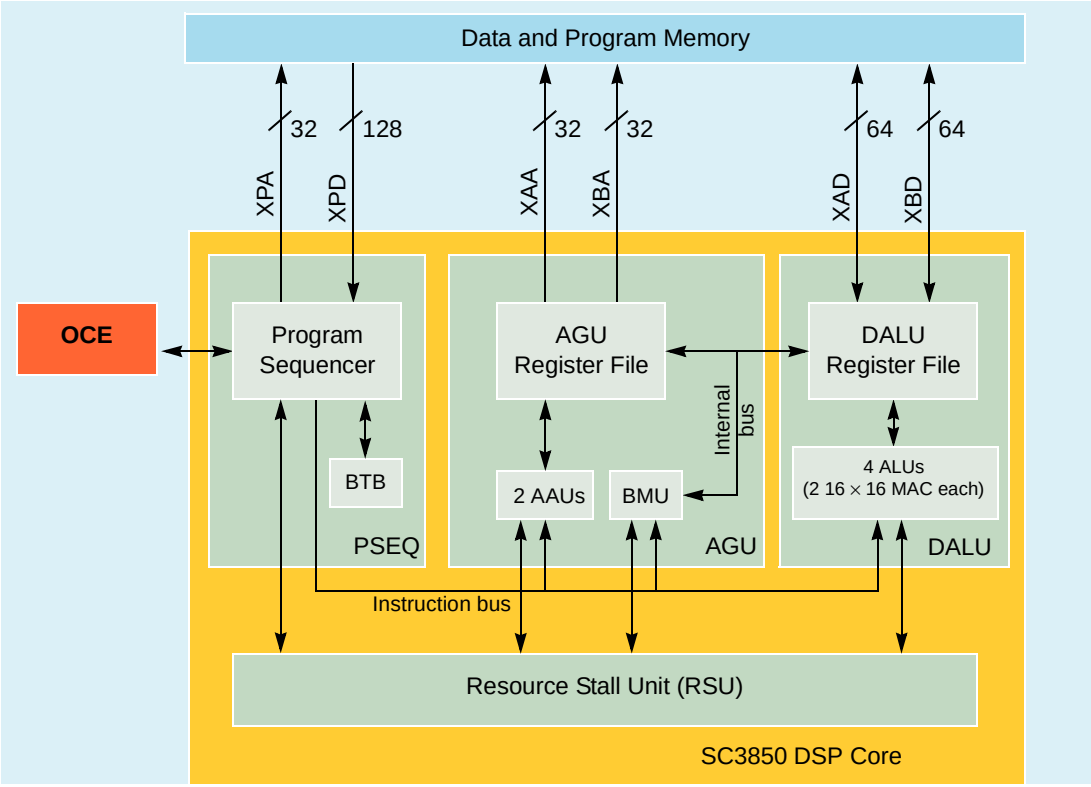

Figure 2-1. SC3850 DSP Core Block Diagram

The SC3850 uses dual-multiply ALUs supporting two 16-bit × 16-bit multipliers that can accumulate results into 40-bit wide destination data registers. In addition, it has a 40-bit parallel barrel shifter. Each ALU performs two MAC operations per clock cycle, so that a single core running at up to 1 GHz can perform 8 billion multiply-accumulates per second (GMACS). This rate is for both 16-bit operands, 8-bit operands, or mixed 8-bit and 16-bit operands.

Each AAU in the AGU can perform one address calculation and drive one data memory access per cycle. Data access widths are flexible and can be between 8 to 64 bits wide. The AGU can support a throughput of up to 128 Gbps between the core and the memory.

The program sequencer manages the instruction fetching from the program memory, dispatching the VLES to the execution units, performing change of flow (COF) and HW loop management

and exception processing. It includes a 48-entry branch target buffer which is used to accelerate the execution of COF operation.

The Resource Stall Unit (RSU) detects dependency hazards and resource requirements as defined by the code semantics. It then activates the internal operand bypass logic or inserts stalls as needed.

The SC3850 supports general microcontroller capabilities that make it a suitable target for advanced operating systems, including support for user and supervisor privilege levels that, with the MMU, enable implementation of a protected software model. The SC3850 supports precise exceptions for program and data accesses, allowing designs to implement advanced memory management schemes and soft error correction. The SC3850 also includes a 48-entry Branch Target Buffer (BTB) that improves performance by reducing the change of flow latency.

3 External Signals

The MSC8157E external signals are organized into functional groups. **Table 3-1** lists the functional groups and references the table that gives a detailed listing of signals within each group.

Table 3-1. MSC8157E Functional Signal Groupings

Functional Group	Detailed Description
Power and ground	**Table 3-2** on **page 3-4**
Clock	**Table 3-3** on **page 3-5**
Reset and Configuration	**Table 3-4** on **page 3-6**
DDR Memory Controller	**Table 3-5** on **page 3-11**
SerDes Multiplexers (Serial RapidIO controllers, PCI Express interface, CPRI, and SGMII signals)	**Table 3-6** on **page 3-12**
CPRI	**Table 3-8** on **page 3-13**
Ethernet	**Table 3-9** on **page 3-16**
Serial peripheral interface (SPI)	**Table 3-10** on **page 3-18**
GPIOs and maskable Interrupts	**Table 3-11** on **page 3-19**
Timers	**Table 3-12** on **page 3-24**
UART	**Table 3-13** on **page 3-26**
I^2C	**Table 3-14** on **page 3-27**
External DMA Interface	**Table 3-15** on **page 3-27**
$\overline{\text{NMI}}$/$\overline{\text{INT\_OUT}}$/$\overline{\text{NMI\_OUT}}$/$\overline{\text{CP\_TX\_INT}}$/$\overline{\text{CP\_RX\_INT}}$	**Table 3-16** on **page 3-28**
OCE module and JTAG Test Access Port	**Table 3-17** on **page 3-29**

Some signals are only sampled during the power-on reset sequence; most of these signal lines are are used by other modules and subsystems during normal operation. Signal multiplexing is determined at the following three levels:

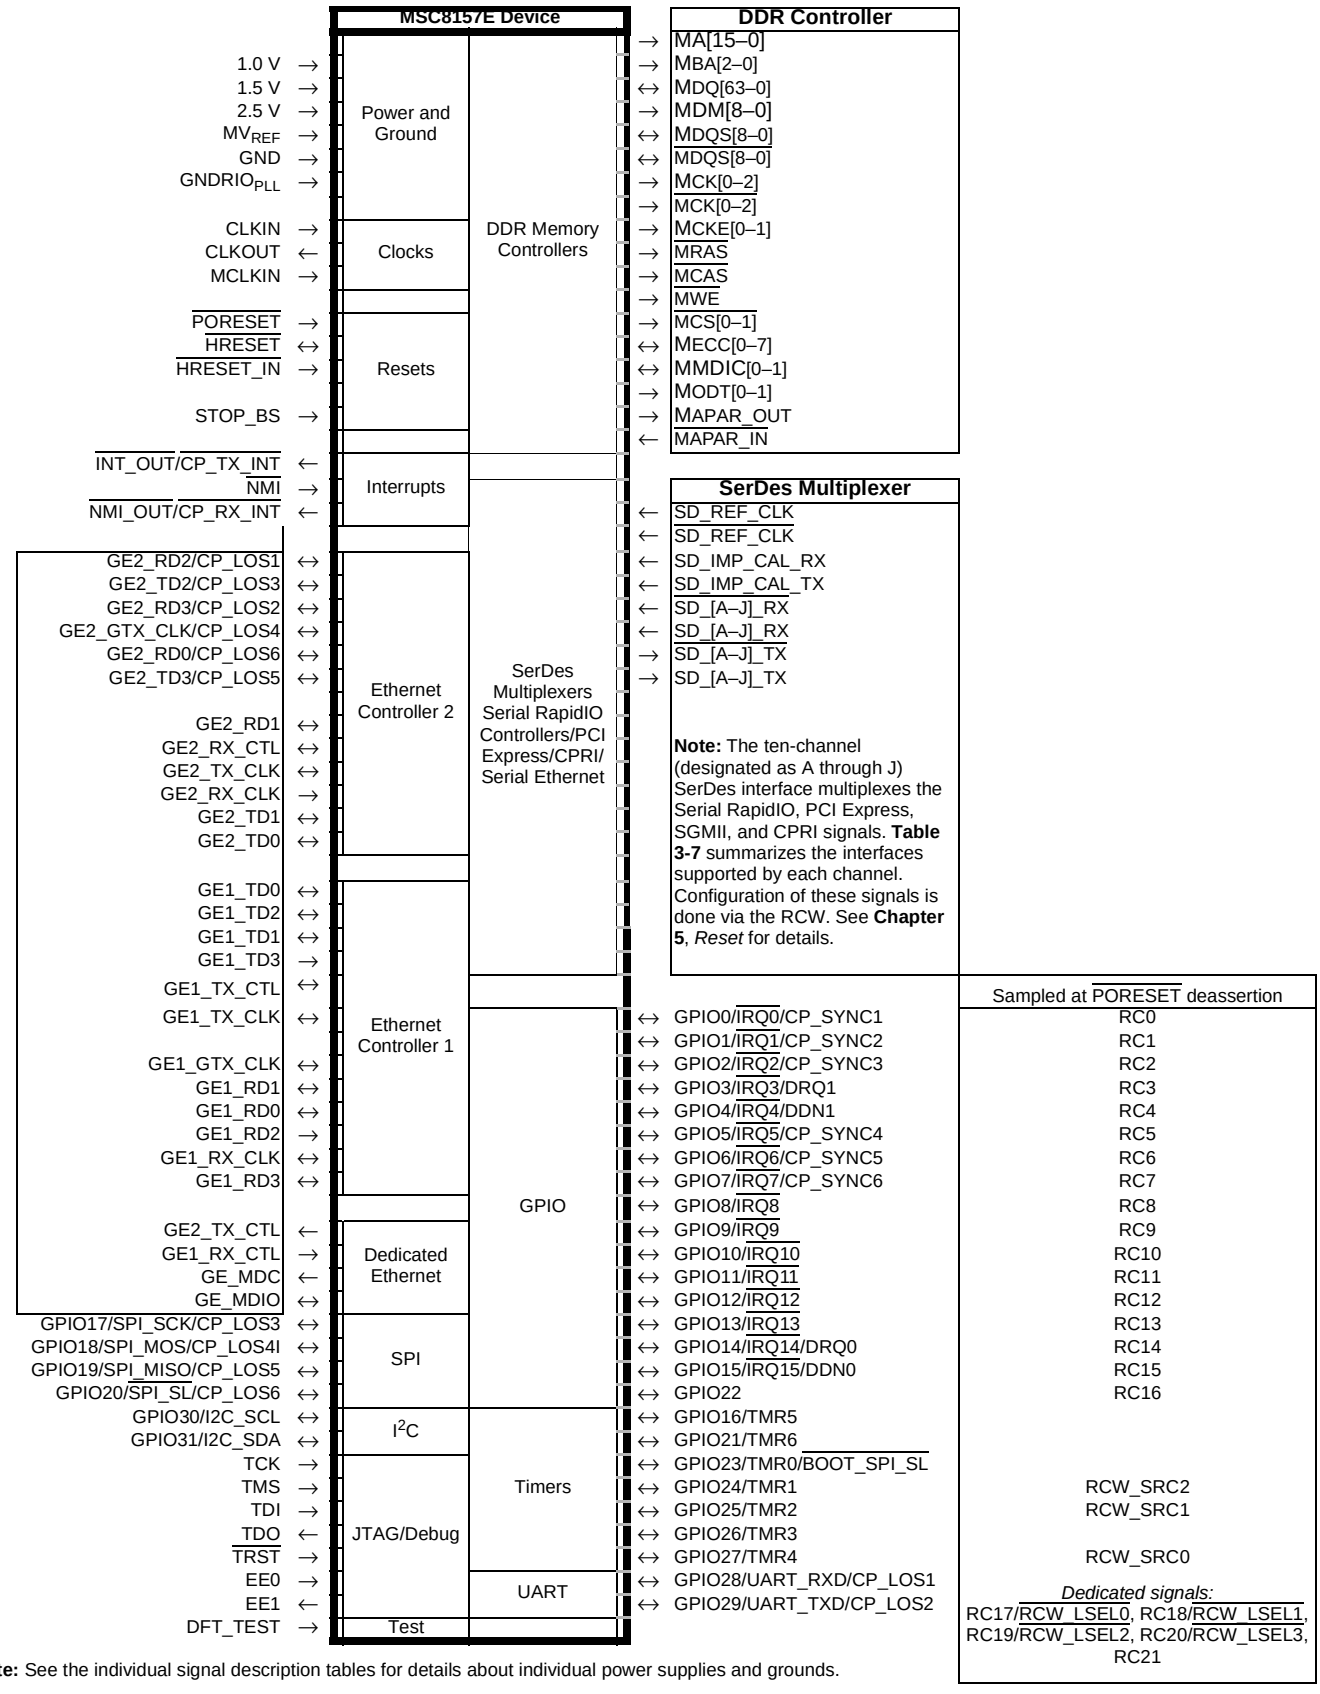
- Ethernet configurations (RGMII/SGMII) are defined by the Ethernet register settings (see the *QUICC Engine Block Reference Manual with Protocol Interworking* for details). Selection of RGMII or SGMII is configured by the QECR (see **Section 8.2.8**, *QUICC Engine Control Register (QECR)*, on page 8-17).
- SerDes Multiplexing. Serial RapidIO interfaces, PCI Express interface, CPRI lanes, and SGMII sharing on the 10-lane SerDes interface. Configured by the Reset Configuration Word (see **Chapter 5**, *Reset* for details).

- GPIO Multiplexing. GPIOs, $\overline{\text{IRQs}}$, I^2C, SPI, DMA external request interface, Timers, and UART sharing. Configured by GPIO configuration registers (see **Chapter 20**, *GPIO* for details).

The PCI Express, serial RapidIO interfaces, CPRI channels, and the Ethernet SGMIIs share the ten SerDes lanes. Access to the SerDes interface block is configured via the RCW bits (see **Chapter 5**, *Reset* for details).

The thirty-two GPIO ports have configurable functionality. Sixteen of the GPIO lines can be configured as $\overline{\text{IRQ}}$ inputs through the GPIO configuration registers; four of these lines can also be configured as the DMA external interface. Fifteen of the other sixteen GPIO lines are multiplexed with other interface units including the CPRI, SPI, timers, UART, and I^2C signals. The specific function is selected through configuration of the GPIO registers (see **Chapter 20**, *GPIO* for details).

Figure 3-1 summarizes the various MSC8157E external signal multiplexing options.



Note: See the individual signal description tables for details about individual power supplies and grounds.

Figure 3-1. MSC8157E External Signals

3.1 Power Signals

Table 3-2. Power and Ground Inputs

Nominal Voltage	Signal Name	Symbol	Description
1.0 V	VDD	V_{DD}	**Main Power** A dedicated well-regulated power source for the device. This supply serves the core subsystems 0–5. Provide an extremely low impedance path to the V_{DD} power rail and adequate external decoupling capacitors.
	M3VDD	V_{DDM3}	**Power for M3 Memory** A dedicated well-regulated power source for 2 Mbyte of the M3 memory. Provide an extremely low impedance path to the V_{DD} power rail and adequate external decoupling capacitors. This input can be disabled when not used to reduce system power requirements. When this input is disabled, 1 Mbyte of M3 memory remains active.
	CRPEVDD	V_{DDCRPE}	**Power for MAPLE-B2 Chip Rate Processing Element** A dedicated well-regulated power source for the MAPLE-B2 chip rate processing element (CRPE). Provide an extremely low impedance path to the V_{DD} power rail and adequate external decoupling capacitors. This input can be disabled when not used to reduce system power requirements.
	CPRIVDD	V_{DDCPRI}	**Power for CPRI** A dedicated well-regulated power source for the CPRI subsystem (all controllers). Provide an extremely low impedance path to the V_{DD} power rail and adequate external decoupling capacitors. This input can be disabled when not used to reduce system power requirements.
	MAVDD	V_{DDPLLM}	**DDR PLL Power** A dedicated well-regulated power for the DDR Phase Lock Loop (PLL).
	PLL0_AVDD	V_{DDPLL0}	**System PLL 0 Power** A dedicated well-regulated power for the system Phase Lock Loop (PLL).
	PLL1_AVDD	V_{DDPLL1}	**System PLL 1 Power** A dedicated well-regulated power for the system Phase Lock Loop (PLL).
	PLL2_AVDD	V_{DDPLL2}	**System PLL 2 Power** A dedicated well-regulated power for the system Phase Lock Loop (PLL).
	SXCVDD	V_{DDSXC}	**SerDes Core Power** A dedicated well-regulated power for the SerDes core circuitry.
	SD_PLL1_AVDD	V_{DDPLL}	**SerDes PLL 1 Power** A dedicated well-regulated power for the first SerDes Phase Lock Loop (PLL).
	SD_PLL2_AVDD	V_{DDPLL}	**SerDes PLL2 Power** A dedicated well-regulated power for the second SerDes Phase Lock Loop (PLL).
1.5 V	GVDD	V_{DDDDR}	**SSTL15 IO Driver Power** A dedicated power source for the DDR controller DRAM interface buffers. Provide adequate external decoupling capacitors. The external decoupling capacitors recommendations are listed in the *MSC8157E Technical Data Sheet*.
	SXPVDD	V_{DDSXP}	**SerDes Pad Power** A dedicated well-regulated power for the SerDes pad circuitry.

Table 3-2. Power and Ground Inputs (Continued)

Nominal Voltage	Signal Name	Symbol	Description
GVDD × 0.5 V	MVREF	MV_{REF}	**SSTL Reference Power** A reference power level for the DDR controller memory interface.
2.5 V	NVDD	V_{DDIO}	**Input/Output Power** The power source for the external I/O signal lines. Provide adequate external decoupling capacitors. The external decoupling capacitors recommendations are listed in the *MSC8157E Technical Data Sheet*.
	QVDD	V_{DDPLL0}	**Input/Output Power** The power source for the external clock, reset, OCE, and JTAG signal lines. Provide adequate external decoupling capacitors. The external decoupling capacitors recommendations are listed in the *MSC8157E Technical Data Sheet*.
0 V	VSS	GND	**System Ground** An isolated ground for the internal processing logic and I/O buffers. This connection must be tied externally to all chip ground connections, except GND_{SXC} and GND_{SXP}.
	SD_PLL1_AGND	GND_{SDPLL1}	**SerDes PLL 1 Ground** Ground dedicated for SerDes PLL 1 use. The connection should be provided with an extremely low-impedance path to ground.
	SD_PLL2_AGND	GND_{SDPLL2}	**SerDes PLL 2 Ground** Ground dedicated for SerDes PLL 2 use. The connection should be provided with an extremely low-impedance path to ground.
	SXCVSS	GND_{SXC}	**SerDes Core Ground** A ground for the SerDes Core circuitry.
	SXPVSS	GND_{SXP}	**SerDes Pad Ground** A ground for the SerDes Pad circuitry.

Note: The external decoupling capacitors recommendations are listed in the *MSC8157E Technical Data Sheet*.

3.2 Clock Signals

Table 3-3. Clock Signals

Signal Name	Type	Signal Description
CLKIN	Input	**Clock In** Primary clock input to the MSC8157E PLLs.
CLKOUT	Output	**Clock Out** The bus clock output.
MCLKIN	Input	**DDR Clock In (optional)** Optional clock input to the DDR PLL. This clock can be used in part of the clock modes if required.

3.3 Reset and Configuration Signals

Table 3-4. Reset and Configuration Signals

Signal Name	Type	Signal Description
PORESET	Input	**Power-On Reset** When asserted, this line causes the MSC8157E to enter power-on reset state. Internally, this signal also resets the TAP and debugging modules. The power-on reset flow resets the MSC8157E device, configures various device attributes including its clock modes, and drives HRESET as an open-drain output.
HRESET	Input/ Output	**Hard Reset** When asserted as an input, this signal causes the MSC8157E to abort all current internal and external transactions, set most registers to their default state, and enter the hard reset state. This signal must be asserted for at least 32 CLKIN cycles. While the device is in the hard reset state, it drives HRESET as open-drain output. This signal requires an external pull-up resistor. The signal is tri-stated after the hard reset flow is complete.
HRESET_IN	Input	**Hard Reset In** Asserted as an input. When asserted, this signal causes the MSC8157E to abort all current internal and external transactions, set most registers to their default state, and enter the hard reset state. This signal must be asserted for at least 32 CLKIN cycles. This signal requires an external pull-up resistor. The signal is tri-stated after the hard reset flow is complete. Unlike HRESET, it does not drive a reset output and therefore can be used to reset a single device in a multi-device system without affecting the other devices.
STOP_BS	Input	**Stop Boot Sequencer** This signal is valid only when the reset configuration words are being loaded from an I^2C EEPROM using the boot sequencer and is asserted only for a reset target device to prevent the loading of the reset configuration words until allowed by the Boot ROM. The signal level must be asserted as long as HRESET/HRESET_IN is asserted. For the reset master or a single device reading from I^2C EEPROM, you must drive this low during the reset sequence. For details, see **Chapter 5**, *Reset*. This signal is also used for booting after reset (for details, see **Chapter 6**, *Boot Program*).
RCW_SRC0	Input	**Reset Configuration Word Source 0** Along with the RCW_SRC[1–2], this signal is sampled at the deassertion of PORESET to identify the source of the reset configuration word. The required signal level must be maintained as long as HRESET/HRESET_IN is asserted.
GPIO27	Input/ Output	**General-Purpose Input Output 27** One of 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
TMR4	Input/ Output	**Timer 4** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 21**, *Timers*.

Table 3-4. Reset and Configuration Signals (Continued)

Signal Name	Type	Signal Description
RCW_SRC1	Input	**Reset Configuration Word Source 1** Along with the RCW_SRC[0, 2], this signal is sampled at the deassertion of PORESET to identify the source of the reset configuration word. The required signal level must be maintained as long as HRESET/HRESET_IN is asserted.
GPIO25	Input/ Output	**General-Purpose Input Output 25** One of 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
TMR2	Input/ Output	**Timer 2** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 21**, *Timers*.
RCW_SRC2	Input	**Reset Configuration Word Source 2** Along with the RCW_SRC[0–1], this signal is sampled at the deassertion of PORESET to identify the source of the reset configuration word. The required signal level must be maintained as long as HRESET/HRESET_IN is asserted.
GPIO24	Input/ Output	**General-Purpose Input Output 24** One of 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
TMR1	Input/ Output	**Timer 1** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 21**, *Timers*.
RC[0–2]	Input	**Reset Configuration Word Bit 0–2** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO[0–2]	Input/ Output	**General-Purpose Input Output 0–2** Three of the 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
IRQ[0–2]	Input	**Interrupt Request 0–2** External lines that can request a service routine via the internal interrupt controller. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 13**, *Interrupt Handling*.
CP_SYNC[1–3]	Input	**CPRI Controller 1–3 Synchronization Signal** Synchronization signals for CPRI controllers 1–3. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.

Table 3-4. Reset and Configuration Signals (Continued)

Signal Name	Type	Signal Description
RC3	Input	**Reset Configuration Word Bit 3** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO3	Input/ Output	**General-Purpose Input Output 3** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
IRQ3	Input	**Interrupt Request 3** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
DRQ1	Input	**DMA External Request 1** When enabled by GPIO multiplexing, asserting this input triggers external DMA request 1. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
RC4	Input	**Reset Configuration Word Bit 4** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO4	Input/ Output	**General-Purpose Input Output 4** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
IRQ4	Input	**Interrupt Request 4** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
DDN1	Output	**DMA External DONE Indication 1** When enabled by GPIO multiplexing, this signal is asserted to indicate that DMA request 1 is done. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
RC[5–7]	Input	**Reset Configuration Word Bit 5–7** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO[5–7]	Input/ Output	**General-Purpose Input Output 5–7** Three of the 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
IRQ[5–7]	Input	**Interrupt Request 5–7** External lines that can request a service routine via the internal interrupt controller. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 13**, *Interrupt Handling*.
CP_SYNC[4–6]	Input	**CPRI Controller 4–6 Synchronization Signal** Synchronization signals for CPRI controllers 4–6. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.

Table 3-4. Reset and Configuration Signals (Continued)

Signal Name	Type	Signal Description
RC[8–13]	Input	**Reset Configuration Word Bit 8–13** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO[8–13]	Input/ Output	**General-Purpose Input Output 8–13** Six of the 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
IRQ[8–13]	Input	**Interrupt Request 8–13** External lines that can request a service routine via the internal interrupt controller. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 13**, *Interrupt Handling*.
RC14	Input	**Reset Configuration Word Bit 14** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO14	Input/ Output	**General-Purpose Input Output 14** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
IRQ14	Input	**Interrupt Request 14** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
DRQ0	Input	**DMA External Request 0** When enabled by GPIO multiplexing, asserting this input triggers external DMA request 0. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
RC15	Input	**Reset Configuration Word Bit 15** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO15	Input/ Output	**General-Purpose Input Output 15** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
IRQ15	Input	**Interrupt Request 15** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
DDN0	Output	**DMA External DONE Indication 0** When enabled by GPIO multiplexing, this signal is asserted to indicate that DMA request 0 is done. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
RC16	Input	**Reset Configuration Word Bit 16** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO16	Input/ Output	**General-Purpose Input Output 16** One of 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
TMR5	Input/ Output	**Timer 5** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.

Table 3-4. Reset and Configuration Signals (Continued)

Signal Name	Type	Signal Description
RC17	Input	**Reset Configuration Word Bit 17** If RCW_SRC[0–2] equals 011, this input is sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
RCW_LSEL0	Output	**Reset Configuration Word Lane 0 Select** If RCW_SRC[0–2] equals 000, this signal is used to enable loading of Lane 0 (RCWLR bits 15–0) of the RCW via RC[15–0] when asserted. See **Chapter 5**, *Reset* for details.
RC18	Input	**Reset Configuration Word Bit 18** If RCW_SRC[0–2] equals 011, this input is sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
RCW_LSEL1	Output	**Reset Configuration Word Lane 1 Select** If RCW_SRC[0–2] equals 000, this signal is used to enable loading of Lane 1 (RCWLR bits 31–16) of the RCW via RC[15–0] when asserted. See **Chapter 5, *Reset*** for details.
RC19	Input	**Reset Configuration Word Bit 19** If RCW_SRC[0–2] equals 011, this input is sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
RCW_LSEL2	Output	**Reset Configuration Word Lane 2 Select** If RCW_SRC[0–2] equals 000, this signal is used to enable loading of Lane 2 (RCWHR bits 15–0) of the RCW via RC[15–0] when asserted. See **Chapter 5, *Reset*** for details.
RC20	Input	**Reset Configuration Word Bit 20** If RCW_SRC[0–2] equals 011, this input is sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
RCW_LSEL3	Output	**Reset Configuration Word Lane 3 Select** If RCW_SRC[0–2] equals 000, this signal is used to enable loading of Lane 3 (RCWHR bits 31–16) of the RCW via RC[15–0] when asserted. See **Chapter 5, *Reset*** for details.
RC21	Input	**Reset Configuration Word Bit 21** If RCW_SRC[0–2] equals 011, this input is sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers. If RCW_SRC[0–2] does not equal 011, this input is ignored.

Note: When RCW_SRC[0–2] equals 011, RC[0–21] are valid only for driving a reduced external reset configuration word value. The signals are sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers. The required signal levels must be maintained as long as HRESET/HRESET_IN is asserted. All other signal drivers connected to these inputs must be tri-stated while HRESET/HRESET_IN is asserted. When RCW_SRC[0–2] equals 000, the device loads all 64 bits of the RCW via RC[0–15] in four beats. In this case, RC[17–20] function as RCW_LSEL[0–3] outputs that are asserted to load the RCW 16 bits at a time and RC21 is ignored. See **Chapter 5**, *Reset* for details.

3.4 Memory Controller

Refer to **Chapter 12**, *DDR SDRAM Memory Controller* for details on configuring these signals.

Table 3-5. Memory Controller Signals

Signal Name	Type	Description
MA[15–0]	Output	**Address Bus** The memory interface address bus used to connect to external memory devices. MA0 is the lsb of the address driven by the DDR controller.
MBA[2–0]	Output	**Bank Address** Selects the DDR DRAM bank. Each DDR SDRAM can support four or eight logically addressable sub-banks. MBA0 must connect to bit zero of the SDRAM input bank address. This line is asserted during the mode register set command to specify the extended mode register.
MDQ[63–0]	Input/ Output	**Data Bus** The MSC8157E device drives the bus during write cycles and the external memory drives the bus during read cycles.
MDM[8–0]	Output	**DDR SDRAM Data Output Mask** Masks unwanted data bytes transferred during a burst write. These signals are used to support sub-burst-size transactions (such as single-byte writes) on SDRAM in which all transactions occur in multi-byte bursts. MDM0 corresponds to the MSB and MDM7 corresponds to the LSB. MDM8 acts as the ECC data mask.
MDQS[8–0]	Input/Output	**DDR SDRAM DQS** Strobe for byte-lane data capture. The signals are inputs driven by the DDR SRAM with read data and outputs driven by the DDR controller with write data. The data strobes may be single-ended or differential. Bit 8 is used as the ECC data mask.
$\overline{\text{MDQS[8–0]}}$	Input/Output	**DDR SDRAM DQS Complement** Complement strobe for byte-lane data capture. The signals are inputs driven by the DDR SRAM with read data and outputs driven by the DDR controller with write data. The data strobes may be single-ended or differential.
MECC[7–0]	Input/Output	**DDR Error Checking and Correcting Codes** As normal mode outputs the ECC signals represent the state of ECC driven by the DDR controller on writes.
MCK[2–0]	Output	**DDR Clock Out** The DDR clock output. Each signal is part of a differential pair.
$\overline{\text{MCK[2–0]}}$	Output	**DDR Clock Out Inverted** The inverted DDR clock. Each signal is part of a differential pair.
MCKE[1–0]	Output	**Clock Enable** When asserted, this signal enables the DDR clock for the DDR DRAM.
$\overline{\text{MRAS}}$	Output	**Row Address Strobe** Connects to DDR DRAM $\overline{\text{RAS}}$ input. This line is asserted for activate commands and is used for mode register set and refresh commands.
$\overline{\text{MCAS}}$	Output	**Column Address Strobe** Connects to DDR DRAM $\overline{\text{CAS}}$ input. This line is asserted for read or write transactions and for mode register set, refresh, and precharge commands.
$\overline{\text{MWE}}$	Output	**Write Enable** Connects to DDR DRAM $\overline{\text{WE}}$ input.

Table 3-5. Memory Controller Signals (Continued)

Signal Name	Type	Description
$\overline{\text{MCS[0–1]}}$	Output	**Chip Select 0–1** Enables specific memory devices or peripherals connected to the bus.
MMDIC[0–1]	Input/Output	**Driver Impedance Calibration** These lines are used for automatic calibration of the DDR I/O.
MODT[0–1]	Output	**On-Die Termination** Memory controller outputs for the ODT to the SDRAM. Each signal represents the corresponding chip select.
MAPAR_OUT	Output	**Parity Output** If enabled, drives the parity bit for the bus.
$\overline{\text{MAPAR\_IN}}$	Input	**Parity Input** Receives the error indication from an open-drain parity error signal.

3.5 SerDes Multiplexed Signals for the Serial RapidIO, PCI Express, CPRI, and SGMII Interfaces

Refer to **Chapter 5**, *Reset*; **Chapter 17**, *PCI Express Controller*; **Chapter 16**, *Serial RapidIO Controller*, **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*, and the *QUICC Engine Block Reference Manual with Protocol Interworking* for configuration information.

Table 3-6. SerDes Multiplexed Signals

Signal Name	Type	Description
SD_IMP_CAL_RX	Input	**SerDes Receiver Impedance Control Signal** Receiver impedance calibration control signal.
SD_IMP_CAL_TX	Input	**SerDes Transmitter Impedance Control Signal** Transmitter impedance calibration control signal.
SD_REF_CLK	Input	**SerDes Reference Clock** Reference clock signal. Each signal is part of a differential pair. For SGMII operation, this provides the input clock.
$\overline{\text{SD\_REF\_CLK}}$	Input	**SerDes Reference Clock Inverted** Inverted reference clock signal. Each signal is part of a differential pair. For SGMII operation, this provides the input clock.
$\overline{\text{SD\_[A–J]\_TX}}$	Output	**SerDes Lane A to J Transmit Data Inverted** Inverted serial data output. Each signal is part of a differential pair.
SD_[A–J]_TX	Output	**SerDes Lane A to J Transmit Data** Serial data output. Each signal is part of a differential pair.
$\overline{\text{SD\_[A–J]\_RX}}$	Input	**SerDes Lane A to J Receive Data Inverted** Inverted serial data output. Each signal is part of a differential pair.
SD_[A–J]_RX	Input	**SerDes Lane A to J Receive Data** Serial data output. Each signal is part of a differential pair.
Note: For proper definition of serial RapidIO modes (x1/x2/x4), PCI Express (x1/x2/x4), CPRI, and SGMII, configure the interfaces using the Reset Configuration Word settings. For details, see **Chapter 5**, *Reset*. **Table 3-7** lists the interfaces supported by each SerDes lane.		

Table 3-7. Summary of Multiplexed Signal Support by Channel

SerDes Lane	Multiplexed Signals					
	Serial RapidIO 1	Serial RapidIO 2	PCI Express	SGMII1	SGMII2	CPRI
A	—	0	0	—	—	—
B	—	0 or 1	1	—	X	—
C	0 or 1	0 or 2	2	X	—	—
D	0 or 1	1 or 3	3	—	X	—
E	0 or 2	1 or 2	—	X	—	6
F	1 or 3	0 or 3	—	—	X	5
G	0 or 2	1	—	X	—	4
H	1 or 3	0	—	—	X	3
I	0 or 2	—	0	X	—	2
J	1 or 3	—	1	—	X	1

Note: Interface support by channel is indicated by the following:
1. — indicates that the channel does not support the interface.
2. A number indicates which data lines the channel supports.
3. X indicates that the channel supports the designated SGMI connection.

3.6 CPRI Signals

Table 3-8. CPRI Signals

Signal Name	Type	Signal Description
RC[0–2]	Input	**Reset Configuration Word Bit 0–2** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
GPIO[0–2]	Input/ Output	**General-Purpose Input Output 0–2** Three of the 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ}}$[0–2]	Input	**Interrupt Request 0–2** External lines that can request a service routine via the internal interrupt controller. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 13**, *Interrupt Handling*.
CP_SYNC[1–3]	Input	**CPRI Controller 1–3 Synchronization Signal** Synchronization signals for CPRI controllers 1–3. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.

Table 3-8. CPRI Signals (Continued)

Signal Name	Type	Signal Description
RC[5–7]	Input	**Reset Configuration Word Bit 5–7** Sampled during the assertion of PORESET to set part of the bits of the Reset Configuration Word Registers.
GPIO[5–7]	Input/ Output	**General-Purpose Input Output 5–7** Three of the 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
IRQ[5–7]	Input	**Interrupt Request 5–7** External lines that can request a service routine via the internal interrupt controller. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 13**, *Interrupt Handling*.
CP_SYNC[4–6]	Input	**CPRI Controller 4–6 Synchronization Signal** Synchronization signals for CPRI controllers 4–6. Selected through GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.
GE2_RD2	Input	**Ethernet 2 Receive Data 2** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS1	Input	**CPRI Optical Loss of Signal Indication for Lane 1** This is the default option. The signal can also be configured on GPIO28.
GPIO28	Input/ Output	**General-Purpose Input Output 28** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
UART_RXD	Input/ Output	**UART Receive Data** For details, see **Chapter 19**, *UART*.
CP_LOS1	Input	**CPRI Optical Loss of Signal Indication for Lane 1** This is an optional configuration. The signal can also be configured on GE2_RD2.
GE2_RD3	Input	**Ethernet 2 Receive Data 3** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS2	Input	**CPRI Optical Loss of Signal Indication for Lane 2** This is the default option. The signal can also be configured on GPIO29.
GPIO29	Input/ Output	**General-Purpose Input Output 29** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
UART_TXD	Output	**UART Transmit Data** For details, see **Chapter 19**, *UART*.
CP_LOS2	Input	**CPRI Optical Loss of Signal Indication for Lane 2** This is an optional configuration. The signal can also be configured on GE2_RD3.
GE1_TD2	Output	**Ethernet 1 Transmit Data 2** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS3	Input	**CPRI Optical Loss of Signal Indication for Lane 3** This is the default option. The signal can also be configured on GPIO17.

Table 3-8. CPRI Signals (Continued)

Signal Name	Type	Signal Description
GPIO17	Input/ Output	**General-Purpose Input Output 17** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes.
SPI_SCK	Input/ Output	**SPI Clock** Gated clock, active only during data transfers. Four combinations of SPI_SCK phase and polarity can be configured. When the SPI is a master, SPI_SCK is the clock output signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO.
CP_LOS3	Input	**CPRI Optical Loss of Signal Indication for Lane 3** This is an optional configuration. The signal can also be configured on GE2_TD2.
GE2_TX_CTL	Output	**Ethernet 2 Transmit Control** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS4	Input	**CPRI Optical Loss of Signal Indication for Lane 4** This is the default option. The signal can also be configured on GPIO18.
GPIO18	Input/ Output	**General-Purpose Input Output 18** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes.
SPI_MOSI	Input/ Output	**SPI Master Output Slave Input** When the SPI is a master, SPI_SCK is the clock input signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO.
CP_LOS4	Input	**CPRI Optical Loss of Signal Indication for Lane 4** This is an optional configuration. The signal can also be configured on GE2_GTX_CLK.
GE2_TD3	Output	**Ethernet 2 Transmit Data 3** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS5	Input	**CPRI Optical Loss of Signal Indication for Lane 5** This is the default option. The signal can also be configured on GPIO19.
GPIO19	Input/ Output	**General-Purpose Input Output 19** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes
SPI_MISO	Input/ Output	**SPI Master Input Slave Output** When the SPI is a master, SPI_SCK is the clock input signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO.
CP_LOS5	Input	**CPRI Optical Loss of Signal Indication for Lane 5** This is an optional configuration. The signal can also be configured on GE2_TD3.
GE2_TD2	Output	**Ethernet 2 Transmit Data 2** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS6	Input	**CPRI Optical Loss of Signal Indication for Lane 6** This is the default option. The signal can also be configured on GPIO20.

Table 3-8. CPRI Signals (Continued)

Signal Name	Type	Signal Description
GPIO20	Input/ Output	**General-Purpose Input Output 20** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes.
$\overline{\text{SPI\_SL}}$	Input	**SPI Select** $\overline{\text{Enable}}$ input to the SPI slave in single master mode. In multi-master environment, $\overline{\text{SPI\_SL}}$ detects an error when more one master is operating. Assertion of an $\overline{\text{SPI\_SL}}$, while it is master, causes an error.
CP_LOS6	Input	**CPRI Optical Loss of Signal Indication for Lane 6** This is an optional configuration. The signal can also be configured on GE2_RD0.

3.7 Ethernet Signals

The RGMII signals are listed and described in **Table 3-9**.

Table 3-9. Ethernet Signals

Signal Name	Type	Description
GE1_RD3	Input	**Ethernet 1 Receive Data 3** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_RD2	Input	**Ethernet 1 Receive Data 2** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_RX_CLK	Input	**Ethernet 1 Receive Clock** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_RD0	Input	**Ethernet 1 Receive Data 0** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_GTX_CLK	Output	**Ethernet 1 Output Transmit Clock** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_RD1	Input	**Ethernet 1 Receive Data 1** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_TX_CLK	Input	**Ethernet 1 Transmit Clock** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_TD3	Output	**Ethernet 1 Transmit Data 3** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_TX_CTL	Output	**Ethernet 1 Transmit Control** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_TD1	Output	**Ethernet 1 Transmit Data 1** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_TD0	Output	**Ethernet 1 Transmit Data 0** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE1_TD2	Output	**Ethernet 1 Transmit Data 2** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS3	Input	**CPRI Optical Loss of Signal Indication for Lane 3** This is the default option. The signal can also be configured on GPIO17.

Table 3-9. Ethernet Signals (Continued)

Signal Name	Type	Description
GE2_TD0	Output	**Ethernet 2 Transmit Data 0** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE2_RX_CLK	Input	**Ethernet 2 Receive Clock** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE2_TD1	Output	**Ethernet 2 Transmit Data 1** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE2_TX_CLK	Input	**Ethernet 2 Transmit Clock** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE2_RD1	Input	**Ethernet 2 Receive Data 1** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE2_RX_CTL	Input	**Ethernet 2 Receive Control** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE2_TD3	Output	**Ethernet 2 Transmit Data 3** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS5	Input	**CPRI Optical Loss of Signal Indication for Lane 5** This is the default option. The signal can also be configured on GPIO19.
GE2_GTX_CLK	Output	**Ethernet 2 Output Transmit Clock** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE2_RD0	Input	**Ethernet 2 Receive Data 0** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE2_RD3	Input	**Ethernet 2 Receive Data 3** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS2	Input	**CPRI Optical Loss of Signal Indication for Lane 2** This is the default option. The signal can also be configured on GPIO29.
GE2_RD2	Input	**Ethernet 2 Receive Data 2** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS1	Input	**CPRI Optical Loss of Signal Indication for Lane 1** This is the default option. The signal can also be configured on GPIO28.
GE2_TD2	Output	**Ethernet 2 Transmit Data 2** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS6	Input	**CPRI Optical Loss of Signal Indication for Lane 6** This is the default option. The signal can also be configured on GPIO20.
GE2_TX_CTL	Output	**Ethernet 2 Transmit Control** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS4	Input	**CPRI Optical Loss of Signal Indication for Lane 4** This is the default option. The signal can also be configured on GPIO18.
GE1_RX_CTL	Input	**Ethernet 1 Receive Control** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GE_MDC	Output	**Ethernet Management Data Clock** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.

Table 3-9. Ethernet Signals (Continued)

Signal Name	Type	Description
GE_MDIO	Input/ Output	**Ethernet Management Data Input/Output** For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.

3.8 Serial Peripheral Interface (SPI) Signal Summary

Table 3-10. SPI Signals

Signal Name	Type	Signal Description
GPIO23	Input/ Output	**General-Purpose Input Output 23** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
TMR0	Input/ Output	**Timer 0** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
BOOT_SPI_SL	Input	**SPI Select During Boot** Enables the input to the SPI slave in single master mode during the boot sequence. In a multi-master environment, BOOT_SPI_SL detects an error when more one master is operating. Assertion of BOOT_SPI_SL while it is master causes an error. For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GPIO20	Input/ Output	**General-Purpose Input Output 20** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes.
SPI_SL	Input	**SPI Select** Enable input to the SPI slave in single master mode. In multi-master environment, SPI_SL detects an error when more one master is operating. Assertion of an SPI_SL, while it is master, causes an error.
CP_LOS6	Input	**CPRI Optical Loss of Signal Indication for Lane 6** This is an optional configuration. The signal can also be configured on GE2_RD0.
GPIO19	Input/ Output	**General-Purpose Input Output 19** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes
SPI_MISO	Input/ Output	**SPI Master Input Slave Output** When the SPI is a master, SPI_SCK is the clock input signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO.
CP_LOS5	Input	**CPRI Optical Loss of Signal Indication for Lane 5** This is an optional configuration. The signal can also be configured on GE2_TD3.
GPIO18	Input/ Output	**General-Purpose Input Output 18** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes.
SPI_MOSI	Input/ Output	**SPI Master Output Slave Input** When the SPI is a master, SPI_SCK is the clock input signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO.
CP_LOS4	Input	**CPRI Optical Loss of Signal Indication for Lane 4** This is an optional configuration. The signal can also be configured on GE2_GTX_CLK.

Table 3-10. SPI Signals (Continued)

Signal Name	Type	Signal Description
GPIO17	Input/ Output	**General-Purpose Input Output 17** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes.
SPI_SCK	Input/ Output	**SPI Clock** Gated clock, active only during data transfers. Four combinations of SPI_SCK phase and polarity can be configured. When the SPI is a master, SPI_SCK is the clock output signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO.
CP_LOS3	Input	**CPRI Optical Loss of Signal Indication for Lane 3** This is an optional configuration. The signal can also be configured on GE2_TD2.

3.9 GPIO and Maskable Interrupt Signal Summary

Table 3-11. GPIO and Maskable Interrupt Summary

Signal Name	Type	Description
GPIO31	Input/ Output	**General-Purpose Input Output 31** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
I2C_SDA	Input/ Output	**I^{2}C-Bus Data Line** This is the data line for the I^{2}C bus. For details, see **Chapter 23**, *I2C*.
GPIO30	Input/ Output	**General-Purpose Input Output 30** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
I2C_SCL	Input/ Output	**I^{2}C-Bus Clock Line** This the clock line for the I^{2}C bus. For details, see **Chapter 23**, *I2C*.
GPIO29	Input/ Output	**General-Purpose Input Output 29** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
UART_TXD	Output	**UART Transmit Data** For details, see **Chapter 19**, *UART*.
CP_LOS2	Input	**CPRI Optical Loss of Signal Indication for Lane 2** This is an optional configuration. The signal can also be configured on GE2_RD3.
GPIO28	Input/ Output	**General-Purpose Input Output 28** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
UART_RXD	Input/ Output	**UART Receive Data** For details, see **Chapter 19**, *UART*.
CP_LOS1	Input	**CPRI Optical Loss of Signal Indication for Lane 1** This is an optional configuration. The signal can also be configured on GE2_RD2.

Table 3-11. GPIO and Maskable Interrupt Summary (Continued)

Signal Name	Type	Description
GPIO27	Input/ Output	**General-Purpose Input Output 27** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
TMR4	Input/ Output	**Timer 4** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
RCW_SRC0	Input	**Reset Configuration Word Source 0** Along with the RCW_SRC[1–2], this signal is sampled at the deassertion of $\overline{\text{PORESET}}$ to identify the source of the reset configuration word. The required signal level must be maintained as long as $\overline{\text{HRESET}}$/$\overline{\text{HRESET\_IN}}$ is asserted.
GPIO26	Input/ Output	**General-Purpose Input/Output 26** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. .
TMR3	Input/ Output	**Timer 3** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
GPIO25	Input/ Output	**General-Purpose Input Output 25** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
TMR2	Input/ Output	**Timer 2** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
RCW_SRC1	Input	**Reset Configuration Word Source 1** Along with the RCW_SRC[0,2], this signal is sampled at the deassertion of $\overline{\text{PORESET}}$ to identify the source of the reset configuration word. The required signal level must be maintained as long as $\overline{\text{HRESET}}$/$\overline{\text{HRESET\_IN}}$ is asserted.
GPIO24	Input/ Output	**General-Purpose Input Output 24** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
TMR1	Input/ Output	**Timer 1** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
RCW_SRC2	Input	**Reset Configuration Word Source 2** Along with the RCW_SRC[0–1], this signal is sampled at the deassertion of $\overline{\text{PORESET}}$ to identify the source of the reset configuration word. The required signal level must be maintained as long as $\overline{\text{HRESET}}$/$\overline{\text{HRESET\_IN}}$ is asserted.

Table 3-11. GPIO and Maskable Interrupt Summary (Continued)

Signal Name	Type	Description
GPIO23	Input/ Output	**General-Purpose Input Output 23** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
TMR0	Input/ Output	**Timer 0** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
BOOT_SPI_SL	Input	**SPI Select During Boot** Enables the input to the SPI slave in single master mode during the boot sequence. In a multi-master environment, BOOT_SPI_SL detects an error when more one master is operating. Assertion of BOOT_SPI_SL while it is master causes an error. For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
GPIO22	Input/ Output	**General-Purpose Input Output 22** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
GPIO21	Input/ Output	**General-Purpose Input Output 21** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
TMR6	Input/ Output	**Timer 6** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 22**, *GPIO*. For functional details, see **Chapter 21**, *Timers*.
GPIO20	Input/ Output	**General-Purpose Input Output 20** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
SPI_SL	Input	**SPI Select** Enable input to the SPI slave in single master mode. In multi-master environment, SPI_SL detects an error when more one master is operating. Assertion of an SPI_SL, while it is master, causes an error. For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS6	Input	**CPRI Optical Loss of Signal Indication for Lane 6** This is an optional configuration. The signal can also be configured on GE2_RD0.
GPIO19	Input/ Output	**General-Purpose Input Output 19** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
SPI_MISO	Input/ Output	**SPI Master Input Slave Output** When the SPI is a master, SPI_SCK is the clock input signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO. For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS5	Input	**CPRI Optical Loss of Signal Indication for Lane 5** This is an optional configuration. The signal can also be configured on GE2_TD3.
GPIO18	Input/ Output	**General-Purpose Input Output 18** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
SPI_MOSI	Input/ Output	**SPI Master Output Slave Input** When the SPI is a master, SPI_SCK is the clock input signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO. For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS4	Input	**CPRI Optical Loss of Signal Indication for Lane 4** This is an optional configuration. The signal can also be configured on GE2_GTX_CLK.

Table 3-11. GPIO and Maskable Interrupt Summary (Continued)

Signal Name	Type	Description
GPIO17	Input/ Output	**General-Purpose Input Output 17** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
SPI_SCK	Input/ Output	**SPI Clock** Gated clock, active only during data transfers. Four combinations of SPI_SCK phase and polarity can be configured. When the SPI is a master, SPI_SCK is the clock output signal that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO. For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.
CP_LOS3	Input	**CPRI Optical Loss of Signal Indication for Lane 3** This is an optional configuration. The signal can also be configured on GE2_TD2.
GPIO16	Input/ Output	**General-Purpose Input Output 16** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
RC16	Input	**Reset Configuration Word Bit 16** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
TMR5	Input/ Output	**Timer 5** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 22**, *GPIO*. For functional details, see **Chapter 21**, *Timers*.
GPIO15	Input/ Output	**General-Purpose Input Output 15** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ15}}$	Input	**Interrupt Request 15** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
DDN0	Output	**DMA External DONE Indication 0** When enabled by GPIO multiplexing, this signal is asserted to indicate that DMA request 0 is done. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
RC15	Input	**Reset Configuration Word Bit 15** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
GPIO14	Input/ Output	**General-Purpose Input Output 14** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ14}}$	Input	**Interrupt Request 14** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
DRQ0	Input	**DMA External Request 0** When enabled by GPIO multiplexing, asserting this input triggers external DMA request 0. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
RC14	Input	**Reset Configuration Word Bit 14** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.

Table 3-11. GPIO and Maskable Interrupt Summary (Continued)

Signal Name	Type	Description
GPIO[13–8]	Input/ Output	**General-Purpose Input Output 13–8** Nine of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ}}$[13–8]	Input	**Interrupt Request 13–8** External lines that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
RC[13–8]	Input	**Reset Configuration Word Bit 13–8** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
GPIO[7–5]	Input/ Output	**General-Purpose Input Output 7–5** Nine of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ}}$[7–5]	Input	**Interrupt Request 7–5** External lines that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
RC[7–5]	Input	**Reset Configuration Word Bit 7–5** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
CP_SYNC[6–4]	Input/ Output	**CPRI Controller 4–6 Synchronization Signal** Synchronization signals for CPRI controllers 4–6. Selected through GPIO configuration. For configuration details, see **Chapter 20, *GPIO***. For functional details, see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.
GPIO4	Input/ Output	**General-Purpose Input Output 4** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ4}}$	Input	**Interrupt Request 4** External lines that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
DDN1	Output	**DMA External DONE Indication 1** When enabled by GPIO multiplexing, this signal is asserted to indicate that DMA request 1 is done. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
RC4	Input	**Reset Configuration Word Bit 4** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
GPIO3	Input/ Output	**General-Purpose Input Output 3** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ3}}$	Input	**Interrupt Request 3** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
DRQ1	Input	**DMA External Request 1** When enabled by GPIO multiplexing, asserting this input triggers external DMA request 1. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
RC3	Input	**Reset Configuration Word Bit 3** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.

Table 3-11. GPIO and Maskable Interrupt Summary (Continued)

Signal Name	Type	Description
GPIO[2–0]	Input/ Output	**General-Purpose Input Output 2–0** Three of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ}}$[2–0]	Input	**Interrupt Request 2–0** External lines that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
RC[2–0]	Input	**Reset Configuration Word Bit 2–0** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
CP_SYNC[3–1]	Input/ Output	**CPRI Controller 1–3 Synchronization Signal** Synchronization signals for CPRI controllers 1–3. Selected through GPIO configuration. For configuration details, see **Chapter 20, *GPIO***. For functional details, see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.

3.10 Timer Signals

Table 3-12 describes the signals in this group.

Table 3-12. Timer Signals

Signal Name	Type	Description
TMR6	Input/ Output	**Timer 6** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 22**, *GPIO*. For functional details, see **Chapter 21**, *Timers*.
GPIO21	Input/ Output	**General-Purpose Input Output 21** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
TMR5	Input/ Output	**Timer 5** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 22**, *GPIO*. For functional details, see **Chapter 21**, *Timers*.
GPIO16	Input/ Output	**General-Purpose Input Output 16** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
RC16	Input	**Reset Configuration Word Bit 16** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.

Table 3-12. Timer Signals (Continued)

Signal Name	Type	Description
TMR4	Input/ Output	**Timer 4** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
GPIO27	Input/ Output	**General-Purpose Input Output 27** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
RCW_SRC0	Input	**Reset Configuration Word Source 0** Along with the RCW_SRC[1–2], this signal is sampled at the deassertion of $\overline{\text{PORESET}}$ to identify the source of the reset configuration word. The required signal level must be maintained as long as $\overline{\text{HRESET}}$/$\overline{\text{HRESET\_IN}}$ is asserted.
TMR3	Input/ Output	**Timer 3** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
GPIO26	Input/ Output	**General-Purpose Input Output 26** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
TMR2	Input/ Output	**Timer 2** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
GPIO25	Input/ Output	**General-Purpose Input Output 25** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
RCW_SRC1	Input	**Reset Configuration Word Source 1** Along with the RCW_SRC[0,2], this signal is sampled at the deassertion of $\overline{\text{PORESET}}$ to identify the source of the reset configuration word. The required signal level must be maintained as long as $\overline{\text{HRESET}}$/$\overline{\text{HRESET\_IN}}$ is asserted.
TMR1	Input/ Output	**Timer 1** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
GPIO24	Input/ Output	**General-Purpose Input Output 24** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
RCW_SRC2	Input	**Reset Configuration Word Source 2** Along with the RCW_SRC[0–1], this signal is sampled at the deassertion of $\overline{\text{PORESET}}$ to identify the source of the reset configuration word. The required signal level must be maintained as long as $\overline{\text{HRESET}}$/$\overline{\text{HRESET\_IN}}$ is asserted.

Table 3-12. Timer Signals (Continued)

Signal Name	Type	Description
TMR0	Input/ Output	**Timer 0** Configured as input to the counter or output from the counter. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For timer functional details, see **Chapter 21**, *Timers*.
GPIO23	Input/ Output	**General-Purpose Input Output 23** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
BOOT_SPI_SL	Input	**SPI Select During Boot** Enables the input to the SPI slave in single master mode during the boot sequence. In a multi-master environment, BOOT_SPI_SL detects an error when more one master is operating. Assertion of BOOT_SPI_SL while it is master causes an error. For details, see the *QUICC Engine Block Reference Manual with Protocol Interworking*.

3.11 UART Signals

Table 3-13. UART Signals

Signal Name	Type	Description
UART_TXD	Output	**UART Transmit Data** Selected through the GPIO configuration. For configuration details, see **Chapter 20, *GPIO***. For functional details, see **Chapter 19, *UART***.
GPIO29	Input/ Output	**General-Purpose Input Output 29** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
CP_LOS2	Input	**CPRI Optical Loss of Signal Indication for Lane 2** This is an optional configuration. The signal can also be configured on GE2_RD3.
UART_RXD	Input/ Output	**UART Receive Data** Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 19**, *UART*.
GPIO28	Input/ Output	**General-Purpose Input Output 28** One of 32 GPIO pins used as GPIO or as a dedicated input or output. For details, see **Chapter 20**, *GPIO*.
CP_LOS1	Input	**CPRI Optical Loss of Signal Indication for Lane 1** This is an optional configuration. The signal can also be configured on GE2_RD2.

3.12 I2C Signals

Table 3-14. I2C Signals

Signal Name	Type	Description
I2C_SDA	Input/ Output	**I2C-Bus Data Line** This is the data line for the I2C bus. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 23**, *I2C*.
GPIO31	Input/ Output	**General-Purpose Input Output 31** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes.
I2C_SCL	Input/ Output	**I2C-Bus Clock Line** This the clock line for the I2C bus. Selected through the GPIO configuration. For configuration details, see **Chapter 20**, *GPIO*. For functional details, see **Chapter 23**, *I2C*.
GPIO30	Input/ Output	**General-Purpose Input/Output 30** One of 32 GPIOs. For details, see **Chapter 20**, *GPIO*. Valid in all modes.

3.13 External DMA Signals

Table 3-15. External DMA Signals

Signal Name	Type	Description
DDN0	Output	**DMA External DONE Indication 0** When enabled by GPIO multiplexing, this signal is asserted to indicate that DMA request 0 is done. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
GPIO15	Input/ Output	**General-Purpose Input Output 15** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ15}}$	Input	**Interrupt Request 15** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
RC15	Input	**Reset Configuration Word Bit 15** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
DRQ0	Input	**DMA External Request 0** When enabled by GPIO multiplexing, asserting this input triggers external DMA request 0. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
GPIO14	Input/ Output	**General-Purpose Input Output 14** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ14}}$	Input	**Interrupt Request 14** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
RC14	Input	**Reset Configuration Word Bit 14** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.

Table 3-15. External DMA Signals (Continued)

Signal Name	Type	Description
DDN1	Output	**DMA External DONE Indication 1** When enabled by GPIO multiplexing, this signal is asserted to indicate that DMA request 1 is done. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
GPIO4	Input/ Output	**General-Purpose Input Output 4** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ4}}$	Input	**Interrupt Request 4** External lines that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
RC4	Input	**Reset Configuration Word Bit 4** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.
DRQ1	Input	**DMA External Request 1** When enabled by GPIO multiplexing, asserting this input triggers external DMA request 1. For details, see **Chapter 14**, *Direct Memory Access (DMA) Controller*,
GPIO3	Input/ Output	**General-Purpose Input Output 3** One of the 32 GPIOs. For details, see **Chapter 20**, *GPIO*.
$\overline{\text{IRQ3}}$	Input	**Interrupt Request 3** External line that can request a service routine via the internal interrupt controller. For details, see **Chapter 13**, *Interrupt Handling*.
RC3	Input	**Reset Configuration Word Bit 3** Sampled during the assertion of $\overline{\text{PORESET}}$ to set part of the bits of the Reset Configuration Word Registers.

Table 3-16. Other Interrupt Signals

Signal Name	Type	Description
$\overline{\text{INT\_OUT}}$	Output	**Interrupt Output** An open-drain output driven from the MSC8157E virtual interrupt 24. Assertion of this output indicates that an unmasked interrupt is pending in the MSC8157E internal interrupt controller.
$\overline{\text{CP\_TX\_INT}}$	Output	**CPRI Transmit Interrupt** CPRI Transmit Interrupt. For Details see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.
$\overline{\text{NMI}}$	Input	**Non-Maskable Interrupt** An external device may assert this line to generate a non-maskable interrupt to the MSC8157E device.
$\overline{\text{NMI\_OUT}}$	Output	**Non-Maskable Interrupt Output** An open-drain pin driven from the MSC8157E virtual interrupt 25. Assertion of this output indicates that a non-maskable interrupt is pending in the MSC8157E internal interrupt controller, waiting to be handled by an external host.
$\overline{\text{CP\_RX\_INT}}$	Output	**CPRI Receive Interrupt** CPRI Receive Interrupt. For Details see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.

3.14 OCE Event and JTAG Test Access Port Signals

The MSC8157E uses two sets of debugging signals for the two types of internal debugging modules: OCE and the JTAG TAP controller. Each internal SC3850 core has an OCE module, but they are all accessed externally by the same two signals EE0 and EE1. The MSC8157E supports the standard set of test access port (TAP) signals defined by **IEEE** Std. 1149.6 Test Access Port and Boundary-Scan Architecture specification and described in **Table 3-17**.

Table 3-17. JTAG TAP Signals

Signal Name	Type	Signal Description
DFT_TEST	Input	**Manufacturing Test Mode** Always connect to VSS. This is not a ground pin.
EE0	Input	**OCE Event Bit 0** Used for putting the internal SC3850 cores into Debug mode. Pulling the signal high asserts the signal and requests that the cores enter Debug mode.
EE1	Output	**OCE Event Bit 1** Indicates that at least one on-chip SC3850 core is in Debug mode. A high output indicates that at least one SC3850 core is in Debug mode.
TCK	Input	**Test Clock** A test clock signal for synchronizing JTAG test logic.
TDI	Input	**Test Data Input** A test data serial signal for test instructions and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TDO	Output	**Test Data Output** A test data serial signal for test instructions and data. TDO can be tri-stated. The signal is actively driven in the shift-IR and shift-DR controller states and changes on the falling edge of TCK.
TMS	Input	**Test Mode Select** Sequences the test controller's state machine, is sampled on the rising edge of TCK, and has an internal pull-up resistor.
$\overline{\text{TRST}}$	Input	**Test Reset** Asynchronous JTAG reset input. Initializes the TAP logic. This signal should always be asserted with $\overline{\text{PORESET}}$.

4 Chip-Level Arbitration and Switching System (CLASS)

The Chip Level Arbitration and Switching System (CLASS) is the central internal interconnect system for the MSC8157E device. The CLASS is a non-blocking, full-fabric interconnect that allows any initiator to access any target in parallel with another initiator-target couple. The CLASS uses a fully pipelined low latency design. The CLASS demonstrates per-target prioritized round-robin arbitration, highly optimized to the target characteristics. The CLASS operates at 667 MHz, and is separate from the SC3850 core frequency to provide an optimized trade-off between power dissipation, memory technology, and miss latency. Controlling the intradevice data flow, the CLASS reduces bottle necks and permits high bandwidth fully pipe-lined traffic. The CLASS system is ready for use and does not require any special configuration to perform non-blocking pipelined transactions from any initiator to any memory. The configurable arbitration features described in this chapter are for fine-tuning the system for specific application requirements.

The fifteen CLASS initiators are:

- Six SC3850 core subsystems (initiator ports 0–5)
- Four MAPLE bridges (initiator ports 6–7 and ports 13–14)
- One 10-lane port shared by two Serial RapidIO controllers, the PCI Express controller, six CPRI controllers, and two SGMIIs (connects to two initiator ports 8 and 12)
- Peripherals bridge shared by the SEC, SPI, RGMII, SGMII, and JTAG interface (initiator port 9)
- Two DMA ports (initiator ports 10–11)

The ten CLASS targets are:

- Configuration Control and Status Registers (CCSR) (target port 0)
- Two DDR ports (target ports 1 for writes and 2 for reads)
- MAPLE module (target port 3)
- Three core subsystem bridges (two core subsystems per bridge) (target ports 4–6)
- Three M3 memory ports (target ports 7–9)

The CLASS initiators and targets are shown in **Figure 4-1**. The arrows indicate the address direction from initiator to target.

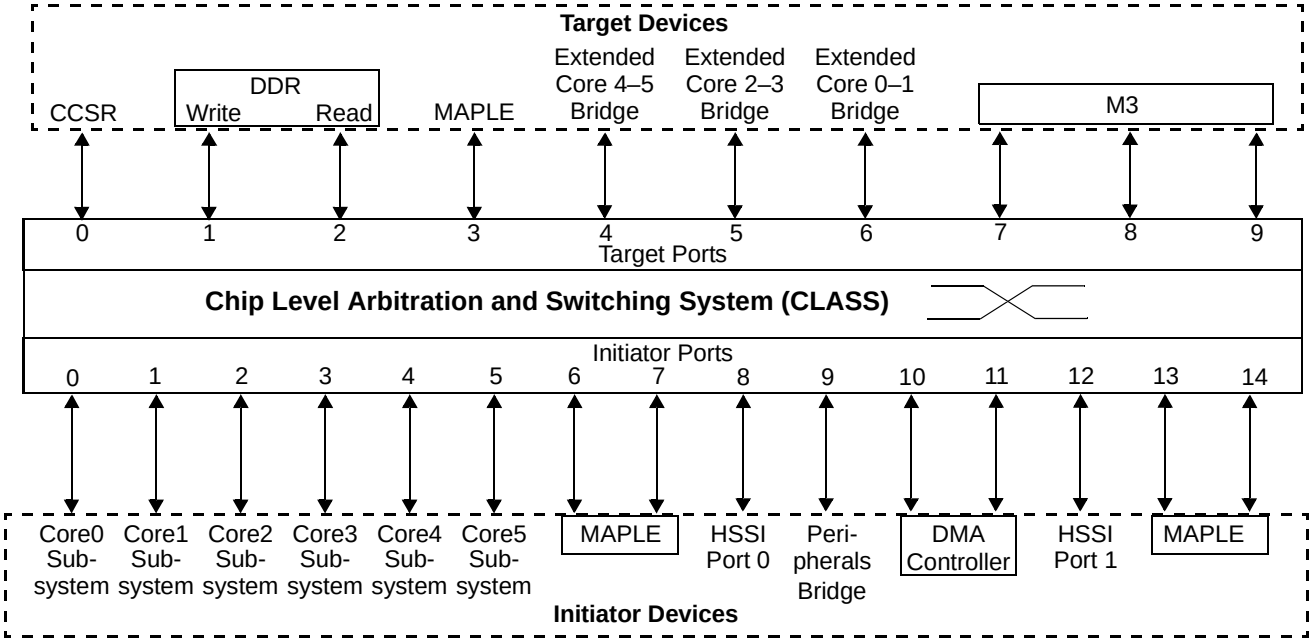


Figure 4-1. CLASS Initiators and Targets in the MSC8157E Device

4.1 CLASS Features

The CLASS modules implement the following features:

- Non blocking, full fabric interconnect.
- Full bandwidth utilization toward each of the targets.
- Allows full pipeline when a specific initiator accesses a specific target.
- Allows full pipeline when accesses are generated by one or more initiators to specific targets.
- Read transactions can have a maximum pipeline of 16 acknowledged requests before completing the transaction toward the initiator.
- Write transactions can have a maximum pipeline of 3 acknowledged requests before completing the transaction toward the initiator.
- Programmable priority mapping.
- Programmable auto priority upgrade.
- Address decoding for target selection and multi target demultiplexing:
  - Programmable address space start/end registers per target, for flexible address decoding (resolution of 4 KB). Not supported in the reduced configuration option.
  - Fixed priority between address decoding results which allows overlapping address windows and deduction of address windows.

- Per-target arbitration algorithm:
  - 4 level prioritization
  - Each level implements pseudo round-robin arbitration algorithm.
  - Weighted arbitration
  - Optimized data bus utilization mode
- Programmable masking priority for starvation elimination.
- Multiplexing the initiator buses according to the arbitration winner.
- Normalizing mode that splits non-aligned transactions according to the target capabilities (maximal burst size, power-of-2 burst, burst alignment, full size burst, data-beat alignment, wrap size)
- Error detection and handling:
  - The CLASS identifies illegal addresses; addresses that do not belong to any of the address windows or fall inside the negative windows.
  - The CLASS stores the illegal address, reports the error, and generates an interrupt.
- Debug and profiling unit (CDPU) support.

4.2 Functional Description

The CLASS is a non blocking interconnect between 15 initiators and 10 targets. The main sub-blocks of the CLASS are: expander, multiplexer and arbiter, normalizer, and the CLASS control interface (CCI) unit that implements the interface and interrupt lines and the CLASS register files. The CLASS also implements an inherent debug and profiling unit (CDPU).

To implement the protocol that deals with the point-to-point bus, the CLASS includes an expander module per initiator that performs address decoding and is used as sampling stage on the initiator side. Each expander module can detect an error address and generate an interrupt. For more details about the expander module see **Section 4.2.1**. From the target side, the CLASS includes a multiplexer and arbiter module and a normalizer module for each target. The multiplexer and arbiter module performs a pseudo round-robin (RR) arbitration algorithm between all the initiators and concentrates them toward one target. For details about multiplexer and arbiter module see **Section 4.2.2**. Each multiplexer and arbiter module has a dedicated normalizer module that is used as the sampling stage on the target side. The normalizer can also be used for normalizing transactions. For more details about normalizer module see **Section 4.2.3**.

4.2.1 Expander Module and Transaction Flow

Each expander module connects to one initiator. The expander module performs address decoding according to the configuration register settings. Each target is presented by a start address and an end address that define a window in the memory space. The address decoding is done by checking whether the transaction address hits one of the active windows. Each expander module is connected to all of the multiplexer and arbiter blocks in the CLASS to implement a full-fabric and non-blocking interconnect between any initiator to any target. If the address decoding hits in more than one window, the CLASS arbiter chooses a window by fixed priority arbitration (target 0 has the lowest priority). After detecting the requested target and the arbiter selects the target window, the expander module starts a transaction toward the associated multiplexer and arbiter module. The CLASS prevents the possibility of simultaneous accessing to more than one target by the same initiator. If there are accesses from one initiator to different targets, the expander module start the transactions to other targets only after all the open accesses to the current target are completed. The expander module is a sampling stage of transaction. For each request (address + attribute), write data is sampled from the initiator and driven to the normalizer module through multiplexer and arbiter module in the following clock cycle; read data is sampled from the normalizer module through multiplexer and arbiter module and driven to the initiator in the following clock cycle.

4.2.2 Multiplexer and Arbiter Module

The multiplexer and arbiter module connects to all the expander modules on one side and to a dedicated normalizer module on the other side. The multiplexer and arbiter module block is a pure logic data path design, that supports up to 16 initiators, performs an arbitration, and concentrates them towards a specific target normalizer module.

4.2.2.1 CLASS Arbiter

The CLASS arbiter performs weighted arbitration algorithm for requestors simultaneously using a pseudo round-robin arbitration algorithm for each of the priority levels and chooses the highest level request. The CLASS arbiter supports four priority levels, where 3 is the highest and 0 is the lowest. The arbitration operation can be done every clock cycle or delayed according to the number of datums of acknowledged transaction (Late Arbitration mode). The CLASS arbiter supports priority upgrade, so the initiator can upgrade the priority level at any clock cycle.

To eliminate starvation for initiators with low priority, the Masking Priority should be enabled. Starvation can occur when the higher priority initiators access continuously and the lower priority initiators can not perform any access (no priority upgrade ability by the initiator and auto priority upgrade in the expander module is disabled). When the Masking Priority is enabled, the arbiter dedicates slots for lower priority initiator in which the higher priority initiators are masked.

4.2.2.1.1 Weighted Arbitration

The CLASS arbiter supports limited weighted arbitration. Weighted arbitration is needed to apply non-uniform distribution of the bandwidth from all initiators toward each target. Weighted arbitration is configurable per CLASS target and gives configurable weights to each initiator. The CLASS arbiter ensures that when a weighted initiator wins the arbitration, it performs Weight + 1 consecutive transactions before transferring control to another initiator with the same or lower priority level.

4.2.2.1.2 Late Arbitration

In late arbitration mode, the request is initiated by the class arbiters as late as possible. At the end of a data burst, this can give better or worse performance for the initiators. The performance depends on the bursty character of the application and the utilization to the target. This mode is activated/deactivated by the appropriate bit in the C0ACR (see **4.7.27**, *CLASS Arbitration Control Register (C0ACR)*). Late arbitration is enabled by default.

4.2.2.1.3 Priority Masking

When C0ACR[PME] is set, the class arbiters are configured to preserve cycle slots for low priority accesses. They reserve 1/16 of all cycles for priority 0, 2/16 of all cycles for priority 1 or 0, and 2/16 of all cycles for priority 2, 1, or 0. This mode can decrease overall performance. This is one of two approaches to eliminate starvation. The other is to use auto-priority upgrade.

4.2.2.1.4 Auto Priority Upgrade

This mode is activated by setting the C0PACRx[AUE] bit (see **4.7.3**, *CLASS Priority Auto Upgrade Control Registers (C0PACRx)*). When active, a pending request has its priority upgraded to the next higher priority after a specified number of cycles specified by C0PAVRx[AUV] (see **4.7.2**, *CLASS Priority Auto Upgrade Value Registers (C0PAVRx)*). The upgrade level and timing depend on the current priority value assigned, as follows:

- For priority 0 requests, the priority is upgraded to priority 1 after AUV cycles.
- For priority 1 requests, the priority is upgraded to priority 2 after AUV/2 cycles.
- For priority 2 requests, the priority is upgraded to priority 3 (highest) after AUV/4 cycles.

The upgrade process continues until the request is processed or it reaches priority 3.

4.2.2.2 CLASS Multiplexer

The CLASS multiplexer includes two FIFOs that connect between the appropriate initiator and the target. The FIFO depth is 16, thus enabling the multiplexer and arbiter module to deal with 16 open transactions, which received their request acknowledge and are waiting for the end-of-data or end-of-transaction signals. The CLASS multiplexer is pure logic for the data path and does not cause any latency.

4.2.3 Normalizer Module

Each normalizer module is connected to the appropriate multiplexer and arbiter module on one side and to a specific CLASS target interface on the other side. Each normalizer module is used as a sampler for full pipeline towards the target. The normalizer module is the only module within the CLASS that can manipulate the transaction (for example, splitting non-aligned transactions). An internal signal is used to indicate that optimization is needed. Only the last normalizer module on the way to the target is used for normalization. All the other normalizer modules should be used only as samplers. The normalizer module supports the fast confirm mechanism for writes.

4.2.4 CLASS Control Interface (CCI)

The CLASS control interface (CCI) enables access to the CLASS configuration, control, and status registers. All write accesses to these registers should use supervisor mode. See **Section 4.7** for programming details.

4.3 CLASS Error Interrupts

The CLASS can generate one error interrupt that is common for all initiators. The error interrupt is created when the CLASS receives a transaction request with an illegal address. Illegal addresses are defined as any one of the following 2 cases:

1. An address which does not belong to any of the address space windows of the enabled address decoders.
2. An address which falls within any of the address space windows of the enabled error address decoders.

When an illegal address is identified by the CLASS, the following events occur.

- The associated **AEIx** bit in the CISR is set.
- The address that was identified as illegal is stored in the associated **CEARx** and **CEEARx**. These registers are locked until the associated **AEIx** bit in the CISR is cleared either by a hardware reset or by writing 1 to this bit.

Note: If the associated **AEIx** bit in the CISR is already set when the illegal address is identified (due to a prior illegal address), then the new error address is not stored.

- If the corresponding **AEIEx** bit in the CIER is set, an IRQ is issued.
- The CLASS does not initiate a transaction to any target. However, the CLASS will continue normally on the initiator side until completion, and report the error. In case of a read transaction, the CLASS delivers invalid data to the initiator.
- If, at the time of the error transaction, there are open transactions that did not receive the end-of-transaction, the expander module stalls all new transaction until all prior

transactions receive the end-of-transaction, close the error transaction, report the end-of-transaction, report the error, and only then continue with subsequent transactions.

- Any subsequent requests with a legal address are serviced normally.

Note: The CLASS does not produce an error when a transaction starts inside a target address window and finishes outside of the window. This situation must be avoided by the user. If it occurs, the results are unpredictable.

The error interrupt is logically ORed with internal error interrupts. The internal error interrupts are associated with each initiator. Thus, the CLASS error interrupt is asserted when at least one internal interrupt is asserted.

4.4 CLASS Debug Profiling Unit

The CLASS supports debug and profiling measurements by the CLASS debug and profiling unit (CDPU).

4.4.1 Profiling

The user can configure the desired measurement in the CIPCRs and CTPCRs.

Note: For each CLASS module, only one PMM field among all C0IPCRx and C0TPCRx can be greater than 0 during profiling.

You can activate the CDPU by:

- Writing a 1 to the CPCR[PE] bit.
- Configuring a watch point event in CPCR[WPEC] field.

The CDPU is deactivated by:

- Writing a 0 to the CPCR[PE] bit.
- Configuring a watch point event in CPCR[WPEC] field.
- Reaching a time-out in the CPTOR when the CPCR[TOE] bit is set.
- CPRCR overflow.

After the desired profiling mode has been chosen, activate the CDPU to perform the measurement. At the beginning of every measurement, the CLASS Profiling Reference Counter (CPRCR) starts counting the clock cycles. Read the CPISR[OVE] bit to verify that the measurement is complete and that the profiling counter values are valid. If the CPISR[OVE] is clear, read the profiling counters CPRCR and CPGCR and analyze the results.

4.4.2 Watch Point Unit

The CLASS includes a watch point unit (WPU) for each of the initiator interfaces and for each of the target interfaces. The WPU can compare programmed values to the real transactions and generate a watch point event when a match occurs.

Note: For each CLASS module, only one WPEN field can be set among all C0IWPCRx and C0TWPCRx when snooping watch point events. That is, only one watch point unit can be active at a time.

Use the following steps to use the watch point unit:

1. Clear C0PCR.
2. Clear C0IPCRx and C0TPCR.
3. For the time-out mechanism, program C0PTOR and set the C0PCR[TOE] bit.
4. Define the transaction to be monitored by writing the desired configuration to C0WPCR, C0WPACR, C0WPEACR, and C0WPAMR.
5. Enable the watch point units through C0IWPCRx and C0TWPCR.
6. Set the C0WPRCR[CE] bit to enable counting of the watch point events. If you use the watch point events to enable/disable the profiling unit according to WPCE, clear this bit.
7. After the measurement are finished check the following registers:

— Read the C0PISR[OVE] bit.
— In time-out mode, read C0PRCR.
— If C0PISR[OVE] is set or if C0PRCR is equal to C0PTOR, the results are not valid.
— Read C0PGCRx to get the number of watch point events during the measurement.

4.4.3 Event Selection

Events are selected using a combination of the CLASS watch point and profiling registers. **Table 4-1** lists the measurement modes, the required configuration settings, and the events measured by the specific CLASS Profiling General Registers for each CLASS module. See **Section 4.7** for the register details.

Table 4-1. C0PGCRx Events Selection

Measurement Mode	Configuration Settings for Each Mode				Events Measured			
	C0WPCR [CE]	C0TPCR [TT]	C0TPCR [PMM]	C0IPCRx [PMM]	C0PGCR0	C0PGCR1	C0PGCR2	C0PGCR3
None selected	0	—	00	00000	—	—	—	—
Initiator Priority and Auto-Upgrade	0	—	00	00001	No. of Initiator Requests with Priority 1	No. of Initiator Requests with Priority 2	No. of Initiator Requests with Priority 3	No. of Initiator Auto-Upgrade
	Allows the user to profile a statistical distribution of transaction priorities. This information can be used to consider whether other arbitration methods (priority mapping, Auto-upgrade, weighted arbitration, priority mask enable) should be considered							
Initiator Access Type	0	—	00	00010	Initiator Pending Request cycles (not acknow-ledged)	No. of Initiator Read Requests	No. of Initiator Real Write Requests (not confirmed)	No. of Initiator Fast Write Requests (not confirmed)
	Real/Fast confirmation refers to the type of eot for writes that are requested per MBus transaction. • Real means that for coherency reasons the eot for write should be high only after the data is written to the target. • Fast means that for performance reasons the eot can be high even before the data is written to the target. Real/Fast confirmation support is initiator dependent and the user cannot change the related settings. A summary follows below: • DSP Cores – Write through uses fast confirmation – Write through with SYNCIO generate real confirmation – Last burst in a line write-back is sent with real confirmation • DMA. Channel transfers come with fast confirm and real confirm on the last data of a transfer. • Serial RapidIO Inbound Transactions. When the transfer comes with a response (NWRITE_R), the last data uses real confirmation and fast confirm for the previous transfer. For NWRITE, data is transferred with fast confirmation • Serial RapidIO Outbound Transactions. Supports fast confirm on the last data transfer per channel transfer and fast confirm for the previous transfer. • QUICC Engine and PCI Express Transactions. Always uses real confirmation The resulting information can be used to redesign the code to minimize stalls related to real confirmations. Use of large transactions reduces the number of real confirmations because they are only required for the last beat of the transfer.							

Table 4-1. C0PGCRx Events Selection (Continued)

Measurement Mode	Configuration Settings for Each Mode				Events Measured			
	C0WPCR [CE]	C0TPCR [TT]	C0TPCR [PMM]	C0IPCRx [PMM]	C0PGCR0	C0PGCR1	C0PGCR2	C0PGCR3
Initiator Stall	0	—	00	00011	No. of Write After Read (WAR) events	No. of stall cycles due to WAR events	—	No. of stall cycles due to Target Switch (TS) events
	By managing WAR and target switching, an initiator can enhance the performance for memory accesses and thus minimize run time. **Note:** Stall at the initiator does not mean that the initiator target data phase is idle; it indicates the delay after which the next access from the initiator starts at the target after a WAR or TS event.							
Initiator Priority Upgrade	0	—	00	00100	Initiator Sample 0 Upgrade cycles	Initiator Sample 1 Upgrade cycles	Initiator Sample 2 Upgrade cycles	—
	Initiator Priority Upgrade measurement counts the number of cycles a low-priority transaction is upgraded because a high-priority transaction was scheduled into the CLASS pipeline. This upgrading mechanism is necessary to reduce the service latency of newly issued transactions because the CLASS is ordered in nature and does not do preemption. A high-priority transaction could otherwise be delayed by preceding lower priority accesses for long periods of time. The upgrade is to the priority level of the high-priority transaction and it is only possible if the transaction is upgradable. The upgrade attribute of a transaction is initiator dependent and it is hard-wired. The system DMA is the only initiator issuing non-upgradable transactions. The counter measurements take place in the early stages of the CLASS pipeline at different sample locations. Transactions in sample 0 are older than transactions on sample 1, and transactions in sample 1 are older than the ones in sample 2. Any type of priority upgrade, including auto-upgrade, is captured by these counters. These counters provide a good view of the starvation dynamics of the system.							
Initiator Priority Non-Upgrade	0	—	00	00101	Initiator Sample 0 No Upgrade cycles	Initiator Sample 1 No Upgrade cycles	Initiator Sample 2 No Upgrade cycles	—
	Initiator Priority No-Upgrade measurement counts the number of cycles an older low-priority transaction is not upgraded despite the fact that a newer high-priority is scheduled by the same initiator. Compare with “Initiator Priority Upgrade”. This applies only to System DMA transactions because they are not upgradable by default. All other initiator transactions can be upgraded. These counts are not very useful for performance analysis, but they provide a good view of the starvation dynamics of the system.							
Initiator Supervisor	0	—	00	00110	Request pending cycles	No. of supervisor accesses	No. of non-supervisor accesses	—
	Supervisor/user accesses can be used to profile the amount of time the OS spends running and how much time is left for the users application. Effective for evaluating the core subsystem supervisor/user mode usage. The implementation depends on the values configured in M_DSDAx[DAPU]/M_DSDAx[DAPS], and so forth. See the *SC3850 Core Subsystem Reference Manual* for configuration details.							
Initiator Bandwidth	0	—	00	00111	No. of Initiator Read Data Acknow-ledges.	No. of Initiator Write Data Acknow-ledges	—	—
	Can be used to profile the number of data reads and writes. The amount of data that passes through the initiator port = [(NumberOfReadAck + NumberOfWriteAck) × W]. where W is the port width. Note that an access may be smaller than the port width.							

Table 4-1. C0PGCRx Events Selection (Continued)

Measurement Mode	Configuration Settings for Each Mode				Events Measured			
	C0WPCR [CE]	C0TPCR [TT]	C0TPCR [PMM]	C0IPCRx [PMM]	C0PGCR0	C0PGCR1	C0PGCR2	C0PGCR3
Initiator-target Bandwidth	0	—	00	10000 + T	No. of Read Data Acknow-ledges between Initiator and Target T	No. of Write Data Acknow-ledges between Initiator and Target T	—	—
	Can be used to profile the number of data reads and writes. between an initiator and a specific target The amount of data that passes through the initiator port = [(NumberOfReadAck + NumberOfWriteAck) × W]. where W is the port width. Note that an access may be smaller than the port width.							
Arbitration Winner Priority	0	0	01	00000	No. of priority 0 trans-actions at Target T	No. of priority 1 trans-actions at Target T	No. of priority 2 trans-actions at Target T	No. of priority 3 trans-actions at Target T
	Can be used to see the priority distribution for a target port							
Target Access Splitting	0	1	01	00000	No. of M-byte accesses toward target T. M = Initiator requests (pre splitting accesses)	No. of N-byte accesses toward target T. N = Initiator requests (post splitting accesses)	—	—
	Target access splitting gives statistical information about the ratio between initiator and target accesses towards every target. It returns the number of accesses in pre and post splitting. For example, say there are only 2 types of accesses to some target #T: 64-Byte and 16-Byte, and this target only supports 16-Byte accesses. Then, if the count shows 10000 initiator accesses and 34000 target accesses, this translates to 8000 × (64-Byte accesses) + 2000 × (16-Byte accesses), and they were split into 8000 × (4 × 16-Byte accesses) + 2000 × (16-Byte access) = 32000 + 2000 = 34000 accesses							
Arbitration Collision	0	0	10	00000	Target T Pending Request cycles	—	—	—
	This represents the number of cycles with more than one request directed to Target T.							
Target Bandwidth	0	1	10	00000	No. of Target T Read Data Acknow-ledges	No. of Target T Write Data Acknow-ledges	—	—
	Can be used to profile the number of data reads and writes to Target T. The amount of data that passes through the target port = [(NumberOfReadAck + NumberOfWriteAck) × W] where W is the port width.Note that an access can be less than the port width							

Table 4-1. C0PGCRx Events Selection (Continued)

Measurement Mode	Configuration Settings for Each Mode				Events Measured			
	C0WPCR [CE]	C0TPCR [TT]	C0TPCR [PMM]	C0IPCRx [PMM]	C0PGCR0	C0PGCR1	C0PGCR2	C0PGCR3
Target Stall	0	—	11	00000	No. of Write after Read (WAR) events	No. of stall cycles due to WAR events	—	—
	By managing WAR event, the system designer can enhance memory access performance and thus minimize run time. **Note:** A WAR stall at the target does not mean that the target bus is idle. It indicates the delay after which the next access from the initiator starts at the target after a WAR event.							
Watch Point	1	—	00	00000	No. of Watch Point Event	—	—	—
	Watch point event scan be snooped on any initiator and any target. It can be used for debug and also for triggering profiling counts that are pre-configured, this is non-intrusive (eliminating the need to write to the registers in the middle of an application)							

4.4.4 Debug and Profiling Events

The CLASS generates two event interrupts:

- Watch point event (WPE)
- Overflow event (OVE)

4.5 CLASS Reset

The CLASS implements 2 kinds of reset:

- Synchronous hard reset.
- Synchronous soft reset.

4.5.1 Soft Reset

This kind of reset has the following effects:

- All the CLASS state machines return to their idle state.
- All the CLASS operation FFs return to their idle state.
- The CLASS configuration registers are reset as described in the table for each register in **4.7**, *Programming Model*.

4.5.2 Hard Reset

This reset brings all states machines to idle state and sets all CLASS registers to the reset values.

4.6 Limitations

- The CLASS does not support split transaction between targets. A split transaction starts inside a targets address space but ends outside of this window. The CLASS does not report an error in this event and the results are unpredictable. You must avoid this situation.
- The CLASS does not support pipelined transactions between different targets by the same initiator. The pipeline is stalled until all transaction to one target are closed before issuing a transaction to a different target.
- Arbitration Fairness. Requests with the higher priority levels may cause transactions with lower priority levels not to be acknowledged, resulting in a starvation condition. This situation can be prevented by using the auto priority upgrade supported by the expander module and/or by the multiplexer and arbiter module priority mask mechanism.
- Do not allow MAPLE-B2 to access itself.
- Core subsystem 0 can only access its own M2 space and the M2 space of core subsystems 2, 3, 4, and 5.
- Core subsystem 1 can only access its own M2 space and the M2 space of core subsystems 2, 3, 4, and 5.
- Core subsystem 2 can only access its own M2 space and the M2 space of core subsystems 4 and 5.
- Core subsystem 3 can only access its own M2 space and the M2 space of core subsystems 4 and 5.
- Core subsystems 4 and 5 can only access their own M2 space.

4.7 Programming Model

All the CLASS registers are 32-bit registers. All the read and write accesses are executed through the bus. The CLASS modules use the following registers:

- CLASS Priority Mapping Registers (see **page 4-15**)
- CLASS Priority Auto Upgrade Value Registers (see **page 4-16**)
- CLASS Priority Auto Upgrade Control Registers (see **page 4-17**)
- CLASS Error Address Registers (see **page 4-18**)
- CLASS Error Extended Address Registers (see **page 4-19**)
- CLASS Initiator Profiling Configuration Registers (see **page 4-20**)
- CLASS Initiator Watch Point Control Registers (see **page 4-22**)
- CLASS Arbitration Weight Registers (see **page 4-23**)
- CLASS Start Address Decoder x (see **page 4-24**)
- CLASS End Address Decoder x (see **page 4-25**)
- CLASS Attributes Decoder x (see **page 4-26** and **page 4-28**)
- CLASS IRQ Status Register (see **page 4-29**)
- CLASS IRQ Enable Register (see **page 4-30**)
- CLASS Target Profiling Configuration Register (see **page 4-30**)
- CLASS Profiling Control Register (see **page 4-32**)
- CLASS Watch Point Control Register (see **page 4-33**)
- CLASS Watch Point Access Configuration Register (**page 4-34**)
- CLASS Watch Point Extended Access Configuration Register (see **page 4-35**)
- CLASS Watch Point Address Mask Register (see **page 4-36**)
- CLASS Profiling Time Out Register (see **page 4-37**)
- CLASS Target Watch Point Control Register (see **page 4-38**)
- CLASS Profiling IRQ Status Register (see **page 4-39**)
- CLASS Profiling IRQ Enable Register (see **page 4-40**)
- CLASS Profiling Reference Counter Register (see **page 4-40**)
- CLASS Profiling General Counter Registers (see **page 4-41**)
- CLASS Arbitration Control Register (see **page 4-42**)

Note: The base address for addressing CLASS registers is 0xFFF18000.

4.7.1 CLASS Priority Mapping Registers (C0PMRx)

C0PMR[0–14] CLASS Priority Mapping Registers Offset 0x800 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															PB
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—		PM3		—		PM2		—		PM1		—		PM0	
Type	R/W															
Reset	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0

C0PMRx is used as a look-up table for mapping the priority received from the initiator. By default the input priority is mapped to an identical value on the output. This register also enables/disables the priority derivation feature.

Note: You cannot write to this register while there are open CLASS transactions.

Table 4-2 lists the C0PMRx bit field descriptions.

Table 4-2. C0PMRx Bit Descriptions

Name	Reset	Description	Settings
— 31–17	0	Reserved. Write to 0 for future compatibility.	
PB 16	0	**Priority Bypass** Enables/disables the priority derivation mechanism.	0 Filter the mapped priority with the priority derivation mechanism. 1 Pass the mapped priority from initiator to target with no filtering.
— 15–14	0	Reserved. Write to 0 for future compatibility.	
PM3 13–12	11	**Priority Mapping 3** Holds the priority value assigned to transactions that arrive with a value of 3.	00 Priority 0 01 Priority 1 10 Priority 2 11 Priority 3
— 11–10	0	Reserved. Write to 0 for future compatibility.	
PM2 9–8	10	**Priority Mapping 2** Holds the priority value assigned to transactions that arrive with a value of 2.	00 Priority 0 01 Priority 1 10 Priority 2 11 Priority 3
— 7–6	0	Reserved. Write to 0 for future compatibility.	
PM1 5–4	01	**Priority Mapping 1** Holds the priority value assigned to transactions that arrive with a value of 1.	00 Priority 0 01 Priority 1 10 Priority 2 11 Priority 3
— 3–2	0	Reserved. Write to 0 for future compatibility.	

Table 4-2. C0PMRx Bit Descriptions (Continued)

Name	Reset	Description	Settings
PM0 1–0	0	**Priority Mapping 0** Holds the priority value assigned to transactions that arrive with a value of 0.	00 Priority 0 01 Priority 1 10 Priority 2 11 Priority 3

4.7.2 CLASS Priority Auto Upgrade Value Registers (C0PAVRx)

C0PAVR[0–14] CLASS Priority Auto Upgrade Value Registers Offset 0x840 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	AUV															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0PAVRx holds the value loaded to the priority auto-upgrade counter.

Note: You can write to this register while there are open CLASS transactions. The AUV field is loaded into the auto-upgrade counter only when you set the AUE bit in C0PACRx. Therefore, always update the AUV field in the C0PAVRx before you set the AUE bit.

Table 4-3 lists the C0PAVRx bit field descriptions.

Table 4-3. C0PAVRx Bit Descriptions

Name	Reset	Description
— 31–16	0	Reserved. Write to 0 for future compatibility.
AUV 15—0	0	**Auto-Upgrade Value** The value loaded into the auto-upgrade counter. The priority of the access determines which bits of this value are used, as follows: • Priority 0: All 16 bits are loaded into the counter. • Priority 1: Bits 15–1 are loaded into bit 14–0 of the counter and a 0 into bit 15. • Priority 2: Bits 15–2 are loaded into bits 13–0 of the counter and 0 into bits 15 and 14.

4.7.3 CLASS Priority Auto Upgrade Control Registers (C0PACRx)

C0PACR[0–14] CLASS Priority Auto Upgrade Control Registers Offset 0x880 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—															AUE
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0PACRx controls the priority auto-upgrade mechanism.

Note: You can write to this register while there are open CLASS transactions.

Table 4-4 lists the C0PACRx bit field descriptions.

Table 4-4. C0PACRx Bit Descriptions

Name	Reset	Description	Settings
— 31–1	0	Reserved. Write to 0 for future compatibility.	
AUE 0	0	**Auto-Upgrade Enable** Enables/disables the auto-upgrade mechanism. **Note:** This bit can only be cleared by a hardware reset.	0 Auto-upgrade mechanism disabled. 1 Auto-upgrade mechanism enabled.

4.7.4 CLASS Error Address Registers (C0EARx)

C0EAR[0–14] CLASS Error Address Registers Offset 0x980 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ERR_ADD															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERR_ADD															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The C0EAR is used to store the address (32 least significant bits) of the internal transaction when an error has been identified by the CLASS. When an error occurs and an error bit is set in the C0ISR, the internal transaction address is stored and the C0EARx is locked and does not update even if another error with a different transactions address occurs. Only when the AEIx bit in the C0ISR is cleared (either by a hardware reset or by writing a 1 to it) is C0EARx unlocked.

Table 4-5 lists the C0EARx bit field descriptions.

Table 4-5. C0EARx Bit Descriptions

Name	Reset	Description
ERR_ADD 31–0	0	**Error Address** This field stores the 32 lsbs of the address of the internal transaction that caused the error.

Note: The generated interrupts correspond to the following sources:

- C0EAR0 = Address generated by core 0.
- C0EAR1 = Address generated by core 1.
- C0EAR2 = Address generated by core 2.
- C0EAR3 = Address generated by core 3.
- C0EAR4 = Address generated by core 4.
- C0EAR5 = Address generated by core 5.
- C0EAR6 = Address generated by MAPLE-B2 port 0.
- C0EAR7 = Address generated by MAPLE-B2 port 1.
- C0EAR8 = Address generated by HSSI port 0.
- C0EAR9 = Address generated by peripheral bridge.
- C0EAR10 = DMA port 0.
- C0EAR11 = DMA port 1.
- C0EAR12 = Address generated by HSSI port 1
- C0EAR13 = Address generated by MAPLE-B2 port 2.
- C0EAR14 = Address generated by MAPLE-B2 port 3.

4.7.5 CLASS Error Extended Address Registers (C0EEARx)

C0EEAR[0–14] CLASS Extended Error Address Registers Offset 0x9C0 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															RW
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	SA	—					SRC_ID					ERR_ADD			
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The C0EEAR stores the most significant 4 bits of the address of the internal transaction when an error has been identified by the CLASS. This register also stores the attributes and the source ID of this transaction. When an error occurs and an error bit is set in the C0ISR, the internal transaction address is stored and the C0EEAR is locked and is not updated even if another error with a different transactions address/attributes occurs. Only when the AEI bit in the CISR is cleared (either by a hardware reset or by writing a 1 to it) is C0EEAR unlocked.

Table 4-6 lists the C0EEARx bit field descriptions.

Table 4-6. C0EEARx Bit Descriptions

Name	Reset	Description	Settings
— 31–17	0	Reserved. Write to 0 for future compatibility.	
RW 16	0	**Read/Write** This field indicates whether the transaction that caused the error was a read or a write.	0 Write. 1 Read.
— 15	0	Reserved. Write to 0 for future compatibility.	
SA 14	0	**Supervisor Access** This field indicates whether the transaction that caused the error was in supervisor mode.	0 Not supervisor. 1 Supervisor.
— 13–9	0	Reserved. Write to 0 for future compatibility.	

Table 4-6. C0EEARx Bit Descriptions (Continued)

Name	Reset	Description	Settings
SRC_ID 8–4	0	**Source ID** Identifies the source ID of the initiator that caused the error.	0x00 Core subsystem 0 0x01 Core subsystem 1 0x02 Core subsystem 2 0x03 Core subsystem 3 0x04 Core subsystem 4 0x05 Core subsystem 5 0x06 MAPLE-B2 port 0 0x07 MAPLE-B2 port 1 0x08 DMA port 0 0x09 DMA port 1 0x0B QUICC Engine subsystem 0x0C Serial RapidIO Port 0 0x0D Serial RapidIO Port 1 0x11 CPRI read 0x12 CPRI write 0x13 eMSG read 0x14 eMSG write 0x15 MAPLE-B2 port 2 0x16 MAPLE-B2 port 3 All other values reserved.
ERR_ADD 3–0	0	**Error Address** This field stores the 4 msbs of the address of the internal transaction that caused the error.	

4.7.6 CLASS Initiator Profiling Configuration Registers (C0IPCRx)

C0IPCR[0–14] CLASS Initiator Profiling Configuration Registers‘Offset 0xA00 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—											PMM				
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0IPCRx controls the CLASS initiator profiling measurements. Each initiator has a dedicated C0IPCR which is numbered according to the initiator number within each CLASS module. The CLASS can perform only one measurement for a specific module at a time. Select the desired measurement for the initiator, enter the PMM value in the associated C0IPCR and make sure all the other C0IPCR and the C0TPCR for that CLASS are cleared.

Note: Only one PMM field among all C0IPCRx and C0TPCR can be greater than 0 during profiling.

Table 4-7 lists the C0IPCRx bit field descriptions.

Table 4-7. C0IPCRx Bit Descriptions

Name	Reset	Description	Settings
— 31–5	0	Reserved. Write to 0 for future compatibility.	
PMM 4–0	0	**Profiling Measurement Mode** Determines the profiling measurement mode for the matching initiator. **Note:** This register can only be cleared by a hardware reset.	00000 No measurement. 00001 Initiator priority and auto-upgrade. 00010 Initiator access type. 00011 Initiator stall. 00100 Initiator priority upgrade. 00101 Initiator priority non-upgrade. 00110 Initiator supervisor. 00111 Initiator bandwidth. 01000– 01111 reserved 10000 Target 0 bandwidth. 10001 Target 1 bandwidth. 10010 Target 2 bandwidth. 10011 Target 3 bandwidth. 10100 Target 4 bandwidth. 10101 Target 5 bandwidth. 10110 Target 6 bandwidth. 10111 Target 7 bandwidth. 11000 Target 8 bandwidth 11001 Target 9 bandwidth 11010– 11111 reserved

Table 4-8. Initiator Numbers

Initiator Number	Initiator Module
0	DSP core subsystem 0

	—															WPEN
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0IWPCRx controls the Watch Point Unit operation for the associated initiator. The Watch Point Unit monitors a specific access defined by the C0WPCRx, C0WPACRx, C0WPEACRx, and C0WPAMR. Each initiator can be enabled/disabled to monitor the selected access. You can write to this register while there are open CLASS transactions.

Note: Only one WPEN field can be set among all C0IWPCRx and C0TWPCRx when snooping watch point events.

Table 4-9 lists the C0IWPCRx bit field descriptions.

Table 4-9. C0IWPCRx Bit Descriptions

Name	Reset	Description	Settings
— 31–1	0	Reserved. Write to 0 for future compatibility.	
WPEN 0	0	**Watch Point Enable** Enables/disables the auto-upgrade mechanism. **Note:** This bit can only be cleared by a hardware reset.	0 The watch point is disabled. 1 The watch point is enabled.

4.7.8 CLASS Arbitration Weight Registers (C0AWRx)

C0AWR[0–14] CLASS Arbitration Weight Registers Offset 0xA80 + x*0x04

The value in C0AWRx determines the arbitration weight for the associated initiator. An initiator with arbitration weight of W is allowed to initiate up to W+1 consecutive transactions.

Note: When another initiator requests for access with higher priority level, the CLASS Arbiter chooses the higher priority request instead of the weighted winner.

Table 4-10 lists the C0AWRx bit field descriptions.

Table 4-10. C0AWRx Bit Descriptions

Name	Reset	Description
— 31–4	0	Reserved. Write to 0 for future compatibility.
WEIGHT 3–0	*For C0AWR[0–9] and C0AWR[12–14]:* 1111 *For C0AWR[10–11]:* 0111	**Weight** Contains the arbitration weight assigned to the associated initiator.

The reset values be changed by the designer according to the application requirements. See **Table 4-30** for recommended initial settings for the CLASS Arbitration Control Register (C0ACR).

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—											SPRW	—			DEN
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

C0ATD1 controls the functionality of each specific decoder for CLASS toward the DDR controller ports. In addition to containing the bit that enables/disables the port 1, this register also contains a bit to determine whether the DDR access uses a direct connection or uses split read/write access split between the two DDR ports.

If a decoder is disabled, it never indicates a hit, even if the address corresponds to the decoder address window. In this case the CLASS treats the space as if it is not assigned to any port. However, any transaction that was acknowledged up to and including the cycle in which DEN is cleared continues normally until completed.

Note: To ensure proper operation, do not enable the specific decoder before the start and end addresses are specified in the associated C0SADx and C0EADx.

This registers is reset by a hardware reset only. **Table 4-26** lists the C0ATD1 bit field descriptions.

Table 4-13. C0ATD1 Bit Descriptions

Name	Reset	Description	Settings
— 31–5	0	Reserved. Write to 0 for future compatibility.	
SPRW 4	1	**Split Read/Write** Determines whether reads and writes both occur on a port or they are split between two ports. **Note:** **Table 4-14** summarizes the DDR access configuration options.	0 DDR read and write accesses use both target ports1 and 2. Address decoding for each port is done by the respective register sets: C0SAD1/C0EAD1 are used for port 1 and C0SAD2/C0EAD2 are used for port 2. Use of this mode may improve performance for applications with an unbalanced proportion of reads and writes toward DDR, or it can be used to divide core access to DDR (for example, some of the cores can use the low DDR address space and the other cores can use the high DDR address space). 1 DDR reads and writes go through different ports (DDR read uses target 2 and DDR writes use target 1). The start and end addresses for both ports are controlled by C0SAD1 and C0EAD1.
— 31–1	0	Reserved. Write to 0 for future compatibility.	
DEN 0	1	**Decoder Enable** Enables/disables the specified decoder.	0 Disables the decoder. 1 Enables the decoder.

Note: Never write to this register when there are open transactions being handled by the CLASS to the specified target controlled by the register.

Table 4-14. DDR Access Configurations

Scenario	C0ATD1[DEN]	C0ATD2[DEN]	COATD1[SPRW]	Result
1	0	0	x	No accesses can be made to DDR
2	0	1	x	All DDR accesses use Target2 as defined by C0SAD2/C0EAD2. (no benefit)
3	1	0	0	All DDR accesses use Target1 as defined by C0SAD1/C0EAD1. (no benefit)
4	1	x	1	Writes to DDR use Target 1. Reads from DDR use Target 2. Both ports are defined by C0SAD1/C0EAD1.
5	1	1	0	Some accesses use Target 1 (defined by C0SAD1/C0EAD1). Some accesses use Target 2 (defined by C0SAD2/C0EAD2). Use for cases of unbalanced reads/writes or to split address space among different masters. **Note:** Target2 has a higher priority than Target1.

C0ATDx controls the functionality of each specific decoder for CLASS toward the DDR controller (C0ATD2 if COATD1[SPWR] is cleared) and the M3 memory (C0ATD[7–9]). They contain the bit that enables/disables the specific port.

If a decoder is disabled, it never indicates a hit, even if the address corresponds to the decoder address window. In this case the CLASS treats the space as if it is not assigned to any port. However, any transaction that was acknowledged up to and including the cycle in which DEN is cleared continues normally until completed.

Note: To ensure proper operation, do not enable the specific decoder before the start and end addresses are specified in the associated C0SADx and C0EADx.

These registers are reset by a hardware reset only. **Table 4-26** lists the C0ATDx bit field descriptions.

Table 4-15. C0ATDx Bit Descriptions

Name	Reset	Description	Settings
— 31–1	0	Reserved. Write to 0 for future compatibility.	
DEN 0	C0ATD2 = 0 C0ATD[7–9] = 1	**Decoder Enable** Enables/disables the specified decoder.	0 Disables the decoder. 1 Enables the decoder.

Note: Never write to these registers when there are open transactions being handled by the CLASS to the specified target controlled by the register.

Note: C0ATD2 is valid only if C0ATD1[SPRW] is clear (0).

4.7.13 CLASS IRQ Status Register (C0ISR)

C0ISR CLASS IRQ Status Register Offset 0xD80

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	AEI14	AEI13	AEI12	AEI11	AEI10	AEI9	AEI8	AEI7	AEI6	AEI5	AEI4	AEI3	AEI2	AEI1	AEI0
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The C0ISR indicates when an event occurs that requires the generation of an interrupt. There is a dedicated bit for each initiator. An interrupt is generated only when a status bit is set and the corresponding bit in the IRQ Enable register is set. Bits are cleared by writing ones to them. Writing a zero has no effect.

Note: You can write to or read this register at any time. The register is reset by a hard or soft reset.

Table 4-16 lists the C0ISR bit field descriptions.

Table 4-16. C0ISR Bit Descriptions

Name	Reset	Description	Settings
— 31–15	0	Reserved. Write to 0 for future compatibility.	
AEI[14–0] 14–0	0	**Address Error Interrupt 14–0** A bit is set if for a received transaction request, it does not belong to any port address space or falls inside one of the error areas.	0 No error. 1 Error detected.

4.7.14 CLASS IRQ Enable Register (C0IER)

C0IER CLASS IRQ Enable Register Offset 0xDC0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0WPEACR, along with C0WPACR, configures the selected access to monitor. The watch point monitoring occurs only if the respective function is enabled in the C0WPCR. The register is reset only by a hardware reset. **Table 4-22** lists the C0WPEACR bit field descriptions.

Table 4-22. C0WPEACR Bit Descriptions

Name	Reset	Description	Settings
UP 31	0	**Upgradeable Access** Defines the upgradeable access type to monitor.	0 Non-upgradeable access. 1 Upgradeable access.
WC 30	0	**Write-with-Confirm Access** Defines the write-with-confirm access type to monitor.	0 Fast confirm access. 1 Write-with-confirm access.
— 29	0	Reserved. Write to 0 for future compatibility.	
EATTR 28–24	0	**EOT Attributes** Defines the EOT attributes to monitor.	0x0– 0x7 Reserved 0x8 Target port 0 CCSRs 0x9 Target port 1 DDR write 0xA Target port 2 DDR read 0xB Target port 3 MAPLE-B2 0xC Target port 4 Cores 4 and 5 0xD Target port 5 Cores 2 and 3 0xE Target port 6 Cores 0 and 1 0xF Target port 7 M3 memory port 0 0x10 Target port 8 M3 memory port 1 0x11 Target port 9 M3 memory port 2 All other values reserved.
— 23–16	0	Reserved. Write to 0 for future compatibility.	

Table 4-22. C0WPEACR Bit Descriptions (Continued)

Name	Reset	Description	Settings

	TO															
Type	R/W															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

C0PTOR is used to stop the profiling unit operation. When the C0PRCR reaches the value stored in C0PTOR and C0PCR[TOE] is set, the CLASS clears the C0PCR[PE] bit to disable the profiling unit. When C0PCR[PE] clears, the CLASS stops all profiling counters. The register is reset only by a hardware reset. **Table 4-24** lists the C0PTOR bit field descriptions.

Table 4-24. C0PTOR Bit Descriptions

Name	Reset	Description
TO 31–0	0xFFFFFFFF	**Time-Out** Holds the time-out value used to stop the profiling unit when the time-out function is enabled.

4.7.22 CLASS Target Watch Point Control Registers (C0TWPCR)

C0TWPCR CLASS Target Watch Point Control Registers Offset 0xE1C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—								WPEN7	WPEN6	WPEN5	WPEN4	WPEN3	WPEN2	WPEN1	WPEN0
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The C0TWPCR controls the watch point unit operation for CLASS targets. The watch point unit monitors a specific access defined in C0WPCR, C0WPACR, C0WPEACR, and C0WPAMR. Each target can be enabled/disabled for monitoring the specified access type. The register is reset by a hard reset only.

Note: Only one WPEN field can be set among all the C0IWPCRx and C0TWPCR. That is, only one watch point unit can be active at a time.

Table 4-16 lists the C0TWPCR bit field descriptions.

Table 4-25. C0TWPCR Bit Descriptions

Name	Reset	Description	Settings
— 31–8	0	Reserved. Write to 0 for future compatibility.	
WPEN[7–0] 7–0	0	**Watch Point Enable 7–0** Each bit enables monitoring of access by the associated target.	0 The watch point unit for the associated target is disabled. 1 The watch point unit for the associated target is enabled.

4.7.23 CLASS Profiling IRQ Status Register (C0PISR)

C0PISR CLASS Profiling IRQ Status Registers Offset 0xE20

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—														WPE	OVE
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0PISR indicates that a watch point event occurred or that the C0PRCR overflowed. An interrupt is generated if the status bit is set and the corresponding bit in C0PIERx is set to enable the interrupt. You can write to or read the register at any time. Write a 1 to a bit to clear it; writing a 0 has no effect. The register is reset by a hard or soft reset. **Table 4-26** lists the C0PISR bit field descriptions.

Table 4-26. C0PISR Bit Descriptions

Name	Reset	Description	Settings
— 31–2	0	Reserved. Write to 0 for future compatibility.	
WPE **1**	0	**Watch Point Event** Enables monitoring of access by the associated target.	0 No watch point event occurred. 1 Watch point event captured.
OVE **0**	0	**Overflow Event** Enables monitoring of access by the associated target.	0 No overflow occurred. 1 C0PRCR overflowed (reached 0xFFFFFFFF) during the last measurement.

4.7.24 CLASS Profiling IRQ Enable Register (C0PIER)

C0PIER CLASS Profiling IRQ Enable Registers Offset 0xE24

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—														WPEE	OVEE
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0PIER enables/disables the generation of interrupts by the debug profiling unit. You can write to the register at any time. The register is reset by a hard reset only. **Table 4-27** lists the C0PIER bit field descriptions.

Table 4-27. C0PIER Bit Descriptions

Name	Reset	Description	Settings
— 31–2	0	Reserved. Write to 0 for future compatibility.	
WPEE **1**	0	**Watch Point Event Enable** Enables/disables a watch point interrupt.	0 Watch point interrupt is masked. 1 Watch point interrupt is enabled.
OVEE **0**	0	**Overflow Event Enable** Enables/disables an overflow interrupt.	0 Overflow interrupt is masked. 1 Overflow interrupt is enabled.

4.7.25 CLASS Profiling Reference Counter Register (C0PRCR)

C0PRCR CLASS Profiling Reference Counter Registers Offset 0xE40

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	C0T															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNT															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0PRCR is the reference counter for all profiling measurements. This read-only register counts the number of cycles occurring during the profiling measurement or during the watch point unit operation. The counter starts counting from zero when the profiling unit is enabled. The C0PRCR stops when the profiling unit is disabled, or when the C0PRCR reaches the value stored in C0PTOR and TOE is set, which causes the CLASS to clear the PE bit to disable the profiling

unit. When PE clears, the CLASS stops all profiling counters. The register is reset only by a hardware reset only. **Table 4-28** lists the C0PRCR bit field descriptions.

Table 4-28. C0PRCR Bit Descriptions

Name	Reset	Description
CNT 31–0	0	**Counter** Holds the reference counter for the profilers.

4.7.26 CLASS Profiling General Counter Registers (C0PGCRx)

C0PGCR[0–3] CLASS Profiling General Counter Registers Offset 0xE44 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNT															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNT															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C0PGCRx is used to count profiling unit or watch point unit events. This read-only register counts the number of cycles occurring during the profiling measurement or during the watch point unit operation. The counter starts counting from zero when the profiling unit is enabled. The C0PRCR stops when the profiling unit is disabled, or when the C0PRCR reaches the value stored in C0PTOR and TOE is set, which causes the CLASS to clear the PE bit to disable the profiling unit. When PE clears, the CLASS stops all profiling counters. The register is reset only by a hardware reset. **Table 4-29** lists the C0PGCR bit field descriptions.

Table 4-29. C0PGCR Bit Descriptions

Name	Reset	Description
CNT 31–0	0	**Counter** Holds the counter value of the selected measurement. **Table 4-1** lists the measurements counted by each counter for each configuration combination.

4.7.27 CLASS Arbitration Control Register (C0ACR)

C0ACR CLASS Arbitration Control Registers Offset 0xFC0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—			PME	—											
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Boot	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—						LA9	LA8	LA7	LA6	LA5	LA4	LA3	LA2	LA1	LA0
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Boot	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1

The C0ACR controls the CLASS arbiters. There is a dedicated bit for each arbiter that controls the Late Arbitration mode of the associated arbiter. When Late Arbitration mode is enabled, the arbiter delays the decision about the winner according to the MDBW parameter and the byte count of the winner access. When Late Arbitration mode is disabled, the arbiter makes a decision every clock cycle.The register is reset by a hard reset only. **Table 4-30** lists the C0ACR bit field descriptions.

Table 4-30. C0ACR Bit Descriptions

Name	Reset	Description	Settings
— 31–29	0	Reserved. Write to 0 for future compatibility.	
PME **28**	0	**Priority Mask Enable** Enables/disables the operation of the priority mask unit for starvation elimination.	0 Priority mask disabled. 1 Priority mask enabled.
— 27–10	0	Reserved. Write to 0 for future compatibility.	
LA[9–0] 9–0	1	**Late Arbitration 9–0** Enables/disables late arbitration mode for the associated arbiter. **Note:** As with the arbitration weight (see **Section 4.7.8**, *CLASS Arbitration Weight Registers (C0AWRx)*, on page 4-23), the default value for this field does not yield optimal performance. Therefore, the boot program after reset, writes a value of 0x3FF to this field. This value assigns late arbitration to the cores, the M2 memory, DDR memory, and the M3 memory. This is just an initial value, and can be changed according to the application requirements and system traffic.	0 Late arbitration disabled. 1 Late arbitration enabled.

5 Reset

The reset and control signals provide many options for MSC8157E operation by configuring various modes and features during power-on reset. Most of these features are configured by loading a reset configuration word to the MSC8157E device that combine with a few direct configuration inputs sampled during the reset sequence. This section describes the various ways to reset and configure the MSC8157E device.

5.1 Reset Operations

The MSC8157E has several inputs to the reset logic:

- Power-on reset ($\overline{\text{PORESET}}$)
- External hard reset ($\overline{\text{HRESET}}$, $\overline{\text{HRESET\_IN}}$) (See **Chapter 3**, *External Signals*for detailed signal descriptions)
- Software watchdog reset
- RapidIO reset
- Software hard reset

All of these reset sources are fed into the reset controller and, depending on the source of the reset, different actions are taken. The reset status register described in **Section 5.3.3** indicates the last sources to cause a reset.

Note: If the device is reset by any source, always reload all data into M3 and M2 memory before continuing operation.

5.1.1 Reset Sources

Table 5-1 describes reset sources.

Table 5-1. Reset Sources

Name	Description
Power-on reset (PORESET)	Input pin. Asserting this pin initiates the power-on reset flow that resets all the device and configures various attributes of the device including its clock modes.
Hard reset (HRESET or HRESET_IN)	HRESET is a bidirectional I/O pin. HRESET is an open-drain pin. HRESET_IN is an input that permits a hard reset of an individual device without invoking a hard reset on other devices in a chain. The MSC8157E can detect an external assertion of HRESET or HRESET_IN only if it occurs while the MSC8157E is not asserting reset.
Software watchdog reset	After the MSC8157E watchdog timer counts to zero, a software watchdog reset is generated. The enabled software watchdog event then generates an internal hard reset sequence.
RapidIO reset	When the RapidIO logic asserts the RapidIO hard reset signal, an internal hard reset sequence is generated.
Software hard reset	A hard reset sequence can be initialized by writing to a memory mapped register (RCR)

5.1.2 Reset Actions

The MSC8157E reset control logic determines the cause of reset, synchronizes it if necessary, and resets the appropriate internal hardware. Each reset flow has different impact on the device logic. Power-on reset has the greatest impact, resetting the entire device, including clock logic and error capture registers. Hard reset resets the entire device excluding clock logic and error capture registers. All reset types generate a reset to the cores. The memory controllers, system protection logic, interrupt controller, and I/O pins are initialized only on hard reset. **Table 5-2** identifies reset actions for each reset source.

Table 5-2. Reset Actions for Each Reset Source

Reset Source	Clocks and PLLs Reset Logic Error Capture Registers	Performance Monitor HSSI PLLs and Logic Timers CLASS (most registers, see Section 4.7, ***Programming Model***, on page 4-14 for details)	Reset Configuration Words Loaded	Other Internal Logic	HRESET or HRESET_IN Driven	Reset Driven to Cores
• Power-on reset	Yes	Yes	Yes	Yes	Yes	Yes
• External hard reset • Software watchdog reset • RapidIO reset • Software hard reset	No	Yes	No	Yes	Yes	Yes

5.1.3 Power-On Reset Flow

Assertion of the external $\overline{\text{PORESET}}$ signal initiates the power-on reset flow. $\overline{\text{PORESET}}$ should be asserted externally for at least 32 input clock cycles after stable external power is applied to the MSC8157E device. When $\overline{\text{PORESET}}$ is deasserted, the MSC8157E starts the configuration process. The MSC8157E asserts $\overline{\text{HRESET}}$ throughout the power-on reset sequence, including during configuration. Configuration time varies according to the configuration source and CLKIN frequency. Initially, the reset configuration inputs are sampled to determine the configuration source and the input clock division mode. Next, the MSC8157E starts loading the reset configuration words. When the clock mode values in the reset configuration word low load, the PLLs begin to lock, after locking, each PLL distributes clock signals to the device. When all clocks are locked and the reset configuration words are loaded, $\overline{\text{HRESET}}$ is released.

5.1.4 Detailed Power-On Reset Flow

The detailed power-on reset ($\overline{\text{PORESET}}$) flow for the MSC8157E is as follows:

1. The user asserts $\overline{\text{PORESET}}$ (and optionally $\overline{\text{HRESET}}$ or $\overline{\text{HRESET\_IN}}$).
2. Power is applied to meet the specifications in the *MSC8157E Technical Data Sheet*.
3. The user asserts $\overline{\text{PORESET}}$ (and optionally $\overline{\text{HRESET}}$ or $\overline{\text{HRESET\_IN}}$) causing all registers to be initialized to their default states and most I/O drivers to be tri-stated (some clock, clock enabled, and system control signals are active).
4. The user applies a stable CLKIN signal and stable reset configuration inputs (RCW_SRC, RC, STOP_BS).
5. Deassert $\overline{\text{PORESET}}$ after at least 32 stable CLKIN clock cycles; counting the 32 cycles should only start after V_{DDIO} has reached its nominal value as specified in the *MSC8157E Technical Data Sheet*.
6. The device samples the reset configuration input signals to determine the reset configuration word source.
7. The device starts loading the reset configuration word. Loading time depends on the reset configuration word source.
8. Once Reset Configuration Word Low is loaded, the system PLL begins to lock.
9. The device keeps driving $\overline{\text{HRESET}}$ low until all PLLs are locked and the reset configuration words are loaded.
10. Deassert the optional $\overline{\text{HRESET}}$, if not done earlier.

Note: The JTAG logic must always be initialized by asserting $\overline{\text{TRST}}$.

11. The internal reset to the cores and the remaining logic is deasserted. I/O drivers are enabled.
12. After $\overline{\text{HRESET}}$ is deasserted, it can take 41000 OCN cycles for the SerDes block to exit reset and lock its internal PLL. Read the HSSI_SR[SERDES1_RST_DONE] and HSSI_SR[SERDES2_RST_DONE] bits to determine when the SerDes reset is complete. See the High Speed Serial Interface Status Register (HSSI_SR] description in **Chapter 8** *General Configuration Registers* for details.
13. If enabled, the HSSI complex interfaces are now ready to accept external requests, and the core boot code fetch can proceed, if enabled. The MSC8157E is now in its ready state.

Figure 5-1 shows a timing diagram of the power-on reset flow.

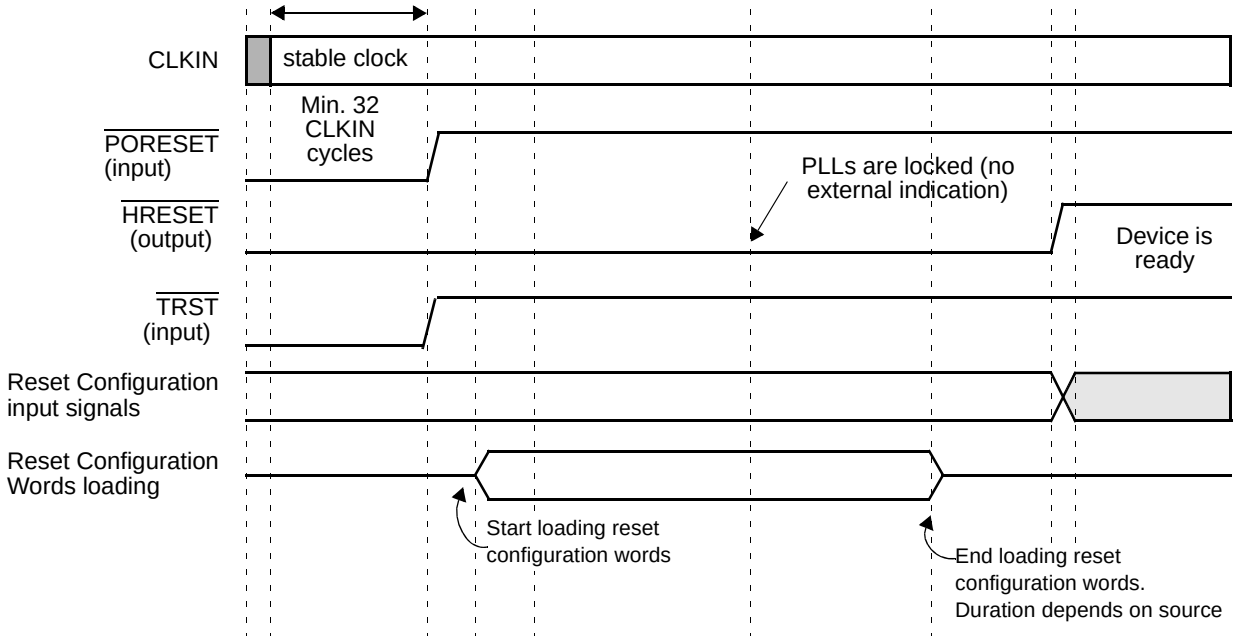

Figure 5-1. Power-On Reset Flow

Figure 5-2 shows a timing diagram of power-on reset flow with RCW_SRC = 000. In this mode, the external pins RC[15–0] are sampled four times in order to get all the 64 bits RCW.

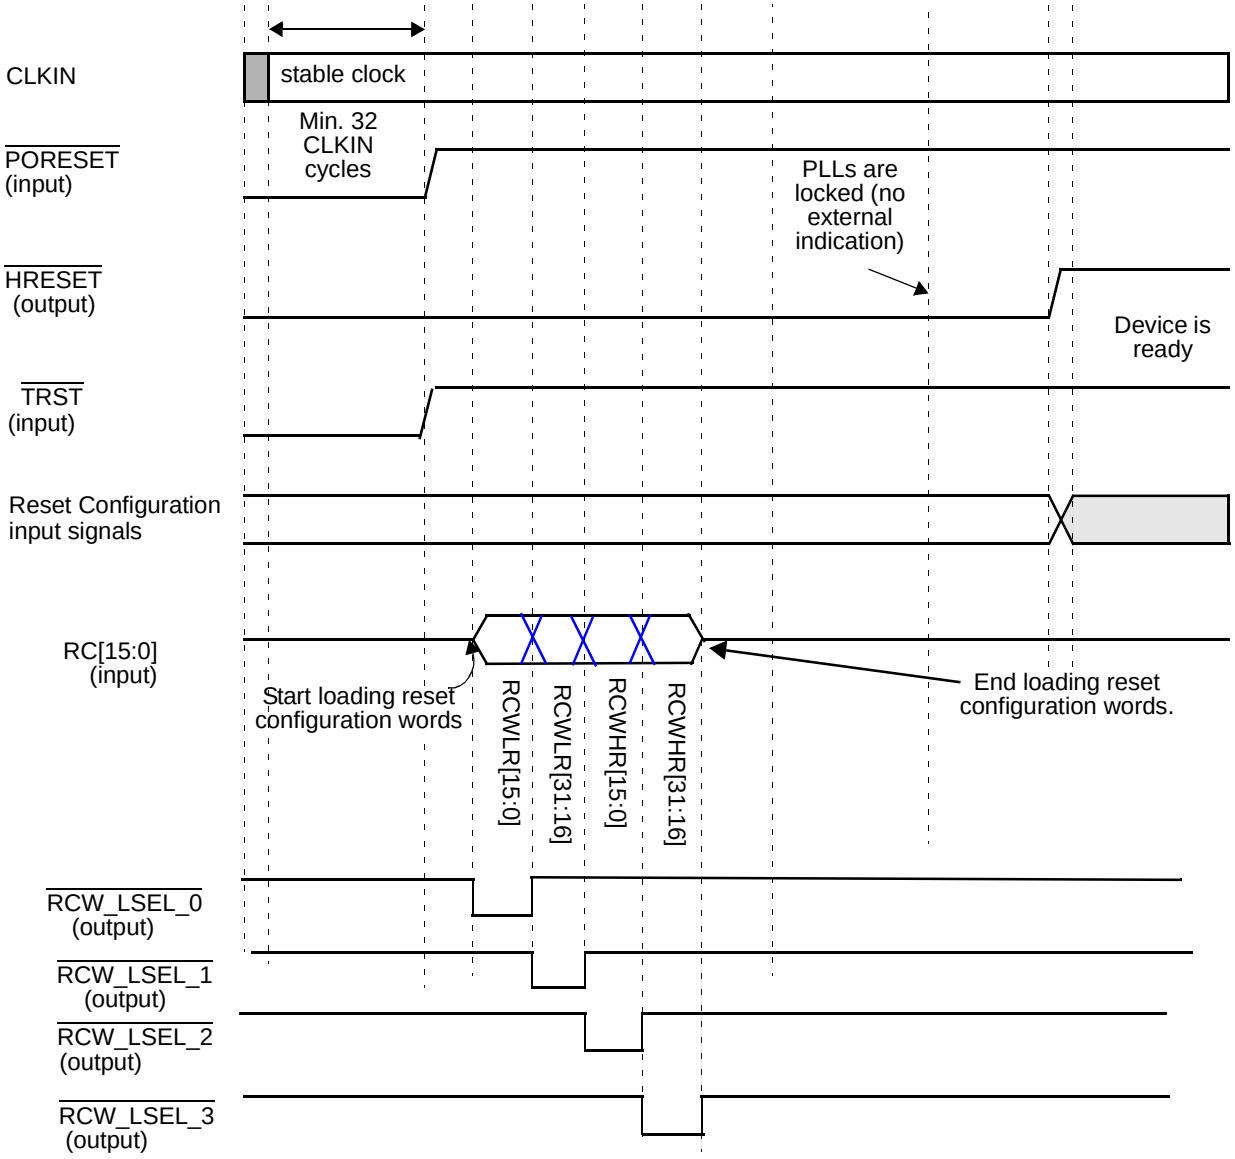

Figure 5-2. Power-on Reset Flow for RCW_SRC = 000

5.1.5 HRESET Flow

The HRESET flow may be initiated externally by asserting HRESET/ HRESET_IN or internally when the MSC8157E detects a reason to assert HRESET. In both cases, the device continues asserting HRESET throughout the HRESET flow. For HRESET, the hard reset sequence time is 4908 CLKIN cycles. The reset configuration source, the reset configuration word, and the input clock division mode are not affected by hard reset (they are only affected by a power-on reset), so the MSC8157E immediately configures the device. For the HRESET_IN signal, the user asserts the signal in the same way as HRESET, but the deassertion is not automatic and is determined by the user; the signal is not held low by the reset block to the end of the reset sequence. After the configuration sequence completes, the MSC8157E releases the HRESET signal and exits the HRESET flow. Use an external pull-up resistor to deassert the signal. After deassertion is detected, the device waits for a 16-cycle period before testing the presence of an external (hard) reset. The HSSI complex logic and PLL are out of reset after about 41000 OCN cycles. Read the HSSI_SR[SERDES1_RST_DONE] and HSSI_SR[SERDES2_RST_DONE] bits to determine when the SerDes reset is complete. See the High Speed Serial Interface Status Register (HSSI_SR) description in **Chapter 8** *General Configuration Registers* for details.

Note: Because the MSC8157E does not sample the reset configuration signals (RCW_SRC, RC, STOP_BS) during a hard reset flow, setting a new value on those pins (different from the settings during power-on reset) has no effect.

Figure 5-3 shows a timing diagram of the hard reset flow.

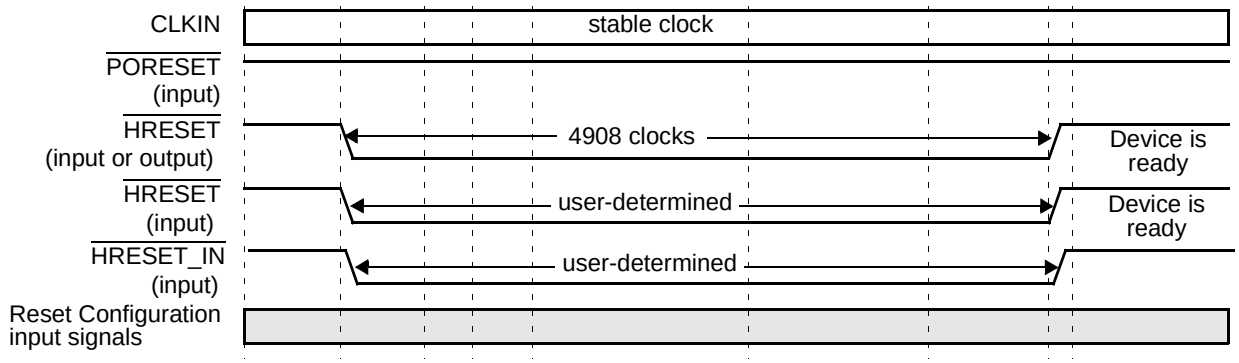

Figure 5-3. Hard Reset Flow

5.2 Reset Configuration

The MSC8157E is initialized using two complementary methods. Initially, a small number of input signals (RCW_SRC[0–2]) are sampled during the first two CLKIN cycles after the deassertion of PORESET (during the power-on reset flow). These signals determine whether a reset configuration word is required and the device source interface from which it is loaded (see **Table 5-1**). The RCW_SRC[0–2] signals should remain valid until the deassertion of HRESET. Depending on the configuration signal values, the MSC8157E may continue with loading the reset configuration word.

5.2.1 Reset Configuration Signals

Reset configuration input signals are located on device pins that have other functions when the device is not in the reset state. These input signals sampled values are written into registers during the assertion of $\overline{\text{PORESET}}$ after a stable clock is supplied (the power-on reset flow). The inputs must be pulled high or low by external resistors as long as $\overline{\text{HRESET}}$ is asserted. During the $\overline{\text{PORESET}}$ flow, all other signal drivers connected to these signals must be tri-stated. Refer to the *MSC8157E Technical Data Sheet* for the recommended resistor values used to pull reset configuration signals high or low. The values loaded from these sampled inputs are accessible to software through memory-mapped registers described in **Section 5.3**. They are used to configure the device operation.

5.2.2 Reset Configuration Words Source

The reset configuration word source options permit the MSC8157E to load reset configuration words from an EEPROM via the I^2C interface, a combination of external pins and hard-coded values, or to use hard-coded default options.

Table 5-3. Reset Configuration Word Sources (Defined by RCW_SRC[0–2])

Value (Binary)	Meaning
000	Multiplexed external RCW loading. The RCW is driven by external logic on RC[15–0]. The $\overline{\text{RCW\_LSEL}}$[3–0] selects which bits should be driven on RC[15–0].
001	Reserved.
010	Reset configuration word is loaded from an I^2C EEPROM in 16-bit addressing mode. MSC8157E hardware reads the RCW from EEPROM slave address 1010000 (or 1010111 in case of multi device and reset slave) with two byte addressing.
011	Some bits of the reset configuration word are loaded from external pins and others by default.
100	Hard coded option #1. Reset configuration word is loaded from internal hard coded option 1.
101	Hard coded option #2. Reset configuration word is loaded from internal hard coded option 2.

Note: The value of the reset configuration signals affects the duration of power-on and hard reset sequences.

5.2.3 Reset Configuration Input Signal Selection and Reset Sequence Duration

Table 5-4 shows how to pull down (0) or pull up (1) the reset configuration input signals (RCW_SRC) for various configurations. The reset sequence duration is measured from the deassertion of $\overline{\text{PORESET}}$ to the deassertion of $\overline{\text{HRESET}}$.

Table 5-4. Selecting Reset Configuration Input Signals

CLKIN Frequency	RCW_SRC[0–2]	Reset Sequence Duration in CLKIN Cycles	Duration in ms
133.33 MHz	000, 011-101	21169	0.159
133.33 MHz	010 **Note:** Loading the RCW via I^2C is the slower method for loading the RCW.	264424	1.98

5.2.4 Reset Configuration Words

Various device functions are initialized by loading the reset configuration words during the power-on reset flow. All configurable features are reconfigured only during a power-on reset flow. The MSC8157E decides which interface is used according to reset configuration input signals, as described in **Section 5.2.2**.

Section 5.3 describes the functions and modes configured by the reset configuration words. Note that the reset configuration settings are accessible to software through the following read-only memory-mapped registers:

- Reset Configuration Word Low Register (RCWLR). See **Section 5.3.1** for details.
- Reset Configuration Word High Register (RCWHR). See **Section 5.3.2** for details.
- Reset Status Register (RSR). See **Section 5.3.3** for details.

5.2.5 Loading The Reset Configuration Words

The MSC8157E loads the reset configuration words from an I^2C serial EEPROM, or combination of default values and external pins, or uses a hard-coded configuration, as selected by the reset configuration inputs described in **Section 5.2.2**. The following subsections describe these options in detail.

Note: The reset configuration word cannot be loaded from an I^2C EEPROM in 8-bit addressing mode.

5.2.5.1 Loading From an I²C EEPROM (RCW_SRC[0–2] = 010)

When a MSC8157E is configured by the reset configuration input signals to load the reset configuration words from an EEPROM via the I²C interface, it uses the I²C unit boot sequencer in a special mode. In this mode, the I²C boot sequencer is activated to load the reset configuration words while the rest of the device remains in the reset state ($\overline{\text{HRESET}}$ is asserted).

5.2.5.1.1 Using The Boot Sequencer For Reset Configuration

Note: For detailed description about the I²C interface and the boot sequencer, refer to **Chapter 24**, *I2C*.

When used to load the reset configuration words, the I²C module addresses the first EEPROM, reads the preamble, and then reads the first two data structures. The device latches the reset configuration words internally and the I²C module enters its reset state until $\overline{\text{HRESET}}$ is deasserted. There should be no other I²C traffic when the boot sequencer is active. After $\overline{\text{HRESET}}$ is deasserted, the boot sequencer mode is disabled.

5.2.5.1.2 EEPROM Slave Address

A reset master MSC8157E is selected by holding its STOP_BS signal low during the power-on reset flow. The reset master uses 0b1010000 for the EEPROM calling address. A reset slave uses 0b1010111 for the EEPROM calling address uses 0b1010000 for the EEPROM calling address. A reset target uses 0b1010111 for the EEPROM calling address. The EEPROM to be addressed must contain the reset configuration information and be programmed to respond to the 0b1010000 0b1010000 address. The EEPROM device must have address inputs connected to GND in multi device reset applications. No additional EEPROMs are accessed by the boot sequencer in reset configuration mode. See also **Section 5.2.5.1.5**, *Loading Multiple Devices From a Single I2C EEPROM*, on page 5-10.

5.2.5.1.3 EEPROM Data Format In Reset Configuration Mode

The I²C module expects a specific data format in the EEPROM. The first three bytes should be the preamble and should contain a value of 0xAA55AA. The I²C module verifies that this preamble is correctly detected before proceeding further. The two reset configuration words, should follow the preamble and should use the required format provided in **Section 6.2.2.3**, *Boot File Format*, on page 6-16. Within each configuration word, the first 3 bytes are reserved and must contain the value 0xFFFFFF. After the first 3 bytes, 4 bytes of data should hold the desired value of the reset configuration word. The boot sequencer assumes that a big endian address is stored in the EEPROM.

If a preamble fail or any other I²C bus error is detected, the device stops processing and remains in a hard reset state with $\overline{\text{HRESET}}$ asserted and most of the I/O drivers are disabled. If reset configuration word loading from the EEPROM fails, the user must assert the $\overline{\text{PORESET}}$ signal for at least 100 µs duration to resume operation.

5.2.5.1.4 Single Device Loading From I²C EEPROM

The MSC8157E can be the only device loading the reset configuration word from the I²C EEPROM. In this case STOP_BS pin must be driven low during the power on and hard reset sequences. The hardware connection is shown in **Figure 5-4**.

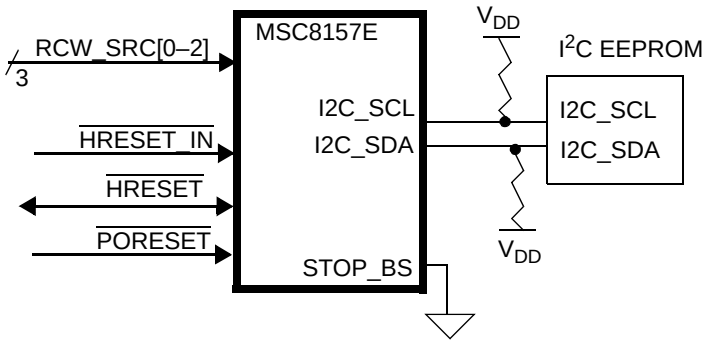

Figure 5-4. Single Device I²C Reset Configuration

5.2.5.1.5 Loading Multiple Devices From a Single I²C EEPROM

When the MSC8157E device shares the I²C EEPROM device with other MSC8157E devices to load the reset configuration words, one device must be a reset master and the rest must be reset slaves. The definition of reset slave or reset master is latched internally during power-on reset sequence. In this mode, the RCW_SRC inputs must be the same for all slaves and the master.

The reset configuration implementation involves a software for the reset master and glue logic. The hardware connection is shown in **Figure 5-5**. The STOP_BS signal input to the reset master must be driven low during the power on reset sequence while all the slaves inputs must be driven high. During the power on reset assertion, the master cannot drive the STOP_BS output bus because its role as master is not enabled yet. Pull-ups are required; refer to the *MSC8157E Technical Data Sheet* for appropriate resistor values to pull the slave STOP_BS input signal high.

In the first stage of reset configuration, the reset master reads its own reset configuration words. It accesses the I²C EEPROM while all other reset slaves are stopped. When PORESET is deasserted, the STOP_BS is latched in the reset block after few cycles and defines the reset master and slaves. It also keeps all the reset slave I²C controllers in idle state while the reset master starts to access the EEPROM slave using address 0b1010000. Then the reset master must exit from reset and run the internal code.

In the second stage, the reset master reads the slave RCWs and stores the values in its memory. See **Chapter 6**, *Boot Program* for how to determine the number of reset slaves to be configured. The reset master core reads the slave RCWs from the I²C EEPROM. Then, it configures its I²C controller to emulate an EEPROM device for each reset slave. The reset master emulates EEPROM using the slave address 0b1010111.

In the last stage, the reset master releases the STOP_BS for each slave in a known order. The released reset slave accesses the I^2C bus to read from slave address 0b1010111. The order of reading the slave RCWs is the order for their connection.

Note: The STOP_SLV_BS glue logic supports a five pin bus. For up to five reset slaves, the master drives STOP_SLV_BS directly to the selected slave. For five to fifteen slaves, the glue logic encodes the signals from the master and selects the slave to drive with STOP_SLV_BS based on its decoded value.

The external reset logic may reset the system as a unit, or it may be configured to reset individual devices. Individual resets permit redundancy support during system debugging to allow problematic devices to be disabled and replaced by a redundant device.

Multi device is described in detail in **Section 6.1.4**, *Multi Device Support for the I2C Bus*, on page 6-4.

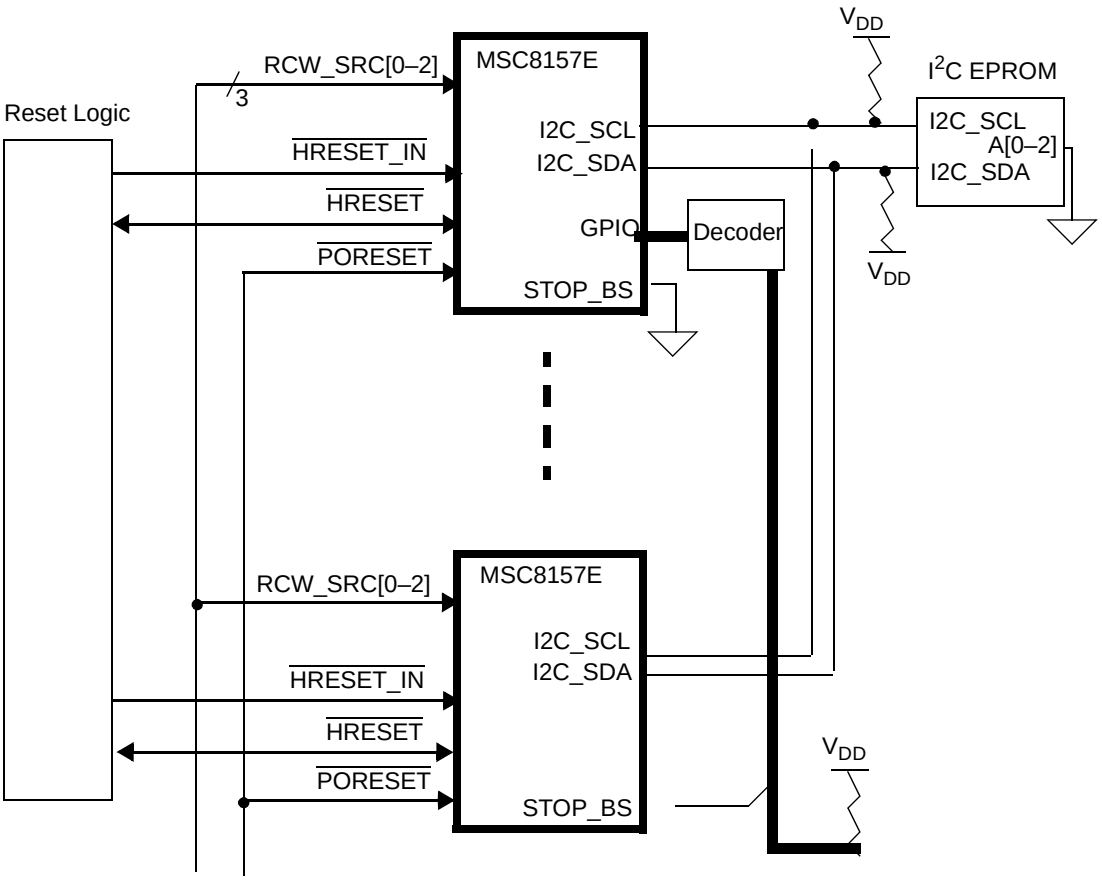

Figure 5-5. Multi Device I^2C Reset Configuration Hardware

5.2.5.2 Loading Multiplexed RCW from External Pins (RCW_SRC[0–2] = 000)

When the MSC8157E device is configured to use the multiplexed loading method, it latches all bits of the reset configuration word from the external pins. In this case, the sampled RCW bits are transferred with $\overline{\text{RCW\_LSEL[0–3]}}$ glue logic using the hardware shown in **Figure 5-6**. In this mode, the 64 bits of the RCW are loaded in four passes using only RC[15–0]. RC16 is not used, and RC[20–17] are redefined as the lane select signals ($\overline{\text{RCW\_LSEL[0–3]}}$, respectively), which provide the gating signals for each set of 16 bits transferred. .

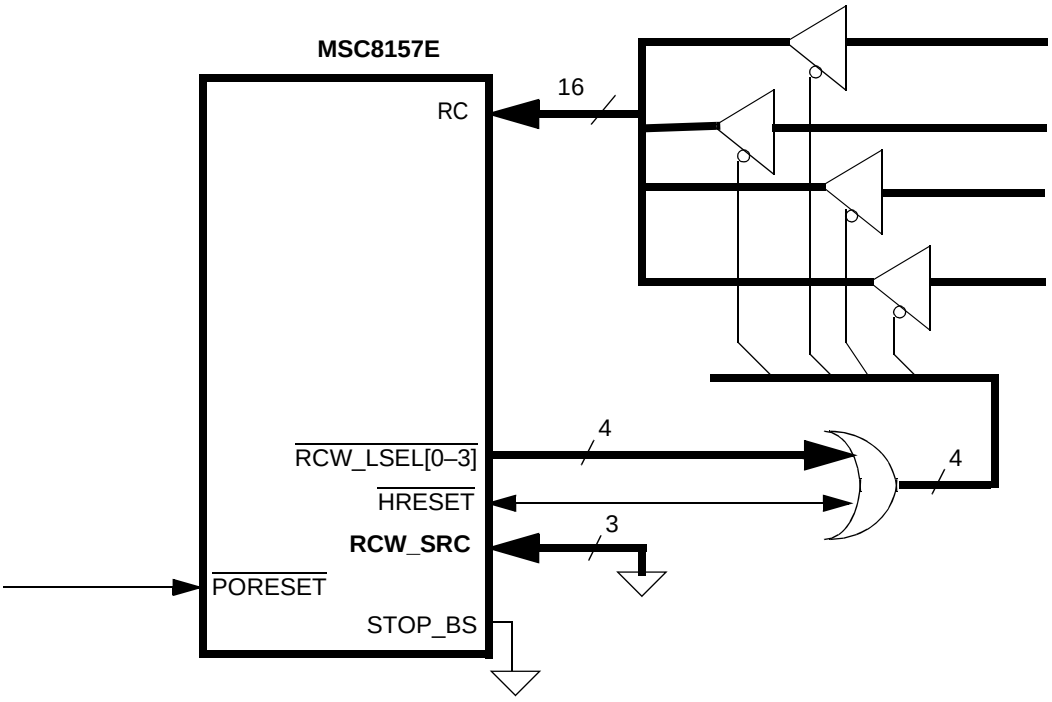

Figure 5-6. Multiplexed External Pins Reset Configuration

Figure 5-2 on page 5-5 shows the timing of the gating signals and indicates which RCW bits are loaded by each lane signal. See Table 3-4 on page 3-6 for a detailed description of the lane select signals. The gating summary is as follows:

- Lane 0 ($\overline{\text{RCW\_LSEL0}}$) gates RC[15–0] to RCWLR bits 15–0
- Lane 1 ($\overline{\text{RCW\_LSEL1}}$) gates RC[15–0] to RCWLR bits 31–16
- Lane 2 ($\overline{\text{RCW\_LSEL2}}$) gates RC[15–0] to RCWHR bits 15–0
- Lane 3 ($\overline{\text{RCW\_LSEL3}}$) gates RC[15–0] to RCWHR bits 31–16

5.2.5.3 Loading Reduced RCW From External Pins (RCW_SRC[0–2] = 011)

When the MSC8157E device is configured to use the reduced RCW, the MSC8157E latches some bits of the reset configuration word from external pins. The other bits of the RCWs are loaded from default hard coded values. The hardware connection is shown in **Figure 5-7**.

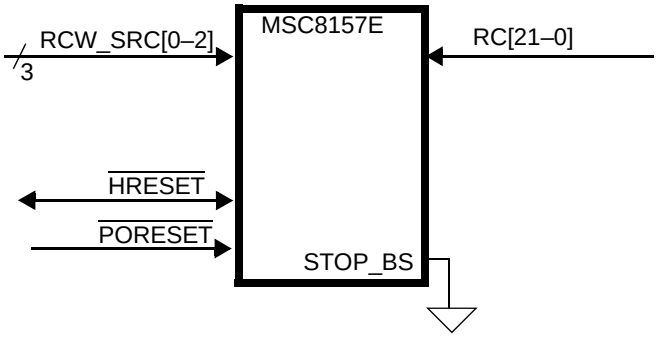

Figure 5-7. External Pins Reduced Reset Configuration

5.2.5.3.1 Reduced External Reset Configuration Word Low Field Values

Table 5-5 defines the combined External and Hard Coded Reset Configuration Word Low field values.

Table 5-5. Combined External and Hard Coded Reset Configuration Word Low Values

Bits	Name	Value	Meaning
31–30	CLKO	00	Select PLL0 divided output clock to be driven on CLKO
29	—	0	Reserved. Should be cleared.
28–22	SP	0, RC[21–18], RC4, RC17	SP. See **Table 5-9** for details.
21–20	R1FREQ	RC[16–15]	Rapid IO Controller 1 frequency
19	—	0	Reserved. Should be cleared.
18	PFREQ	0	PCI Express Controller frequency
17	SCLK1	RC14	SerDes PLL2 reference clock. • 0 selects 100 Mhz (SRIO/PCI Express/SGMII) • 1 selects 125 MHz (SRIO/PCI Express/SGMII)/122.88 MHz (CPRI). See **Table 5-9** for details and limitations.
16	SCLK0	RC14	SerDes PLL1 reference clock. • 0 selects 100 Mhz (SRIO/PCI Express/SGMII) • 1 selects 125 MHz (SRIO/PCI Express/SGMII). See **Table 5-9** for details and limitations.
15-13	CFREQ	000	CPRI Controllers frequency
12–11	R2FREQ	RC [16-15]	Rapid IO Controller 2 frequency
10	P3V	0	PLL3 visibility
9-6	—	0000	Reserved. Should be cleared
5–0	MODCK	00, RC[13–10]	MODCK[5–4] = 00, MODCK[3–0] = RC[13–10].

5.2.5.3.2 Reduced External Reset Configuration Word High Field Values

Table 5-6 defines the combined External and Hard Coded Reset Configuration Word High field values.

Table 5-6. Combined External and Hard Coded Reset Configuration Word High Field Values

Bits	Name	Value	Meaning
31	—	00	Reserved. Should be cleared.
30	RC	0	PCI Express End-Point/Root Complex Select
29	EWDT	0	Disable Watch Dog Timers.
28	PRDY	0	PCI Express not ready.
27–24	BPRT	0, RC[9–7]	See for details **Table 5-12**.
23	RIO	1	RapidIO access enabled.
22	RPT	RC6	RapidIO pass-through enable bit.
21	RHE	0	RapidIO host mode disabled.
20	SBETH		Enable Simple Boot Over Ethernet
19	—	0	Reserved. Should be cleared.
18	RM	0	Not reset master.
17	BP	0	Boot patch disabled.
16–11	—	0000000	Reserved. Should be cleared.
10	R1A	0	RapidIO Controller 1 does not accept all.
9	R2A	0	RapidIO Controller 2 does not accept all.
8–3	DEVID	00, RC[3–0]	DEVID[5–4] = 00, DEVID[3–0] = RC[3–0]
2	RIO2EB	0	Enable RapidIO Controller 2 Enumeration Boundary Reached
1	RIO1EB	0	Enable RapidIO Controller 1 Enumeration Boundary Reached
0	CTLS	1	Common transport type is Large System.

5.2.5.4 Default Reset Configuration Words (RCW_SRC[0–2] = 100 or 101)

When the MSC8157E device is configured not to load the RCW from I^2C EEPROM or external pins, it can be initialized using one of the two hard-coded default options listed in **Table 5-7** and **Table 5-8**.

5.2.5.4.1 Hard Coded Reset Configuration Word Low Field Values

Table 5-7 defines the Hard Coded Reset Configuration Word Low field values.

Table 5-7. Hard Coded Reset Configuration Word Low Field Values

Bits	Name	Value	Meaning
31–30	CLKO	00	Select PLL0 divided output clock to be driven on CLKO
29	—	0	Reserved. Should be cleared.
28–22	SP	0110000	SP. See **Table 5-9** for details.

Table 5-7. Hard Coded Reset Configuration Word Low Field Values (Continued)

Bits	Name	Value	Meaning
21–20	R1FREQ	00	Rapid IO Controller 1 frequency
19	—	0	Reserved. Should be cleared.
18	PFREQ	0	PCI Express Controller frequency
17	SCLK1	RC14	SerDes PLL2 reference clock. • 0 selects 100 Mhz (SRIO/PCI Express/SGMII) • 1 selects 125 MHz (SRIO/PCI Express/SGMII)/122.88 MHz (CPRI). See **Table 5-9** for details and limitations.
16	SCLK0	RC14	SerDes PLL1 reference clock. • 0 selects 100 Mhz (SRIO/PCI Express/SGMII) • 1 selects 125 MHz (SRIO/PCI Express/SGMII). See **Table 5-9** for details and limitations.
15-13	CFREQ	000	CPRI Controllers frequency
12–11	R2FREQ	00	Rapid IO Controller 2 frequency
10	P3V	0	PLL3 visibility
9-6	—	0000	Reserved. Should be cleared
5–0	MODCK	000000 101000	Clock Mode

5.2.5.4.2 Hard Coded Reset Configuration Word High Field Values

Table 5-8 defines the Hard Coded Reset Configuration Word High field values.

Table 5-8. Hard Coded Reset Configuration Word High Field Values

Bits	Name	Value	Meaning
31	—	0	Reserved. Should be cleared.
30	RC	0	PCI Express End-Point/Root Complex Select
29	EWDT	0	Disable Watch Dog Timers
28	PRDY	0	PCI Express not ready.
27–24	BPRT	0000	See for details **Table 5-12**.
23	RIO	1	RapidIO access is enabled.
22	RPT	0	RapidIO pass-through is disabled.
21	RHE	0	RapidIO host mode is disabled.
20	SBETH	0	Enable Simple Boot Over Ethernet
19	—	0	Reserved. Should be cleared.
18	RM	0	Not reset master
17	BP	0	Boot patch disabled.
16–11	—	000000	Reserved. Should be cleared
10	R1A	0	RapidIO Controller 1 does not accept all.
9	R2A	0	RapidIO Controller 2 does not accept all.
8-3	DEVID	000000	DEVID[5–4] = 00, DEVID[3–0] = RC[3–0]
2	RIO2EB	0	Enable RapidIO Controller 2 Enumeration Boundary Reached

Table 5-8. Hard Coded Reset Configuration Word High Field Values (Continued)

Bits	Name	Value	Meaning
1	RIO1EB	0	Enable RapidIO Controller 1 Enumeration Boundary Reached
0	CTLS	1	Common transport type is Large System.

5.3 Reset Programming Model

This section describes the following reset registers in detail:

- Reset Configuration Word Low Register (RCWLR), **page 5-16**.
- Reset Configuration Word High Register (RCWHR), **page 5-20**.
- Reset Status Register (RSR), **page 5-22**.
- Reset Protection Register (RPR), **page 5-24**.
- Reset Control Register (RCR), **page 5-25**.
- Reset Control Enable Register (RCER), **page 5-26**.

Note: The Reset register base address is 0xFFF24800.

5.3.1 Reset Configuration Word Low Register (RCWLR)

RCWLR Reset Configuration Word Low Register Offset 0x00

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CLKO		—	SP							R1FREQ		—	PFREQ	SCLK1	SCLK0
Type	R															
Reset	Value depends on the reset configuration word low loaded during reset flow.															

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CFREQ			R2FREQ		P3V	—				MODCK					
Type	R															
Reset	Value depends on the reset configuration word low loaded during reset flow.															

The RCWLR is a read-only register set according to the reset configuration word low loaded during the reset flow. **Table 5-9** defines the RCWLR bit fields

Note: In the event that an unsupported protocol or invalid configuration is entered, the protocol defaults to a hard-coded option (SP = 0110000).

Table 5-9. RCWLR Bit Descriptions

Name	Reset	Description	Settings
CLKO 31–30	0	**CLKOUT Source** This field selects the source for CLKOUT. See **Chapter 7**, *Clocks* for source clock definitions.	Used with P3V to determine source. See **Table 5-10** for details.
— 29	0	Reserved. Write to one for future compatibility.	
SP 28–22	0	**SerDes Protocol** Selects the SerDes protocols to use.	See **Table 5-11** for setting descriptions.s

Table 5-9. RCWLR Bit Descriptions (Continued)

Name	Reset	Description	Settings
R1FREQ 21–20	0	**SRIO1 Frequency** Selects the SRIO1 frequency.	00 5 GHz. 01 3.125 GHz 10 2.5 GHz 11 1.25 GHz
— 19	0	Reserved. Write to one for future compatibility.	
PFREQ 18	0	**PCI Express Frequency** Selects the PCI Express frequency	0 5 GHz 1 2.5 GHz
SCLK1 17	0	**SerDes PLL2 Reference Clock** Selects the SerDes PLL2 reference clock. 100 MHz clock can work for all protocols and frequencies except for 3.125 Gbaud RapidIO; 125 MHz works for all protocols and frequencies except for CPRI; 122.88 MHz works for all frequencies of CPRI.	0 SerDes reference clock = 100 MHz (SRIO/PCI Express/SGMII). 1 SerDes reference clock = 125 MHz.(SRIO/PCI Express/SGMII)/122.88 MHz for CPRI,
SCLK0 16	0	**SerDes PLL1 Reference Clock** Selects the SerDes PLL1 reference clock. 100 MHz clock can work for all protocols and frequencies except for 3.125 Gbaud RapidIO and CPRI; 125 MHz works for all protocols and frequencies except for CPRI.	0 SerDes reference clock = 100 MHz (SRIO/PCI Express/SGMII). 1 SerDes reference clock = 125 MHz (SRIO/PCI Express/SGMII).
CFREQ 15–13	0	**CPRI Frequency** Selects the CPRI frequency.	000 6.1440 GHz 001 4.9152 GHz 010 3.0720 GHz 011 2.4576 GHz 100 1.2288 GHz. 101 reserved 110 reserved 111 Power down.
R2FREQ 12–11	0	**SRIO2 Frequency** Selects the SRIO2 frequency.	00 5 GHz. 01 3.125 GHz 10 2.5 GHz 11 1.25 GHz
P3V 10	0	**DDRPLL Selection** Controls use of the DDRPLL with CLKOUT.	See **Table 5-10** for details.
— 9–6	0	Reserved. Write to one for future compatibility.	
MODCK 5–0	0	**Clock Mode** Defines the clock operating mode.	See **Chapter 7**, *Clocks*.

Table 5-10. CLKO Selection

RCWLR[CLKO]	RCWLR[P3V]	CLKOUT Source
00	0	PLL0 output / 16
01	0	PLL1 output / 10
10	0	PLL2 output / 10
11	0	always low
00	1	DDRPLL output / 8
01	1	reserved

Table 5-10. CLKO Selection

RCWLR[CLKO]	RCWLR[P3V]	CLKOUT Source
10	1	reserved
11	1	reserved

Exceptions

1. RapidIO interface cannot run at 3.125 GHz.
2. If 3.125 GHz RapidIO interface is required, both RapidIO controllers must run at the same frequency.
3. Boot from RapidIO interface at 3.125 GHz is not supported.
4. Boot from RapidIO interface at frequencies other than 3.125 GHz is not supported.

Note: The frequency of each protocol is configured in the RCWLR as shown below. Refer to the reference manual for more details on the protocol frequency.

- RCWLR[R1FREQ] selects the frequency for the RapidIO port 1
- RCWLR[R2FREQ] selects the frequency for the RapidIO port 2
- RCWLR[PFREQ] selects the frequency for the PCI Express
- RCWLR[CFREQ] selects the frequency for the CPRI
- RCWLR[SCLK1, SCLK2] select the SerDes reference clock

Exceptions	
	1. RapidIO interface cannot run at 3.125 GHz. 2. If 3.125 GHz RapidIO interface is required, both RapidIO controllers must run at the same frequency. 3. Boot from RapidIO interface at 3.125 GHz is not supported. 4. Boot from RapidIO interface at frequencies other than 3.125 GHz is not supported.

5.3.2 Reset Configuration Word High Register (RCWHR)

RCWHR Reset Configuration Word High Register Offset 0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	RC	EWDT	PRDY	BPRT				RIO	RPT	RHE	SBETH	—	RM	BP	—
Type	R															
Reset	Value depends on the reset configuration word high loaded during reset flow.															

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—					R1A	R2A	DEVID						RIO1 EB	RIO2 EB	CTLS
Type	R															
Reset	Value depends on the reset configuration word high loaded during reset flow.															

The RCWHR is a read-only register that derives its values from the reset configuration word high loaded during the reset flow. **Table 5-12** defines the RCWHR bit fields.

Table 5-12. RCWHR Bit Descriptions

Name	Description	Settings
— 31	Reserved. Write to one for future compatibility.	
RC 30	**Selects PCI Express RC Mode** When set, selects the PCI Express root complex (RC) mode of operation. An RC device connects the core processor/memory subsystem to I/O devices while an EP device typically denotes a peripheral or I/O device. See **Chapter 17**, *PCI Express Controller* for details. This field is always 0 in the preconfigured modes (reduced RCW or hard-coded).	0 PCI Express end point (EP) mode on the PCI Express bus. 1 PCI Express root complex (RC) mode on the PCI Express bus.
EWDT 29	**Enable Watchdog Timers** Selects the status of the software watchdog timers when coming out of reset. The user can override this value by writing to any of the System Watchdog Control Registers (SWCRR[SWEN]) during system initialization.	0 Watchdog timers initially disabled. 1 Watchdog timers initially enabled.
PRDY 28	**PCI Express Ready** Indicates whether the PCI Express controller is ready to be configured.	0 PCI Express not ready. 1 PCI Express ready.
BPRT 27–24	**Boot Port Select** Defines the boot port interface configuration. If RapidIO port is selected as boot port, the RapidIO interface, used for boot port, must be configured to a valid RapidIO protocol using the RCWLR[SP] bit.	0000 I^2C. 0001 RapidIO interface without I^2C 0010 RapidIO interface with I^2C 0011 SPI 0100 RGMII1 without I^2C 0101 SGMII1 without I^2C 0110 RGMII1 with I^2C 0111 SGMII1 with I^2C 1000 Reserved. 1001 SGMII2 without I^2C 1010 Reserved 1011 SGMII2 with I^2C 1100–1111 Reserved.

Table 5-12. RCWHR Bit Descriptions (Continued)

Name	Description	Settings
RIO 23	**RapidIO Host Access Enable** Enables RapidIO host access to internal memory after boot.	0 Host access after boot disabled. 1 Host access after boot enabled.
RPT 22	**RapidIO Pass-Through Enable** Selects the reset value of P0PTAACR[PTE] and P1PTAACR[PTE] which determines whether pass-through is disabled or enabled.	0 Pass-through disabled. (P0PTAACR[PTE] and P1PTAACR[PTE] reset value is 0) 1 Pass-through enabled. (P0PTAACR[PTE] and P1PTAACR[PTE] reset value is 1)
RHE 21	**RapidIO Host Enable** Selects whether the RapidIO controller can act as a host. When enabled as host, it uses the base device ID (RapidIO register BDIDCSR) taken from the three least significant bits of the device ID (RCWHR[DEVID]).	0 RapidIO controller is agent. 1 RapidIO controller is host.
SBETH 20	**Simple Boot Over Ethernet** Indicates whether the device uses a simple boot over Ethernet. See **Section 6.2.3**, *Simple Ethernet Boot*, on page 6-18 for details. This field is always 0 in the preconfigured modes (reduced RCW or hard-coded).	0 Not simple boot over Ethernet. 1 Simple boot over Ethernet.
— 19	Reserved. Write to zero for future compatibility.	
RM 18	**Reset Master** This bit should be set when the device is a reset master or when booting from a dedicated I^2C EEPROM device.	0 Reset slave. 1 Reset master.
BP 17	**Boot Patch** This bit enables loading patch code for booting from I^2C.	0 Boot patch disabled. 1 Boot patch enabled.
— 16–11	Reserved. Write to zero for future compatibility.	
R1A 10	**RapidIO Controller 1 Accept All** Selects the reset value of P0PTAACR[AA]. When set, RapidIO controller 1 accepts all device IDs.	0 Do not accept all device IDs. (P0PTAACR[AA] reset value is 0). 1 Accept all device IDs. (P0PTAACR[AA] reset value is 1).
R2A 9	**RapidIO Controller 2 Accept All** Selects the reset value of P1PTAACR[AA]. When set, RapidIO controller 2 accepts all device IDs.	0 Do not accept all device IDs. (P1PTAACR[AA] reset value is 0). 1 Accept all device IDs. (P1PTAACR[AA] reset value is 1).
DEVID 8–3	**Device ID** Stores the value of the signals sampled during reset.	000000 Master device/Device 0. 000001– 111111 Slave device number (from 1 to 63).
RIO1EB 2	**Enable RapidIO Controller 1 Enumeration Boundary Reached** Enables/disables the enumeration boundary reached.	0 Enumeration Boundary Reached not enabled. 1 Enumeration Boundary Reached enabled.

Table 5-12. RCWHR Bit Descriptions (Continued)

Name	Description	Settings
RIO2EB 1	**Enable RapidIO Controller2 Enumeration Boundary Reached** Enables/disables the enumeration boundary reached.	0 Enumeration Boundary Reached not enabled. 1 Enumeration Boundary Reached enabled.
CTLS 0	**RapidIO Common Transport Large System** This value is written to the RapidIO register PEFCAR[CTLS]	0 Common transport type is small system 1 Common transport type is large system

Note: The value of fields in the reset configuration word registers (RCWLR and RCWHR) reflect only their state during the reset flow. Some of these parameters and modes can be modified by changing their values in other unit memory mapped registers. Modifying values in other unit memory mapped registers does not affect RCWLR and RCWHR.

5.3.3 Reset Status Register (RSR)

RSR Reset Status Register Offset 0x10

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCWSRC			—					SW0	SW1	SW2	SW3	SW4	SW5	SW6	SW7
Type	R/W															
Reset	RCW_SRC[0–2]			1	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	BSF	—	SWHR	RM	JPO	JH	—					RIO2	RIO1	RS	—
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The reset status register captures various reset events in the device. This register fields are sticky and can be cleared by writing 1, writing 0 has no effect (except RM field which is read-only). **Table 5-13** defines the RSR bit fields.

Table 5-13. RSR Bit Descriptions

Name	Reset	Description	Settings
RCWSRC 31–29	0	**Reset Configuration Word Source** Stores the value of the RCW_SRC[0–2] signals sampled during reset. See **Section 5.2.2**, *Reset Configuration Words Source*. Changing this field has no effect.	000 Multiplexed external RCW loading. 001 Reserved. 010 I^2C EEPROM in 16-bit addressing mode. 011 Input pins and default settings. 100 Hard coded option 1. 101 Hard coded option 2.
— 28–24	10000	Reserved. Write to 0b10000 for future compatibility.	
SW0 23	0	**Software Watchdog Timer 0** Indicates whether watchdog timer 0 expired.	0 Software watchdog timer 0 not expired. 1 Software watchdog timer 0 expired.
SW1 22	0	**Software Watchdog Timer 1** Indicates whether watchdog timer 1 expired.	0 Software watchdog timer 1 not expired. 1 Software watchdog timer 1 expired.

Table 5-13. RSR Bit Descriptions (Continued)

Name	Reset	Description	Settings
SW2 21	0	**Software Watchdog Timer 2** Indicates whether watchdog timer 2 expired.	0 Software watchdog timer 2 not expired. 1 Software watchdog timer 2 expired.
SW3 20	0	**Software Watchdog Timer 3** Indicates whether watchdog timer 3 expired.	0 Software watchdog timer 3 not expired. 1 Software watchdog timer 3 expired.
SW4 19	0	**Software Watchdog Timer 4** Indicates whether watchdog timer 4 expired.	0 Software watchdog timer 4 not expired. 1 Software watchdog timer 4 expired.
SW5 18	0	**Software Watchdog Timer 5** Indicates whether watchdog timer 5 expired.	0 Software watchdog timer 5 not expired. 1 Software watchdog timer 5 expired.
SW6 17	0	**Software Watchdog Timer 6** Indicates whether watchdog timer 6 expired.	0 Software watchdog timer 6 not expired. 1 Software watchdog timer 6 expired.
SW7 16	0	**Software Watchdog Timer 7** Indicates whether watchdog timer 7 expired.	0 Software watchdog timer 7 not expired. 1 Software watchdog timer 7 expired.
— 15	0	Reserved. Write to zero for future compatibility.	
BSF 14	0	**Boot Sequencer Fail** If set, indicates the I^2C boot sequencer has failed while loading the reset configuration words.	0 No boot sequencer failure. 1 Boot sequencer failure.
— 13	0	Reserved. Write to zero for future compatibility.	
SWHR 12	0	**Software Hard Reset** Indicates whether a software hard reset has occurred.	0 No software hard reset. 1 Software hard reset initiated.
RM 11	0	**Reset Master** Indicates whether the device is the reset master.	0 Reset slave. 1 Reset master.
JPO 10	0	**JTAG Power-On Reset** Indicates whether a power-on reset request was received via a JTAG command. When this bit is set, out of reset, it also sets RSR[SRS].	0 No JTAG power-on reset request. 1 JTAG power-on reset request received.
JH 9	0	**JTAG Hard Reset** Indicates whether JTAG hard reset request was received via a JTAG command.	0 No JTAG hard reset. 1 JTAG hard reset initiated.
— 8–4	0	Reserved. Write to zero for future compatibility.	
RIO2 3	0	**RapidIO Interface 2 Reset Status** Indicates whether the RapidIO interface 2 received a reset request.	0 No reset request received. 1 Reset request received.
RIO1 2	0	**RapidIO Interface 1 Reset Status** Indicates whether the RapidIO interface 1 received a reset request.	0 No reset request received. 1 Reset request received.
RS 1	0	**Reset Status** When an external or internal reset event is detected, RS is set.	0 No reset event. 1 A reset event was detected.
— 0	0	Reserved. Write to zero for future compatibility.	

Note: The RSR accumulates reset events. For example, because a software watchdog timer expiration results in a hard reset, RSR[RS] is set after a software watchdog reset. These must be cleared individually. RSR only returns to its complete reset value when a power-on reset occurs.

5.3.4 Reset Protection Register (RPR)

RPR Reset Protection Register Offset 0x18

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	RCPW															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	RCPW															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The RPR enables or disables writing to the reset control register (RCR). The RPR protects unintended software reset requests due to writes to the reset control register (RCR). To enable the RPR, write the value 0x52535445 (“RSTE” in ASCII) to the RPR. When enabled, the control register enable bit in the reset control enable register (RCER[CRE]) is set. Reading the RPR always returns all zeros. To disable writes to the RCR, write a 1 to the RCER[CRE] bit. **Table 5-14** defines the bit fields of RPR.

Table 5-14. RPR Bit Descriptions

Name	Reset	Description
RCPW 31–0	0	**Reset Control Protection Word** Protects unintended software reset request caused by writes to the RCR. Write the value 0x52535445 (“RSTE” in ASCII) to the RCPW to enable the RCR. When the RCR is enabled, the RCER[CRE] bit is set. Reading the RPR always returns all zeros. To disable write to the RCR, write a 1 to RCER[CRE].

5.3.5 Reset Control Register (RCR)

RCR Reset Control Register Offset 0x1C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—														SWHR	—
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The RCR is used by software to initiate a hard reset sequence. To allow writing to this register, the user must first enable it by writing the value 0x52535445 to the reset protection register (RPR). **Table 5-15** defines the RCR bit fields.

Table 5-15. RCR Bit Descriptions

Name	Reset	Description	Settings
— 31–2	0	Reserved. Write to zero for future compatibility.	
SWHR 1	0	**Software Hard Reset** Setting this bit cause the MSC8157E to begin a hard reset flow. This bit returns to its reset state during the reset sequence, so reading it always returns a 0.	0 Normal operation. 1 Initiates a hard reset.
— 0	0	Reserved. Write to zero for future compatibility.	

Note: When issuing a reset command by accessing the register, the device enters reset mode immediately. The host transaction does not terminate normally. Always consider the possible outcome when any host is programmed to issue the software reset command.

5.3.6 Reset Control Enable Register (RCER)

RCER Reset Control Enable Register Offset 0x20

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—															CRE
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The reset control enable register shown in indicates by the CRE field that the reset protection register (RPR) was accessed with a value that enables the reset control register (RCR). **Table 5-16** defines the RCER bit fields.

Table 5-16. RCER Bit Descriptions

Name	Reset	Description	Settings
— 31–1	0	Reserved. Write to zero for future compatibility.	
CRE 0	0	**Control Register Enabled** Indicates the status of the reset control register (RCR). Writing 1 to this bit disables the RCR and clears this bit. Writing zero has no effect.	0 RCR is disabled. 1 The enable value is written to the reset protection register (RPR) to enable the RCR.

6 Boot Program

The boot program initializes the MSC8157E after it completes a reset sequence. The MSC8157E can boot from an external host through the RapidIO interface or download a user boot program through the I^2C, SPI, or Ethernet ports. The default boot code is located in an internal 96 KB ROM at 0xFEF00000–0xFEF17FFF and is accessible to all cores. For readability, the internal boot code is written in C and is based on the Freescale SmartDSP OS.

When cores finish the reset sequence, they all jump to the ROM starting address (0xFEF00000) and run the boot code. Specific tasks may differ based on the core ID.

Note: Boot data is located in the M3 memory at 0xC0000000–0xC00063FF (25 KB). Do not write to this area during boot loading. Always use at least an 8 Kbyte EEPROM for boot.

When the cores finish the boot sequence, they all jump to a user-defined address.

Special conditions for boot code operation include the following:

- The boot code services the watchdog timer if the EWDT bit in the reset configuration word high register (RCWHR) is set (recommended).
- If the boot process fails, the core goes into a debug state and writes an indication of the root error cause to address 0xC0000004 in M3 memory (see **Section 6.5**, *Boot Errors*, on page 6-24 for details).
- The boot program does not configure the DDR controller. Therefore, if you want to place data in the DDR memory, you must first configure the DDR controller to support the type of DDR memory in the system. To configure the controller, write the configuration data to the DDR controller memory-mapped registers before writing data to the DDR memory. See **Chapter 12**, *DDR SDRAM Memory Controller* for details.
- In any reset state other than PORESET, the device does not execute the multi-device support for using the reset configuration word (RCW) flow with I^2C as described in **Section 6.1.4**. The rest of the boot flow remains the same as described in this chapter.
- The boot code is run by all cores. Task differ by core ID.

Note: Parity error checking is not supported by the boot code because parity errors are unlikely to occur.

6.1 Functional Description

The boot code is divided into five parts shown in **Figure 6-1**:

- *Private configuration (all cores)*. Includes general configuration of all cores.
- *Shared configuration (core 0)*. Includes general configuration of internal CLASS, I^2C, RapidIO interface and QUICC Engine subsystem.
- *Patch mode.* The boot can load additional code from I^2C EEPROM.
- *Boot mode select (core 0)*. This part includes downloading of code from one of the MSC8157E bootable ports as defined by the RCWHR[BPRT] field.
- *Boot completion*. All cores complete the boot operation and jump to a user-specified address.

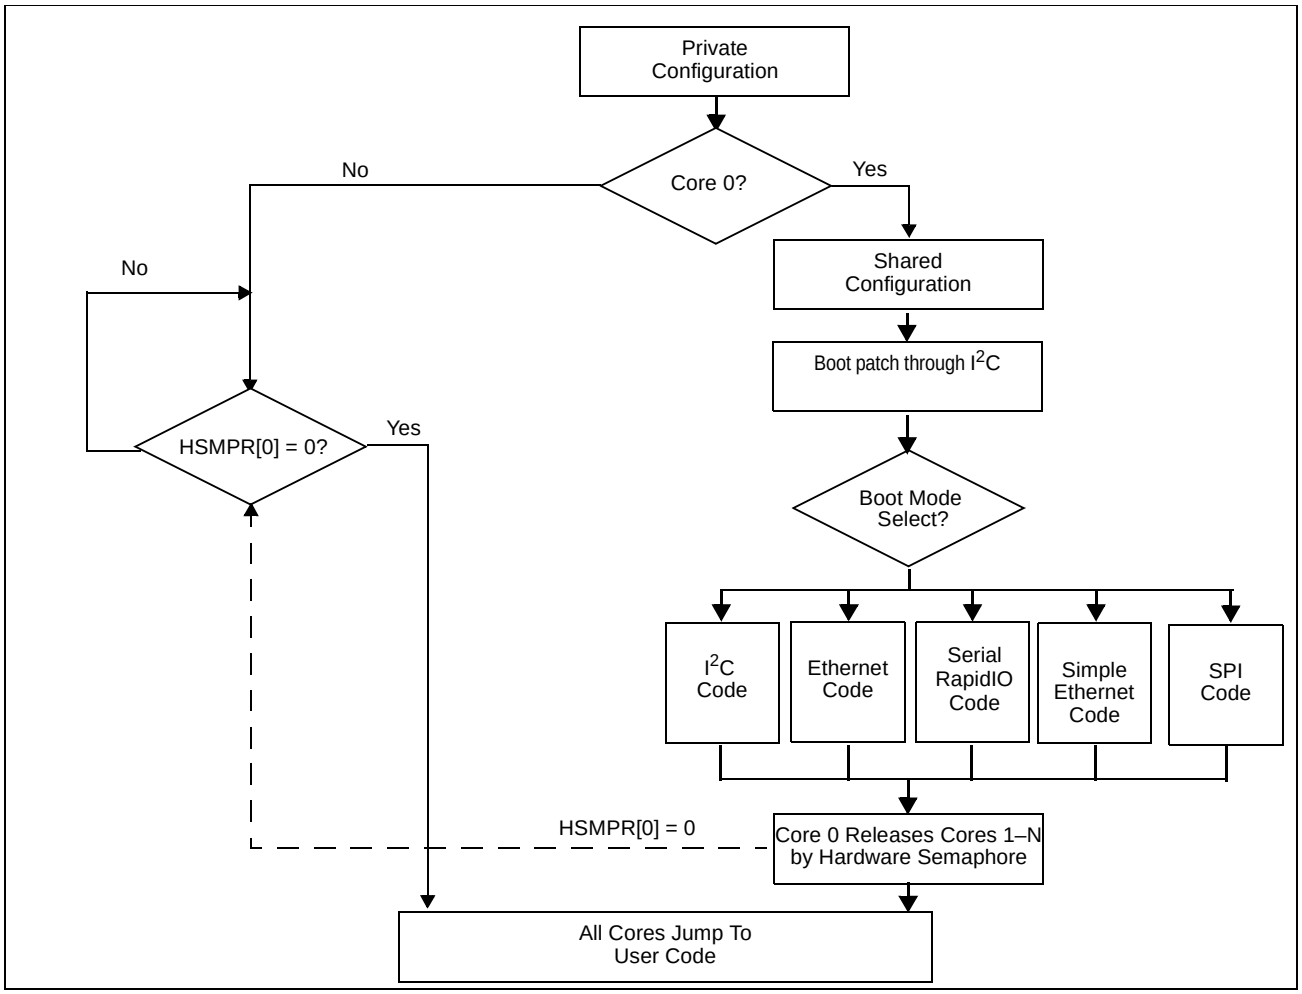

Figure 6-1. Boot Sequence Diagram

6.1.1 Private Configuration

Private configuration includes the following:

- VBA register initialization. The value stored in ROM (0xFEF17000) is used to initialize the Vector Base Address (VBA) register in the SC3850 core. After initialization of the VBA register, any interrupt places the core in debug mode.
- The EPIC is programmed to handle all NMIs correctly.
- The L1 ICache is enabled.
- The stack pointer is set to reside in the M3 memory space dedicated to the boot operation.
- The Error Detection Code (EDC) exception is enabled.

Note: The EPIC, L1 ICache, and MMU are part of the SC3850 DSP core subsystem. See the the *SC3850 DSP Core Subsystem Reference Manual* for configuration details. The manual is only available with a signed non-disclosure agreement (NDA). Contact your Freescale sales office or representative for more information.

6.1.2 Shared Configuration

The shared configuration includes the following:

- In case of power down of M3 (upper 2MB) the boot code closes the appropriate class windows towards the relevant power domain.
- If the I^2C controller is used to load the RCW for multi-device slaves (see **Section 6.1.4**, *Multi Device Support for the I2C Bus*, on page 6-4) the necessary number of GPIO lines from the {GPIO[0–3], GPIO[21]} of the master device are set to output and used to drive STOP_BS signals as follows:
  - For up to 5 slaves, the lines drive the signals directly, and the number of lines equals the number of slaves.
  - For up to 15 slaves, using glue logic to drive the STOP_BS signals; the number of required lines is equal to $1 + \lceil \log_2 numSlaves \rceil$.
- If RCWHR[RIO] is set or boot is over the RapidIO interface:
  - LCSBA1CSR is set to 0x1FFE0000, thereby allowing the configuration register space to be physically mapped. This allows configuration and maintenance of the registers through regular read and write operations rather than by maintenance operations.
  - The necessary bits of L[A–J]GCR1 are set in order to disable the tri-state on the Serial RapidIO lanes based on RCWLR[SP].
  - The necessary bits of P0CCSR and P1CCSR (RapidIO) are set to enable the port.
- QUICC Engine module priority is set to be 1 with emergency not masked (that is SDMR[EB1_PR] = 01).

6.1.3 Patch Mode

- The Patch mode is enabled if RCWHR[BP] is set. See **Chapter 5**, *Reset* for details.
- Boot loads patch code from I^2C and executes in the same way like boot over I^2C.
- After the patch is executed, the boot code continues to load boot code from the boot port which is defined by RCWHR[BPRT].
- If the boot port is I^2C, the boot code generates an error and the core goes into a debug state.

6.1.4 Multi Device Support for the I^2C Bus

The MSC8157E can share the I^2C EEPROM device with other MSC8157E devices for loading the reset configuration word (RCW), as well as for reading configuration during boot loading and execution. When the bus is shared, the bus must distinguish among reset masters, reset slaves, and EEPROM slaves:

The reset master (indicated by RCWHR[RM]) holds the $\overline{\text{STOP\_BS}}$ signals of all the slaves high and releases them one by one, thus arbitrating which slave has access to the bus at any moment. When the master deasserts $\overline{\text{STOP\_BS}}$ for a slave, the slave device attempts to access an EEPROM at address 0x57. The actual EEPROM address is 0x50, but the master emulates the EEPROM using address 0x57 to drive the RCW to each slave in turn.

There are a number of assumptions and limitations imposed when multiple devices share the I^2C bus:

- For each EEPROM in the system, there must be at least one EEPROM master. The EEPROM master is also the reset master (RCWHR[RM])
- For each EEPROM, there can be 0 or more EEPROM slaves. An EEPROM slave is defined as a device that reads its RCW from the EEPROM and uses data on the bus during boot. The number of EEPROM slaves is stored as a single byte at address 0x96 of the EEPROM.
- For each EEPROM, there can be 0 or more reset slaves. A reset slave is defined as a device that only reads its RCW from the EEPROM but does not read data from it during boot. The number of reset slaves is stored as a single byte at address 0x18 of the EEPROM.
- Every EEPROM slave must also be a reset slave.
- There may be up to 15 reset slaves per EEPROM
- As a consequence of the conditions listed in 1–5, the limitations on the number of slaves is defined as $0 \le$ #EEPROM slaves $\le$ #reset slaves ≤ 15
- The lowest numbered reset slave must be a higher numbered slave than the highest numbered EEPROM slave (for example, if EEPROM slaves are slaves 0–4, then reset slaves are slaves 5–12).

- EEPROM slaves must be numbered sequentially from 0 upward.
- All devices connected to the same EEPROM must have $\overline{\text{PORESET}}$ asserted simultaneously, that is, no single device go through the PORESET sequence without the others.
- *For the case of multi device RCW only*: The EEPROM master can have its $\overline{\text{HRESET}}$ asserted without the reset slaves being in reset as well. Each reset slave may have its $\overline{\text{HRESET}}$ asserted without the master being reset
- *For the case of multi device RCW And boot using I^2C*: If the EEPROM master have its $\overline{\text{HRESET}}$ asserted, the EEPROM slaves must have their $\overline{\text{HRESET}}$ asserted as well. The EEPROM slaves can have their $\overline{\text{HRESET}}$ asserted without the master being reset. However, there must be an external logic that toggles the EEPROM slaves STOP_BS as the master performs during its boot sequence (The logic may be implemented using an FPGA or other implementation).
- If there is a shared EEPROM in use in any stage of the reset/boot flow (RCW, serial RapidIO interface configuration, MAC address, I^2C boot), all devices MUST load their RCW from the shared EEPROM.

Note: If the reset master (RCWHR[RM]) fails (due to a stuck I2C_SDA) to read the data at 0x18 or 0x96 of the EEPROM or fails during the sequence of driving the RCW to the reset slaves, the core goes into a debug state and writes the appropriate error code to the M3 memory (see **Section 6.5**).

6.1.5 Example Configuration

Figure 6-2 describes a I^2C multi device system in which MSC8157E #0 is a reset master and MSC8157E #1 is a reset slave. The reset master uses {GPIO[0–3], GPIO[21]} to release the reset slaves. The MSC8157E boot supports up to 15 slaves on a single EEPROM (for RCW). There are two possibilities as to how the reset slave $\overline{\text{STOP\_BS}}$ signals are handled:

- If there are 5 slaves or less, connect each GPIO line directly to one of the slaves. The master deasserts and asserts the lines when necessary.
- If there are more than 5 slaves, GPIO[21] is used to latch the values of GPIO[0–3] into the decoder glue logic (latch when high). This value indicates which of the slave $\overline{\text{STOP\_BS}}$ signals to pull low. When an all 1 values are latched, all $\overline{\text{STOP\_BS}}$ signals should be pulled high.

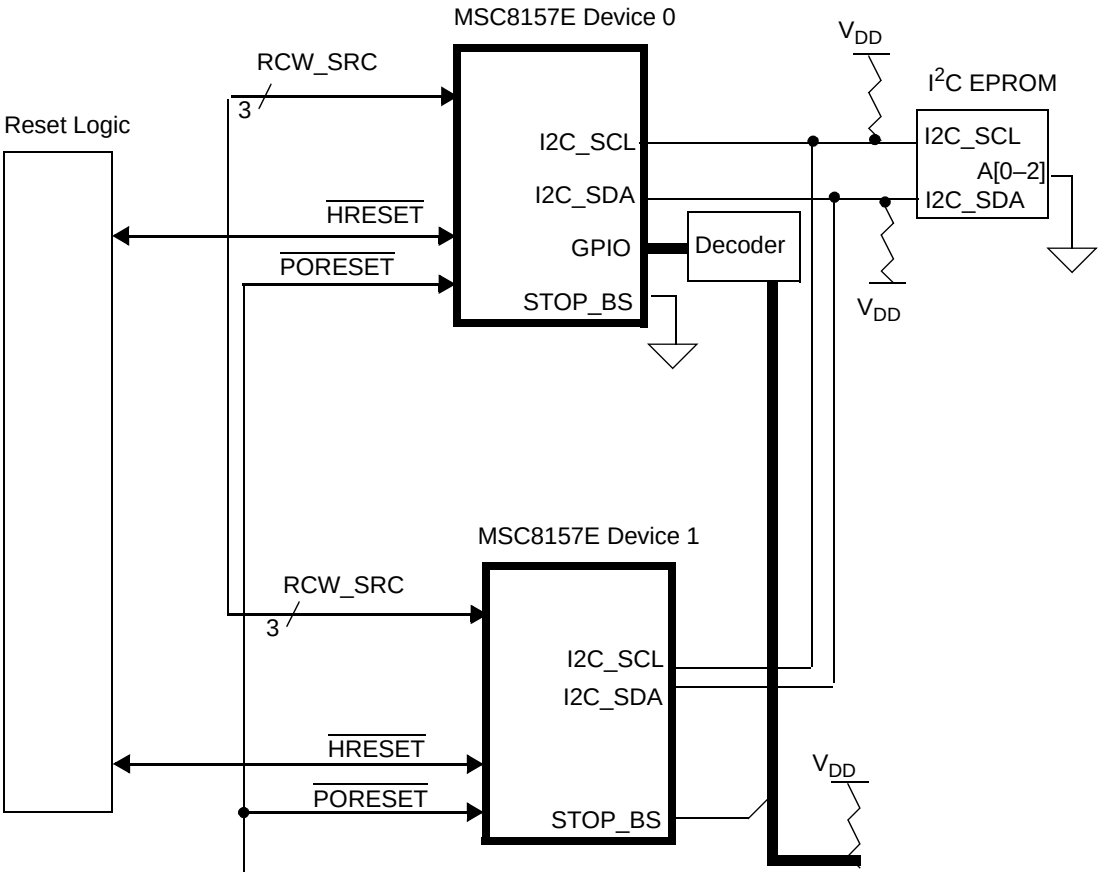

Figure 6-2. I^2C Multi Device System

Figure 6-3 shows the I^{2}C initialization and multi device support.

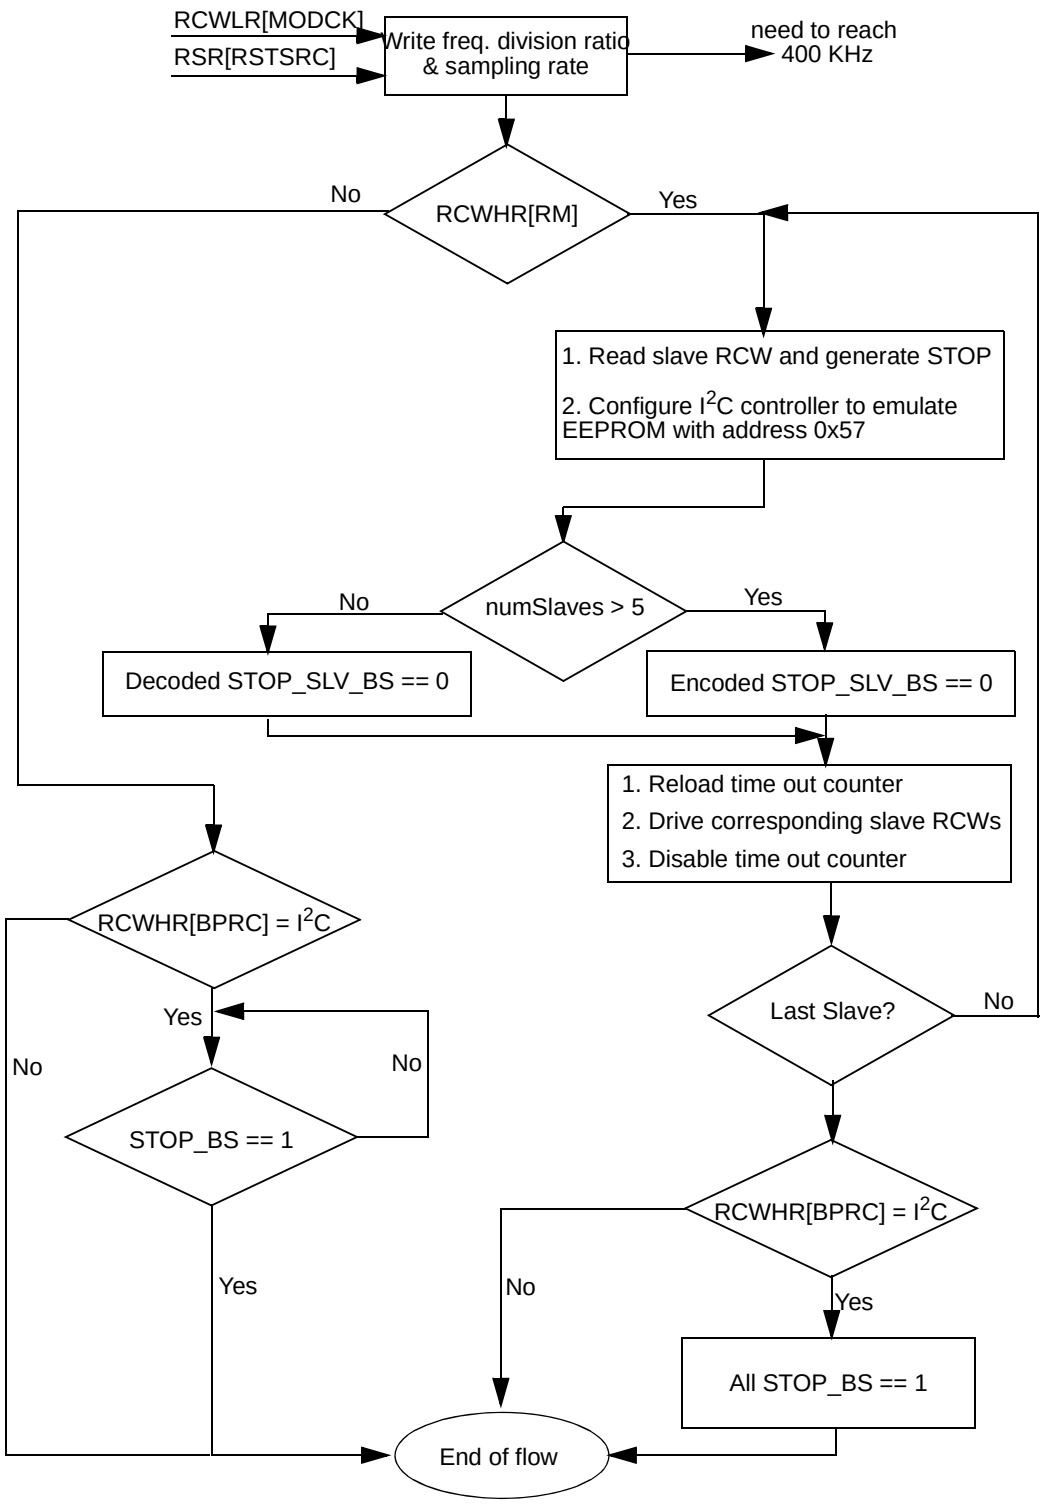

Figure 6-3. I^{2}C initialization and Multi Device Support

The following stages are performed to serve as the master chip on a multi-device board.

1. The MSC8157E reads RSR register to determine if the reset is PORESET. If it is not PORESET, this section of the boot is bypassed entirely.
2. The MSC8157E reads RCWHR[RM] to determine if it is the master on the multi-device board or a slave on the multi device board.
3. If the MSC8157E is the master on the multi-device board:
   a. I2CFDR and I2CDFSSR are programed based on the following data
      - RCWLR[MODCK]
      - RSR[RSTSRC]

      The frequency used for I2C_SCL is set as closely as possible to 400 kHz.
   b. The reset master reads the slaves RCW from their place in the I2C EEPROM (with address 0x50) and store them in M3.
   c. The reset master's I^2C controller is configured to work as an EEPROM (slave mode) with address 0x57.
   d. The reset master deassert $\overline{\text{STOP\_BS}}$ for the current slave (directly or via the decoder). From this stage the reset slave starts reading its RCW from the reset master (that emulates an I^2C EEPROM with address 0x57)
   e. The reset master:
      Drive preamble 0xAA55AA
      Drive header 0xFFFFFF
      Drive RCWLR
      Drive header 0xFFFFFF
      Drive RCWHR
      Drive header 0x000000000000FF
      For the read request of the reset slave after which the reset slave generates a STOP condition on the bus.
   f. Repeat steps a–e for all slaves.
   g. {GPIO[0–3}, GPIO[21]} are set to 0x1F thus deasserting all the slaves $\overline{\text{STOP\_BS}}$ signals, and the MASTER can continue performing its boot flow.
4. After getting its RCW the reset slave starts to run the boot program.
   If the MSC8157E is also an EEPROM slave, the boot waits until $\overline{\text{STOP\_BS}}$ is pulled high before continuing with the boot program, thus allowing all reset slaves to read their reset word before any device tries to access the EEPROM for boot code.

6.2 Boot Modes

The Boot Mode is selected by the value in the RCWHR[BPRT] field. The following sections describe the operation of each boot mode.

Note: If RSR[RSTSRC] is 0b100 or 0b101 (Hard coded RCW) than the RCWHR[BPRT] field is ignored and the boot port is *Serial RapidIO Interface without I²C support*. The RCWLR[SP] is 0b0110000 (x4 SRIO1)

6.2.1 I²C EEPROM

The MSC8157E boot expects the I²C EEPROM to be divided in to four sections:

- Reset words. This section starts at address 0x0000 of the EEPROM and includes the reset words for the reset master, an indication as to the number of reset slaves and the reset words for all the slaves.
- Reserved.
- Boot configuration. This section starts at address 0x0097 of the EEPROM and can contain one of the following:
  - MAC addresses for up to 64 devices (6 bytes per address). The boot knows to associate each address with the appropriate device based on an offset of 6 × RCWHR[DEVID]. The expected format is consecutive 6 byte fields.
  - Serial RapidIO configuration. This option allows the user to configure up to 47[1] registers in the device. This feature is most commonly used to configure registers in the general configuration block. The expected format is {address, data} pairs. The 8 bytes following the last pair should always be set to {0xFFFFFFFF, 0xFFFFFFFF}, regardless of the actual number of pairs placed in the EEPROM to signal that no more configurations are necessary.
- Boot code. This section starts at address 0x0218 of the EEPROM and contains the user code. The value in the Destination Address field must be 32-bit aligned.

Note: Although not all sections are used by all boot port options, the section addresses are fixed. However, if an I²C EEPROM is required in the system for any reason (RCW, configuration, and so on), addresses 0x000–0x216 must be valid.

1. 47 pairs along with 8 bytes end flag of {0xFFFFFFFF,0xFFFFFFFF} is the amount that fits in the same space as 64 MAC addresses ($\lfloor (64 \cdot 6)/(2 \cdot 4) \rfloor = 47 + 1$)

Figure 6-4 shows a complete example of an EEPROM contents:

Address	0	1	2	3	4	5	6	7	Description

Figure 6-4. EEPROM Contents (Continued)

The I^2C boot loading is performed with the I^2C controller. To allow for EEPROMs of up to 64 Kbytes, 19-bit addressing is used. The 7 msb of the I^2C slave address are always 1010000. The I^2C controller expects a specific memory image when trying to read data during the EEPROM as shown in **Figure 6-5**.

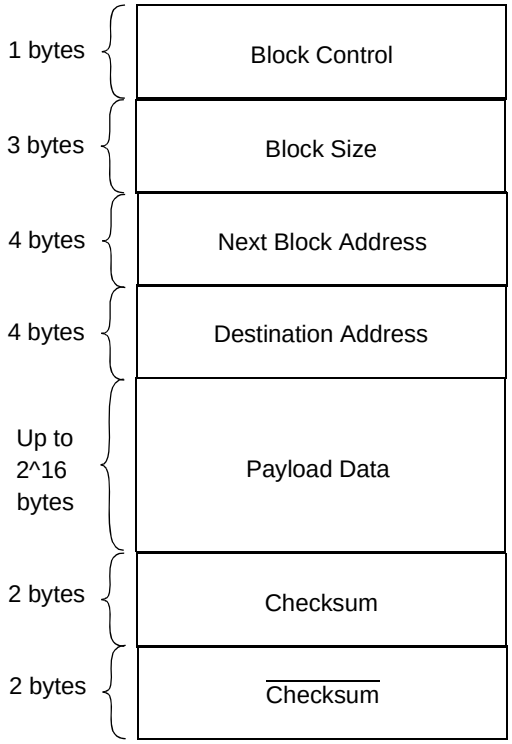

Figure 6-5. EEPROM Data Format

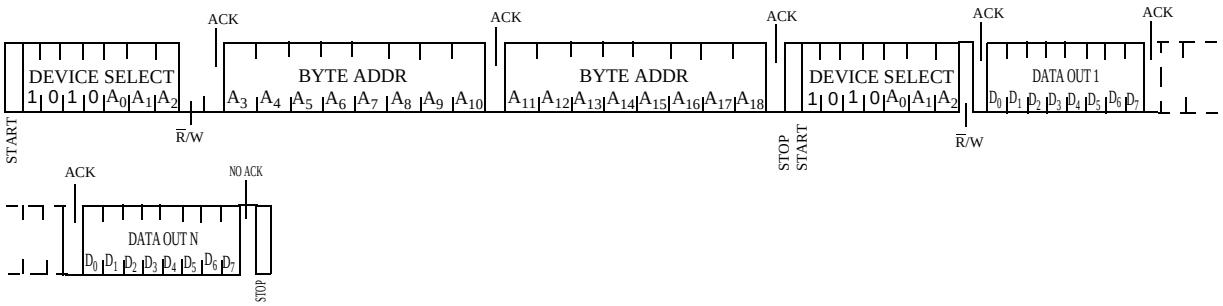
The I^2C memory image consists of:

- *Block Control***.** A 1-byte control field that contains:
  - — 1 bit of CSE. A 1 indicates that the checksum is enabled.
  - — 1 reserved bit that should be cleared (0).
  - — 6 bits of CHIP_ID indicate the destination chip. 0x3F means broadcast.
- *Block Size***.** These 3 bytes represent the number of bytes in the payload data field (e.g if the payload size is 12 bytes, Block Size = {0x00, 0x00, 0x0C}).
- *Next Block Address*. The address in which the next block is located. If the next block address equals 0x0 the bootloader assumes that the next block is sequential. If next block address equals 0xFFFFFFFF, this block is the end block.
- *Destination Address*. The address to which the payload data should be written.
- *Payload Data***.** Holds $1<=size<2^{16}$ bytes (up to 64 Kbytes) of data to be written to on-device memory according to the destination address.
- *Checksum***.** A 2-byte field that holds the XOR of all previous data (Block Control and on). The boot code XORs each received 2 bytes with the previous checksum value and verifies the validation by comparing it to this field.
- $\overline{Checksum}$**.** A 2-byte field that holds bitwise-not of the Checksum.

The I^2C bootloader expects the 4 bytes of Checksum and $\overline{Checksum}$ regardless of the CSE value. If the Checksum is disabled, these 4 bytes are not checked. By using Checksum and $\overline{Checksum}$, the boot ensures that all values of the bits are real values and that there are no stuck signals. If both Checksum and $\overline{Checksum}$ are erroneous in a block, core 0 enters the debug state.

The I2C_SCL frequency is set as closely to 400KHz as possible, as mentioned in **Section 6.1.4**. For each block, the Software I^2C read access begins with the boot code driving the device select ({A0, A1, A2} = 3'b000) and 2 bytes of address, followed by a RESTART condition. The I^2C slave drives its data (beginning with the Block Control byte) until the end of the block. The last byte of each block is not acknowledged by the MSC8157E. After the ninth unacknowledged bit, the boot code generates a STOP condition. **Figure 6-6** describes the Software I^2C read access.



Note: A_0 and D_0 are the most significant bits.

Figure 6-6. I^2C Read Access

6.2.2 Ethernet

The MSC8157E device can load files through the Ethernet port using DHCP (Dynamic Host Configuration Protocol) and TFTP (Trivial File Transfer Protocol).

- Supports RGMII @1000 Mbps and SGMII @1000 Mbps full duplex.
- For DHCP, each client must have its own unique MAC (Media Access Control) address. This MAC address can be based on RCWHR[DEVID] or be user-defined.
- This DHCP implementation supports IPv4.

Booting over Ethernet is enabled on UEC0 (UCC1) and UEC1 (UCC3) depending on the values of RCWHR[BPRT] and RCWLR[SP]. For boot over Ethernet in SGMII mode the RCWLR[SP] field must have a valid SGMII option (See **Chapter 5**, *Reset* for details). Booting over Ethernet in RGMII mode is enabled on UEC0 (UCC1) only. **Figure 6-7** describes the Ethernet bootloader flow.

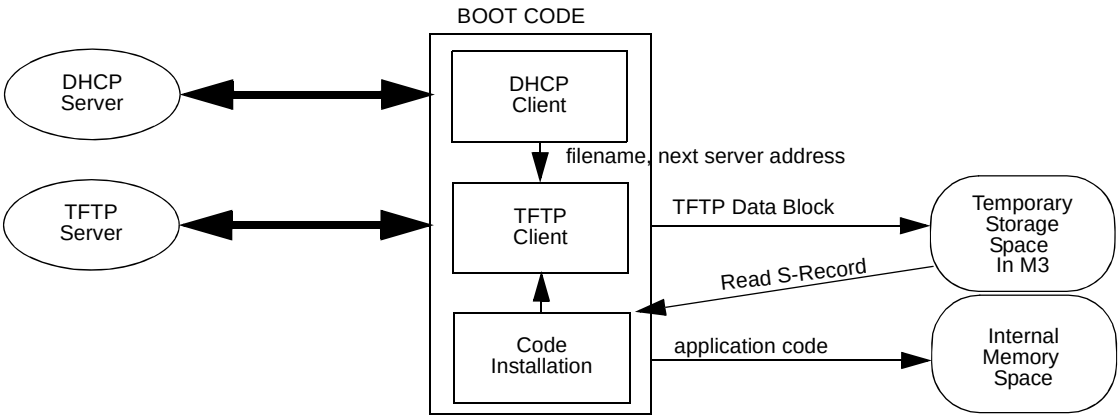


Figure 6-7. Ethernet Bootloader Flow

:The Ethernet bootloader flow includes:

1. Configuring the QUICC Engine drivers based on RCWHR[BPRT].
2. Finding a DHCP server and receive configuration parameters (filename, server address, and so on).
3. Reading a block of the boot file, in S-Record format, from a TFTP server.
4. Processing each TFTP data block and placing it in its memory destination.
5. Sending a TFTP acknowledge to the TFTP server.
6. Repeating steps 2–5 until the end of the data is transferred.

6.2.2.1 DHCP Client

The basic steps that occur when a DHCP client requests an IP address from a DHCP server are shown in **Figure 6-8**.

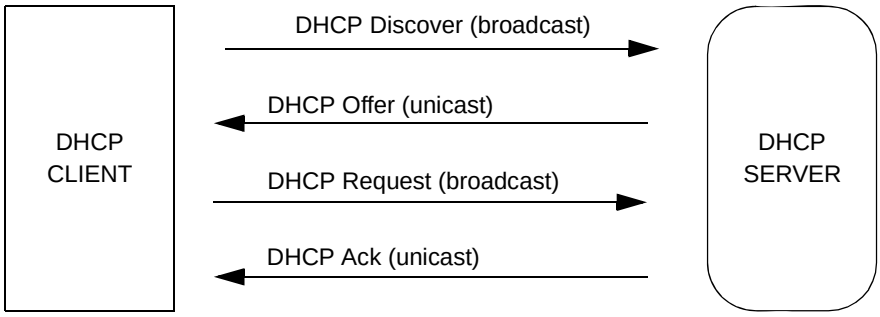

Figure 6-8. DHCP Transactions

- The client sends a DHCP DISCOVER broadcast message to locate a DHCP server.
- A DHCP server offers configuration parameters (such as an IP address, a TFTP server IP address, bootfile name...).
- The client returns a formal request for the first offered IP address to the DHCP server in a DHCPREQUEST broadcast message.
- The DHCP server confirms that the IP address has been allocated to the client by returning a DHCPACK unicast message to the client.

There are two possibilities for setting the MSC8157E MAC address during the boot:

- User defined and read from an I^2C EEPROM. See **Section 6.2.1** for details.
- Predefined default using the following fields:
  - A constant of 32 bits: {0x1E, 0xF7, 0xD5, 0x00}
  - 8 bits consisting of (RCWHR[DEVID]) (aligned to the right and padded with 0)
  - A constant of 8 bits: {0x00}

The predefined option is configured to be an individual locally administered address in accordance with **IEEE** Std. 802-2001.

6.2.2.2 TFTP Client

This implementation supports three types of messages: TFTP REQUEST, TFTP DATA and TFTP ACK. **Figure 6-9** describes the TFTP handshake.

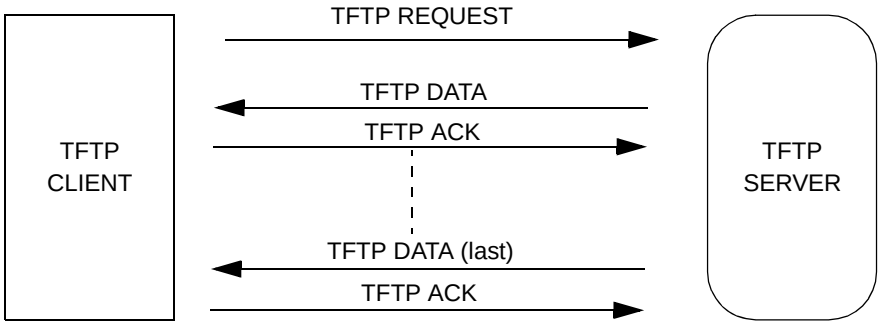

Figure 6-9. TFTP Transactions

- The TFTP transfer is initiated by the client when it issues a TFTP REQUEST (which contains the file name to download).
- In response, the server provides the application with a series of TFTP DATA messages.
- The client handshakes each data block by issuing a TFTP ACK allowing the server to proceed with subsequent TFTP DATA messages.
- This process repeats until all data blocks are received.

6.2.2.3 Boot File Format

The Ethernet bootloader expects an application file in the form of an S-Record file. The S-Record file is a text representation of the binary program code.

The Ethernet bootloader supports up to 128 Mbytes of S-Record file size. The S-Record file structure is described in **Figure 6-10**.

Figure 6-10. S-Record File Structure

Each line of an S-Record file corresponds to any of start record, data record or end record. Each record is terminated with a line feed.

Note: The S-Record that is downloaded during boot over Ethernet should include no whitespaces and no newlines.

A record has the following format:

S<type><length><address><data><checksum>

Note: This implementation supports only record of types: S0, S3 or S7.

- The description of fields is described in **Table 6-1**.

Table 6-1. S-Record description of Fields

Field	Width in Characters	Description
S<type>	2	The type of record (S0, S3 or S7)
<length>	2	The count of remaining character pairs in the record
<address>	4	The address at which the data field is to be loaded into memory
<data>	≤64	The memory loadable data or descriptive information
<checksum>	2	The least significant byte of the ones complement of the sum of the byte values represented by the pairs of characters making up the length, the address, and the data fields

- *S0 Record***.** Starting record. The address and data fields are ignored and checksum check is executed.
- *S3 Record***.** Data record. The address field is interpreted as a 4-byte address. The data field is composed of memory loadable data.
- *S7 Record***.** Termination record. The address fields is interpreted as the 4-byte address to which to jump after boot. No checksum check is executed.

Shown below is a typical S-record format file:

S0030000FC
S30D00002FE731DC3180BEF09E7062
S70500000000FA

The S0 record is composed as follows:

- **S0.** Indicating it is a starting record.
- **03.** Hexadecimal 03 (decimal 3). Indicating that three character pairs (or ASCII bytes) follow.
- 0000. Information string (ignored)
- **FC.** Checksum field.

The S3 record is composed as follows:

- **S3.** Indicating it is a data record to be loaded at a 4-byte address.
- **0D.** Hexadecimal D (decimal 13), representing a 4 byte address, 8 bytes of binary data, and a 1 byte checksum, follow.
- **00002FE7.** Eight character 4-byte address field.
- **31DC3180BEF09E70.** 8-character pairs representing the actual binary data.
- **62.** Checksum field.

The S7 record is composed as follows:

- **S7.** Indicating it is the last record.
- **05.** Hexadecimal 05 (decimal 5). Indicating that five character pairs (4 byte address and a 1 byte checksum follow).
- 00000000. Address field to jump to at the end of boot (is written to 0xC0000010).
- **FA**. Checksum field.

Each S-Record line includes an address field that maps the lines data content to a memory location in MSC8157E. Core 0 moves the data to this address.

Note: Because the MSC8157E uses 32-bit addressing, use of S3 and S7 is recommended.

6.2.3 Simple Ethernet Boot

The MSC8157E supports a simple Ethernet boot mode. This mode is selected by setting the RCWHR[SBETH] bit during the $\overline{\text{PORESET}}$ sequence (See **Chapter 5**, *Reset* for details).

In this procedure, an Ethernet master waits for the MSC8157E boot program to finish its default initialization and then initializes the device by typically loading code and data to the on device memory.

- Supports RGMII @1000 and SGMII @1000Mbps full duplex.
- Each client could have its own unique Media Access Control (MAC) address. This MAC address may be based on RCWHR[DEVID], or be user defined and read from I^2C EEPROM.

6.2.3.1 Simple Ethernet Boot Flow

The simple Ethernet boot mode uses the following sequence for processing:

- The bootloader configures the QUICC Engine subsystem drivers based on the RCWHR[BPRT].
- There are two possibilities for setting the MSC8157E MAC address during the boot. See **Section 6.2.2.1** for details.

- When the Ethernet interface is configured, the bootloader sends the start handshake data 0x17171717.
- The boot data is read a block at a time by the bootloader using a simple Ethernet frame format:

  <MAC Dest >< MAC Source> <Length><2 Bytes Data_Length><4 Bytes Address> <Data>.
- The bootloader processes each data block: <data_length><address><data> and places it in the destination memory location.
- The bootloader continues to process blocks until the end handshake data 0xA5A5A5A5 is written to address 0xC0000000.
- All cores jump to the address written in 0xC0000010. The value in this address should be written during the boot loading process.

Figure 6-11 describes the Simple Ethernet bootloader flow

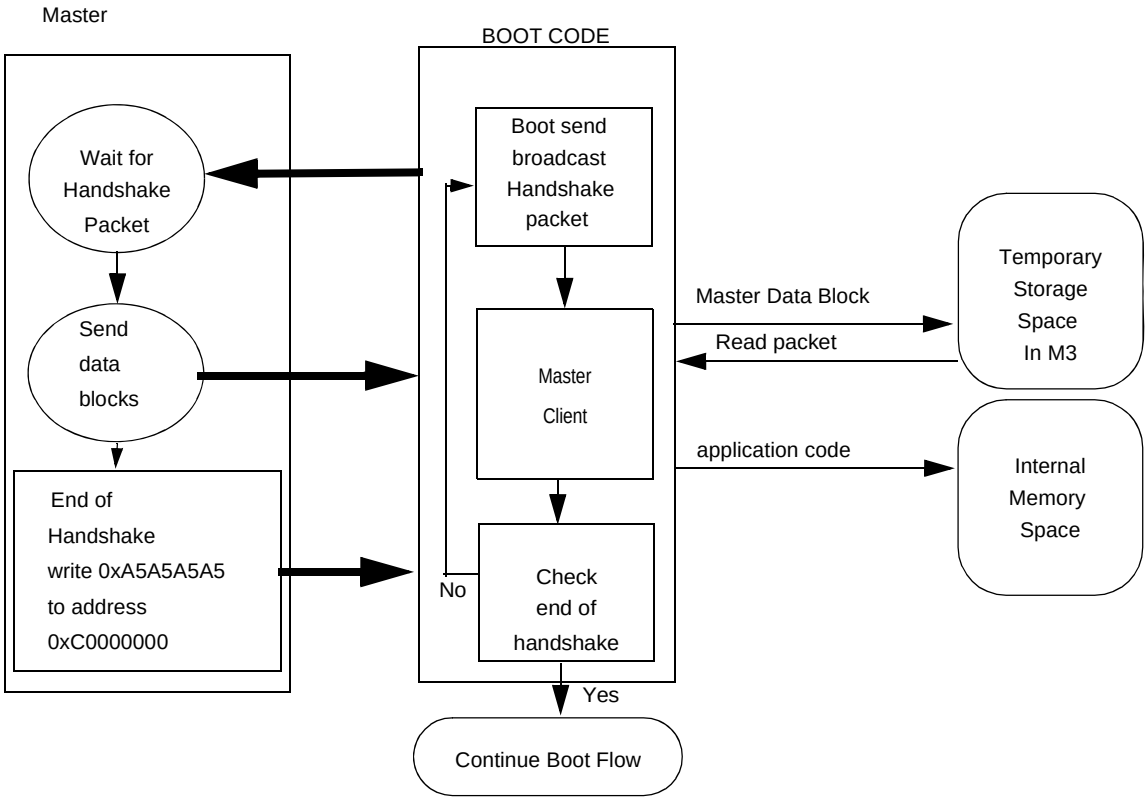

Figure 6-11. Ethernet Bootloader Flow

6.2.3.2 Simple Ethernet Boot Ports

Booting over Ethernet is enabled on UEC0 (UCC1) and UEC1 (UCC3) depending on the values of RCWHR[BPRT] and RCWLR[SP]. For simple boot over Ethernet in SGMII mode the RCWLR[SP] field must have a valid SGMII option (See **Chapter 5**, *Reset* for details).

Note: Booting over Ethernet in RGMII mode is enabled on UEC0 (UCC1) only.

6.2.3.3 Boot File Format

The Ethernet bootloader expects an application file in the format of a Simple Ethernet. The Simple Ethernet has the following format: <lengh><address><data> The description of fields is described in Table 6-2:

Table 6-2. Simple-Ethernet description of fields

FIELD	WIDTH IN CHARACTERS	DESCRIPTION
<length>	2	Length of data in bytes
<address>	4	The address at which the data field is to be loaded into memory
<data>		The memory loadable data or descriptive information

Each Simple-Ethernet address field maps the data content to a memory location in MSC8157E. Core 0 moves the data to this address.

The following code shows a typical Simple-Ethernet packet for End of handshake between Ethernet master and the MSC8157E boot:

```
1E7FD5000000
1E7FD5100000
002E
0004
C0000000
A5A5A5A5
```

The End of handshake packet which is sent by Ethernet Master consists of the following:

- **1E7FD5000000.** Destination MAC address (Default MSC8157E MAC address).
- **1E7FD5100000.** Source MAC address.
- 002E. The minimal length field according to IEEE 802.3 standard.
- 0004. Data length is 4 bytes.
- **C0000000.** The address at which the data field is to be loaded into memory. This is the Handshake address for the MSC8157E device.
- **A5A5A5A5.** Handshake data.

6.2.4 Serial RapidIO Interconnect

In this procedure a Serial RapidIO master waits for the MSC8157E boot program to finish its default initialization and then initializes the device by typically loading code and data to the on device memory.

6.2.4.1 Serial RapidIO Interface Without I^{2}C Support

The boot code configures PxCCSR and L[A–J]GCR1 according to RCWLR[SP] and writes 0x17171717 to address 0xC0000000.
The flow is:

1. Disable port by writing to PxCCSR register.
2. Enable lanes by writing to the L[A–J]GCR1 registers.
3. Enable the port by writing to PxCCSR register.
4. Polling address 0xC0000000 until the serial RapidIO master writes 0xA5A5A5A5 to it, thereby indicating that it has finished its code loading.

Figure 6-12 describes the boot flow from Serial RapidIO interconnect**.**

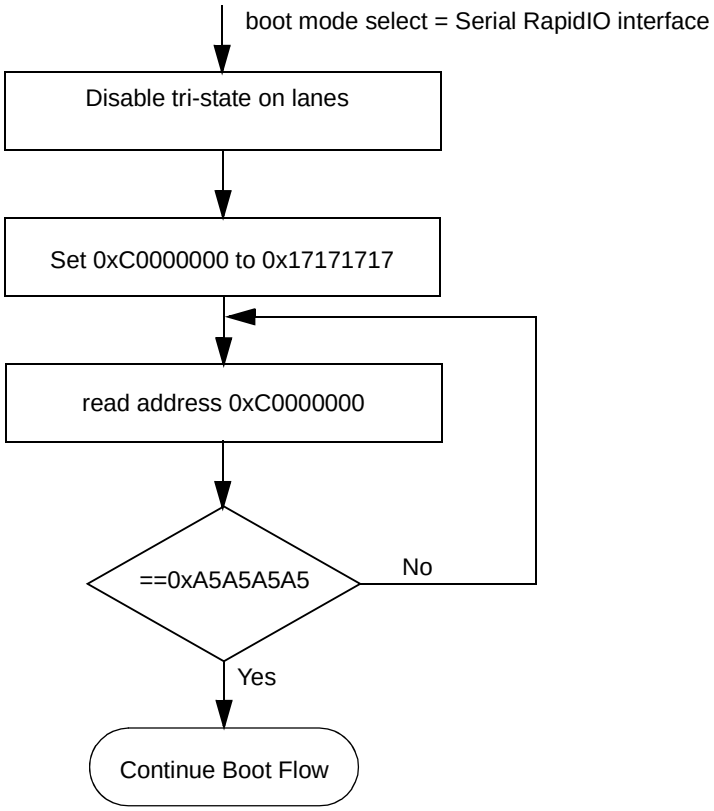

Figure 6-12. Serial RapidIO Interface Boot Flow

6.2.4.2 Serial RapidIO Interface with I²C Support

The user can place {addr, data} pairs in the I²C EEPROM to configure various registers. The address field should be as seen by the SC3850 DSP core. This feature is most commonly used to configure registers in the general configuration block (see **Section 6.2.1**, *I2C EEPROM*, on page 6-9 for details). The boot supports up to 47 such pairs.

The 8 bytes following the last pair should always be set to {0xFFFFFFFF, 0xFFFFFFFF}, regardless of the actual number of pairs placed in the I²C EEPROM.

Note: Multiple devices connected to a shared EEPROM see the same address/data pairs.

6.2.5 SPI

The MSC8157E can boot from a Flash memory on the SPI. The boot expects a Flash memory that latches on the rising edge of the clock and on which data is valid after the falling edge. The chip-select should be a $\overline{CS}$ low signal. The boot code expects to see the same data format used for the I²C EEPROM (see described in **Section 6.2.1**, *I2C EEPROM*, on page 6-9, item 4 for details on the boot code requirements) starting at address 0 of the SPI.

A shared SPI bus is arbitrated by all the devices connected to it by polling $\overline{CS}$. All signals should be connected as open-drain if more than one device is connected to the SPI flash. The SPI bus will run no faster than 400 KHz to support multiple devices connected with an open drain.

Note: If the RCW is read from EEPROM, the device for which RCWHR[RM] equals 1 should have RCWHR[DEVID] of 0. Using this configuration setting saves on arbitration cycles towards the SPI flash.

Note: During boot over SPI, the pins described in **Chapter 21**, *GPIO* are used per their SPI functionality. In addition, GPIO23 is used as a chip-select signal ($\overline{CS}$) to control access to the SPI Flash memory.

6.3 Jump to User Code

Before finishing its tasks the boot code preforms these actions:

- If RCWHR[RIO] is cleared, the boot code disables host accesses by RapidIO interface to internal memory space by putting the lanes into tri-state high impedance state.
- Invalidate all range of ICaches and close MMU program windows.
- Core internal registers (other than R0 and VBA) are set to 0x00000000.
- All configurations which were done by the boot code are cleared.
  - Module registers
  - GPIO configurations
  - Write 0x00000000 to GIER (see **Chapter 8**, *General Configuration Registers*) to clear the register.
  - Disable all interrupts (NMI excluded)
  - Clear all QUICC Engine registers by writing 1 to CECR[RST]
- 0x900D900D is written to 0xC000000C in M3 to indicate that the boot has finished executing.
- All cores jump to the address written in 0xC0000010. The value in this address should be written during the boot loading process.

6.4 System after Boot

- All MATTs in the MMUs are set to their reset value values (except M_xSDBx[PBS] which is set to 0x2).
- L1 I-Cache is enabled, but there are no cacheable windows.
- All NMIs will be configured as NMIs in the EPIC.
- VBA equals 0xFEF17000. Any interrupt in the EPIC puts the core in debug.
- EDC is enabled.
- Core register values are not guaranteed and should be initialized before use.

6.5 Boot Errors

If the boot code fails, an indication as to the root cause is written to 0xC0000004. The possible reasons are listed in **Table 6-3**.

Table 6-3. Boot Error Codes

Error Code	Description
0x003FEFFF	Catastrophic Error. SmartDSP OS Function failed
0x003FEFFE	DHCP server time out
0x003FEFFD	Corrupted boot file. The possible causes are: • Checksum wrong in TFTP file • Checksum wrong in I^2C file • Unsupported S-Record type
0x003FEFFC	TFTP server time out
0x003FEFFA	TFTP server sent ERROR code (05)
0x003FEFF9	Unsupported boot port
0x003FEFF8	Reset slave does not respond
0x003FEFF5	Boot over Ethernet or RapidIO isn't supported with current RCW configuration
0x003FEFF4	Too many I^2C RCW slaves in address 0x18 of the EEPROM
0x003FEFF3	Error in protocol between I^2C RCW master and slave
0x003FEFF2	Boot port trying to write to area designated for boot (0xC0000018–0xC00063FF)
0x003FEFF1	In patch mode the boot port is I^2C
0x0027EFFE	Lost arbitration on I^2C bus.
0x0027EFFD	Time-out on I^2C acknowledge (9th clock).
0x0027EFFC	Stuck I2C_SDA (I^2C bus).
0x00000000	Unexpected debug condition in the SC3850 Core (unexpected interrupt, EE0 asserted and so on)

7 Clocks

The clock circuits contain the following six PLLs:

- Three PLLs driven from a single CLKIN signal generated by a crystal-based oscillator that generates the clocks for most of the system as described in **Figure 7-1**
- One PLL driven from either from the CLKIN signal or from a dedicated MCLKIN signal that generates clocks for the DDR-SDRAM memory controller.
- Two PLLs that generate clocks for the SerDes interfaces. The selection of the individual clock frequencies for the interfaces is done by the settings of the Reset Configuration Word (see **Chapter 5**, *Reset* for details). For the CPRI lanes, the initial configuration determines the starting frequency, but the actual connection frequency is negotiated and adjusted by dividers in the CPRI framer block (see **Chapter 18**, *Common Public Radio Interface (CPRI) Complex* for details).

7.1 Clock Generation Components and Modes

The clock generation components and clock scheme are shown in **Figure 7-1**.

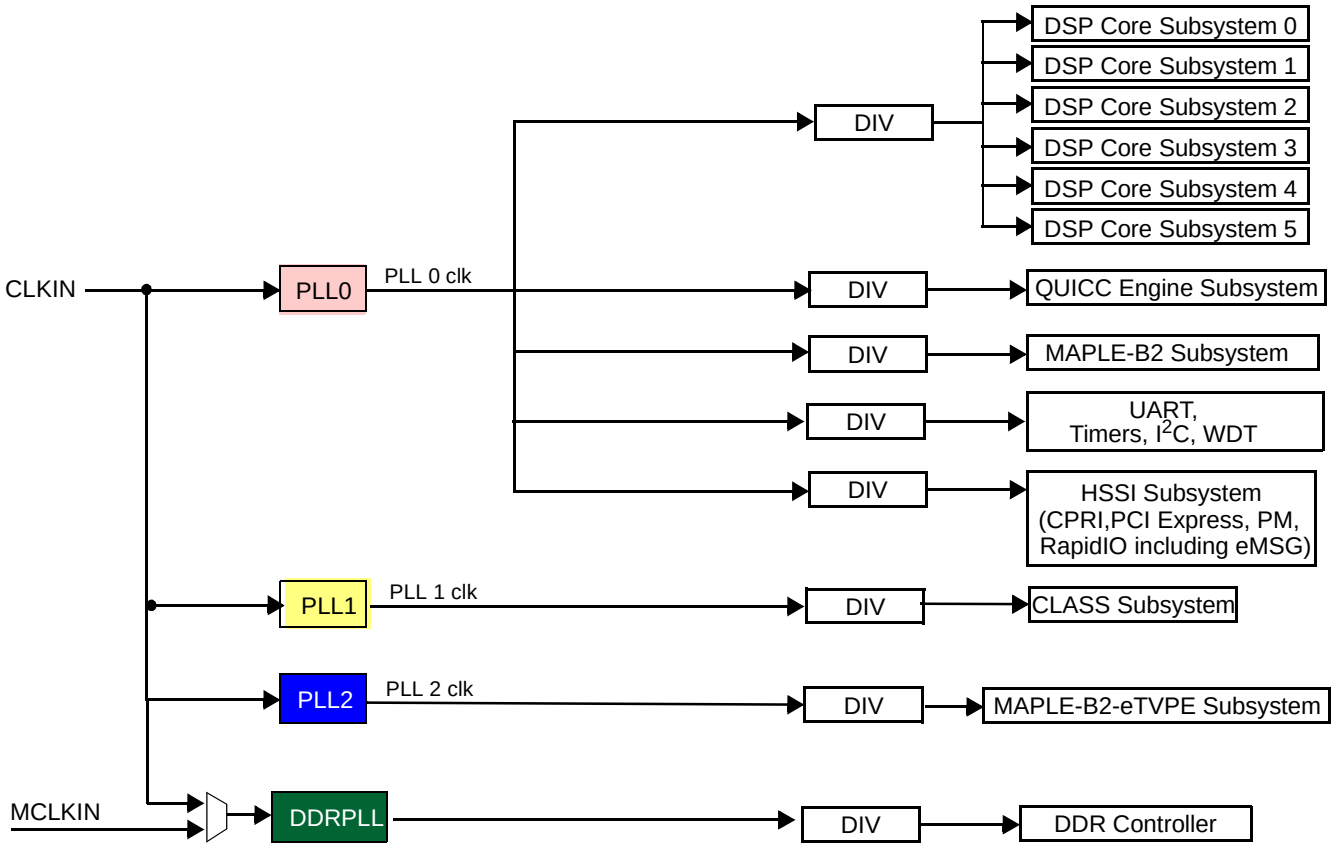

Figure 7-1. MSC8157E Clock Scheme

Each PLL uses its input clock to generate a fast clock that is synchronized to the input clock. The fast clock is distributed to each of the clock dividers to generate the clocks that are distributed to the system blocks.

The MSC8157E clock modes are listed in **Table 7-1**.

Table 7-1. MSC8157E Clock Modes

Mode	CLKIN	MCLKIN	PLL0	PLL1	PLL2	DDR PLL	CLASS	UART, Timers, I^2C, WDT	DSP Core Sub-systems	HSSI (CPRI, PCI Express, PM, RapidIO inc. eMSG)	QUICC Engine Sub-system	MAPLE-B2	eTVPE	DDR
0	133.33	n/a	2000	667	800	1333	667	500	1000	500	500	500	800	1333
40	133.33	133.33	2000	667	800	1333	667	500	1000	500	500	500	800	1333

Notes: **1.** The color of each cell, states which PLL drives its clock domain. PLL 0 is red, PLL1 is yellow, PLL2 is blue with white lettering and DDRPLL is green with white lettering.

2. In mode 40 the DDR PLL is fed by the MCLKIN

The CLKOUT pin can be driven from either PLL with selection determined by the value of RCWLR[CLKO] and RCWLR[P3V] (bits 31–30 and 10 of the low part of the reset configuration word—for details, see **Chapter 5**, *Reset*). The possible CLKOUT frequencies are listed in **Table 7-2**.

Table 7-2. MSC8157E CLK_OUT Frequencies

Mode	PLL0	PLL1	PLL2	DDRPLL	CLK_OUT from PLL0	CLK_OUT from PLL1	CLK_OUT from PLL2	CLKOUT2 from DDRPLL
0	2000	667	800	1333.3	125	66.7	80	166.6
40	2000	667	800	1333.3	125	66.7	80	166.6

7.2 System Clock Control Register (SCCR)

SCCR System Clock Control Register Offset 0x000

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLASS DIS	PER DIS	—	HSSI DIS	QEDIS	MAPLE DIS	ETVPE DIS	TITDIS	—							
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The SCCR can be used to shut down the clock for some of the clock domains. This register can only be reset by a power-on reset. **Table 7-3** defines the SCCR bit fields.

Table 7-3. SCCR Bit Descriptions

Name	Reset	Description	Settings
— 31–16	0	Reserved. Write to zero for future compatibility.	
CLASSDIS 15	0	**CLASS Clock Domain Disable** Used to disable the CLASS clock domain to conserve power.	0 CLASS clock domain enabled. 1 CLASS clock domain disabled.
PERDIS 14	0	**Peripherals Clock Domain Disable** Used to disable the Peripherals clock domain to conserve power.	0 UART, Timers, I^2C, WDT clock domain enabled. 1 UART, Timers, I^2C, WDT clock domain disabled.
13	0	Reserved. Write to zero for future compatibility.	
HSSIDIS 12	0	**HSSI Clock Domain Disable** Used to disable the HSSI clock domain to conserve power.	0 HSSI (CPRI, PCI Express, PM, RapidIO including eMSG) clock domain enabled. 1 HSSI (CPRI, PCI Express, PM, RapidIO including eMSG) clock domain disabled.
QEDIS 11	0	**QUICC Engine Clock Domain Disable** Used to disable the QUICC Engine subsystem clock domain to conserve power.	0 QUICC Engine clock domain enabled. 1 QUICC Engine clock domain disabled.
MAPLEDIS 10	0	**MAPLE-B Clock Domain Disable** Used to disable the MAPLE-B clock domain to conserve power.	0 MAPLE-B clock domain enabled. 1 MAPLE-B clock domain disabled.
ETVPDIS 9	0	**eTVPE Clock Domain Disable** Used to disable the eTVPE controller clock domain to conserve power.	0 eTVPE clock domain enabled. 1 eTVPE clock domain disabled.
TITDIS 8	0	**Core Subsystem Clock Domain Disable** Used to disable the Core Subsystem controller clock domain to conserve power.	0 Core Subsystem clock domain enabled. 1 Core Subsystem clock domain disabled.
— 7–0	0	Reserved. Write to zero for future compatibility.	

General Configuration Registers 8

The MSC8157E device includes a general configuration block that includes fifty-six 32-bit registers. This block provides sets of control and status registers for modules in the device that do not include their own control and status registers.

8.1 Programming Model

The general configuration registers include the following:

- General Interrupt Enable Register 3 for Cores 0–5 (GIER3_[0–5]), see **page 8-40**
- General Interrupt Register 5 (GIR5), see **page 8-42**
- General Interrupt Enable Register 5 for Cores 0–5 (GIER5_[0–5]), see **page 8-44**
- General Control Register 11 (GCR11), see **page 8-46**
- General Control Register 13 (GCR13), see **page 8-47**
- General Status Register 8 (GSR8), see **page 8-48**
- DMA Request0 Control Register (GCR_DREQ0), see **page 8-49**
- DMA Request1 Control Register (GCR_DREQ1), see **page 8-53**
- DMA Done Control Register (GCR_DDONE), see **page 8-57**
- DDR Controller General Configuration Register (DDRC_GCR), see **page 8-60**
- Core Subsystem Slave Port General Configuration Register (CORE_SLV_GCR), see **page 8-62**
- QUICC Engine Input General Control Register (QE_PIO_IN_GCR), see **page 8-63**
- QUICC Engine Output General Status Register (QE_PIO_OUT_GSR), see **page 8-64**
- L2Q Arbitration Control of Cores 0 and 1 (MEX_T2_0_1_ARB), see **page 8-65**
- L2Q Arbitration Control of Cores 2 and 3 (MEX_T2_2_3_ARB), see **page 8-66**
- L2Q Arbitration Control of Cores 4 and 5 (MEX_T2_4_5_ARB), see **page 8-67**
- General Interrupt Register 6 (GIR6), see **page 8-68**
- General Interrupt Enable Register 6 for Cores 0–5 (GIER6_[0–5]), see **page 8-71**
- General Interrupt Register 7 (GIR7), see **page 8-74**
- General Interrupt Enable Register 7 for Cores 0–5 (GIER7_[0–5]), see **page 8-76**
- DDR View Through L2 Memory Core Subsystems 0–3 (L2MAP_0_3), see **page 8-79**
- DDR View Through L2 Memory Core Subsystems 4–5 (L2MAP_4_5), see **page 8-80**
- eMSG to QUICC Engine External Request Enable (CPCEER), see **page 8-81**
- Ethernet 1 High Resolution Delay Register (UCC1_DELAY_HR), see **page 8-84**
- Ethernet 2 High Resolution Delay Register (UCC3_DELAY_HR), see **page 8-86**
- General Interrupt Register 8 (GIR8), see **page 8-88**
- CPRI Interrupt to MAPLE External Request Enable (MAPLE_EXT_REQ_EN_1), see **page 8-89**

Note: The base address for the general configuration registers is: 0xFFF28000.

8.2 Detailed Register Descriptions

8.2.1 General Configuration Register 1 (GCR1)

GCR1 General Configuration Register 1 **Offset 0x00**

Bit	31	30	29	28	27	26	25	24
	MPL_TRB_SEL	PM_HSSI_EN	—		MPL_ETVPE_SYNC_BYPASS	MAPLE_SYNC_MODE_EN	—	
Type	R/W							
Reset	0	1	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	—							UART_STOP
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	MEX_DMM	DDRW_PIPE_LMT					DDRR_PIPE_LMT	
Type	R/W							
Reset	0	1	0	0	0	0	1	0

Bit	7	6	5	4	3	2	1	0
	DDR_PIPE_LMT			—				
Type	R/W							
Reset	0	0	0	0	0	0	0	0

GCR1 configures various general functions for the MSC8157E device. **Table 8-1** lists the GCR1 bit field descriptions.

Table 8-1. GCR1 Bit Descriptions

Name	Reset	Description	Settings
MPL_TB_SEL 31	0	**MAPLE Trace Buffer Enable** Selects the trace buffers to output.	0 Output trace buffers 1 and 2. 1 Output trace buffers 3 and 4.
PM_HSSI_EN 30	1	**HSSI PM Enable** Enables/disables the PM signals coming out of the HSSI.	0 HSSI PM disabled. 1 HSSI PM enabled.
— 29–28	0	Reserved. Write to 0 for future compatibility.	
MPL_ETVPE_SYNC_BYPASS 27	0	**MAPLE ETVPE Sync Mode Enable** Enables/disables the ETVPE CDC logic by setting DCF sync bypass.	0 Sync mode disabled. 1 Sync mode enable.
MAPLE_SYNC_MODE_EN 26	0	**MAPLE Sync Mode Enable** Selects the signal for the internal clock multiplexer in MAPLE for MAPLE sync mode.	0 1
— 25–17	0	Reserved. Write to 0 for future compatibility.	
UART_STOP 16	0	**UART Stop** Stops the UART clock.	0 Normal operation. 1 UART clock stopped.

Table 8-1. GCR1 Bit Descriptions (Continued)

Name	Reset	Description	Settings
MEX_DMM 15		**MBus Bridge Memory Mode** Determines the mode used by the MBus bridges between the CLASS and the core subsystems. In MSC8156 mode, the core subsystems can only access the M2 memory within its own subsystem. In MSC8157 mode, cores can access M2 memory as follows: • Core 0 can access M2 in subsystem 0, 2, 3, 4, and 5. • Core 1 can access M2 in subsystem 1, 2, 3, 4, and 5. • Core 2 can access M2 in subsystem 2, 4, and 5. • Core 3 can access M2 in subsystem 3, 4, and 5. • Core 4 can access M2 in subsystem 4. • Core 5 can access M2 in subsystem 5.	0 MSC8157 mode 1 MSC8156 mode
DDRW_PIPE_LMT 14–10	10000	**DDR Write Pipeline Limit** Specifies the DDR write pipeline depth.	
DDRR_PIPE_LMT 9–5	10000	**DDR Read Pipeline Limit** Specifies the DDR read pipeline depth.	
— 4–0	0	Reserved. Write to 0 for future compatibility.	

8.2.2 General Configuration Register 2 (GCR2)

GCR2 General Configuration Register 2 **Offset 0x04**

Bit	31	30	29	28	27	26	25	24
	PRESCALE_OV_EN	SRIO_PRESCALE_CFG						
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	—							DMA_DBG
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	—		CORE5_STP_EN	CORE4_STP_EN	CORE3_STP_EN	CORE2_STP_EN	CORE1_STP_EN	CORE0_STP_EN
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	—		CORE5_DBG_REQ	CORE4_DBG_REQ	CORE3_DBG_REQ	CORE2_DBG_REQ	CORE1_DBG_REQ	CORE0_DBG_REQ
Type	R/W							
Reset	0	0	0	0	0	0	0	0

GCR2 configures various general functions for the MSC8157E device. **Table 8-2** lists the GCR2 bit field descriptions.

Table 8-2. GCR2 Bit Descriptions

Name	Reset	Description	Settings
PRESCALE_OV_EN 31	0	**Prescale Configuration Source** Determines the source to use for the pre-scale configuration.	0 RCW 1 GCR
SRIO_PRESCALE_CFG 30–24	0	**Serial RapidIO Prescale Configuration** When GCR is selected as the source (GCR2[PRESCALE_OV_EN] = 1), provides the prescalers for the Serial RapidIO PHY wrapper.	
— 23–17	0	Reserved. Write to 0 for future compatibility.	
DMA_DBG 16	0	**DMA Debug Mode Request** When set, initiates a request for the DMA controller to enter Debug mode. See **Section 14.6.17**, *DMA Debug Event Status Register (DMADESR)*, on page 14-43	0 No request. 1 DMA debug request.
— 15–14	0	Reserved. Write to 0 for future compatibility.	
CORE5_STP_EN 13	0	**Core 5 Stop Enable** Enables core 5 subsystem to stop.	0 Stop disabled. 1 Stop enabled.
CORE4_STP_EN 12	0	**Core 4 Stop Enable** Enables core 4 subsystem to stop.	0 Stop disabled. 1 Stop enabled.
CORE3_STP_EN 11	0	**Core 3 Stop Enable** Enables core 3 subsystem to stop.	0 Stop disabled. 1 Stop enabled.
CORE2_STP_EN 10	0	**Core 2 Stop Enable** Enables core 2 subsystem to stop.	0 Stop disabled. 1 Stop enabled.
CORE1_STP_EN 9	0	**Core 1 Stop Enable** Enables core 1subsystem to stop.	0 Stop disabled. 1 Stop enabled.
CORE0_STP_EN 8	0	**Core 0 Stop Enable** Enables core 0 subsystem to stop.	0 Stop disabled. 1 Stop enabled.
— 7–6	0	Reserved. Write to 0 for future compatibility.	
CORE5_DBG_REQ 5	0	**Core 5 Debug Request** Asserts a debug request to core 5 subsystem.	0 No debug request. 1 Debug request.
CORE4_DBG_REQ 4	0	**Core 4 Debug Request** Asserts a debug request to core 4 subsystem.	0 No debug request. 1 Debug request.
CORE3_DBG_REQ 3	0	**Core 3 Debug Request** Asserts a debug request to core 3 subsystem.	0 No debug request. 1 Debug request.
CORE2_DBG_REQ 2	0	**Core 2 Debug Request** Asserts a debug request to core 2 subsystem.	0 No debug request. 1 Debug request.
CORE1_DBG_REQ 1	0	**Core 1 Debug Request** Asserts a debug request to core 1 subsystem.	0 No debug request. 1 Debug request.
CORE0_DBG_REQ 0	0	**Core 0 Debug Request** Asserts a debug request to core 0 subsystem.	0 No debug request. 1 Debug request.

8.2.3 General Status Register 1 (GSR1)

GSR1 General Status Register 1 **Offset 0x08**

Bit	31	30	29	28	27	26	25	24
	—		CORE_WAIT_ACK5	CORE_WAIT_ACK4	CORE_WAIT_ACK3	CORE_WAIT_ACK2	CORE_WAIT_ACK1	CORE_WAIT_ACK0

Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	—		CORE_STOP_ACK5	CORE_STOP_ACK4	CORE_STOP_ACK3	CORE_STOP_ACK2	CORE_STOP_ACK1	CORE_STOP_ACK0
Type	R							
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	—	M3_PU_1	M3_PU_0	MAPLE_PSIF_PU	—			
Type	R							
Reset	0	0	0	1	0	0	1	1

Bit	7	6	5	4	3	2	1	0
	—		CORE_DBG_STS5	CORE_DBG_STS4	CORE_DBG_STS3	CORE_DBG_STS2	CORE_DBG_STS1	CORE_DBG_STS0
Type	R							
Reset	0	0	0	0	0	0	0	0

GSR1 reports the status various general functions for the MSC8157E device. **Table 8-3** lists the GSR1 bit field descriptions.

Table 8-3. GSR1 Bit Descriptions

Name	Reset	Description	Settings
— 31–30	0	Reserved. Write to 0 for future compatibility.	
CORE_WAIT_ACK5 29	0	**Core Wait Acknowledge 5** Reflects whether core 5 subsystem is in Wait state.	0 Core subsystem not in Wait state. 1 Core subsystem in Wait state.
CORE_WAIT_ACK4 28	0	**Core Wait Acknowledge 4** Reflects whether core 4 subsystem is in Wait state	0 Core subsystem not in Wait state. 1 Core subsystem in Wait state.
CORE_WAIT_ACK3 27	0	**Core Wait Acknowledge 3** Reflects whether core 3 subsystem is in Wait state.	0 Core subsystem not in Wait state. 1 Core subsystem in Wait state.
CORE_WAIT_ACK2 26	0	**Core2 Wait Acknowledge 2** Reflects whether core 2 subsystem is in Wait state	0 Core subsystem not in Wait state. 1 Core subsystem in Wait state.
CORE_WAIT_ACK1 25	0	**Core1 Wait Acknowledge 1** Reflects whether core 1 subsystem is in Wait state.	0 Core subsystem not in Wait state. 1 Core subsystem in Wait state.
CORE_WAIT_ACK0 24	0	**Core Wait Acknowledge 0** Reflects whether core 0 subsystem is in Wait state.	0 Core subsystem not in Wait state. 1 Core subsystem in Wait state.

Table 8-3. GSR1 Bit Descriptions (Continued)

Name	Reset	Description	Settings
— 23–22	0	Reserved. Write to 0 for future compatibility.	
CORE_STOP_ACK5 21	0	**Core Stop Acknowledge 5** Reflects whether core 5 subsystem is in Stop state.	0 Core subsystem not in Stop state. 1 Core subsystem in Stop state.
CORE_STOP_ACK4 20	0	**Core Stop Acknowledge 4** Reflects whether core 4 subsystem is in Stop state	0 Core subsystem not in Stop state. 1 Core subsystem in Stop state.
CORE_STOP_ACK3 19	0	**Core Stop Acknowledge 3** Reflects whether core 3 subsystem is in Stop state.	0 Core subsystem not in Stop state. 1 Core subsystem in Stop state.
CORE_STOP_ACK2 18	0	**Core Stop Acknowledge 2** Reflects whether core 2 subsystem is in Stop state	0 Core subsystem not in Stop state. 1 Core subsystem in Stop state.
CORE_STOP_ACK1 17	0	**Core Stop Acknowledge 1** Reflects whether core 1 subsystem is in Stop state.	0 Core subsystem not in Stop state. 1 Core subsystem in Stop state.
CORE_STOP_ACK0 16	0	**Core Stop Acknowledge 0** Reflects whether core 0 subsystem is in Stop state.	0 Core subsystem not in Stop state. 1 Core subsystem in Stop state.
— 15	0	Reserved. Write to 0 for future compatibility.	
M3_PU_1 14	0	**M3 Second 1 MB Power Up** Reflects the M3 second 1 MB power up status.	0 Second 1 MB M3 powered down. 1 Second 1 MB KB M3 powered up.
M3_PU_0 13	0	**M3 First 1 MB Power Up** Reflects the M3 first 1 MB power up status.	0 First 1 MB M3 (1st half) powered down. 1 First 1 MB M3 (1st half) powered up.
MAPLE_PSIF_PU 12	1	**MAPLE Power Up (excluding TVPE and EQPE)** Reflects the MAPLE block power status except for TVPE and EQPE.	0 Powered down. 1 Powered up.
— 11–6	001100	Reserved. Write the reset value (0b0001100) for future compatibility.	
CORE_DBG_STS5 5	0	**Core Debug Status 5** Reflects the mode of core 5 subsystem.	0 Not in Debug mode. 1 In Debug mode.
CORE_DBG_STS4 4	0	**Core Debug Status 4** Reflects the mode of core 4 subsystem.	0 Not in Debug mode. 1 In Debug mode.
CORE_DBG_STS3 3	0	**Core Debug Status 3** Reflects the mode of core 3 subsystem.	0 Not in Debug mode. 1 In Debug mode.
CORE_DBG_STS2 2	0	**Core Debug Status 2** Reflects the mode of core 2 subsystem.	0 Not in Debug mode. 1 In Debug mode.
CORE_DBG_STS1 1	0	**Core Debug Status 1** Reflects the mode of core 1 subsystem.	0 Not in Debug mode. 1 In Debug mode.
CORE_DBG_STS0 0	0	**Core0 Debug Status 0** Reflects the mode of core 0 subsystem.	0 Not in Debug mode. 1 In Debug mode.

8.2.4 High Speed Serial Interface Status Register (HSSI_SR)

HSSI_SR High Speed Serial Interface Status Register **Offset 0x0C**

Bit	31	30	29	28	27	26	25	24
	HSSI_IPG_STOP_ACK	CPRI_IPG_STOP_ACK	—			DMA1_PD_STATUS	SRIO1_PD_STATUS	SE_CB_PD_STATUS

HSSI_SR controls part of the SerDes operation for the MSC8157E device. The register is reset on a Hard reset. Write accesses can only be performed in Supervisor mode. **Table 8-4** lists the HSSI_SR bit field descriptions.

Table 8-4. HSSI_SR Bit Descriptions

Name	Reset	Description	Settings
HSSI_IPG_STOP_ACK 31	0	**HSSI Stop Acknowledge** Indicates whether the HSSI Stop request is acknowledged.	0 Not acknowledged. 1 Acknowledged.
CPRI_IPG_STOP_ACK 30	0	**CPRI Stop Acknowledge** Indicates whether the CPRI Stop request is acknowledged.	0 Not acknowledged. 1 Acknowledged.
— 29–27	0	Reserved. Write to 0 for future compatibility.	
DMA1_PD_STATUS 26	0	**DMA1 Power Down Status** Indicates the power status of DMA1. Can be powered down by the Reset Control Word or GCR control.	0 Power up. 1 Power down.
SRIO1_PD_STATUS 25	0	**Serial RapidIO Port 1 Power Down Status** Indicates the power status of the serial RapidIO Port 1. Can be powered down by the Reset Control Word or GCR control.	0 Power up. 1 Power down.

Table 8-4. HSSI_SR Bit Descriptions (Continued)

Name	Reset	Description	Settings
SD_CB_PD_STATUS 24	x	**SerDes Control Bloc Power Down Status** Indicates the power status of the SerDes control block. The default value of this status bit depends on the value of the RCW[SP] field.	0 Power up. 1 Power down.
SD_ISO_RING_PD 23	x	**SerDes Control Isolation Ring Powered** Indicates the power status of the SerDes isolation ring. This can be powered down by the RCW or by GCR control. The default value of this status bit depends on the value of the RCW.	0 Power up. 1 Power down.
SD_FORCE_STOPPED 22	x	**SerDes Force Stop Status** Indicates whether the SerDes had a force stop. The default value of this status bit depends on the value of the RCW.	0 Normal. 1 Stopped.
DMA0_PD_STATUS 21	x	**DMA0 Power Down Status** Indicates the power status of DMA0. Can be powered down by the Reset Control Word or GCR control. The default value of this status bit depends on the value of the RCW[SP] field.	0 Power up. 1 Power down.
SRIO0_PD_STATUS 20	x	**Serial RapidIO Port 0 Power Down Status** Indicates the power status of the serial RapidIO Port 0. Can be powered down by the Reset Control Word or GCR control. The default value of this status bit depends on the value of the RCW[SP] field.	0 Power up. 1 Power down.
PEX_PD_STATUS 19	x	**PCI Express Power Down Status** Indicates the power status of the PCI Express controller. Can be powered down by the Reset Control Word or GCR control. The default value of this status bit depends on the value of the RCW[SP] field.	0 Power up. 1 Power down.
OCN_PD_STATUS 18	x	**OCN Fabric Power Down Status** Indicates the power status of the OCN fabric. Can be powered down by the Reset Control Word or GCR control. The default value of this status bit depends on the value of the RCW[SP] field.	0 Power up. 1 Power down.
EMSG_PD_STATUS 17	x	**RapidIO Enhanced Messaging Unit Power Down Status** Indicates the power status of the RapidIO Enhanced Messaging Unit. Can be powered down by the Reset Control Word or GCR control. The default value of this status bit depends on the value of the RCW[SP] field.	0 Power up. 1 Power down.
SRIO1_STOP_ACK 16	0	**Serial RapidIO Port 1 Stop Acknowledge Status** Indicates the serial RapidIO Port 1 Stop Acknowledge status.	0 Not stopped. 1 Stop ACK issued.
SRIO0_STOP_ACK 15	0	**Serial RapidIO Port 0 Stop Acknowledge Status** Indicates the serial RapidIO Port 0 Stop Acknowledge status.	0 Not stopped. 1 Stop ACK issued.
PEX_STOP_ACK 14	0	**PCI Express Stop Acknowledge Status** Indicates the PCI Ex[press Stop Acknowledge status.	0 Not stopped. 1 Stop ACK issued.

Table 8-4. HSSI_SR Bit Descriptions (Continued)

Name	Reset	Description	Settings
EMSG_STOP_ACK 13	0	**RapidIO Enhanced Messaging Unit Stop Acknowledge Status** Indicates the EMSG Stop Acknowledge status.	0 Not stopped. 1 Stop ACK issued.
— 12	0	Reserved. Write to 0 for future compatibility.	
SERDES2_RST_DONE 11	0	**SERDES PLL2 Reset Done** Indicates whether the SERDES PLL2 has completed the reset sequence. **Note:** Although the reset value is 0, the bit will change to 1 within 160 µs after reset depending on whether the SerDes port is used.	0 Reset not complete. 1 Reset complete.
SERDES_PD 10	0	**SERDES Power Down Status** Indicates the power status of the SERDES PHY.	0 Power up. 1 Power down (PLL is not working).
SRIO1_IDLE 9	0	**Serial RapidIO Port 1 Idle** Indicates whether the Serial RapidIO Port 1 is idle, that is, no transactions in progress.	0 Active. 1 Idle.
SRIO1_OB_IDLE 8	0	**Serial RapidIO Port 1 Outbound Idle** Indicates whether the Serial RapidIO Port 1 outbound activity is idle, that is, no outbound transactions in progress.	0 Active. 1 Idle.
SERDES1_RST_DONE 7	0	**SERDES PLL1 Reset Done** Indicates whether the SERDES PLL1 has completed the reset sequence. **Note:** Although the reset value is 0, the bit will change to 1 within 160 µs after reset depending on whether the SerDes port is used.	0 Reset not complete. 1 Reset complete.
— 6	0	Reserved. Write to 0 for future compatibility.	
SRIO0_IDLE 5	0	**Serial RapidIO Port 0 Idle** Indicates whether the Serial RapidIO Port 0 unit is idle, that is, no transactions in progress.	0 Active. 1 Idle.
SRIO0_OB_IDLE 4	0	**Serial RapidIO Port 0 Outbound Idle** Indicates whether the Serial RapidIO Port 0 outbound activity is idle, that is, no outbound transactions in progress.	0 Active. 1 Idle.
PEX_IDLE 3	0	**PCI Express Idle** Indicates whether the Serial PCI Express unit is idle, that is, no transactions in progress.	0 Active. 1 Idle.
PEX_OB_IDLE 2	0	**PCI Express Outbound Idle** Indicates whether the PCI Express outbound activity is idle, that is, no outbound transactions in progress.	0 Active. 1 Idle.
— 1	0	Reserved. Write to 0 for future compatibility.	
EMSG_IDLE 0	0	**EMSG Idle** Indicates whether the EMSG is idle, that is, no transactions in progress.	0 Active. 1 Idle.

8.2.5 DDR General Control Register (DDR_GCR)

DDR_GCR DDR General Control Register **Offset 0x10**

Bit	31	30	29	28	27	26	25	24
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	—		DDR_QUEUE_DEPTH_DI		DDR_IO_REC_ADJ			—
Type	R/W							
Reset	0	0	0	0	1	1	0	0

Bit	7	6	5	4	3	2	1	0
	DDR_COP_DRAIN_QUEUES_FOR_SLEEP	DDR_COP_USE_POR_SAMPLED_VALUE	DDR_COP_TERMSEL_OVERRIDE_VALUE			DDR_COP_TERMSEL_OVERRIDE_EN	—	DDR_NO_WRAP_32
Type	R/W							
Reset	0	0	0	0	0	0	0	1

DDR_GCR controls the DDR operation the MSC8157E device. The register is reset on a Hard reset. Write accesses can only be performed in Supervisor mode. **Table 8-5** lists the DDR_GCR bit field descriptions.

Table 8-5. DDR_GCR Bit Descriptions

Name	Reset	Description	Settings
— 31–14	0	Reserved. Write to 0 for future compatibility.	
DDR_QUEUE_DEPTH_DI 13–12	00	**DDR Input Queue Depth Select** Selects the depth of the input queue.	00 5 entries. 01 2 entries. 10 3 entries 11 4 entries
DDR_IO_REC_ADJ 11–9	110	**DDRC I/O Select Setting** Sets the value for the termination select override.	
— 8	0	Reserved. Write to 0 for future compatibility.	
DDR_COP_DRAIN_QUEUES_FOR_SLEEP 7	0	**DDRC Drain Queues for Sleep** Indicates whether to drain the queues when entering Sleep mode.	0 Do not drain input queue. 1 Drain input queue.
DDR_COP_USE_POR_SAMPLED_VALUE 6	0	**DDRC Use POR Sampled Value** Indicates whether to use the sampled value for driver impedance.	0 Do not use sampled value. 1 Use sampled value.

Table 8-5. DDR_GCR Bit Descriptions (Continued)

Name	Reset	Description	Settings
DDR_COP_TERMSEL_OVERRIDE_VALUE 5–3	000	**DDRC Termination Select Override Value** Sets the value for the termination select override.	
DDR_COP_TERMSEL_OVERRIDE_EN 2	0	**DDRC Termination Select Override Enable** Disables/enables the termination select override.	0 Disable 1 Enable.
— 1	0	Reserved. Write to 0 for future compatibility.	
DDR_NO_WRAP_32 0	1	**DDRC No Wrap 32 Mode** Indicates where to wrap the memory.	0 Wrap occurs on 32-byte boundary. 1 Wrap occurs on 64-byte boundary.

8.2.6 High Speed Serial Interface Control Register 1 (HSSI_CR1)

HSSI_CR1 High Speed Serial Interface Control Register 1 **Offset 0x14**

Bit	31	30	29	28	27	26	25	24
	—		GPEX_ECC_ERR_INJECT	PEX2O_ECC_ERR_INJECT	DMA2OCN1_ECC_ERR_INJECT	DMA2OCN0_ECC_ERR_INJECT	SRIO1_DOZE	DMA2OCN1_ECC_D
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Type	R/W							
Reset	0	0	0	0	0	0	1	1

HSSI_CR1 controls various functions within the SerDes block for the MSC8157E device. The register is reset on a hard reset. Write accesses can only be performed in Supervisor mode. **Table 8-6** lists the HSSI_CR1 bit field descriptions.

Table 8-6. HSSI_CR1 Bit Descriptions

Name	Reset	Description	Settings
— 31–30	0	Reserved. Write to 0 for future compatibility.	
GPEX_ECC_ERR_INJECT 29	0	**PCI Express Multi-Bit ECC Error Inject** Indicates whether to inject a multibit error into the PCI Express controller.	0 Do not inject error. 1 Inject error.
PEX2O_ECC_ERR_INJECT 28	0	**PCI Express to OCN ECC Error Inject** Indicates whether to inject a multibit error into the PCI Express to OCN bridge.	0 Do not inject error. 1 Inject error.
DMA2OCN1_ECC_ERR_INJECT 27	0	**DMA to OCN Bridge1 Multi-Bit ECC Error Inject** Indicates whether to inject a multibit error into the DMA to OCN Bridge 1.	0 Do not inject error. 1 Inject error.
DMA2OCN0_ECC_ERR_INJECT 26	0	**DMA to OCN Bridge0 Multi-Bit ECC Error Inject** Indicates whether to inject a multibit error into the DMA to OCN Bridge 0.	0 Do not inject error. 1 Inject error.
SRIO1_DOZE 25	0	**Serial RapidIO Port 1 Doze** Used to select Doze mode, in which all register accesses are acknowledged, but writes are not written and reads do not contain valid data. Setting this bit prevents lockup of the device internal bus while the Serial RapidIO clock is stopped.	0 Normal operation. 1 Doze mode.
DMA2OCN1_ECC_D 24	0	**Disable DMA to OCN1 ECC** Enables/disables DMA to OCN1 bridge ECC.	0 ECC enabled. 1 ECC disabled.
SRIO1_PD 23	0	**Serial RapidIO Port 1 Power Down** Shuts down serial RapidIO Port 1 power.	0 Power up. 1 Power down.
EMSG_STOP 22	0	**EMSG Stop** Stops the RapidIO Enhanced Messaging Unit.	0 EMSG not stopped. 1 EMSG stopped.
SRIO1_ECC_D 21	0	**Disable Serial RapidIO Port 1 ECC** Enables/disables serial RapidIO Port 1 ECC.	0 ECC enabled. 1 ECC disabled.
SD_CB_PD 20	0	**SerDes Control Block Power Down** Shuts down SerDes control block power.	0 Power up. 1 Power down.
SD_ISOR_PD 19	0	**SerDes Isolation Ring Power Down** Shuts down the SerDes Isolation Ring power.	0 Power up. 1 Power down.
SD_DOZE 18	0	**SerDes Doze** Used to select Doze mode, in which all register accesses are acknowledged, but writes are not written and reads do not contain valid data. Setting this bit prevents lockup of the device internal bus while the SerDes clock is stopped.	0 Normal operation. 1 Doze mode.
SRIO1_ECC_ERR_INJECT 17	0	**Serial RapidIO Port 1 Multi-Bit ECC Error Inject** Indicates whether to inject a multibit error into the Serial RapidIO Port 1.	0 Do not inject error. 1 Inject error.
SRIO0_ECC_ERR_INJECT 16	0	**Serial RapidIO Port 0 Multi-Bit ECC Error Inject** Indicates whether to inject a multibit error into the Serial RapidIO Port 0.	0 Do not inject error. 1 Inject error.

Table 8-6. HSSI_CR1 Bit Descriptions (Continued)

Name	Reset	Description	Settings
SRIO0_DOZE 15	0	**Serial RapidIO Port 0 Doze** Used to select Doze mode, in which all register accesses are acknowledged, but writes are not written and reads do not contain valid data. Setting this bit prevents lockup of the device internal bus while the Serial RapidIO clock is stopped.	0 Normal operation. 1 Doze mode.
DMA2OCN0_ECC_D 14	0	**Disable DMA to OCN0 ECC** Enables/disables DMA to OCN0 bridge ECC.	0 ECC enabled. 1 ECC disabled.
SRIO0_PD 13	0	**Serial RapidIO Port 0 Power Down** Shuts down serial RapidIO Port 0 power.	0 Power up. 1 Power down.
PEX_STOP 12	0	**PCI Express Stop** Stops the PCI Express complex.	0 PCI Express not stopped. 1 PCI Express stopped.
SRIO0_ECC_D 11	0	**Disable Serial RapidIO Port 0 ECC** Enables/disables serial RapidIO Port 0 ECC.	0 ECC enabled. 1 ECC disabled.
— 10	0	Reserved. Write to 0 for future compatibility.	
PEX_PD 9	0	**PCI Express Power Down** Shuts down PCI Express clock power.	0 Power up. 1 Power down.
PEX_DOZE 8	0	**PCI Express Doze** Used to select Doze mode, in which all register accesses are acknowledged, but writes are not written and reads do not contain valid data. Setting this bit prevents lockup of the device internal bus while the PCI Express controller is stopped.	0 Normal operation. 1 Doze mode.
PEX2O_ECC_D 7	0	**Disable PCI Express to OCN ECC** Enables/disables PCI Express to OCN ECC.	0 ECC enabled. 1 ECC disabled.
GPEX_ECC_D 6	0	**Disable PCI Express ECC** Enables/disables PCI Express ECC.	0 ECC enabled. 1 ECC disabled.
OCN_PD 5	0	**OCN Power Down** Shuts down OCN fabric power.	0 Power up. 1 Power down.
EMSG_PD 4	0	**EMSG Power Down** Shuts down EMSG power.	0 Power up. 1 Power down.
EMST_DOZE 3	0	**EMSG Doze** Used to select Doze mode, in which all register accesses are acknowledged, but writes are not written and reads do not contain valid data. Setting this bit prevents lockup of the device internal bus while the EMSG is stopped.	0 Normal operation. 1 Doze mode.
EMSG_ECC_ERR_INJECT 2	0	**EMSG Multi-Bit ECC Error Inject** Indicates whether to inject a multibit error into the EMSG.	0 Do not inject error. 1 Inject error.
— 1–0	0	Reserved. Write to 0 for future compatibility.	

Note: Doze mode is a special mode used by the MSC8157E to allow register reads/writes to continue and be acknowledged without changing or reporting any register contents while the peripheral clocking is stopped. Processing of reads/writes can continue after the peripheral has entered power down mode. Without Doze mode, the device could hang up waiting for a response from the peripheral. This mode permits acknowledgement of the read or write, but does not read or write any meaningful data.

8.2.7 High Speed Serial Interface Control Register 2 (HSSI_CR2)

HSSI_CR2 High Speed Serial Interface Control Register 2 **Offset 0x18**

Bit	31	30	29	28	27	26	25	24
	—			CPRI_RESET	—			
Type	R/W							
Reset	0	0	0	1	0	0	0	0

Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	—						EMSG_ECC_D	—
Type	R/W							
Reset	0	0	0	0	0	0	0	0

HSSI_CR2 controls various functions within the SerDes block for the MSC8157E device. The register is reset on a hard reset. Write accesses can only be performed in Supervisor mode. **Table 8-7** lists the HSSI_CR2 bit field descriptions.

Table 8-7. HSSI_CR2 Bit Descriptions

Name	Reset	Description	Settings
— 31–29	0	Reserved. Write to 0 for future compatibility.	
CPRI_RESET 28	0	**CPRI Reset** Use to reset the CPRI controllers	0 Reset CPRI 1 Do not reset CPRI.
— 27–24	0	Reserved. Write to 0 for future compatibility.	
CPRI_LINK_RATE 23–20	1010	**CPRI Link Rate** Selects the CPRI link rate.	0010 1.2288 GHz 0100 2.4576 GHz 0101 3.072 GHz 1000 4.9152 GHz 1010 6.144 GHz 1111 CPRI powered down All other values reserved.
PD_SRIO_1_TO_SD 19	0	**SerDes Power Down** Powers down the SRIO1 pipe interface to SerDes if the SerDes PLL2 becomes unstable.	0 No action. 1 Power down SRIO1 pipe.
PD_SRIO__0_TO_SD 18	0	**SerDes Power Down** Powers down the SRIO0 pipe interface to SerDes if the SerDes PLL1 becomes unstable.	0 No action. 1 Power down SRIO0 pipe.

Table 8-7. HSSI_CR2 Bit Descriptions (Continued)

Name	Reset	Description	Settings
HSSI_STOP 17	0	**HSSI Stop** With the HSSI_IPG_STOP_ACK received from the HSSI, actively stops the clock to the HSSI complex and to its memory. If the memory is not put in self-refresh mode separately prior to ipg-stop activation, data will be lost,.	0 No action. 1 Stop clock.
CPRI_STOP 16	0	**CPRI Stop** With the CPRI_IPG_STOP_ACK received from the CPRI, actively stops the clock to the CPRI and to its memory. If the memory is not put in self-refresh mode separately prior to ipg-stop activation, data will be lost,.	0 No action. 1 Stop clock.
— 15–13	0	Reserved. Write to 0 for future compatibility.	
CPRI_REC_CLK0 12–10	0	**Reconstructed Clock Select** Used to choose the reconstructed clock to output to GPIO from the SerDes complex.	
— 9–2	0	Reserved. Write to 0 for future compatibility.	
EMSG_ECC_D 1	0	**RapidIO Enhanced Messaging Unit ECC Disable** Enables/disables the EMSG ECC.	0 ECC enabled. 1 ECC disabled.
— 0	0	Reserved. Write to 0 for future compatibility.	

8.2.8 QUICC Engine Control Register (QECR)

QECR QUICC Engine Control Register **Offset 0x1C**

Bit	31	30	29	28	27	26	25	24
	—							
Type	R							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16

Type	R/W							
Reset	1	1	1	1	1	1	1	1

GPUER enables/disables the individual GPIO pull-up resistors. The register is reset on a Hard reset. Write accesses can only be performed in Supervisor mode. **Table 8-9** lists the GPUER bit field descriptions.

Table 8-9. GPUER Bit Descriptions

Name	Reset	Description	Settings
PUE_B[31–0] 31–0	0xFFFFFFFF	**Pull-Up Enable 31–0** Each bit in this field enables/disables the GPIO pull-up resistor corresponding to the bit index number.	0 Pull-up input is enabled. 1 Pull-up input is disabled.

8.2.10 GPIO Input Enable Register (GIER)

GIER GPIO Input Enable Register **Offset 0x24**

Bit	31	30	29	28	27	26	25	24
	IE31	IE30	IE29	IE28	IE27	IE26	IE25	IE24
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	IE23	IE22	IE21	IE20	IE19	IE18	IE17	IE16
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	IE7	IE6	IE5	IE4	IE3	IE2	IE1	IE0
Type	R/W							
Reset	0	0	0	0	0	0	0	0

GIER enables/disables the individual GPIO signals. The register is reset on a hard reset. Write accesses can only be performed in Supervisor mode. **Table 8-10** lists the GIER bit field descriptions.

Table 8-10. GIER Bit Descriptions

Name	Reset	Description	Settings
IE[31–0] 31–0	0	**Input Enable 31–0** Each bit in this field enables/disables the individual GPIO corresponding to the bit index number.	0 Input is disabled. 1 Input is enabled.

8.2.11 System Part and Revision ID Register (SPRIDR)

SPRIDR System Part and Revision ID Register **Offset 0x28**

Bit	31	30	29	28	27	26	25	24
	PARTID							
Type	R							
Reset	1	0	0	0	0	0	1	1
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	PARTID							
Type	R							
Reset	0	0	0	0	1	1	0	1

	REVID							
Type	R							
Reset	0	0	0	0	0	0	0	0

SPRIDR provides information about the device and revision numbers. **Table 8-11** lists the SPRIDR bit field descriptions.

Table 8-11. SPRIDR Bit Descriptions

Name	Reset	Description
PARTID 31–16	0x830D	**Part Identification** Mask-programmed with a code corresponding to the device number.
REVID 15–0	0x0000	**Revision Identification** Mask-programmed with a code corresponding to the revision number of the part identified by the PARTID value.

8.2.12 General Control Register 4 (GCR4)

GCR4 General Control Register 4 Offset 0x30

Bit	31	30	29	28	27	26	25	24
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	—				UCC3RCLKID		UCC3TCLKID	
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	UCC3CLKOD		UCC3RXDD		UCC3TXDD		UCC1RCLKID	
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	UCC1TCLKID		UCC1CLKOD		UCC1RXDD		UCC1TXDD	
Type	R/W							
Reset	0	0	0	0	0	0	0	0

GCR4 controls the delay lines for UCC1 and UCC3. The register is reset on a Hard reset. Write accesses can only be performed in Supervisor mode.

The MSC8157E Data Sheet includes recommended default values for this register to use with a standard RGMII PHY device. **AN4134** *RGMII Ethernet Timing in StarCore Based MSC8157 DSPs* (available under NDA) provides guidelines for adjusting GCR4 values for specific applications, if required.

Table 8-8 lists the GCR4 bit field descriptions.

Table 8-12. GCR4 Bit Descriptions

Name	Reset	Description	Settings
— 31–20	0	Reserved. Write to 0 for future compatibility.	
UCC3RCLKID 19–18	0	**UCC3 RX Clock In Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
UCC3TCLKID 17–16	0	**UCC3 TX Clock In Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
UCC3CLKOD 15–14	0	**UCC3 Clock Out Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.

Table 8-12. GCR4 Bit Descriptions (Continued)

Name	Reset	Description	Settings
UCC3RXDD 13–12	0	**UCC3 RX Data Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
UCC3TXDD 11–10	0	**UCC3 TX Data Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
UCC1RCLKID 9–8	0	**UCC1 RX Clock In Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
UCC1TCLKID 7–6	0	**UCC1 TX Clock In Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
UCC1CLKOD 5–4	0	**UCC1 Clock Out Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
UCC1RXDD 3–2	0	**UCC1 RX Data Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
UCC1TXDD 1–0	0	**UCC1 TX Data Delay** Adds a delay to the specified signal.	00 No delay. 01 One delay unit. 10 Two delay units. 11 Three delay units.
Note: The clock for the delay unit is the TX clock.			

8.2.13 General Control Register 5 (GCR5)

GCR5 General Control Register 5 Offset 0x34

Bit	31	30	29	28	27	26	25	24
	—	QE_STOP_MODE_B	SCOP_STOP	—				
Type	R/W							
Reset	0	1	0	0	0	0	0	0

	—				OCNDMA0_POWER DOWN	OCNDMA0_DOZE	OCNDMA0_STOP	—
Type	R/W							
Reset	0	0	0	0	0	0	0	0

GCR5 performs various control functions. All bits are cleared on reset.

Table 8-13. GCR5 Bit Descriptions

Name	Reset	Description	Settings
— 31	0	Reserved. Write to zero for future compatibility.	
QE_STOP_MODE_B 30	0	**Stop QUICC Engine Block** Stops the QUICC Engine block operation.	0 Normal operation. 1 Stopped.
SCOP_STOP 29	0	**Stop SEC Block** Stops the SEC block operation.	0 Normal operation. 1 Stopped.
— 28–23	0	Reserved. Write to zero for future compatibility.	
DROWSY_M3_V 22	0	**Drowsy M3 Voltage Select** Selects the drowsy M3 memory voltage.	0 200 mV. 1 300 mV.
— 21	0	Reserved. Write to zero for future compatibility.	
DROWSY_M2_V 20	0	**Drowsy M2 Voltage Select** Selects the drowsy M2 memory voltage.	0 200 mV. 1 300 mV.

Table 8-13. GCR5 Bit Descriptions (Continued)

Name	Reset	Description	Settings
— 19	0	Reserved. Write to zero for future compatibility.	
DROWSY_M3_EN 18	0	**Drowsy M3 Enable** Enables/disables the drowsy memory feature.	0 Disabled. 1 Enabled.
DROWSY_M2_EN 17	0	**Drowsy M2 Enable** Enables/disables the drowsy memory feature.	0 Disabled. 1 Enabled.
DROWSY_OVERRIDE_EN 16	0	**Drowsy Memory Override Enable** Enables/disables the drowsy memory override function. When disabled, override control is done via the RCW settings.	0 Disabled. 1 Enabled.
— 15–13	0	Reserved. Write to zero for future compatibility.	
PEX_IRQ_OUT 12	0	**PCI Express Message Signaled Interrupt Enable** Enables/disables triggering of a PCI Express message-signaled interrupt.	0 Disabled. 1 Enabled.
OCNDMA1_POWER DOWN 11	0	**OCNDMA 1 Complex Power Down** Makes the OCNDMA1 complex power down.	0 OCNDMA1 powered up. 1 OCNDMA1 power down (Stop ACK).
OCNDMA1_DOZE 10	0	**OCNDMA 1 Doze** Used to select Doze mode, in which all register accesses are acknowledged, but writes are not written and reads do not contain valid data. Setting this bit prevents lockup of the device internal bus while the OCNDMA1 is stopped.	0 Normal operation. 1 Doze mode.
OCNDMA1_STOP 9	0	**OCNDMA 1 Stop** Makes the OCNDMA1 enter Stop mode.	0 OCNDMA1 normal operation. 1 OCNDMA1 Stop mode.
— 8–4	0	Reserved. Write to zero for future compatibility.	
OCNDMA0_POWER DOWN 3	0	**OCNDMA 0 Complex Power Down** Drives the ips_wait signal to 0 in preparation for power down to avoid ips transactions becoming stuck.	0 OCNDMA0 powered up. 1 OCNDMA0 power down (Stop ACK).
OCNDMA0_DOZE 2	0	**OCNDMA 0 Doze** Used to select Doze mode, in which all register accesses are acknowledged, but writes are not written and reads do not contain valid data. Setting this bit prevents lockup of the device internal bus while the OCNDMA0 is stopped.	0 Normal operation. 1 Doze mode.
OCNDMA0_STOP 1	0	**OCNDMA 0 Stop** Makes the OCNDMA0 enter Stop mode.	0 OCNDMA0 normal operation. 1 OCNDMA0 Stop mode.
— 0	0	Reserved. Write to zero for future compatibility.	

8.2.14 General Status Register 2 (GSR2)

GSR2 General Status Register 2 Offset 0x38

Bit	31	30	29	28	27	26	25	24
	—		DDR_IDLE_MEM	DDR_YMMC_STOP_ACK	—

Reset	0	0	1	0	1	0	1	0

GSR2 reflects the status of various functions. All bits are cleared on reset.

Table 8-14. GSR2 Bit Descriptions

Name	Reset	Description	Settings
— 31–30	0	Reserved. Write to zero for future compatibility.	
DDR_IDLE_MEM 29	0	**DDR Controller Idle** Reflects the current status of DDR Controller.	0 Memory controller active. 1 Memory controller idle.
DDR_YMMC_STOP_ACK 30	0	**DDR Controller Refresh Mode** Reflects the current status of DDR Controller refresh mode.	0 Memory controller not in self-refresh mode. 1 Memory controller in self-refresh mode.
— 27–22	0	Reserved. Write to zero for future compatibility.	
CORE_STOP_REQ5 21	0	**Core 5 Stop Request** Reflects whether a core stop was requested.	0 Core 5 stop not requested. 1 Core 5 stop requested.
CORE_STOP_REQ4 20	0	**Core 4 Stop Request** Reflects whether a core stop was requested.	0 Core 4 stop not requested. 1 Core 4 stop requested.

Table 8-14. GSR2 Bit Descriptions (Continued)

Name	Reset	Description	Settings
CORE_STOP_REQ3 19	0	**Core 3 Stop Request** Reflects whether a core stop was requested.	0 Core 3 stop not requested. 1 Core 3 stop requested.
CORE_STOP_REQ2 18	0	**Core 2 Stop Request** Reflects whether a core stop was requested.	0 Core 2 stop not requested. 1 Core 2 stop requested.
CORE_STOP_REQ1 17	0	**Core 1 Stop Request** Reflects whether a core stop was requested.	0 Core 1 stop not requested. 1 Core 1 stop requested.
CORE_STOP_REQ0 16	0	**Core 0 Stop Request** Reflects whether a core stop was requested.	0 Core 0 stop not requested. 1 Core 0 stop requested.
— 15–9	0	Reserved. Write to zero for future compatibility.	
STOP_BS 8	0	**STOP_BS Input Status** Reflects the current status of the STOP_BS input signal.	0 STOP_BS not asserted. 1 STOP_BS asserted.
— 7–6	0	Reserved. Write to zero for future compatibility.	
SCOP_ IDLE 5	0	**SCOP Idle** Reflects the current status of the SEC block.	0 Active 1 Idle
SCOP_ STOP_ACK 2	0	**SCOP Stop Acknowledge** Indicates that the SEC block acknowledged a Stop request.	0 No stop ACK issued. 1 Stop ACK issued.
OCNDMA1_ IDLE 3	0	**OCNDMA1 Idle** Reflects the current status of the OCNDMA1 block.	0 Active 1 Idle
OCNDMA1_ STOP_ACK 2	0	**OCNDMA1 Stop Acknowledge** Indicates that the OCNDMA1 block acknowledged a Stop request.	0 No stop ACK issued. 1 Stop ACK issued.
OCNDMA0_ IDLE 1	0	**OCNDMA0 Idle** Reflects the current status of the OCNDMA0 block.	0 Active 1 Idle
OCNDMA0_ STOP_ACK 0	0	**OCNDMA0 Stop Acknowledge** Indicates that the OCNDMA0 block acknowledged a Stop request.	0 No stop ACK issued. 1 Stop ACK issued.

8.2.15 Core Subsystem Slave Port Priority Control Register (TSPPCR)

TSPPCR Core Subsystem Slave Port Priority Control Register Offset 0x3C

Bit	31	30	29	28	27	26	25	24
	—							
Type	R							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16

Type	R							
Reset	0	0	0	0	0	0	0	0

GSR3 includes the status of several events. Those bits are not sticky and only sample the events. The GSR3 is reset by a hard reset event. All bits are cleared on reset.

Table 8-16. GSR3 Bit Descriptions

Name	Reset	Description	Settings
CP_LOS6 31	0	**CPRI6 LOS Reported** Indicates whether the smallform-factor pluggable (SFP) optical transceiver connected to CPRI6 indicates a loss-of-signal (LOS) status, meaning that the received optical power is below the worst-case receiver sensitivity.	0 Normal operation. 1 SFP device reported LOS.
CP_LOS5 30	0	**CPRI5 LOS Reported** Indicates whether the smallform-factor pluggable (SFP) optical transceiver connected to CPRI5 indicates a loss-of-signal (LOS) status, meaning that the received optical power is below the worst-case receiver sensitivity.	0 Normal operation. 1 SFP device reported LOS.
CP_LOS4 29	0	**CPRI4 LOS Reported** Indicates whether the smallform-factor pluggable (SFP) optical transceiver connected to CPRI4 indicates a loss-of-signal (LOS) status, meaning that the received optical power is below the worst-case receiver sensitivity.	0 Normal operation. 1 SFP device reported LOS.

Table 8-16. GSR3 Bit Descriptions (Continued)

Name	Reset	Description	Settings
CP_LOS3 28	0	**CPRI3 LOS Reported** Indicates whether the smallform-factor pluggable (SFP) optical transceiver connected to CPRI3 indicates a loss-of-signal (LOS) status, meaning that the received optical power is below the worst-case receiver sensitivity.	0 Normal operation. 1 SFP device reported LOS.
CP_LOS2 27	0	**CPRI2 LOS Reported** Indicates whether the smallform-factor pluggable (SFP) optical transceiver connected to CPRI2 indicates a loss-of-signal (LOS) status, meaning that the received optical power is below the worst-case receiver sensitivity.	0 Normal operation. 1 SFP device reported LOS.
CP_LOS1 26	0	**CPRI1 LOS Reported** Indicates whether the smallform-factor pluggable (SFP) optical transceiver connected to CPRI1 indicates a loss-of-signal (LOS) status, meaning that the received optical power is below the worst-case receiver sensitivity.	0 Normal operation. 1 SFP device reported LOS.
— 25	0	Reserved. Write to zero for future compatibility.	
PD_SRIO_1_ TO_ SD_ STATUS 24	x	**SRIO1 to SerDes Power Down Status** Reflects the status of the SRIO1 to SerDes port power. The default value depended on the value of the RCW[SP] field.	0 Power up. 1 Power down.
PD_SRIO_0_ TO_ SD_ STATUS 23	x	**SRIO0 to SerDes Power Down Status** Reflects the status of the SRIO0 to SerDes port power. The default value depended on the value of the RCW[SP] field.	0 Power up. 1 Power down.
SD2_RST_ERR 22	0	**SerDes PLL2 Reset Error** Reflects whether a SerDes PLL2 reset error occurred.	0 No error. 1 Error occurred.
SD1_RST_ERR 21	0	**SerDes PLL1 Reset Error** Reflects whether a SerDes PLL1 reset error occurred.	0 No error. 1 Error occurred.
— 21–5	0	Reserved. Write to zero for future compatibility.	
CPRI_PU 4	0	**CPRI Power Up** Reflects the status of the CPRI power (all lanes).	0 Power down. 1 Power up.
MAPLE_ETVPE_PD 3	0	**MAPLE-B ETVPE Power Down** Reflects the status of the MAPLE-B TVPE power.	0 Power up. 1 Power down.
MAPLE_CRPE_PU 2	0	**MAPLE-B CRPE Power Up** Reflects the status of the MAPLE-B CRPE power.	0 Power down. 1 Power up.
MAPLE_EQPE_PD 1	0	**MAPLE-B EQPE Power Down** Reflects the status of the MAPLE-B CRPE power.	0 Power up. 1 Power down.
ERASE_DONE 0	0	**Erase Done** Reflects the status of the erase operation.	0 Erase not done. 1 Erase done.

8.2.17 General Control Register 6 (GCR6)

GCR6 General Control Register 6 Offset 0x64

Bit	31	30	29	28	27	26	25	24
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	—					RGMII2_SEL	—	
Type	R/W							
Reset	0	0	0	0	0	0	0	0

GCR6 selects whether the RGMII2 pins support the CP_LOSx inputs or the RGMII2 signals. All bits are cleared on reset.

Table 8-17. GCR6 Bit Descriptions

Name	Reset	Description	Settings
— 31–3	0	Reserved. Write to zero for future compatibility.	
RGMII2_SEL 29–24	0	**RGMII2 Select** The six CP_LOSx signals are multiplexed with six of the RGMII2 signals as follows: • CP_LOS1/GE2_RD2 • CP_LOS2/GE2_TD2 • CP_LOS3/GE2_RD3 • CP_LOS4/GE2_GTX_CLK • CP_LOS5/GE2_RD0 • CP_LOS6/GE2_TD3 This bit selects the signal set reflected at the connecting pins. The default (0) selects the six CP_LOSx signals. If the bit is set (1), it selects the RGMII2 signals. The remaining RGMII signals have dedicated connections that are not multiplexed.	0 CP_LOSx signals selected 1 RGMII2 signals selected.
— 1–0	0	Reserved. Write to zero for future compatibility.	

8.2.18 General Control Register 7 (GCR7)

GCR7 General Control Register 7 Offset 0x68

Bit	31	30	29	28	27	26	25	24
	—		TIMER_32B_0_MUX3_SEL					
Type	R/W							
Reset	0	0	0	0	0	0	0	0

GIR1 includes the interrupt status of several events that are rare. Those bits are not sticky and only sample the events. The GIR1 is reset by a hard reset event. All bits are cleared on reset.

Table 8-22. GIR1 Bit Descriptions

Name	Reset	Description	Settings
SWT7 31	0	**Software Watchdog Timer 7** Reflects the status of the watchdog timer interrupt.	0 Interrupt not asserted 1 Interrupt asserted
SWT6 30	0	**Software Watchdog Timer 6** Reflects the status of the watchdog timer interrupt.	0 Interrupt not asserted 1 Interrupt asserted
SWT5 29	0	**Software Watchdog Timer 5** Reflects the status of the watchdog timer interrupt.	0 Interrupt not asserted 1 Interrupt asserted
SWT4 28	0	**Software Watchdog Timer 4** Reflects the status of the watchdog timer interrupt.	0 Interrupt not asserted 1 Interrupt asserted
SWT3 27	0	**Software Watchdog Timer 3** Reflects the status of the watchdog timer interrupt.	0 Interrupt not asserted 1 Interrupt asserted
SWT2 26	0	**Software Watchdog Timer 2** Reflects the status of the watchdog timer interrupt.	0 Interrupt not asserted 1 Interrupt asserted
SWT1 25	0	**Software Watchdog Timer 1** Reflects the status of the watchdog timer interrupt.	0 Interrupt not asserted 1 Interrupt asserted
SWT0 24	0	**Software Watchdog Timer 0** Reflects the status of the watchdog timer interrupt.	0 Interrupt not asserted 1 Interrupt asserted
O2M1_ERR 23	0	**O2M 1 Error** Reflects the status of the O2M1 error interrupt.	0 Interrupt not asserted 1 Interrupt asserted
O2M0_ERR 22	0	**O2M 0 Error** Reflects the status of the O2M0 error interrupt.	0 Interrupt not asserted 1 Interrupt asserted
— 21	0	Reserved. Write to zero for future compatibility.	
DMA_ERR 20	0	**DMA Error** Reflects the status of the DMA error interrupt.	0 Interrupt not asserted 1 Interrupt asserted
CE_IECC 19	0	**QUICC Engine IRAM Error** Reflects the status of the QUICC Engine IRAM ECC error interrupt.	0 Interrupt not asserted 1 Interrupt asserted
CE_DECC 18	0	**QUICC Engine DRAM Error** Reflects the status of the QUICC Engine DRAM ECC error interrupt.	0 Interrupt not asserted 1 Interrupt asserted
— 17–0	0	Reserved. Write to zero for future compatibility.	

8.2.22 General Interrupt Enable Register 1 (GIER1_x)

GIER1_0 ‘General Interrupt Enable Register 1 for Cores 0–5 Offset 0x84
GIER1_1 Offset 0x88
GIER1_2 Offset 0x8C
GIER1_3 Offset 0x90
GIER1_4 Offset 0x94
GIER1_5 Offset 0x98

Bit	31	30	29	28	27	26	25	24

GCR_DONE controls DMA external request DONE for requestor 1 and 2.

Table 8-33. GCR_DDONE Bit Descriptions

Name	Reset	Description	Settings
— 31–14	0	Reserved. Write to zero for future compatibility.	
V1 13	0	**Valid DONE1** Indicates whether the value of DONE1_CH is valid.	0 DONE1_CH is not valid. 1 DONE1_CH is valid.

Table 8-33. GCR_DDONE Bit Descriptions (Continued)

Name	Reset	Description	Settings
DONE1_CH 12–8	0	**DMA DONE1 Channel Select** Defines the unidirectional channel that drives the DONE1 signal. The signal is valid when GCR_DDONE[V1] is set.	00000 Channel 0 source. 00001 Channel 0 destination. 00010 Channel 1 source. 00011 Channel 1 destination. 00100 Channel 2 source. 00101 Channel 2 destination. 00110 Channel 3 source. 00111 Channel 3 destination. 01000 Channel 4 source. 01001 Channel 4 destination. 01010 Channel 5 source. 01011 Channel 5 destination. 01100 Channel 6 source. 01101 Channel 6 destination. 01110 Channel 7 source. 01111 Channel 7 destination. 10000 Channel 8 source. 10001 Channel 8 destination. 10010 Channel 9 source. 10011 Channel 9 destination. 10100 Channel 10 source. 10101 Channel 10 destination. 10110 Channel 11 source. 10111 Channel 11 destination. 11000 Channel 12 source. 11001 Channel 12 destination. 11010 Channel 13 source. 11011 Channel 13 destination. 11100 Channel 14 source. 11101 Channel 14 destination. 11110 Channel 15 source. 11111 Channel 15 destination.
— 7–6	0	Reserved. Write to zero for future compatibility.	

Table 8-33. GCR_DDONE Bit Descriptions (Continued)

Name	Reset	Description	Settings
V0 5	0	**Valid DONE0** Indicates whether the value of DONE0_CH is valid.	0 DONE0_CH is not valid. 1 DONE0_CH is valid.
DONE0_CH 4–0	0	**DMA DONE0 Channel Select** Defines the unidirectional channel that drives the DONE0 signal. The signal is valid when GCR_DDONE[V0] is set.	00000 Channel 0 source. 00001 Channel 0 destination. 00010 Channel 1 source. 00011 Channel 1 destination. 00100 Channel 2 source. 00101 Channel 2 destination. 00110 Channel 3 source. 00111 Channel 3 destination. 01000 Channel 4 source. 01001 Channel 4 destination. 01010 Channel 5 source. 01011 Channel 5 destination. 01100 Channel 6 source. 01101 Channel 6 destination. 01110 Channel 7 source. 01111 Channel 7 destination. 10000 Channel 8 source. 10001 Channel 8 destination. 10010 Channel 9 source. 10011 Channel 9 destination. 10100 Channel 10 source. 10101 Channel 10 destination. 10110 Channel 11 source. 10111 Channel 11 destination. 11000 Channel 12 source. 11001 Channel 12 destination. 11010 Channel 13 source. 11011 Channel 13 destination. 11100 Channel 14 source. 11101 Channel 14 destination. 11110 Channel 15 source. 11111 Channel 15 destination.

8.2.33 DDR Controller General Configuration Register (DDRC_GCR)

DDRC_GCR DDR Controller General Configuration Register Offset 0x12C

Bit	31	30	29	28	27	26	25	24
	—						MBUS_PLUS_REF_RWB	MBUS_PLUS_REF_SRC_ID
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	MBUS_PLUS_REF_SRC_ID				MBUS_PLUS_LATE_ARB_CTL	MBUS_PLUS_INIT1_WTD_ARB_CTL		
Type	R/W							
Reset	0	0	0	0	1	1	1	1

Bit	15	14	13	12	11	10	9	8
	MBUS_PLUS_INIT1_WTD_ARB_CTL				MBUS_PLUS_INIT0_WTD_ARB_CTL			
Type	R/W							
Reset	1	1	1	1	1	1	1	1

Bit	7	6	5	4	3	2	1	0
	MBUS_PLUS_INIT0_WTD_ARB_CTL			MBUS_PLUS	—	DDRC_STOP	DDRC_DOZE	DDRC_PWR_DOWN
Type	R/W							
Reset	1	1	1	1	0	0	0	0

DDRC_GCR controls part of the DDR controller operation. All bits are cleared on a hard reset event.

Table 8-34. DDRC_GCR Bit Descriptions

Name	Reset	Description	Settings
— 31–26	0	Reserved. Write to zero for future compatibility.	
MBUS_PLUS_REF_RWB 25	0	**MBus Plus Read Write Bit** Used to enter a read/write bit for profiling.	
MBUS_PLUS_REF_SRC_ID 24–20	00000	**MBus Plus Source ID** Used to identify the source ID for profiling.	
MBUS_PLUS_LATE_ARB_CTL 19	1	**MBus Plus Late Arbitration Control** Enables/disables late arbitration.	0 Do not enable late arbitration. 1 Enable late arbitration.

Table 8-34. DDRC_GCR Bit Descriptions (Continued)

Name	Reset	Description	Settings
MBUS_PLUS_INIT1_WTD_ARB_CTL 18–12	1111111	**MBus Plus Initialor 1 Weighted Arbitration Control** Selects the weighted value for initiator 1.	
MBUS_PLUS_INIT0_WTD_ARB_CTL 11–5	1111111	**MBus Plus Initialor 0 Weighted Arbitration Control** Selects the weighted value for initiator 0.	
MBUS_PLUS 4	1	**MBus Plus** Used to select MBus plus mode.	0 MBus Plus not selected. 1 MBus Plus selected.
— 3	0	Reserved. Write to zero for future compatibility.	
DDRC_STOP 2	0	**DDRC Stop** With the DDRC Stop ACK, actively stops the controller and DDR memory clock. If the memory is not put in self-refresh mode prior to activating Stop mode, data is lost.	0 DDRC Stop not requested. 1 DDRC Stop requested.
DDRC_DOZE 1	0	**DDRC Doze** Used to select Doze mode, in which all register accesses are acknowledged, but writes are not written and reads do not contain valid data. Setting this bit prevents lockup of the device internal bus while the DDR controller is stopped. **Note:** To conserve power, when DDR is not used by an application, set this bit as soon as possible after reset. This step should be included as part of the initialization code.	0 Normal operation. 1 Doze mode.
DDRC_POWER_DOWN 0	0	**DDRC Power Down** When set, powers down all DDR areas with gated clocks.	0 DDRC power up. 1 DDRC power down.

8.2.34 Core Subsystem Slave Port General Configuration Register (CORE_SLV_GCR)

CORE_SLV_GCR Core Subsystem Slave Port General Configuration Register Offset 0x138

Reset	0	0	0	0	0	0	0	0

CORE_SLV_GCR controls the status of the slave ports for the core subsystems.

Table 8-35. CORE_SLV_GCR Bit Descriptions

Name	Reset	Description	Settings
— 31–6	0	Reserved. Write to zero for future compatibility.	
CORE_SLV_WIN_CLOSE5 5	0	**Peripheral Access to Core 5 L2/M2 Disable** Set the bit to 1 to disable accesses by the device peripherals (that is, DMAC, QUICC Engine module, and so on) to M2/L2 in core 5.	0 Enable peripheral access to Core 5 M2/L2 memory. 1 Disable peripheral access to Core 5 M2/L2 memory.
CORE_SLV_WIN_CLOSE4 4	0	**Peripheral Access to Core 4 L2/M2 Disable** Set the bit to 1 to disable accesses by the device peripherals (that is, DMAC, QUICC Engine module, and so on) to M2/L2 in core 4.	0 Enable peripheral access to Core 4 M2/L2 memory. 1 Disable peripheral access to Core 4 M2/L2 memory.
CORE_SLV_WIN_CLOSE3 3	0	**Peripheral Access to Core 3 L2/M2 Disable** Set the bit to 1 to disable accesses by the device peripherals (that is, DMAC, QUICC Engine module, and so on) to M2/L2 in core 3.	0 Enable peripheral access to Core 3 M2/L2 memory. 1 Disable peripheral access to Core 3 M2/L2 memory.
CORE_SLV_WIN_CLOSE2 2	0	**Peripheral Access to Core 2 L2/M2 Disable** Set the bit to 1 to disable accesses by the device peripherals (that is, DMAC, QUICC Engine module, and so on) to M2/L2 in core 2.	0 Enable peripheral access to Core 2 M2/L2 memory. 1 Disable peripheral access to Core 2 M2/L2 memory.

Table 8-35. CORE_SLV_GCR Bit Descriptions (Continued)

Name	Reset	Description	Settings
CORE_SLV_WIN_CLOSE1 1	0	**Peripheral Access to Core 1 L2/M2 Disable** Set the bit to 1 to disable accesses by the device peripherals (that is, DMAC, QUICC Engine module, and so on) to M2/L2 in core 1.	0 Enable peripheral access to Core 15 M2/L2 memory. 1 Disable peripheral access to Core 1 M2/L2 memory.
CORE_SLV_WIN_CLOSE0 0	0	**Peripheral Access to Core 0 L2/M2 Disable** Set the bit to 1 to disable accesses by the device peripherals (that is, DMAC, QUICC Engine module, and so on) to M2/L2 in core 0.	0 Enable peripheral access to Core 0 M2/L2 memory. 1 Disable peripheral access to Core 0 M2/L2 memory.

8.2.35 QUICC Engine Input General Control Register (QE_PIO_IN_GCR)

QE_PIO_IN_GCR QUICC Engine Input General Control Register Offset 0x13C

Bit	31	30	29	28	27	26	25	24
	QE_PIO_IN							
Type	R/W							
Reset	0	0	0	0	0	0	0	0
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	QE_PIO_IN							
Type	R/W							
Reset	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	QE_PIO_IN							
Type	R/W							
Reset	0	0	0	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

QE_PIO_IN_GCR controls the QUICC Engine input bus. It allows a master to write to registers available to the QUICC Engine RISC engines. All bits are cleared on reset.

Table 8-36. QE_PIO_IN_GCR Bit Descriptions

Name	Reset	Description	Settings
QE_PIO_IN 31–8	0	**QUICC Engine Input** Allows a master to write to registers available to the QUICC Engine RISC engines.	
— 7–0	0	Reserved. Write to zero for future compatibility.	

8.2.36 QUICC Engine Output General Status Register (QE_PIO_OUT_GSR)

QE_PIO_OUT_GSR QUICC Engine Output General Status Register Offset 0x140

Bit	31	30	29	28	27	26	25	24
	QE_PIO_OUT							
Type	R							
Reset	0	0	0	0	0	0	0	0
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	QE_PIO_OUT							
Type	R							
Reset	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	QE_PIO_OUT							
Type	R							
Reset	0	0	0	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—							
Type	R							
Reset	0	0	0	0	0	0	0	0

QE_PIO_OUT_GSR receives values from the QUICC Engine subsystem output bus. All bits are cleared on reset.

Table 8-37. QE_PIO_OUT_GSR Bit Descriptions

Name	Reset	Description	Settings
QE_PIO_OUT 31–8	0	**QUICC Engine Output** Allows a master to read from registers available to the QUICC Engine RISC engines.	
— 7–0	0	Reserved. Write to zero for future compatibility.	

8.2.37 L2Q Arbitration Control for Core Subsystems 0 and 1 (MEX_T2_0_1_ARB)

MEX_T2_0_1_ARB L2Q Arbitration Control for Core Subsystems 0 and 1 Offset 0x150

Bit	31	30	29	28	27	26	25	24
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	—							T_0_1_UPGRADE_EN
Type	R/W							
Reset	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	T_0_1_UPGRADE_VALUE

	T_2_3_UPGRADE_VALUE							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

MEX_T2_2_3_ARB enables and sets the priority auto-upgrade value for Core Subsystems 2 and 3. All bits are cleared on reset.

Table 8-39. MEX_T2_2_3_ARB Bit Descriptions

Name	Reset	Description	Settings
— 31–17	0	Reserved. Write to zero for future compatibility.	
T_2_3_ UPGRADE_EN 16	0	**L2Q Arbitration Control Enable** Controls whether priority auto-upgrade is enabled.	0 Disabled 1 Enabled
T_2_3_ UPGRADE_ VALUE 15–0	0	**L2Q Arbitration Value** Determines the value to use for priority auto upgrade when enabled.	

8.2.39 L2Q Arbitration Control for Core Subsystems 4 and 5 (MEX_T2_4_5_ARB)

MEX_T2_4_5_ARB L2Q Arbitration Control for Core Subsystems 4 and 5 Offset 0x158

Bit	31	30	29	28	27	26	25	24
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0
Bit	**23**	**22**	**21**	**20**	**19**	**18**	**17**	**16**
	—							T_4_5_ UPGRADE_EN
Type	R/W							
Reset	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**
	T_4_5_UPGRADE_VALUE							
Type	R/W							
Reset	0	0	0	0	0	0	0	0
Bit	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	T_4_5_UPGRADE_VALUE							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

MEX_T2_4_5_ARB enables and sets the priority auto-upgrade value for Core Subsystems 4 and 5. All bits are cleared on reset.

Table 8-40. MEX_T2_4_5_ARB Bit Descriptions

Name	Reset	Description	Settings
— 31–17	0	Reserved. Write to zero for future compatibility.	
T_4_5_ UPGRADE_EN 16	0	**L2Q Arbitration Control Enable** Controls whether priority auto-upgrade is enabled.	0 Disabled 1 Enabled
T_4_5_ UPGRADE_ VALUE 15–0	0	**L2Q Arbitration Value** Determines the value to use for priority auto upgrade when enabled.	

8.2.40 General Interrupt Register 6 (GIR6)

GIR6 General Interrupt Register 6 Offset 0x170

L2MAP_0_3 controls the windows used by the L2 cache for each of the core subsystems 0–3. The window seen for a specific core subsystem is defined by the following formula:.

$$\text{Core Subsystem Window n} = 40000000 + (\text{L2MAP\_n} \times 32\ \text{MB}) - (41\text{FFFFFF} + (\text{L2MAP\_n} \times 32\ \text{MB}))$$

n is valid for 0 to 15, n is reserved for 16 to 63.

All bits are cleared on reset.

Table 8-45. L2MAP_0_3 Bit Descriptions

Name	Reset	Description
— 31–30	0	Reserved. Write to zero for future compatibility.
L2MAP_3 29–24	0	**L2 Map for Core Subsystem 3** Defines the core subsystem window seen by the DDR memory through the L2 cache.
— 23–22	0	Reserved. Write to zero for future compatibility.
L2MAP_2 21–16	0	**L2 Map for Core Subsystem 2** Defines the core subsystem window seen by the DDR memory through the L2 cache.
— 15–14	0	Reserved. Write to zero for future compatibility.
L2MAP_1 13–8	0	**L2 Map for Core Subsystem 1** Defines the core subsystem window seen by the DDR memory through the L2 cache.
— 7–6	0	Reserved. Write to zero for future compatibility.
L2MAP_0 5–0	0	**L2 Map for Core Subsystem 0** Defines the core subsystem window seen by the DDR memory through the L2 cache.

8.2.45 DDR View Through L2 Memory Core Subsystems 4–5 (L2MAP_4_5)

UCC1_DELAY_HR allows fine-tuning of the clock and data signal delays for RGMII1. These adjustments are added to the values supplied in GCR4. All bits are cleared on reset.

Table 8-48. UCC1_DELAY_HR Bit Descriptions

Name	Reset	Description	Settings
— 31–20	0	Reserved. Write to zero for future compatibility.	
UCC1RCLK1_BYPASSSHRT_2 19	0	**UCC1 RX Clock In Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the RGMII1 RX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1RCLK1_BYPASSSHRT_1 18	0	**UCC1 RX Clock In Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the RGMII1 RX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1RCLK1_BYPASSMED_2 17	0	**UCC1 RX Clock In Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the RGMII1 RX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1RCLK1_BYPASSMED_1 16	0	**UCC1 RX Clock In Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the RGMII1 RX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1TCLK1_BYPASSSHRT_2 15	0	**UCC1 TX Clock In Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the RGMII1 TX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.

Table 8-48. UCC1_DELAY_HR Bit Descriptions (Continued)

Name	Reset	Description	Settings
UCC1TCLK1_ BYPASSSHRT_1 14	0	**UCC1 TX Clock In Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the RGMII1 TX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1TCLK1_ BYPASSMED_2 13	0	**UCC1 TX Clock In Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the RGMII1 TX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1TCLK1_ BYPASSMED_1 12	0	**UCC1 TX Clock In Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the RGMII1 TX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1CLKOD_ BYPASSSHRT_2 11	0	**UCC1 Clock Out Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the RGMII1 clock-out delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1CLKOD_ BYPASSSHRT_1 10	0	**UCC1 Clock Out Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the RGMII1 clock-out delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1CLKOD_ BYPASSMED_2 9	0	**UCC1 Clock Out Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the RGMII1 clock-out delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1CLKOD_ BYPASSMED_1 8	0	**UCC1 Clock Out Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the RGMII1 clock-out delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1RXDD_ BYPASSSHRT_2 7	0	**UCC1 RX Data Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the RX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1RXDD_ BYPASSSHRT_1 6	0	**UCC1 RX Data Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the RX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1RXDD_ BYPASSMED_2 5	0	**UCC1 RX Data Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the RX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1RXDD_ BYPASSMED_1 4	0	**UCC1 RX Data Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the RX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1TXDD_ BYPASSSHRT_2 3	0	**UCC1 TX Data Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the TX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1TXDD_ BYPASSSHRT_1 2	0	**UCC1 TX Data Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the TX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1TXDD_ BYPASS250_2 1	0	**UCC1 TX Data Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the TX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC1TXDD_ BYPASSMED_1 0	0	**UCC1 TX Data Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the TX data delay.	0 Enables the tap delay. 1 Disables the tap delay.

Note: There are four high resolution tap delays that can be added for each signal line: two short delays and two medium delays. The sum of the stow short delays plus the two medium delays is equal to one long delay (see **Table 8-12** for details on how the delays are combined).

UCC3_DELAY_HR allows fine-tuning of the clock and signal delays for RGMII1. These adjustments are added to the values supplied in GCR4. All bits are cleared on reset.

Table 8-49. UCC3_DELAY_HR Bit Descriptions

Name	Reset	Description	Settings
— 31–20	0	Reserved. Write to zero for future compatibility.	
UCC3RCLK1_BYPASSSHRT_2 19	0	**UCC3 RX Clock In Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the RGMII2 RX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3RCLK1_BYPASSSHRT_1 18	0	**UCC3 RX Clock In Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the RGMII2 RX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3RCLK1_BYPASSMED_2 17	0	**UCC3 RX Clock In Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the RGMII2 RX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3RCLK1_BYPASSMED_1 16	0	**UCC3 RX Clock In Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the RGMII2 RX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3TCLK1_BYPASSSHRT_2 15	0	**UCC3 TX Clock In Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the RGMII2 TX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.

Table 8-49. UCC3_DELAY_HR Bit Descriptions (Continued)

Name	Reset	Description	Settings
UCC3TCLK1_ BYPASSSHRT_1 14	0	**UCC3 TX Clock In Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the RGMII2 TX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3TCLK1_ BYPASSMED_2 13	0	**UCC3 TX Clock In Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the RGMII2 TX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3TCLK1_ BYPASSMED_1 12	0	**UCC3 TX Clock In Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the RGMII2 TX clock-in delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3CLKOD_ BYPASSSHRT_2 11	0	**UCC3 Clock Out Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the RGMII2 clock-out delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3CLKOD_ BYPASSSHRT_1 10	0	**UCC3 Clock Out Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the RGMII2 clock-out delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3CLKOD_ BYPASSMED_2 9	0	**UCC3 Clock Out Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the RGMII2 clock-out delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3CLKOD_ BYPASSMED_1 8	0	**UCC3 Clock Out Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the RGMII2 clock-out delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3RXDD_ BYPASSSHRT_2 7	0	**UCC3 RX Data Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the RX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3RXDD_ BYPASSSHRT_1 6	0	**UCC3 RX Data Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the RX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3RXDD_ BYPASSMED_2 5	0	**UCC3 RX Data Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the RX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3RXDD_ BYPASSMED_1 4	0	**UCC3 RX Data Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the RX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3TXDD_ BYPASSSHRT_2 3	0	**UCC3 TX Data Delay—Bypass Short 2** Allows you to include/exclude a short tap delay to the TX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3TXDD_ BYPASSSHRT_1 2	0	**UCC3 TX Data Delay—Bypass Short 1** Allows you to include/exclude a short tap delay to the TX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3TXDD_ BYPASSMED_2 1	0	**UCC3 TX Data Delay—Bypass Medium 2** Allows you to include/exclude a medium tap delay to the TX data delay.	0 Enables the tap delay. 1 Disables the tap delay.
UCC3TXDD_ BYPASSMED_1 0	0	**UCC3 TX Data Delay—Bypass Medium 1** Allows you to include/exclude a medium tap delay to the TX data delay.	0 Enables the tap delay. 1 Disables the tap delay.

Note: There are four high resolution tap delays that can be added for each signal line: two short delays and two medium delays. The sum of the stow short delays plus the two medium delays is equal to one long delay (see **Table 8-12** for details on how the delays are combined).

8.2.49 General Interrupt Register 8 (GIR8)

GIR8 General Interrupt Register 8 Offset 0x1E8

Bit	31	30	29	28	27	26	25	24
	—							
Type	R							
Reset	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
	—							
Type	R							
Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8

Reset	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
	—							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
	—					CPRI3_MPL_EN	CPRI2_MPL_EN	CPRI1_MPL_EN
Type	R/W							
Reset	0	0	0	0	0	0	0	0

MAPLE_EXT_REQ_EN_1 includes interrupt enable bits for the CPRI to the MAPLE interrupt external request input. All bits are cleared on reset.

Table 8-51. MAPLE_EXT_REQ_EN_1 Bit Descriptions

Name	Reset	Description	Settings
— 31–3	0	Reserved. Write to zero for future compatibility.v	
CPRI3_MPL_ EN 2	0	**CPRI to MAPLE Interrupt 3 External Request Enable** Enables/disables the interrupt.	0 Interrupt disabled 1 Interrupt enabled
CPRI2_MPL_ EN 1	0	**CPRI to MAPLE Interrupt 2 External Request Enable** Enables/disables the interrupt.	0 Interrupt disabled 1 Interrupt enabled
CPRI1_MPL_ EN 0	0	**CPRI to MAPLE Interrupt 1 External Request Enable** Enables/disables the interrupt.	0 Interrupt disabled 1 Interrupt enabled

9 Memory Map

This section describes the memory map of MSC8157E.

The MSC8157E incorporates four address spaces:

- Shared memory (M3, DDR, QUICC Engine subsystem, boot ROM, and MAPLE-B2) address space.
- Shared SC3850 DSP core subsystem M2/L2 memories
- SC3850 DSP core subsystem internal address space, accessible only by the SC3850 core. Each SC3850 core can access its own internal address space.
- Control Configuration and Status Registers (CCSR) address space.

9.1 Shared Memory Address Space

The shared memory address space resides within addresses 0x40000000–0xFEFFFFFF. It is identical to the MSC8156 DSP family, except for the MAPLE-B2, which uses 4 MB instead of 1 MB; M3 memory which was enlarged from 1 MB to 3 MB; and the second DDR controller, which was eliminated. The memory space includes the M3 memory, DDR memory, MAPLE-B2, QUICC Engine subsystem, and the boot ROM.

Note: The CCSR address space is not part of the shared memory space because the SC3850 DSP core subsystem internal memory resides in the middle (the CCSR address space starts at address 0xFFF10000).

Table 9-1. Shared Memory Address Space

Address	Purpose	Size in Bytes
0x40000000–0xBFFFFFFF	DDR Memory (default value)	2 G
0xC0000000–0xC02FFFFF	M3 Memory	3 M
0xC0300000–0xCFFFFFFF	Reserved	253 M
0xD0000000–0xD09FFFF	Reserved (used for M3 memory in the MSC8144 DSP)	10 M
0xD0A00000–0xDFFFFFFF	Reserved	246 M
0xE0000000–0xE03FFFFF	MAPLE-B2	4 M
0xE0400000–0xFEDFFFFF	Reserved	490 M
0xFEE00000–0xFEE3FFFF	QUICC Engine Subsystem	256 K
0xFEE40000–0xFEEFFFFF	Reserved (QUICC Engine Subsystem)	768 K
0xFEF00000–0xFEF17FFF	Boot ROM	96 K

Table 9-1. Shared Memory Address Space (Continued)

Address	Purpose	Size in Bytes
0xFEF18000–0xFEFFFFFF	Reserved	928 K
0xFF000000–0xFFF0FFFF	SC3850 subsystem internal address space	15 M + 64 K

9.2 Shared SC3850 DSP Core Subsystem M2/L2 Memories

Each SC3850 core subsystem includes 512 KB of level-2 memory that can be partitioned into M2 memory and L2 cache. The minimal size of each partition is 64 KB and each core can have a unique combination of M2 and L2 memory partitions. The partition size can be changed during operation, but the user must make sure that all ongoing accesses are terminated before making the change. The default partitioning out of reset defines all of the level-2 memory as shared M2 memory. The boot program configures the MMU to support that configuration and sets the CLASS values accordingly.

When partitioned as M2 memory, the memory is available as a shared memory that can be used as private memory by the core to which it belongs and accessed by all other system masters and external hosts, but not by all other cores. Other cores can access another core *n* in accordance with the following policy:

- Core subsystem 0 can access the M2/L2 memory of core subsystems 0, 2, 3, 4, and 5.
- Core subsystem 1 can access the M2/L2 memory of core subsystems 1, 2, 3, 4, and 5.
- Core subsystem 2 can access the M2/L2 memory of core subsystems 2, 4, and 5.
- Core subsystem 3 can access the M2/L2 memory of core subsystems 3, 4, and 5.
- Core subsystem 4 can only access the M2/L2 memory of core subsystem 4 (itself).
- Core subsystem 5 can only access the M2/L2 memory of core subsystem 5 (itself).

Although the M2 memories have different physical addresses, all cores use a virtual address of 0x0 to access their own M2 memory and uses MMU translation to access the correct memory space.

When partitioned as L2 cache memory, the L2 cache can only be accessed by the core to which it belongs and by other masters in the system, but not by all other cores. Other cores can access a core *n* in accordance with the following policy:

- Core subsystem 0 can access the L2 memory of core subsystems 0, 2, 3, 4, and 5.
- Core subsystem 1 can access the L2 memory of core subsystems 1, 2, 3, 4, and 5.
- Core subsystem 2 can access the L2 memory of core subsystems 2, 4, and 5.
- Core subsystem 3 can access the L2 memory of core subsystems 3, 4, and 5.
- Core subsystem 4 can only access the L2 memory of core subsystem 4 (itself).
- Core subsystem 5 can only access the L2 memory of core subsystem 5 (itself).

The L2 accesses are translated through the core subsystem slave ports to the L2 cache, allowing DDR access for specific core cache. The size in bytes is shown in **Table 9-2** which indicates the total DDR access range.

Each core can access a 32 MB window in the DDR memory. The memory space between 0x40000000 and 0xBFFFFFFF is partitioned into 64 non-overlapping ranges of 32 MB each. The window is mapped to each core subsystem using the L2MAP_0_3 and L2MAP_4_5 general configuration registers. See **Section 8.2.44**, *DDR View Through L2 Memory Core Subsystems 0–3 (L2MAP_0_3)*, on page 8-79 and **Section 8.2.45**, *DDR View Through L2 Memory Core Subsystems 4–5 (L2MAP_4_5)*, on page 8-80 for details.

As shown at the **Table 9-2**, when an initiator other than the core accesses L2 cache, its address range is limited to 32 MB. Before hitting the cache, this address range is always mapped to the first 32 MB of DDR which uses the address range (0x40000000 + Y × 32 MB) to (0x41FFFFFF + Y × 32 MB), where Y is a 6-bit integer value configured by a register in the general configuration register space. Thus, the memory space between 0x40000000 and 0xBFFFFFFF is partitioned into 64 non-overlapping ranges, each 32 MB is size. The mapping is different for each DSP subsystems. The default setting is Y = 0 for all cores, that is, this address range is always mapped to the first 32 MB of DDR memory, which uses the address range 0x40000000–0x41FFFFFF. If L2 acts as a shared cache by the core and the additional initiators, this feature has the following benefits:

- In the DMA model in which the DMA controller transfers data to L2 cache and the core can use it, the scheduling restriction between DMA job completion and core job start is relaxed (in comparison to DMA and M2). If the core starts reading data not written by the DMA controller, a miss is generated to the DDR and data is read directly.
- If an initiator must read the same data from DDR several times to save DDR bandwidth, the data resides in L2 after the first read and is than read from L2 repeatedly without having to access the DDR memory.
- This feature can be used in conjunction with cache partitioning in which the cache can be used as two separate caches, one for the core and the other for another initiator.

Table 9-2. Shared M2/L2 Memories Address Space

Address	Purpose	Size in Bytes	Comments
0x20000000–0x23FFFFFF	Reserved	64 M	—
0x24000000–0x25FFFFFF	DDR through Core 5 L2	32 M	Seen by the L2 Cache as (40000000 + Y × 32 MB) to (41FFFFFF + Y × 32 MB). Y is the Core5 slave port 6-bit mapping from the GCR. Y = 0 to 63 and mapped to the DDR.

Table 9-2. Shared M2/L2 Memories Address Space (Continued)

Address	Purpose	Size in Bytes	Comments
0x26000000–0x27FFFFFF	DDR through Core 4 L2	32 M	Seen by the L2 Cache as (40000000 + Y × 32 MB) to (41FFFFFF + Y × 32 MB). Y is the Core4 slave port 6-bit mapping from the GCR. Y = 0 to 63 and mapped to the DDR.
0x28000000–0x29FFFFFF	DDR through Core 3 L2	32 M	Seen by the L2 Cache as (40000000 + Y × 32 MB) to (41FFFFFF + Y × 32 MB). Y is the Core3 slave port 6-bit mapping from the GCR. Y = 0 to 63 and mapped to the DDR.
0x2A000000–0x2BFFFFFF	DDR through Core 2 L2	32 M	Seen by the L2 Cache as (40000000 + Y × 32 MB) to (41FFFFFF + Y × 32 MB). Y is the Core2 slave port 6-bit mapping from the GCR. Y = 0 to 63 and mapped to the DDR.
0x2C000000–0x2DFFFFFF	DDR through Core 1 L2	32 M	Seen by the L2 Cache as (40000000 + Y × 32 MB) to (41FFFFFF + Y × 32 MB). Y is the Core1 slave port 6-bit mapping from the GCR. Y = 0 to 63 and mapped to the DDR.
0x2E000000–0x2FFFFFFF	DDR through Core 0 L2	32 M	Seen by the L2 Cache as (40000000 + Y × 32 MB) to (41FFFFFF + Y × 32 MB). Y is the Core0 slave port 6-bit mapping from the GCR. Y = 0 to 63 and mapped to the DDR.
0x30000000–0x3007FFFF	Core0 M2 memory	512 K max.	Not all of the 512 KB are always allocated as M2. The allocation and illegal access detection are controlled by the core subsystem.
0x30080000–0x30FFFFFF	Reserved	16 M – 512 K	
0x31000000–0x3107FFFF	Core 1 M2 memory	512 K max.	Not all of the 512 KB are always allocated as M2. The allocation and illegal access detection are controlled by the core subsystem.
0x31080000–0x31FFFFFF	Reserved	16 M – 512 K	
0x32000000–0x3207FFFF	Core 2 M2 memory	512 K max.	Not all of the 512 KB are always allocated as M2. The allocation and illegal access detection are controlled by the core subsystem.
0x32080000–0x32FFFFFF	Reserved	16 M – 512 K	
0x33000000–0x3307FFFF	Core 3 M2 memory	512 K max.	Not all of the 512 KB are always allocated as M2. The allocation and illegal access detection are controlled by the core subsystem.
0x33080000–0x33FFFFFF	Reserved	16 M – 512 K	
0x34000000–0x3407FFFF	Core 4 M2 memory	512 K max.	Not all of the 512 KB are always allocated as M2. The allocation and illegal access detection are controlled by the core subsystem.

Table 9-2. Shared M2/L2 Memories Address Space (Continued)

Address	Purpose	Size in Bytes	Comments
0x34080000–0x34FFFFFF	Reserved	16 M – 512 K	
0x35000000–0x3507FFFF	Core 5 M2 memory	512 K max.	Not all of the 512 KB are always allocated as M2. The allocation and illegal access detection are controlled by the core subsystem.
0x35080000–0x37FFFFFF	Reserved	48 M – 512 K	
Note: Each of the M2 memory areas is configurable in size in 64 KB increments starting from the lowest 64 KB address block up to the maximum 512 KB. Any blocks not allocated as M2 memory are reserved.			

9.3 SC3850 DSP Core Subsystem Internal Address Space

Each SC3850 core can access the internal address space of its DSP core subsystem. The SC3850 internal address space is located from address 0xFF000000–0xFFF0FFFF (15 MB + 64 KB). **Table 9-3** lists details for the DSP core subsystem internal address space.

Table 9-3. SC3850 DSP Core Subsystem Internal Address Space

Address	Purpose	Size (Bytes)	Remarks
0xFF000000–0xFFEFFDFF	Reserved	15 M – 512	
0xFFEFFE00–0xFFEFFFFF	OCE	512	User/Supervisor
0xFFF00000[2]–0xFFF003FF	Reserved	1K	
0xFFF00400–0xFFF007FF	EPIC	1K	Supervisor
0xFFF00800–0xFFF00BFF	Data Cache registers	1K	Supervisor
0xFFF00C00–0xFFF00FFF	Instruction Cache registers	1K	Supervisor
0xFFF01000–0xFFF05FFF	Reserved	20 K	
0xFFF06000–0xFFF09FFF	MMU	16 K	Supervisor
0xFFF0A000–0xFFF0A2FF	DPU	768	User/Supervisor
0xFFF0A300–0xFFF0A3FF	TIMERS	256	User/Supervisor
0xFFF0A400–0xFFF0EFFF	Reserved	19 K	
0xFFF0F0000–0xFFF0F3FF	L2 cache controller	1 K	Supervisor
0xFFF0F400–0xFFF0FFFF	Reserved	3 K	
Note: Access in both User and Supervisor modes is allowed only if enabled via the EMR[EMEA] bit in the core.			

Note: See the *SC3850 DSP Subsystem Reference Manual* for details.

9.4 CCSR Address Space

The MSC8157E CCSR is mapped within a contiguous block of memory starting as 0xFFF10000. The size of the CCSR in MSC8157E is 956 KB. **Table 9-4** details the CCSR address space.

Table 9-4. CCSR Address Space

Address	Purpose	Size (Bytes)
0xFFF10000–0xFFF103FF	DMA	1 K
0xFFF10400–0xFFF17FFF	Reserved	31 K
0xFFF18000–0xFFF18FFF	CLASS0	4 K
0xFFF19000–0xFFF1BFFF	Reserved	12 K

Table 9-4. CCSR Address Space (Continued)

Address	Purpose	Size (Bytes)

0xFFFA8000–0xFFFA8FFF	Dedicated DMA Controller 0	4 K
0xFFFA9000–0xFFFA9FFF	DMA Controller 0 to OCN	4 K
0xFFFAA000–0xFFFAAFFF	Dedicated DMA Controller 1	4 K
0xFFFAB000–0xFFFABFFF	DMA Controller 1 to OCN	4 K
0xFFFAC000–0xFFFACFFF	Reserved	4 K
0xFFFAD000–0xFFFAD7FF	SerDes PHY 1	2 K
0xFFFAD800–0xFFFB6FFF	Reserved	38 K
0xFFFB7000–0xFFFB7FFF	PCI Express	4 K

Table 9-4. CCSR Address Space (Continued)

Address	Purpose	Size (Bytes)
0xFFFB8000–0xFFFB9FFF	Reserved	8 K
0xFFFBA000–0xFFFBAFFF	CLASS1	4K
0xFFFBB000–0xFFFBB7FF	Reserved	2 K
0xFFFBB800–0xFFFBB8FF	Performance Monitor Registers	256
0xFFFBB900–0xFFFCFFFF	Reserved	82 K – 256
0xFFFD0000–0xFFFDFFFF	Security Engine (SEC)	64 K
0xFFFE0000–0xFFFFEFFF	Reserved	124 K

9.5 Initiators Views of the System Address Space

Addressing within the system address space depends on the device addressing the system memory space. The following sections define how the cores and system peripherals address this space.

9.5.1 SC3850 (Data) View of the System Address Space

Table 9-5 describes the system address space as seen by each SC3850 core subsystem.

Table 9-5. SC3850 (Data) View of the System Address Space

Address		Purpose	Size (Bytes)	Comment
0x00000000–0x1FFFFFFF		Reserved	768 M	
The allocation of the shared core subsystem L2 space (core subsystem 0–3) is as follows:				
0x20000000–0x2BFFFFFF		Shared L2 space for Cores 0 and 1		Only L2 spaces are available. Others are reserved.
0x20000000–0x27FFFFFF		Shared L2 space for Cores 2 and 3		
The reserved L2 space (core subsystem 0–5) is as follows:				
0x2C000000–0x2FFFFFFF		Reserved for Core 0		End address is computed as 0x30000000 + (core index × 0x1000000) – 1
0x2C000000–0x30FFFFFF		Reserved for Core 1		
0x28000000–0x31FFFFFF		Reserved for Core 2		
0x28000000–0x32FFFFFF		Reserved for Core 3		
0x20000000–0x33FFFFFF		Reserved for Core 4		
0x20000000–0x34FFFFFF		Reserved for Core 5		
The allocation of the private M2 memory space f is core subsystem dependent as follows:				
Core 0	0x30000000–0x30FFFFFF	Private M2 memory (maximum)	512 K maximum	Not all of the 512 KB is always allocated. Allocation and illegal access detection are done by the core subsystem.
Core 1	0x31000000–0x31FFFFFF	Private M2 memory (maximum)	512 K maximum	
Core 2	0x32000000–0x32FFFFFF	Private M2 memory (maximum)	512 K maximum	
Core 3	0x33000000–0x33FFFFFF	Private M2 memory (maximum)	512 K maximum	
Core 4	0x34000000–0x34FFFFFF	Private M2 memory (maximum)	512 K maximum	
Core 5	0x35000000–0x35FFFFFF	Private M2 memory (maximum)	512 K maximum	
The reserved M2 space (core subsystem 0–5) is as follows:				
0x31000000–0x31FFFFFF		Reserved for Core 0		For cores 0–3, the end address is computed as 0x30000000 + ((core index + 2) × 0x1000000) – 1. For cores 4–5, the end address is fixed.
0x32000000–0x32FFFFFF		Reserved for Core 1		
0x33000000–0x33FFFFFF		Reserved for Core 2		
0x34000000–0x34FFFFFF		Reserved for Core 3		
0x35000000–0x3FFFFFFF		Reserved for Core 4		
0x36000000–0x3FFFFFFF		Reserved for Core 5		

Table 9-5. SC3850 (Data) View of the System Address Space (Continued)

Address		Purpose	Size (Bytes)	Comment
The shared M2 space (core subsystem 0–3 only) is as follows:				
Core 0	0x32000000–0x3FFFFFFF	Shared M2 space		Only M2 spaces are available. Others are reserved.
Core 1	0x32000000–0x3FFFFFFF	Shared M2 space		
Core 2	0x34000000–0x3FFFFFFF	Shared M2 space		
Core 3	0x34000000–0x3FFFFFFF	Shared M2 space		
Other memory space is as follows:				
0x40000000–0xFEFFFFFF		Shared Memory Address Space	3 G – 16 M	
0xFF000000–0xFFF0FFFF		SC3850 DSP core subsystem Internal Address Space	15 M + 64 K	
0xFFF10000–0xFFFFEFFF		CCSR Address Space	956 K	
0xFFFFF000–0xFFFFFFFF		Reserved	4 K	

9.5.2 Peripherals View of the System Address Space

Table 9-6 describes the system address space as seen by the MSC8157E peripherals (RapidIO and PCI Express controllers, JTAG, QUICC Engine subsystem, DMA, and MAPLE-B–both MBus interfaces).

Table 9-6. Peripherals View of the System Address Space

Address	Purpose	Size (Bytes)
0x00000000–0x1FFFFFFF	Reserved	512 M
0x20000000–0x3FFFFFFF	Shared L2/M2 Memory Space	512 M
0x40000000–0xFEFFFFFF	Shared Memory Address Space	3 G – 16 M
0xFF000000–0xFFF0FFFF	Reserved	15M + 64K
0xFFF10000–0xFFFFEFFF	CCSR Address Space	956 K
0xFFFFF000–0xFFFFFFFF	Reserved	4 K

An external initiator (to the MSC8157E device) can generate accesses to the system address space using the:

- Test Access Port/JTAG with direct addressing.
- The RapidIO subsystem/PCI Express controller using the RapidIO/PCI Express inbound address translation.

9.5.3 Security Engine View of the System Address Space

Table 9-7. describes the system address space as seen by the Security Engine (SEC).

Table 9-7. SEC View of the System Address Space

Address	Purpose	Size (Bytes)
0x00000000–0x1FFFFFFF	Reserved	512 M
0x20000000–0x3FFFFFFF	Shared L2/M2 memory space	512 M

Table 9-7. SEC View of the System Address Space

Address	Purpose	Size (Bytes)
0x40000000–0xFEFFFFFF	Shared memory address space	3 G – 16 M
0xFF000000–0xFFFFFFFF	Reserved	16 M

9.6 Detailed System Memory Map

Table 9-8. Detailed System Memory Map

Address	Name/Status	Acronym
0x00000000–0x3FFFFFFF	Reserved	
0x40000000–0xFEFFFFFF	Shared memory	
• 0x40000000–0xBFFFFFFF	DDR memory	
• 0xC0000000–0xD09FFFFF	M3 Memory	
• 0xD0A00000–0xDFFFFFFF	reserved	
• 0xE0000000–0xE03FFFFF	MAPLE-B2 (see **Chapter 26**, *Multi Accelerator Platform Engine, Baseband 2 (MAPLE-B2)*)	
– 0xE0000000–0xE00004FF	Parameter RAM	
– 0xE0000000–0xE0000003	reserved	
– 0xE0000004–0xE0000007	MAPLE BD Rings Configuration Parameter 0	MBDRCP0
– 0xE0000008–0xE000000B	MAPLE BD Rings Configuration Parameter 1	MBDRCP1
– 0xE000000C–0xE000000F	reserved	
– 0xE0000010–0xE0000013	MAPLE UCode Version Number	MUCVP
– 0xE0000014–0xE0000017	reserved	
– 0xE0000018–0xE000001B	MAPLE Timer Period Parameter	MP_TPP
– 0xE000001C–0xE000001F	reserved	
– 0xE0000020–0xE0000023	MAPLE Mode Configurations 0 Parameter. (programmed by API)	MMC0P
– 0xE0000024–0xE0000027	MAPLE Mode Configurations 1 Parameter. (programmed by API)	MMC1P
– 0xE0000028–0xE000002B	MAPLE eTVPE Configuration parameter (programmed by API)	MTVCP
– 0xE000002C–0xE000002F	CRPE-DL Output Mode Configuration Parameter. (programmed by API)	CDOMCP

Table 9-8. Detailed System Memory Map (Continued)

Address	Name/Status	Acronym
– 0xE0000030–0xE0000033	CRPE-ULB Mode Configuration Parameter. (programmed by API)	CUBMCP
– 0xE0000034–0xE000003F	reserved	
– 0xE0000040–0xE0000043	MAPLE CRPE Reset Completion Indication Parameter	MCRRCIP
– 0xE0000044–0xE000007F	reserved	
– 0xE0000080–0xE0000083	MAPLE eTVPE BD Ring High Priority A 0 Parameter	MTVBRHPA0P
– 0xE0000084–0xE0000087	MAPLE eTVPE BD Ring High Priority B 0 Parameter	MTVBRHPB0P

10 SC3850 DSP Subsystem

Each SC3850 core is embedded in an DSP subsystem that enhances the power of the SC3850 core and provides a simple interface to each SC3850 core. The DSP core subsystem includes:

- SC3850 core.
- Instruction channel with a 32-Kbyte instruction cache that supports advanced prefetching.
- Data channel built around a 32-Kbyte data cache, which supports advanced prefetching.
- Memory management unit (MMU) for task protection and address translation.
- Unified 512-Kbyte L2 cache with partitioning support for multitasking reconfigurable in 64-Kbyte partitions as M2 memory.
- Write queue that interfaces between the core and the data channel
- Dual timer for internal use (such as RTOS).
- Extended programmable interrupt controller (EPIC) supporting 256 interrupts.
- Real-time debug support with the OCE and a debug and profiling unit (DPU).

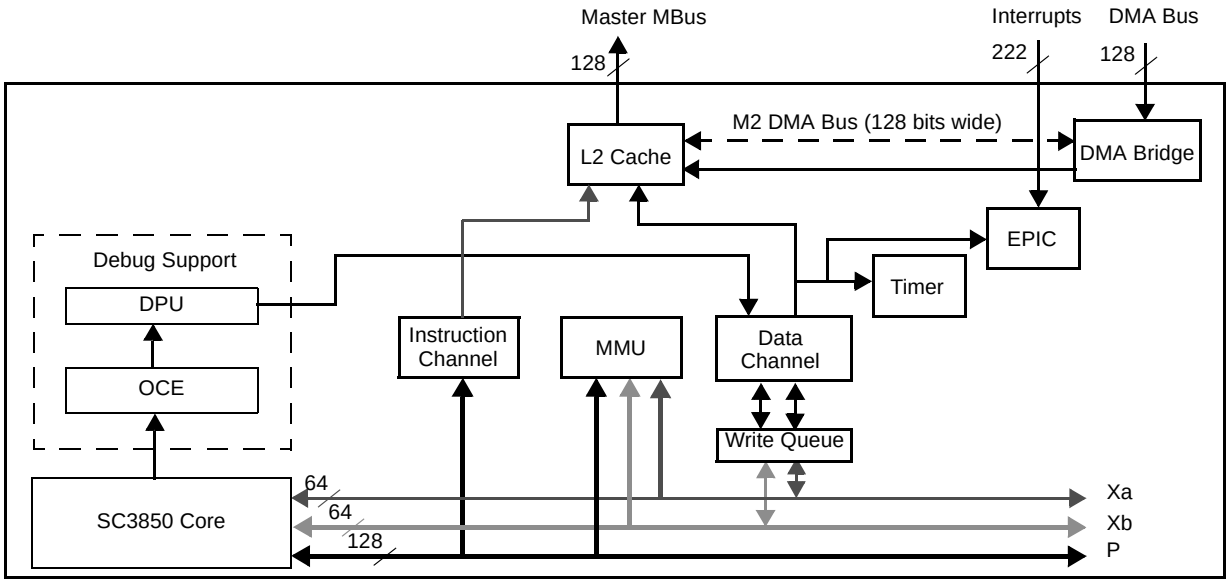

Figure 10-1. DSP Core Subsystem

Note: *The SC3850 DSP Core Reference Manual* and the *SC3850 DSP Core Subsystem Reference Manual* have detailed information on the DSP core and core subsystem. Both manuals are available with a signed non-disclosure agreement. Contact your local Freescale dealer or sales representative for more information.

The remainder of this chapter describes each of these DSP core subsystem components.

10.1 SC3850 DSP Core Subsystem Features

The subsystem has the following units and distinctive features:

- SC3850 DSP core (see **Chapter 2**, *SC3850 Core Overview* for details).
- Instruction cache (ICache):
  - 32 Kbytes
  - 8 ways with 16 lines per way
  - Multi-task support
  - Prefetch capability
  - Software coherency support (‘Sweep’)
  - PFETCH touch loading instruction support
- Data cache (DCache):
  - 32 Kbytes
  - 8 ways with 16 lines per way
  - Can serve two data accesses in parallel (XA, XB)
  - Multi-task support
  - Software coherency support (Cache ISA or “Sweep”)
  - Write-back writing policy
  - Write-through writing policy
  - Hardware line prefetch capability
  - Cache performance ISA support (DFETCH touch loading and DMALLOC)
- Memory management unit (MMU):
  - Virtual to physical address translation
  - Task protection
  - Multi-tasking
  - Defines the memory and access attributes of memory regions
- Unified L2 cache:
  - 512 KB
  - 8 ways with 1024 indices
  - 64-byte line size
  - Physically addressed
  - Maximum user flexibility for real-time support through address partitioning of the cache

  - Rich cache policy support
  - Multi channel, two dimensional software prefetch support
  - Software coherency support with seamless transition from L1 cache coherency operation.
  - External memory Interface:
    - MBus unified address separate data bus, with 32-bit address and 128-bit data
    - Supports asynchronous clock ratio
- Debug and profiling:
  - On-chip emulator (OCE) for core-related debug and profiling support
  - Debug and profiling unit (DPU) for subsystem level debug and profiling support
  - Debug state, single stepping and command insertion from the host debugger
  - Breakpoints on PC, data address, and data bus values
  - More than 40 event counting options in 6 parallel counters
  - Cache debug mode enabling to observe the cache state (cache array, tags, valid and dirty bits, and so on) and to change the contents of the data cache array.
  - Real-time tracing of PC, task ID, and profiling information to the main memory
- Interrupt handling:
  - Extended programmable interrupt controller (EPIC) to handle 256 interrupts, including from internal sources
  - Supports 222 interrupts external to the SC3850 DSP subsystem, independently configured as maskable or non-maskable
  - 32 priority levels for interrupts
  - Asynchronous and synchronous interrupts.
- Timer. Two general-purpose 32-bit timers for RTOS support
- Low-power design modes of operation:
  - Wait processing state, where the clocks of the core and caches are gated but peripherals operate.
  - Stop processing state for full clock gating

10.2 SC3850 Core

The SC3850 core is an improved superset of the SC3400 architecture that is binary compatible with the previous StarCore architectures, including the SC140/SC140e and SC3400. The SC3850 core is organized the same way as the StarCore architectures. See **Chapter 2**, *SC3850 Core Overview* and the *SC3850 DSP Core Reference Manual* for details on the SC3850 core.

10.3 Instruction Channel

The instruction channel, which comprises the instruction cache (ICache) and the instruction fetch unit (IFU), provides the core with instructions that are stored in higher-level memory. The ICache operates at core speed and stores recently accessed instructions. Whenever an addressed instruction (from the cacheable memory area) is found in the array, it is immediately made available to the core (ICache hit). When the required address is not found in the array, it is loaded to the ICache from the external (off-subsystem) memory by the IFU (ICache miss). The IFU operates in parallel with the core to implement a HW line prefetching algorithm that loads the ICache with information that has a high probability of being needed soon. This action reduces the number of cache misses. When an instruction is addressed from a non-cacheable area, the IFU fetches it directly to the XP bus of the core without writing it to the cache.

10.3.1 Instruction Cache

The ICache has the following parameters:

- A size of 32 Kbytes with 256 bytes per cache line (total of 128 lines in the cache) arranged in an 8 way set-associative structure.
- A cache line logically divided into 16 valid bit resolutions (VBRs), each 16 bytes long. This is the resolution for hit or miss detection.

Upon a cache miss, the ICache fetches the required information. A pseudo-LRU replacement algorithm is used to select the line to be replaced when required. The flexible ICache has a locking mechanism that can lock some ways, thus partitioning the cache between tasks. The programmer can flush the full contents of the ICache (meaning, invalidate all tags and VBRs) or selectively flush its contents between programmable address boundaries.

The cache fetches a core instruction for touch loading (PFETCH) by queuing it and initiating it when there is a free slot on the program bus. Using this touch loaded instruction can dramatically reduce the average cache miss penalty. In addition, a programmable HW next line prefetch is used to further reduce the miss ratio for code that is sequential in nature.

The ICache supports real-time and non-real-time debugging and profiling. In real time, it provides information on misses and hits. In non-real-time, it supports access to all its internal information, namely, the tag, the replacement status, and the valid arrays. The cache array itself can be either read or written. This information is accessed through the JTAG interface in Debug processing state.

10.3.2 Instruction Fetch Unit

The IFU controls the fetching of instructions from cacheable external memory when a miss indication is received from the ICache. It controls information updates in the ICache. The programmer can control the IFU HW line prefetching to adjust it for better performance for an application. For a request from a non-cacheable area, the information from the external memory is made available directly to the core through the XP bus. To minimize the idle time of the core, the IFU implements critical word first external access and also supports prefetch hit.

10.4 Data Channel

The data channel comprises the data cache (DCache), the data fetch unit (DFU), the data control unit (DCU), the write-back buffer (WBB), and the write-through buffer (WTB). This two-way channel reads and writes information from the core to/from higher-level memory (M2 or L2) and control memory (internal blocks and external peripherals) spaces.

The DCache, which operates at core speed, keeps the recently accessed data. When addressed data (from a cacheable memory area) is found in the array, it is immediately made available to the core (DCache hit) in a read and updated if written to. When the required address is not found in the array, a DCache miss occurs, and the DFU loads the data to the DCache from the external (off-subsystem) memory and drives it to the core. The DFU operates in parallel with the core and implements a HW line prefetch algorithm that loads the DCache with information that has a high probability of being needed soon, thus reducing the number of data cache misses.

The channel differentiates between cacheable and non-cacheable addresses. For cacheable addresses, it supports the write-back allocate and write-through writing policies. The selection is made on an address segment basis, as programmed in the MMU. The data channel supports the arrangement of data in big-endian formats. Core data types can be byte, word, long (4 bytes), or 2 long (8 bytes) wide.

10.4.1 Data Cache

The DCache has the following parameters:

- A size of 32 Kbytes with 256 bytes per cache line (total of 128 lines in the cache) arranged in an 8 way set-associative structure.
- A cache line logically divided into 16 VBRs, each 16 bytes long. This is the resolution for hit or miss detection. Big-endian byte arrangements are supported.

A data access that is identified as a hit in the DCache is served without freezing the core, with the exception of DCache contention (dual access from two core buses to the same module). If the requested data is not in the cache, the DFU fetches it. If the requested data belongs to a cache line that is not in the cache, the line is allocated at the expense of another line. A pseudo-LRU (PLRU) replacement algorithm selects the line to be replaced. If the line to be replaced contains

valid and dirty VBRs, it must be written (thrashed) to the external memory. The DCache implements the write-back and write-through writing policies. To speed up the freeing of the cache line, a write is directed to the write-back buffer and later copied from there to the external memory.

A great deal of control flexibility is offered by the sweep command, by which information in the DCache is managed according to its virtual address. The programmer defines a virtual address range and a specific operation to be carried out on cache lines within that range. The operation can involve line invalidation, line synchronization, or line flush. The operation can execute in parallel with core operation. The core can be interrupted at the end of the operation. In addition to sweep, the cache supports SC3850 coherency instructions Flush memory block (DFLUSH) that writes back and invalidates a block of 64 bytes belonging to the specified address and Synchronize memory block (DSYNC) that writes back a block of 64 bytes belonging to the specified address back to memory.

The cache supports touch loading data fetch core instructions (DFETCH) by queuing them and initiating them when there is a free slot on the data bus. Using this instruction can dramatically reduce the average cache miss penalty.

The cache also supports the data memory allocation instruction (DMALLOC), which causes the cache to allocate a line matching the designated address and validating a 64 byte resolution (wrapped on 64-byte boundary) with almost zero overhead without actually fetching the data from memory.

The DCache supports real-time and non-real-time debugging and profiling. In real time, it provides information on misses, hits, and other cache-related events. In non-real time (debug processing state), it enables access to all of its internal information, such as the tag, the PLRU, the valid arrays, and the DCache array. The cache array can be written to as well. This information is accessed through the JTAG interface in debug processing state.

10.4.2 Data Fetch Unit

The DFU controls data fetches from cacheable external memory when it receives a miss indication from the DCache. The unit controls information updates in the DCache. The programmer can control its HW line prefetch to adjust for better performance for an application. For a request from a non-cacheable area, the information from the external memory is made available directly to the core through the requesting bus, WA or WB without updating the cache. The programmer can control the burst size, as well as turn the HW line prefetch mechanism on or off. To minimize the time that the core stalls, the DFU implements critical word first external access and also supports prefetch hit.

10.4.3 Write-Back Buffer

The WBB expedites freeing of the DCache to enable fetching of new data with minimal core delay. Modified data from the DCache array is transferred to the WBB, thus freeing the array for additional data fetch from a higher-level memory. This effectively splits the thrashing process into two separate operations. During the first operation, the data to be thrashed is stored in the WBB until after the fetch operation completes. The second operation writes the data to be thrashed out to the higher-level memory.

The WBB has the size of 16 VBRs arranged as 8 entries of 2 VBRs each. It operates as a FIFO buffer. It sends data to the external memory using the QBus protocol through the DCU. It provides the DCU with priority information, either normal or high. Normal priority is used for standard DCache line replacement. High priority is used for the DCache flushing operation.

The WBB also snoops the external core accesses (the physical addresses that are translated from the virtual addresses by the MMU) to detect a hazard situation in which a request is made for a line in the WBB before it gets to the higher-level memory. When such a situation occurs, the WBB is flushed as a high priority request for updating the higher-level memory before fetching from the memory continues. This ensures data coherency.

10.4.4 Write-Through Buffer

The WTB provides a short route for writing data to the data QBus memory space, meaning to external (off-subsystem) memory through the MBus and to internal subsystem registers and external peripherals. The WTB block generates write accesses from the write queue output buses to the devices connected to the data QBus when the application requires a non-cacheable or write-through write access. The WTB also serves write accesses when the cache is disabled, in debug, or missed when in lock. The WTB is arranged as six 64-bit entries. It operates as a FIFO buffer to buffer the latency of the write accesses passing through it from the DSP core.

10.4.5 Data Control Unit

The DCU prioritizes and arbitrates between the various write transactions (from the WBB, the WTB, and the trace writes from the TWB) and the read transactions of the DFU. The DCU transfers the transactions to the data QBus after mastership on the bus is obtained or directly when it accesses the internal subsystem memory-mapped registers.

10.4.6 Write Queue

The write queue (WRQ) interfaces between the SC3850 core and the data channel. The WRQ stores up to 14 write accesses from both the XA and the XB buses and has the following primary functions:

- Bridge the core pipeline gap between the address generation and the data drive.
- Enable read accesses to bypass write accesses (unless there is a read after write hazard).
- Store write accesses (already with data) until they have an available memory slot, thus freeing the core to execute instructions.
- Identify a read-after-write hazard and forward newer write data of pending accessed to replace the older data bytes were read from memory.
- Handles core DCache instructions like DFETCH, DSYNC, DMALLOC, and others.
- Buffer DFETCH and write-back misses that the system currently can not handle without stalling the core until the WRQ is full.

10.5 Memory Management Unit (MMU)

The MMU performs three main functions:

- Memory hardware protection for instruction and data access with two privilege levels (user and supervisor).
- High-speed address translation from virtual to physical address to support memory relocation.
- Cache and bus controls for advanced memory management

Memory protection increases the reliability of the system so that errant tasks cannot ruin the privileged state and the state of other tasks. Program and data accesses from the core can occur at either the user or supervisor level. The MMU checks each access to determine whether it matches the permissions defined for this task in the memory attributes and translation table (MATT). If it does not, the access is killed and a memory exception is generated.

The MMU performs address translation on external (off-subsystem) addresses, from virtual addresses (used by the software that runs on the core) to physical addresses (used by the system buses). Benefits of address translation include the following:

- Enables software to be written without consideration of the physical location of the code in memory, thereby providing a simpler software model that enhances modularity and reuse.
- Allows true dynamic code relocation without performance cost or overhead.

The same virtual addresses can be reused between tasks without a need to flush the caches between tasks because the caches store the task ID in their line tags and thus have a unique

memory image per task. Protection and address translation are applied to memory segments defined in the MMU. A segment descriptor (SD) can set cacheable/non-cacheable, prefetch policy, shared/non-shared, and more. The MMU controls up to 20 data and up to 12 program segment descriptors.

The SC3850 DSP subsystem introduces a new programming model for more flexible memory mapping of the SD that reduces previous constraints allowing reduction in the number of descriptors needed and memory waste. For compatibility, the MMU also supports the old programming model.

10.6 L2 Cache

The L2 cache processes data and program accesses to the external M3/DDR memory. Caching the accesses requested by the L1 subsystem reduces the average penalty of accessing the high latency M3. The L2 cache includes a slave arbitration and tag unit, cache logic and arrays, along with a write buffer for write back and write through accesses, fetch logic to fetch data from the off platform memory upon a miss or a non-cacheable access, and a master arbiter that arbitrates between the different internal units.

Features of the L2 cache are as follows:

- A size of 512 Kbytes with 64 bytes per cache line (total of 8192 lines in the cache) arranged in an 8 way set-associative structure.
- 64Byte valid bit resolution (VBR) and dirty bit resolution (DBR). Fetch the whole line at once. Write back the whole line at once when a dirty line is thrashed from the cache.
- Physically addressed
- Dynamically configurable as a DMA accessible M2 RAM
- Software coherency support with seamless transition from L1 cache coherency operation
- Multichannel (4) L2 software prefetch for two-dimensional arrays
- Cache partitioning by way
- Write policies:
  - Non-cacheable and non-cacheable on read and write (NC)
  - Cacheable write-through and cacheable on read non-cacheable on write (WT). Update the cache on hit.
  - Cacheable write back; both read and write are cacheable (WB)
  - Adaptive write policy (AWP). Cacheable WB on hit and NC on miss.
- WB composed of eight 32-byte entries
- Full ECC support

The main components of the L2 cache are as follows:

- L2 Qbus arbiter (L2Q) to arbitrate the input data QBus, instruction QBus, and the slave port to one output bus (necessary because the cache serves one access per cycle).
- Cache logic to manage the cache arrays and state machines
- Fetch unit (L2FU) to fetch cacheable accesses from the M3/DDR memory, including L2 SW prefetching of data and instructions not yet requested by the core.
- Write buffer (L2WB) to temporarily hold modified (dirty) cache lines thrashed by the cache and also serve as a buffer for non-cacheable memory.
- Arbitration unit (L2AU) to arbitrate among the different masters (access generators) of the L2 cache (L2FU and L2WB).
- QBus to MBus interface (Q2M) to interface the external memory IF bus asynchronously while maintaining the pipeline.
- Register file to hold the L2 cache status and control registers. Mapped to the internal peripherals on bank0.

10.7 On-Chip Emulator and Debug and Profiling Unit

The on-chip emulator (OCE) and the debug and profiling unit (DPU) are hardware blocks for debugging and profiling. The OCE performs the following tasks:

- Communicates with the host debugger through the SoC JTAG test access port (TAP) controller
- Enables the SC3850 core to enter the debug processing state upon a varied set of conditions to:
  - Single step
  - Execute core commands inserted from the host debugger to upload and download memory and core registers.
- Sets up to six address-related breakpoints on either PC or a data address
- Sets a data breakpoint on a data value, optionally combined with a data address
- Generates the PC tracing flow, optionally filtered to a subset of events such as only jumps/returns from subroutine, interrupts, and so on.

The DPU has the following characteristics:

- Enables parallel counting of subsystem events in six dedicated counters, from more than 40 events
- Filters, processes, and adds task ID and profiling information on the OCE PC trace information

10.8 Extended Programmable Interrupt Controller

The internal extended programmable interrupt controller (EPIC) manages internal and external interrupts. The EPIC handles up to 256 interrupts, 222 of which are external subsystem inputs. The rest of the interrupts serve internal subsystem conditions. The external interrupts can be configured as either maskable interrupts or non-maskable interrupts (NMIs). The EPIC can handle 33 levels of interrupt priorities, of which 32 levels are maskable at the core and 1 level is NMI.

10.9 Timer

The timer block includes two 32-bit general-purpose counters with pre-loading capability. It counts clocks at the core frequency. It is intended mainly for operating system use.

10.10 Interfaces

The interfaces transfer data from the subsystem to the rest of the system and vice versa.

10.10.1 QBus to MBus Interface Bridge

The instruction QBus to MBus interface (IQ2MA) bridge translates the bus from the L2 Cache, which uses the proprietary QBus protocol, to the MBus line protocol. The Q2M is placed between two different asynchronous clock domains:

- Internal, SC3850 DSP subsystem clock domain
- External (out of subsystem) clock domain, which is slower or equal to the internal clock domain.

10.10.2 MBus to DMA Bridge

The MBus to DMA bridge converts the signals coming from the MBus to the protocol used by the L2 Cache slave port. The bridge is placed between two different asynchronous clock domains:

- Internal, SC3850 DSP subsystem clock domain
- External (out of subsystem) clock domain, which is slower or equal to the internal clock domain.

10.11 Entering and Exiting Wait and Stop States Safely

The following subsections describe how to enter and exit from the Wait and Stop states safely.

10.11.1 Wait State

The Wait state is described in **Section 2.12.4** of the *SC3850 DSP Subsystem Reference Manual*. The subsystem enters the Wait processing state when the SC3850 core executes the **wait** instruction. The subsystem exits from the Wait state when an enabled level interrupt request is asserted or the subsystem transfers to the Debug or Reset state. During a Wait state, the subsystem L2/M2 memory is available for access through the slave port. No further steps are required.

10.11.2 Stop State

The Stop state is described in **Section 2.12.5** of the *SC3850 DSP Subsystem Reference Manual*.

10.11.2.1 Procedure for Entering DSP Subsystem Stop State Safely

Note: Before entering the Stop state, terminate any L2 software prefetch activities to reduce the time needed to enter Stop.

Use the following procedure to enter the Stop state:

1. Stop all accesses to the M2/L2 memory in the core subsystem by peripherals and external hosts (if applicable).
2. Close the subsystem slave port window by writing a 1 to the relevant bit in the CORE_SLV_GCR (see **Section 8.2.38**, *Core Subsystem Slave Port General Configuration Register (CORE_SLV_GCR)*, on page 8-66 for details).
3. Read the CORE_SLV_GCR to make sure that the 1 is written and the bit is set.

Note: After the slave port window is closed, all core accesses will generate an error interrupt to the core.

4. Send a read request from the specified core and subsystem to an adjacent core M2 according to its index, as follows: from Core0 to Core1, from Core1 to Core0, from Core2 to Core3, or from Core3 to Core2.
5. Step 4 generates an address error interrupt. Read GIR5 to make sure that the interrupt is generated by the specified core (see **Section 8.2.29**, *General Interrupt Register 5 (GIR5)*, on page 8-46 for details).
6. Make sure that the appropriate Stop ACK is asserted in GSR1. If not, assert the bit. (see **Section 8.2.3**, *General Status Register 1 (GSR1)*, on page 8-6 for details).
7. Issue a **stop** command to the specified core.

10.11.2.2 Procedure for Exiting the Stop State Safely

Use the following process to exit from the Stop state:

1. Initiate an enabled level subsystem interrupt. This causes the subsystem to exit the Stop state.
2. The core will open its own slave port window by deasserting the relevant bit in the CORE_SLV_GCR (see ***Section 8.2.38***, *Core Subsystem Slave Port General Configuration Register (CORE_SLV_GCR)*, on page 8-66).

10.12 Programming Restrictions

The MSC8157E has the following programming restrictions when using the SC3850 DSP Subsystem:

- A write hit in the cache combined with DFLUSH/DSYNC can be lost for the following scenarios:
  - Write hit lost after DSYNC/DFLUSH with parallel WRITE/FETCH with no match.
  - Write hit before DSYNC is lost when the entrance to LWB is delayed by contentions.

  Use the following steps to prevent the write hit loss:

1. Insert a SYNCM instruction between a READ/WRITE/DFETCH/DMALLOC to the same 256 bytes followed by a DFLUSH/DSYNC command.
2. Use a SYNCM instruction after the last DFLUSH/DSYNC instruction.
3. No write is allowed between the first DFLUSH/DSYNC and the last DFLUSH/DSYNC SYNCM.

- To reduce performance degradation when the slave port is configured to low priority, always configure the Subsystem Port Priority Control Register (TSPPCR) general configuration register to high priority. The L2 cache arbiter does not treat the slave port access as part of the Round Robin arbitration scheme. Therefore, when the slave port accesses the cache with high priority, it always wins the arbitration. Because the slave port operates at half the frequency of the L2 and L1 caches, the cumulative L1 (I$ and D$) theoretical bandwidth can drop to 50% versus 33% in full Round Robin. When the slave port accesses the cache at low priority, the L1 (I$ and D$) always wins the arbitration and the slave port performance can decrease significantly. Arbitration between I$ and D$ is round robin with priority as defined.

11 Internal Memory Subsystem

The internal memory system supports 6624 KB of internal memory and includes:

- Memory management unit (MMU) per core.
- Instruction channel with 32 KB L1 ICache per core.
- Data channel with 32 KB L1 DCache per core.
- 512 KB L2 shared unified Cache, configurable in 64 KB blocks as M2 memory, per core.
- 1 MB + 2 MB128-bit wide M3 memory connected to six internal memory buses. The 2 MB block can be turned off to reduce power consumption. The M3 memory supports semaphores and the RapidIO mail boxes.
- 96 KB of boot ROM accessible from the cores.

Note: The MMU, L1 ICache, L1 DCache, and L2 Cache/M2 memory are part of the MSC8157E SC3850 DSP core subsystem. For detailed programming and functional information, refer to the *SC3850 DSP Core Reference Manual*, available with a signed non-disclosure agreement. Contact your local Freescale dealer or sales representative for more information.

Note: The default burst size for the caches and MMU is 1 VBR, but for most operations, programming the burst size as 4 VBR provides the best performance.

11.1 Memory Management Unit (MMU)

The MMU provides a high-speed address translation mechanism to enable memory relocation, and checks access permissions for core instructions and data buses. It also controls hardware task protection and provides cache and bus controls for advanced memory management. The MMU enables better integration of system resources and defines a cleaner software model. For example, programing protected regions, address translation regions, cacheable regions, and so on can be combined. In addition, cache usage can be optimized based on the specific attributes controlled by the MMU programming. For memory protection, the MMU enables the implementation of an RTOS with MMU support, thereby protecting the operating system, task code, and data from errant tasks. Address translation enables implementation of a software model in which the code uses virtual addresses that are translated to physical addresses accessing memory. The MMU provides a virtual memory software model with a hole for the OCE and internal device registers and peripherals. The core generates virtual addresses during its operation. The virtual address together with the task ID from the MMU become the task-extended (TE) virtual address. The MMU translates between virtual and physical addresses during each core access, providing control attributes for each core access per memory segment, such as burst size, prefetch enable, write-policy, cacheability, and so forth.

The MMU has the following functions and features:

- A memory attributes and translation table (MATT), composed of 20 data segment descriptors and 12 program segment descriptors.
- Each segment descriptor defines a related memory region and its cache and attributes, protection and address translation.
- The descriptor related memory space has a long-range variable mapping size. The size is designated in steps as a power of 2, starting from 256 bytes. The mapping size can be between 256 bytes to 4 GB. The base address must be aligned to a segment size.
- The memory region dedicated cache and attributes support the following:
  - Cacheable access.
  - A burst size of 1, 2, or 4 for the data fetch unit (DFU) and instruction fetch unit (IFU).
  - Hardware line prefetch enable.
  - Hardware next line prefetch enable (instruction only)
  - System/shared attributes
  - Write policy for data memory
  - L2 cache policy

- Hardware data and program access protection is defined for each data/program memory region for two privilege levels: user and supervisor. The MMU provides abort signals for the Xa/Xb/P buses for errant accesses. The MMU provides memory region support, as follows:
  - For the program memory region, provides read allowed/not allowed access for both the Supervisor and User levels
  - For the data memory region, provides read/write allowed/not allowed for both the Supervisor and User levels
- Address translation is defined for each data/program memory region, enabling allocation of a virtual memory region to a valid physical memory space.
- Priority mechanism between descriptors, allowing memory regions overlapping.
- Stores the program task ID and data task ID for multi-task mechanism. Up to 255 different Program IDs and 255 different data IDs are available.
- Subsystem ID register and general-purpose register among its control and status registers.
- Access error detection including non-mapped memory access and misaligned memory access.
- Captures error status bits and enables a fast error diagnostic.
- Precise interrupts allowing handling MMU MATT misses supporting a virtually paged operating system.
- Core branch target buffer (BTB) that enables manual and automatic BTB maintenance.
- Subsystem error detection code (EDC) recovery scheme.
- Enable/disable EDC exception mechanism.
- Subsystem master and slave error handling.
- Program and data query mechanism.

11.2 Instruction Channel (ICache and IFU)

The Instruction Channel comprises the Instruction Cache (ICache) and the Instruction Fetch Unit (IFU). This channel provides the core with instructions that are stored in higher-level memory. The ICache, which operates at core speed, stores recently accessed instructions. Whenever an addressed instruction (from the cacheable memory area) is found in the array, it is immediately made available to the core (ICache hit). When the required address is not found in the array, it is loaded to the ICache from the external (not part of the DSP core subsystem) memory by the IFU (ICache miss). The IFU operates in parallel to the core to implement a prefetch algorithm that loads the ICache with information that with high probability will be needed soon. This action reduces the number of cache misses. Whenever an instruction is addressed from a non-cacheable area, the IFU fetches it directly to the P bus of the core without writing it to the cache.

Instruction channel features include:

- Aligned 128-bit XP core accesses.
- Concurrent cacheable and non-cacheable accesses, as identified in the MMU based on the address ranges.
- Task-extended virtually addressed cache. The 8-bit task ID from the MMU is stored as part of the line tag that allows a task-specific cache image that is not overridden by other tasks that use the same virtual address. This feature can support multi-task mechanism. This extended tag is named the ETAG.
- Cacheable shared memory between tasks marked by the MMU according to the memory range, and stored in the cache with TASKID 0.
- Cache hit access without wait states (except during memory conflicts).
- Issues 128-bit accesses to the higher level memory when a cache miss occurs.
- Programmable to issue hardware line prefetch accesses upon cache miss that fetch data to the end of the cache line (256 bytes).
  - Hardware line prefetching is aborted in case of a new miss on a burst size boundary.
  - Programmable burst size of 1, 2, or 4 VBRs.
- A miss access identified as a prefetch by the prefetch hit stalls the core to reduce the number of wait states relative to a simple miss.
- Automatic hardware next line prefetch on a mis or a hit to a previously fetched line controlled by the MMU.
- Supports SC3850 core touch loading PFETCH command that allows the user to prepare specific memory lines in the cache to reduce or remove the penalty for miss accesses.
- Pseudo-LRU (PLRU) as the cache line replacement mechanism (LRM).
- Global lock allows locking of all cache lines to reduce the cache restoration penalty of a restored task. In this case, the cache does not serve cache misses.
- User-initiated cache sweep operations for coherency support. These operations are performed on each line in a user-specified address range. An invalidate discards the cache line (clears the valid bits).
- Cache debug mode in which the cache state (ETAG values, Valid, PLRU state) can be read and the memory array can be read or written.
- Dedicated programmable cache control registers that control or reflect its operation.
- EDC (error detection) support.
- Dedicated exceptions for each of the following events:
  - *End of sweep operation*. This exception indicates the completion of the sweep operation.
  - *XP non-cacheable hit access*. This exception indicates that an access is a hit access, even though the MMU classifies it as a non-cacheable access. This type of situation can occur if the memory space attributes changed in the MMU without invalidating the

appropriate cache lines Assertion of the exception is not guaranteed when the attribute change that led to this error is not performed with SYNCIO as restricted.

— *XP double match.* This is an error that occurs when a task-shared access has an address that matches a non-shared cache line.

11.3 Data Channel and Write Queue (DCache)

The data channel and write queue is a two-way channel for reading and writing information from the core to/from higher level memory (M2 or L2) and Control Memory (internal blocks and external peripherals) spaces. The DCache, which operates at core speed, keeps the recently accessed data. Whenever addressed data (from a cacheable memory area) is found in the array, it is immediately made available to the core (DCache hit) in a read, and updated if written. When the required address is not found in the array, a DCache miss occurs, and the data is loaded to the DCache from the external (not part of the DSP core subsystem) memory by the DFU, and driven through the write queue to the core.

The data channel is fed by accesses from the write queue buses and not directly from the core XA/XB data buses. Data reads are normally forwarded directly from the write queue, so there is no delay in processing them. On the other hand, data writes can be delayed for extended periods in the write queue. Therefore, they are bypassed by read accesses and their processing in the data channel is completely detached from the core execution flow. The write queue performs the necessary hazard checks and enforces the access order issued by the core.

The DFU operates in parallel with the core and implements a prefetch algorithm to load to the DCache, information that with high probability will be needed soon, thus reducing the number of data cache misses. The channel differentiates between cacheable and non-cacheable addresses as defined by the MMU. For cacheable addresses, it supports the write-back allocate or write-through accesses. Cacheable accesses activate the cache (if the cache is enabled) and respond to the core with no wait states when a hit occurs. For a miss, the data channel issues a fetch request to higher-level memory and typically executes hardware line prefetches limited at most by the end of the cache line. Write-through accesses do not allocate a new line in the cache for a write-miss access.

Cacheable write back data writes wait in the cache until a line is flushed, either automatically as part of the replacement policy or when initiated by the user. During flushing, the writes wait in the write back buffer until they are written to higher-level memory. Hardware line prefetching and write backs are issued on the QBus as compact 128-bit transactions, which helps reduce the traffic on the DSP subsystem connection to the higher level memories. Non-cacheable accesses are written through the data channel without changing the cache state. Cacheable write-through accesses, however, are written to the higher level memory, and they update the cache when there is a hit access.

The data channel has the following features:

- Handling 2 parallel core accesses WA/WB each with a width of 1, 2, 4 or 8 bytes
- Supports both cacheable and non-cacheable accesses concurrently, as identified in the MMU based on their address ranges.
- Task-extended virtually addressed cache. The 8-bit task ID from the MMU is stored as part of the line tag, which allows a task-specific cache image that is not overridden by other tasks that use the same virtual address. This feature can support multi-task mechanism. This extended tag is named ETAG.
- Supports cacheable shared memory between tasks that is marked by the MMU according to the memory range, and is stored in the cache with task ID 0.
- Serves a cache hit access without wait states (except memory conflicts).
- Upon a cache miss, issues 128-bit accesses to the higher level memory
- Upon a cache miss, could be programmed to issues prefetch accesses that will bring in data until the end of the cache line (256 bytes).
  - Hardware line prefetching is aborted when there is a new miss on a burst size boundary.
  - Programmable burst size of 1, 2, or 4 VBRs.
- Miss access, identified as being hardware line prefetched (prefetch hit), stalls the core for a reduced number of wait states relative to a simple miss.
- Supports SC3850 core cache maintenance instructions that are operable for both user and supervisor levels:
  - DMALLOC. Allocate a line used later in the code and validate 4 VBRs in the line. Saves time and bus resources need to fetch VBRs from main memory when going to overwrite it.
  - DFETCH/W. Allocate a line and fetch the relevant data (at least one memory burst) that is used later in the code. Adding the W indicate to the L2 cache not to allocate the data even if it is cacheable to reduce cache inclusiveness.
  - DFLUSH. The DCache writes back and invalidates a cache line belonging to the specified address of the M3 or external memory.
  - DSYNC. The DCache writes back a cache line belonging to the specified address of the M3 or external memory.

- Pseudo-LRU (PLRU) as the cache Line Replacement Mechanism (LRM).
- Global lock allows locking of all cache lines to reduce cache restoration penalty of a restored task. Miss accesses are not served by the cache in this case.
- Supports user-initiated cache sweep operations for coherency support. These operations are performed on each line in a user-specified address range:
  - Synchronize: write back the cache line if it was modified, clearing its “dirty” bit without affecting its validity.
  - Flush: write back any cache line (and clear the “dirty” bit), and also invalidate it in the cache (clearing the “valid” bit).
  - Invalidate: discard the cache line without writing it back (clear both “dirty” and “valid” bits).
- Cache debug mode where the cache state (ETAG values, Valid-Dirty, PLRU state) could be read and the memory array could be read or written.
- Dedicated programmable cache control registers that control or reflect its operation.
- EDC (error detection) support.
- Provides dedicated exceptions for each of the following events:
  - End of sweep operation: This exception indicates the completion of the sweep operation.
  - WA/WB non-cacheable hit access: This exception indicates that an access is a hit (or prefetch hit) access, although it is indicated by the MMU as a non-cacheable access. This type of situation can occur if the memory space attributes are changed in the MMU without flushing/invalidating the appropriate cache lines Assertion of the exception is not guaranteed if the attribute change that leads to the error was not done with the SYNCIO command as restricted.
  - WA/WB double match: This is an error that occurs when a task-shared access has an address that matches a non-shared cache line.

11.4 L2 Unified Cache/M2 Memory

Each core subsystem contains a memory region that can be allocated as L2 unified cache or M2 memory. Allocation of M2 memory is done in 64 KB blocks from 0 to 512 KB (the full memory space). Whatever portion is not allocated as M2 memory is used as L2 cache. Allocation can be done dynamically, but must be done when the L2 cache is disabled. The selection of 64 KB blocks is done through address partitioning. After the M2 region is defined, the cache should be flushed and after the flush is completed, the L2 cache controller is enabled and the defined M2 region becomes available for addressing with the remainder of the space available to the L2 cache controller (L2Cache).

The L2Cache is responsible for processing data and program accesses to the M3 and external DDR memory. By caching the accesses requested by the L1 subsystem, the average penalty of accessing the high latency M3/DDR memory is reduced. The L2Cache includes slave arbitration and a Tag unit, cache logic and arrays along with a write buffer for write back and write through accesses, fetch logic that is responsible for fetching data from the M3/DDR memory on a miss or a non-cacheable access, and a master arbiter that arbitrates between the different units.

The main L2Cache components include the following:

- Cache logic. Responsible on managing the cache arrays and state machines.
- Fetch Unit (L2FU). Responsible for fetching cacheable accesses from the M3/DDR memory, including the rest of the line.
- Write Buffer (L2WB). A buffer for temporarily holding modified (dirty) cache lines that were thrashed by the cache and also serving as a buffer for non-cacheable memory.
- Control Unit (L2AU). Responsible for arbitration between the different masters (access generators) of the L2Cache (L2FU and L2WB) and interface to the asynchronous bus.
- QBus to MBus (Q2M). Enables the interface to the external memory bus asynchronously while maintaining the pipeline.
- Register file. Holds the L2Cache status and control registers that are mapped to the internal peripherals on Bank0.

The cache has the following characteristics:

- Up to 512 KB cache memory.
- 8 ways
- 1024 cache indexes.
- 64-byte cache line.
- 64-byte Valid Bit Resolution (VBR) and Dirty Bit Resolution (DBR). Fetches the whole line at once. Writes back the whole line at once when a dirty line is thrashed from the cache.
- 8192 cache lines (TAGs).

- Physically addressed.
- L2WB comprises eight 32-byte entries.
- Slave port support.

The L2 Cache Controller is connected to the Data and Instruction QBus. The L2 Cache Controller has a chip select input that signals the access to it. Each access is qualified by the cache policy bits that are linked to the access address, as either a cacheable (CA) access, non-cacheable (NC) access, cacheable write-through (WT), and Adaptive Write Policy (AWP), that is, a CA on a read access or a hit access, and NC on a write miss. Cacheable accesses activate the cache and, in case of a hit, answer after a minimum of five cycles. In case of a miss, the L2 Cache Controller issues fetch requests to the higher-level memory (M3/DDR), and fetches more data than asked for by requesting the whole cache line to reduce the performance impact due to subsequent accesses. In case the access is a WB or AWP hit, the data writes wait in the cache until the line is flushed (automatically as part of the replacement policy or if initiated by the user). Upon flushing, the writes wait in the Write Buffer (L2WB) until they are written to the higher-level memory. Miss fetch and write backs are issued on the MBus as 128-bit transactions, which help reduce the traffic on the platform connection to the higher level memories. NC accesses, WT or AWP miss are written through the L2Cache without changing the cache state via the L2WB. The cache does not calculate hits for NC accesses. To prevent a coherency problem, the cache must be flushed when changing an area from CA policy to NC policy in the MMU MATT descriptors.

The L2 Cache Controller has the following features:

- Input ports (DQBus, IQBus, and MBus):
  - Handling 2 input QBuses and 1 input MBus, arbitrating them to one internal bus with pipeline support.
  - Slave ports (Qbus and MBus) supporting partial bus width accesses of 1, 2, 4, and 8 bytes and full bus bursts of 1, 2, and 4 beats of 128-bit accesses.
  - Round-Robin arbitration according to the access type signal and the origin of the access.
  - Physically addressed.
- Output Port (MBus):
  - Interface to the external memory (Master bus) with a bus working in MBus protocol and supporting asynchronous connection.
  - The maximum accumulative burst size is 64 bytes. The number of beats in the burst is equal to the burst size divided by the bus size.The maximum accumulative burst size is 64 bytes which is made in 4 beats of 128 bits.

- Access handling:
  - Supports the following cache policies:
    - Noncacheable on read and write (NC).
    - Cacheable write-through on read noncacheable on write (WT)
    - Cacheable write back on both read and write are cacheable (WB)
    - Adaptive write policy (AWP). Cacheable WB on read or hit and NC on write miss.
    - Adaptive read cacheability according to a read-with-intent-to-write indiction.
    - Policy is identified by the cache policy bits (defined by MMU programming) that are part of the accesses attributes signals.
  - Supports user-initiated D/PFL2_x commands.
  - Upon a cache miss, brings the entire line using critical word first and wraps on 64-byte boundaries.
  - Identifies data that is being fetched (prefetch hit), which reduces the number of wait states relative to a simple miss and reduces the external memory bus load.
  - Detects hazards for reads that use data that was flushed (or noncacheable) and is still in the L2WB. The access is stalled until the write is completed.
  - Supports fast write and response request
  - Issues a transfer acknowledge as soon as the write data is sampled. When response is high, issues the transfer acknowledge signal when the write access is sampled at the end target.
  - Supports core atomic accesses to external memory. Atomic access to L2 cacheable location or to L2 as M2 is not supported (will always succeed)
  - Constantly memory maps the cache array to enable read and write to it for debug purposes and also to allow use as M2 with DMA connectivity.
- Replacement mechanism:
  - Uses random cache line replacement mechanism (LRM).—Partitioning mechanism by ways and address ranges
  - Allows assignment of a subset of cache lines to an address range to reduce cache restoration penalty of a restored task. This mechanism is useful when rapid task switching is required, thereby preventing a situation in which a task thrashes important data or instructions associated with other tasks.
- ECC is able to fix 1 error in 64 bits. In addition, ECC test mode is supported. This mode enables the user to check the ECC mechanism by initiation of error.
- Cache programming:
  - Dedicated programmable cache control registers that control or reflect its operation.
  - Supports reading and writing memory mapped registers through memory mapped bank0.
- Supports user-initiated SW-PF (L2 software prefetch) operation. This operation enables PF of a specific (two-dimensional) address space as programmed in the cache registers.

- Supports SW cache coherency:
  - SW initiated DFLUSH/DSYNC operations. These operations are performed in a line resolution.
  - SW initiated cache sweep operations for coherency support. These operations are performed on each line in a user-specified address range:
    - Synchronize: write back the cache line if it was modified, clearing its dirty bit without affecting its validity.
    - Flush: write back any dirty cache line (and clear the dirty bit), and also invalidate it in the cache (clearing the valid bit).
    - Invalidate: discard the cache line without writing it back (clear both dirty and valid bits).
- Cache debug mode where the cache state (tag, valid, and dirty) could be read through the DQbus slave port.
- Provides dedicated interrupts for each of the following events:
  - Master port () error: This interrupt indicates that one of the accesses generated by the L2 cache to the off platform memories has failed (that is, non-mapped access).
  - End of sweep operation: This interrupt indicates the completion of the sweep operation.
  - End of SW-PF operation: This interrupt indicates the completion of a L2 software prefetch operation.
  - Noncacheable hit error: This interrupt indicates that an access to a noncacheable area was found to be hit. This indicates user violation of a restriction, which obligates the user to flush the cache before changing descriptors' attributes.
  - Non-aligned non-allocate error: This interrupt indicates that a non-aligned access from the slave port isn't allocated in the cache and is forwarded to the external memory instead.
  - M2 non-mapped access error: This interrupt indicates that an access intended to access the L2 cache as M2, has exceeded the M2 boundaries indicating an issue with memory mapping to M2 configuration.
- Disabled on reset. Cannot be disabled after enabled.

11.5 M3 Memory

The 3 MB M3 memory can be used for storing critical program and data shared between the cores and the device peripherals. The M3 memory has a 128-bit wide port and runs at 667 MHz. The M3 memory is ECC protected for soft errors.

The M3 memory uses 64 KB compiled memory banks of SRAM. The memory is divided into six 512 KB groups, each with its own bus controller. The first two groups of memory are located at addresses 0xC0000000 through 0xC00FFFFF in the MSC8157E memory map. The last four groups are located at addresses 0xC010000 through 0xC02FFFFF. To support decreased power consumption, power to the last four 512 KB memory groups can be disabled. All of the M3 memory supports semaphores and the RapidIO mail boxes. When the power is removed from the four 512 KB memory groups, the remaining two 512 KB groups still have power to provide support for the hardware semaphores and the RapidIO mail boxes.

11.6 Internal Boot ROM

The MSC8157E device includes 96 KB of boot ROM accessible from all of the cores. This ROM provides the basic loading programming that allows the device to complete its initialization and load additional configuration and booting from external sources.

12 DDR SDRAM Memory Controller

The fully programmable DDR SDRAM controller supports most JEDEC standard x8 and x16 DDR3 available memories. In addition, unbuffered and registered DIMMs are supported. However, mixing different memory types or unbuffered and registered DIMMs in the same system is not supported. Built-in error checking and correction (ECC) ensures very low bit-error rates for reliable high-frequency operation. Dynamic power management and auto-precharge modes simplify memory system design. A large set of special features, including ECC error injection, support rapid system debug.

Note: In this chapter, the word *bank* refers to a physical bank specified by a chip select; *logical bank* refers to one of the four or eight sub-banks in each SDRAM chip. A sub-bank is specified by the 2 or 3 bits on the bank address (MBA) pins during a memory access.

Figure 12-1 shows a high-level view of the DDR memory controller with its associated interfaces.

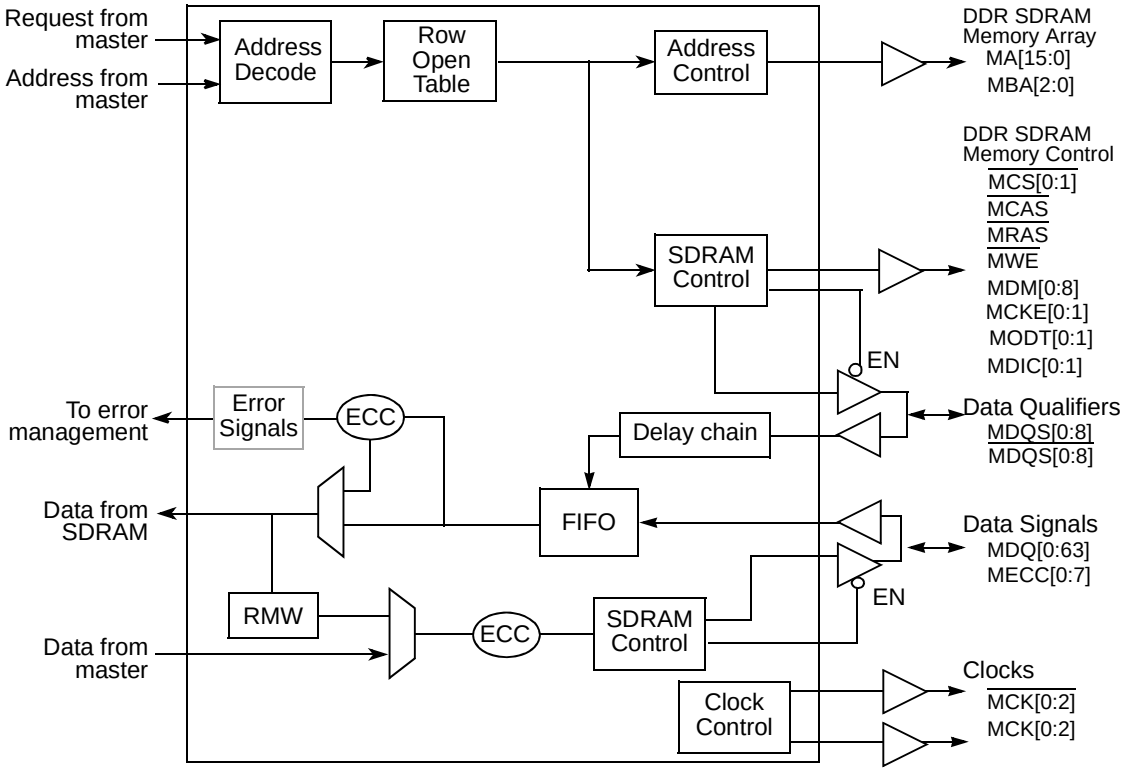

Figure 12-1. DDR SDRAM Memory Controller Simplified Block Diagram

12.1 DDR Memory Controller Features

The DDR memory controller includes these distinctive features:

- Support for DDR3 SDRAM
- 64-/72-bit SDRAM data bus, 32-/40-bit SDRAM for DDR3
- Programmable settings for meeting all SDRAM timing parameters
- The following SDRAM configurations are supported:
  - As many as two physical banks (chip selects), each bank independently addressable
  - 512-Mbit to 4-Gbit devices depending on internal device configuration with x8/x16 data ports (no direct x4 support)
  - Unbuffered and registered DIMMs
- Chip select interleaving support
- Partial array self refresh support
- Support for data mask signals and read-modify-write for sub-double-word writes. Note that a read-modify-write sequence is only necessary when ECC is enabled.
- Support for double-bit error detection and single-bit error correction ECC (8-bit check word across 64-bit data)
- Support for address parity for registered DIMMs
- Open page management (dedicated entry for each logical bank)
- Automatic DRAM initialization sequence or software-controlled initialization sequence
- Automatic DRAM data initialization
- Write leveling supported for DDR3 memories
- Support for up to eight posted refreshes
- Support for error injection

12.2 DDR Memory Controller Modes of Operation

The DDR memory controller supports the following modes:

- *Dynamic power management mode*. The DDR memory controller can reduce power consumption by negating the SDRAM CKE signal when no transactions are pending to the SDRAM.
- *Auto-precharge mode*. Clearing DDR_SDRAM_INTERVAL[BSTOPRE] causes the memory controller to issue an auto-precharge command with every read or write transaction. Auto-precharge mode can be enabled for separate chip selects by setting CS*n*_CONFIG[AP_*n*_EN].

12.3 DDR Controller Functional Description

The DDR SDRAM controller controls processor and I/O interactions with system memory. It provides support for JEDEC-compliant DDR3 SDRAMs. The memory system allows a wide range of memory devices to be mapped to any arbitrary chip select, and support is provided for registered DIMMs and unbuffered DIMMs. However, registered DIMMs cannot be mixed with unbuffered DIMMs.

Figure 12-2 is a high-level block diagram of the DDR memory controller. Requests are received from the internal mastering device and the address is decoded to generate the physical bank, logical bank, row, and column addresses. The transaction is compared with values in the row open table to determine if the address maps to an open page. If the transaction does not map to an open page, an active command is issued.

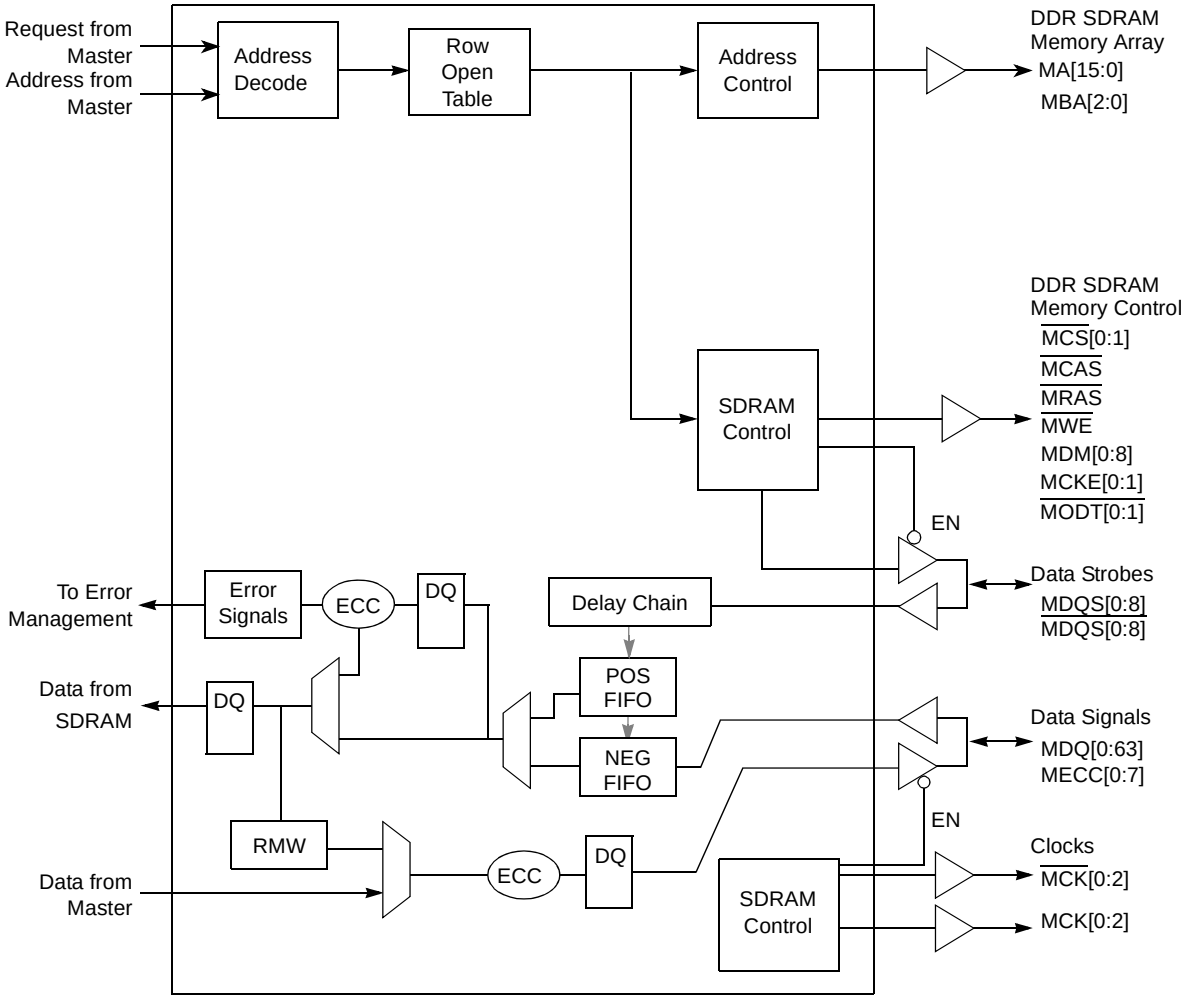

Figure 12-2. DDR Memory Controller Block Diagram

The memory interface supports as many as two physical banks of 64-/72-bit wide or 32-/40bit bit wide memory. Bank sizes up to 2 Gbytes are supported, providing up to a maximum of 2 Gbytes of DDR main memory. Programmable parameters allow for a variety of memory organizations and timings. Optional error checking and correcting (ECC) protection is provided for the DDR SDRAM data bus. Using ECC, the DDR memory controller detects and corrects all single-bit errors within the 64- or 32-bit data bus, detects all double-bit errors within the 64- or 32- bit data bus, and detects all errors within a nibble. The controller allows as many as 16 pages to be open simultaneously. The amount of time (in clock cycles) the pages remain open is programmable with DDR_SDRAM_INTERVAL[BSTOPRE].

Read and write accesses to memory are burst oriented; accesses start at a selected location and continue for a programmed number of higher locations (4 or 8) in a programmed sequence. Accesses to closed pages start with the registration of an ACTIVE command followed by a READ or WRITE. Accessing open pages does not require an ACTIVE command. The address bits registered coincident with the activate command specifies the logical bank and row to be accessed. The address coincident with the READ or WRITE command specify the logical bank and starting column for the burst access.

The data interface is source synchronous, meaning whatever sources the data also provides a clocking signal to synchronize data reception. These bidirectional data strobes (MDQS[0:8]) are inputs to the controller during reads and outputs during writes. The DDR SDRAM specification requires the data strobe signals to be centered within the data tenure during writes and to be offset by the controller to the center of the data tenure during reads. This delay is implemented in the controller for both reads and writes. When ECC is enabled, 1 clock cycle is added to the read path to check ECC and correct single-bit errors. ECC generation does not add a cycle to the write path.

The address and command interface is also source synchronous, although 1/8 cycle adjustments are provided for adjusting the clock alignment. **Figure 12-3** shows an example DDR SDRAM configuration with four logical banks.

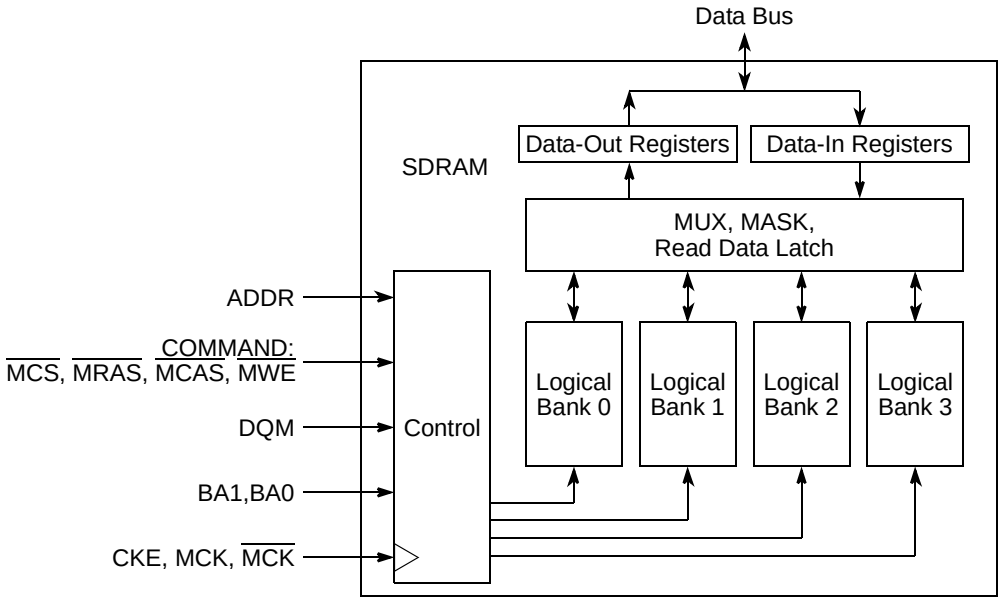

Figure 12-3. Typical Dual Data Rate SDRAM Internal Organization

Figure 12-4 shows some typical signal connections.

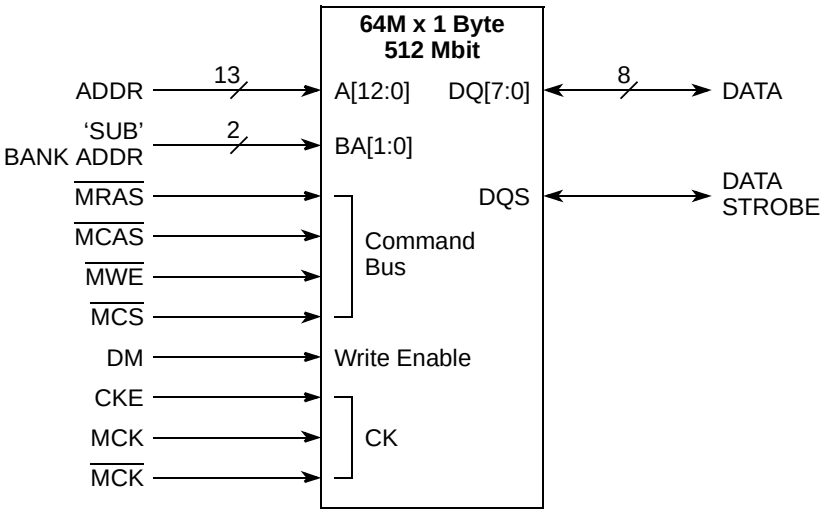

Figure 12-4. Typical DDR SDRAM Interface Signals

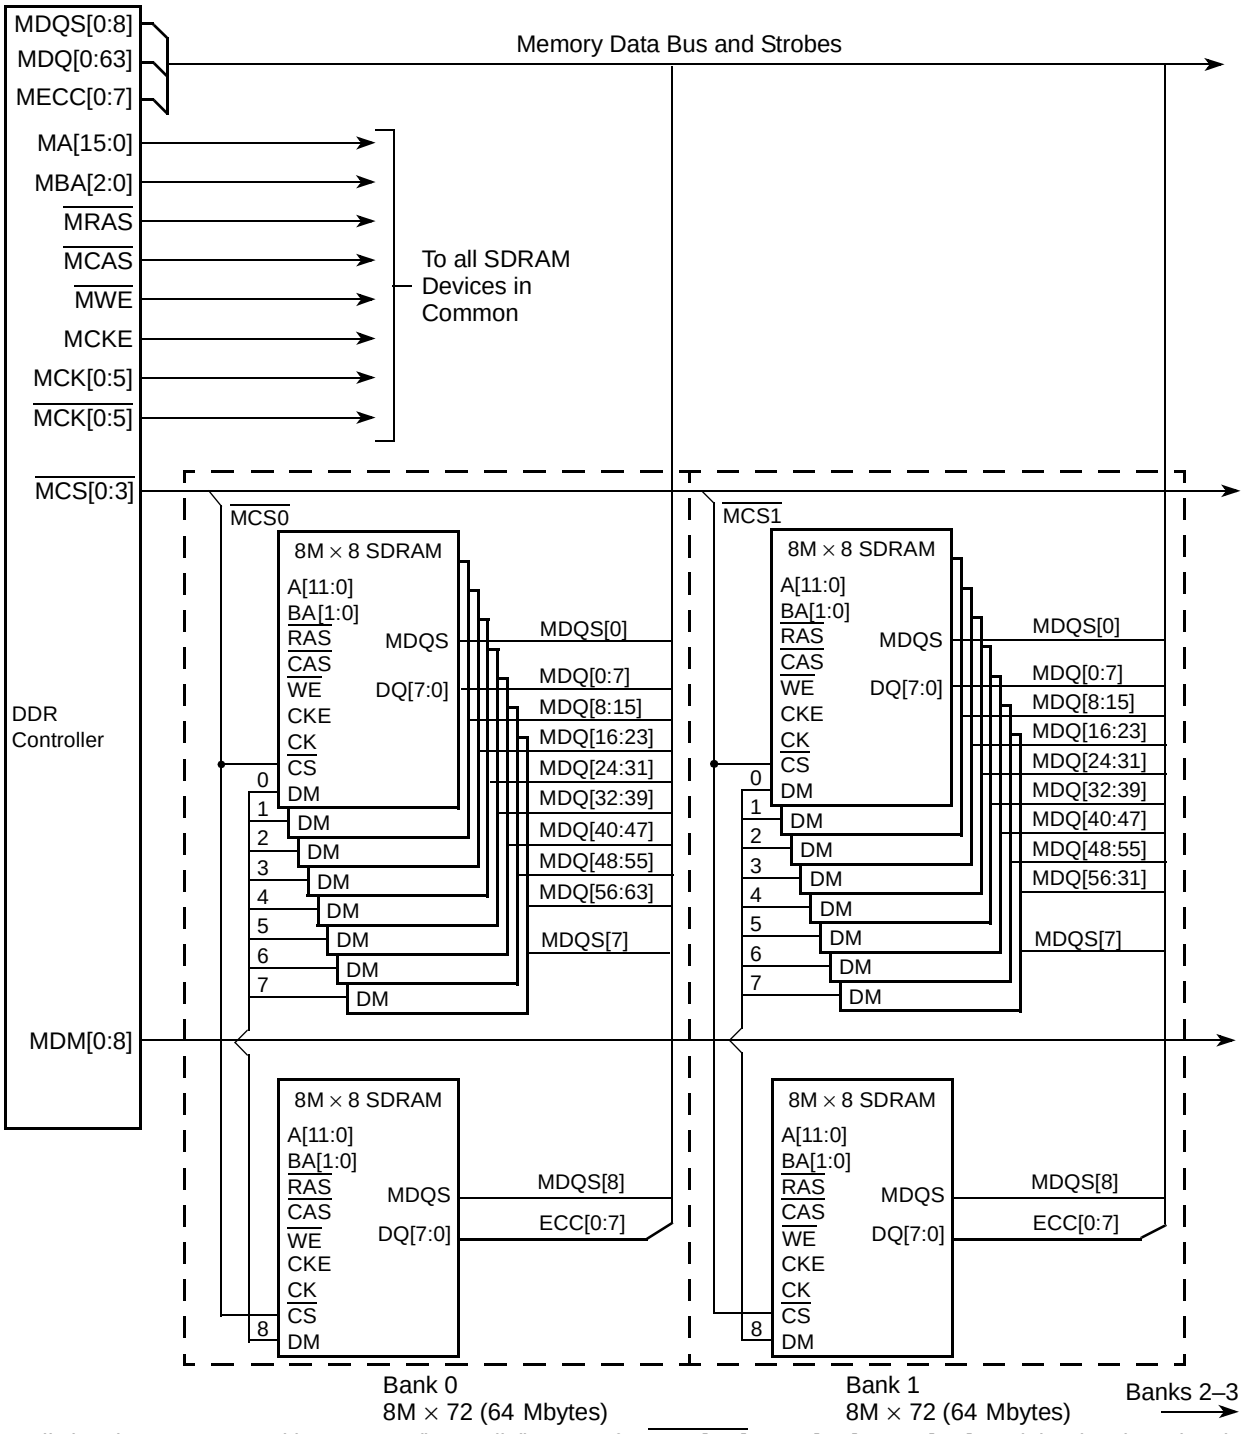
Figure 12-5 shows an example DDR SDRAM configuration with two physical banks each comprised of nine 8M × 8 DDR modules for a total of 128 Mbytes of system memory. One of the nine modules is used for the memory ECC checking function. Certain address and control lines may require buffering. Analysis of the device AC timing specifications, desired memory operating frequency, capacitive loads, and board routing loads can assist the system designer in deciding signal buffering requirements.

The DDR memory controller drives 16 address pins, but in this example the DDR SDRAM devices use only 12 bits. **Section 12.3.14**, *Error Management* explains how the DDR memory controller handles errors.



1. All signals are connected in common (in parallel) except for $\overline{\text{MCS}}[0:1]$, MCK[0:5], MDM[0:8], and the data bus signals.
2. Each of the $\overline{\text{MCS}}[0:1]$ signals correspond with a separate physical bank of memory.
3. Buffering may be needed if large memory arrays are used.
4. MCK[0:5] may be apportioned among all memory devices. Complementary bus is not shown.

Figure 12-5. Example 64-Mbyte DDR SDRAM Configuration

12.3.1 DDR SDRAM Interface Operation

The DDR memory controller supports many different DDR SDRAM configurations. SDRAMs with different sizes can be used in the same system. Sixteen multiplexed address signals and three logical bank select signals support device densities from 512 Mbits to 4 Gbits. Two chip select ($\overline{CS}$) signals support up to one DIMM. The DDR SDRAM physical banks can be built from standard memory modules or directly-attached memory devices. The data path to individual physical banks is 64 or 32 bits wide, 72 or 40 bits with ECC. The DDR memory controller supports physical bank sizes from 512 Mbytes to 2 Gbytes. The physical banks can be constructed using x8 or x16 memory devices. The memory technologies supported are 512 Mbits, 1 Gbit, 2 Gbits, and 4 Gbits. Nine data qualifier (DQM) signals provide byte selection for memory accesses.

Note: An 8-bit DDR SDRAM device has a DQM signal and eight data signals (DQ[0:7]). A 16-bit DDR SDRAM device has two DQM signals associated with specific halves of the 16 data signals (DQ[0:7] and DQ[8:15]).

When ECC is enabled, all memory accesses are performed on double-word boundaries (that is, all DQM signals are set simultaneously). However, when ECC is disabled, the memory system uses the DQM signals for byte lane selection.

12-1 shows the DDR memory controller's relationships between data byte lane0–7, MDM[0:7], MDQS[0:7], and MDQ[0:63] when DDR SDRAM memories are used with x8 or x16 devices.

Table 12-1. Byte Lane to Data Relationship

Data Byte Lane	Data Bus Mask	Data Bus Strobe	Data Bus 64-Bit Mode
0 (MSB)	MDM[0]	MDQS[0]	MDQ[0:7]
1	MDM[1]	MDQS[1]	MDQ[8:15]
2	MDM[2]	MDQS[2]	MDQ[16:23]
3	MDM[3]	MDQS[3]	MDQ[24:31]
4	MDM[4]	MDQS[4]	MDQ[32:39]
5	MDM[5]	MDQS[5]	MDQ[40:47]
6	MDM[6]	MDQS[6]	MDQ[48:55]
7 (LSB)	MDM[7]	MDQS[7]	MDQ[56:63]

12.3.2 Supported DDR SDRAM Organizations

Although the DDR memory controller multiplexes row and column address bits onto 16 memory address signals and 3 logical bank select signals, a physical bank may be implemented with memory devices requiring fewer than 32 address bits. The physical bank may be configured to provide from 12 to 15 row address bits, plus 3 logical bank-select bits and from 8–11 column address bits. **Table 12-2** describes DDR SDRAM device configurations supported by the DDR memory controller.

Note: DDR SDRAM is limited to 30 total address bits.

Table 12-2. Supported DDR3 SDRAM Device Configurations

SDRAM Device	Device Configuration	Row x Column x Sub-bank Bits	64-Bit Bank Size	Two Banks of Memory
1 Gbits	128 Mbits x 8	14 x 10 x 3	1 Gbyte	2 Gbytes
1 Gbits	64 Mbits x 16	13 x 10 x 3	512 Mbytes	1 Gbytes
2 Gbits	256Mbits x 8	15 x 10 x 3	2 Gbytes	—
2 Gbits	128Mbits x 16	14 x 10 x 3	1 Gbyte	2 Gbytes
4 Gbits	512Mbits x 8	16 x 10 x 3	—	—
4 Gbits	256Mbits x 16	15 x 10 x 3	2 Gbytes	—
Note: The MSC8157E controller supports a total of 2 Gbyte of DDR SDRAM using one or two banks of memory.				

If a transaction request is issued to the DDR memory controller and the address does not lie within any of the programmed address ranges for an enabled chip select, a memory select error is flagged. Errors are described in detail in **Section 12.3.14**, *Error Management*.

By using a memory-polling algorithm at power-on reset or by querying the JEDEC serial presence detect capability of memory modules, system firmware uses the memory-boundary registers to configure the DDR memory controller to map the size of each bank in memory. The memory controller uses its bank map to assert the appropriate $\overline{\text{MCS}}n$ signal for memory accesses according to the provided bank starting and ending addresses. The memory banks are not required to be mapped to a contiguous address space.

12.3.3 DDR SDRAM Address Multiplexing

Table 12-4 shows the address bit encodings for each DDR SDRAM configuration. The address presented at the memory controller signals MA[15:0] use MA[15] as the msb and MA[0] as the lsb. Also, MA[10] is used as the auto-precharge bit in DDR3 mode for reads and writes, so the column address can never use MA[10].

Chip select interleaving is supported for the memory controller, and is programmed in DDR_SDRAM_CFG[BA_INTLV_CTL]. Interleaving is supported between chip selects 0 and 1. When interleaving is enabled, the chip selects being interleaved must use the same size of memory. One extra bit in the address decode is used for the interleaving to determine which chip select to access.

Table 12-5 illustrates examples of address decode when interleaving between two chip selects.

Partial Array Self Refresh (PASR) can be enabled for any chip select using the CS*n*_CONFIG_2[PASR_CFG] fields. If PASR is enabled for a given chip select, then the sub-bank and row decode is swapped, and the sub-bank is decoded as the most significant portion of the DRAM address, as shown in **Table 12-6**. If chip select interleaving and PASR are enabled for a chip select, then the interleaved chip select bit is placed immediately to the left of the column decode, as shown in **Table 12-7**.

12.3.4 JEDEC Standard DDR SDRAM Interface Commands

This section describes the commands and timings the controller uses when operating in DDR3 mode. All read or write accesses to DDR SDRAM are performed by the DDR memory controller using JEDEC standard DDR SDRAM interface commands. The SDRAM device samples command and address inputs on rising edges of the memory clock; data is sampled using both the rising and falling edges of DQS. Data read from the DDR SDRAM is also sampled on both edges of DQS.

The following DDR SDRAM interface commands (summarized in **Table 12-8**) are provided by the DDR controller. All actions for these commands are described from the perspective of the SDRAM device.

- Row activate—Latches row address and initiates memory read of that row. Row data is latched in SDRAM sense amplifiers and must be restored by a precharge command before another row activate occurs.
- Precharge—Restores data from the sense amplifiers to the appropriate row. Also initializes the sense amplifiers in preparation for reading another row in the memory array, (performing another activate command). Precharge must occur after read or write, if the row address changes on the next open page mode access.
- Read—Latches column address and transfers data from the selected sense amplifier to the output buffer as determined by the column address. During each succeeding clock edge, additional data is driven without additional read commands. The amount of data transferred is determined by the burst size, which is set to 8 by the DDR controller.
- Write—Latches column address and transfers data from the data pins to the selected sense amplifier as determined by the column address. During each succeeding clock edge, additional data is transferred to the sense amplifiers from the data pins without additional write commands. The amount of data transferred is determined by the data masks and the burst size, which is set to 8 by the DDR memory controller.

- Refresh (similar to $\overline{\text{MCAS}}$ before $\overline{\text{MRAS}}$)—Causes a row to be read in all logical banks (JEDEC SDRAM) as determined by the refresh row address counter. This refresh row address counter is internal to the SDRAM. After being read, the row is automatically rewritten in the memory array. All logical banks must be in a precharged state before executing a refresh. The memory controller also supports posted refreshes, where several refreshes may be executed at once, and the refresh interval may be extended.
- Mode register set (for configuration)—Allows setting of DDR SDRAM options. These options are: $\overline{\text{MCAS}}$ latency, additive latency (for DDR3), write recovery (for DDR3), burst type, and burst length. $\overline{\text{MCAS}}$ latency may be chosen as provided by the preferred SDRAM (some SDRAMs provide $\overline{\text{MCAS}}$ latency {1,2,3}, some provide $\overline{\text{MCAS}}$ latency {1,2,3,4,5}, etc.). Burst type is always sequential. Although some SDRAMs provide burst lengths of 1, 2, 4, 8, and page size, this memory controller supports a burst length of 4. A burst length of 8 is supported for DDR3 memory only. The mode register set command is performed by the DDR memory controller during system initialization. Parameters such as mode register data, $\overline{\text{MCAS}}$ latency, burst length, and burst type, are set by software in DDR_SDRAM_MODE[SDMODE] and transferred to the SDRAM array by the DDR memory controller after DDR_SDRAM_CFG[MEM_EN] is set. If DDR_SDRAM_CFG[BI] is set to bypass the automatic initialization, then the MODE registers can be configured through software via use of the DDR_SDRAM_MD_CNTL register.
- Self refresh (for long periods of standby)—Used when the device is in standby for very long periods of time. Automatically generates internal refresh cycles to keep the data in all memory banks refreshed. Before execution of this command, the DDR controller will place all logical banks in a precharged state.

Table 12-8. DDR SDRAM Command Table

Operation	CKE Prev.	CKE Current	$\overline{\text{MCS}}$	$\overline{\text{MRAS}}$	$\overline{\text{MCAS}}$	$\overline{\text{MWE}}$	MBA	MA10	MA
Activate	H	H	L	L	H	H	Logical bank select	Row	Row

12.3.5 DDR SDRAM Interface Timing

The DDR memory controller supports eight-beat bursts to SDRAM. For single-beat reads, the DDR memory controller performs an eight-beat burst read, but ignores the last seven beats. Single-beat writes are performed by masking the last seven beats of the eight beat burst using the data mask MDM[0:8]. If ECC is disabled, writes smaller than 64 bits are performed by appropriately activating the data mask. If ECC is enabled, the controller performs a read-modify write.

Note: If a second read or write is pending, reads shorter than eight beats are not terminated early even if some data is irrelevant.

To accommodate available memory technologies across a wide spectrum of operating frequencies, the DDR memory controller allows the setting of the intervals defined in **Table 12-9** with granularity of one memory clock cycle, except for CASLAT, which can be programmed with 1/2 clock granularity.

Table 12-9. DDR SDRAM Interface Timing Intervals

Timing Intervals	Definition
ACTTOACT	The number of clock cycles from a bank-activate command until another bank-activate command within a physical bank. This interval is listed in the AC specifications of the SDRAM as t_{RRD}.
ACTTOPRE	The number of clock cycles from an activate command until a precharge command is allowed. This interval is listed in the AC specifications of the SDRAM as t_{RAS}.
ACTTORW	The number of clock cycles from an activate command until a read or write command is allowed. This interval is listed in the AC specifications of the SDRAM as t_{RCD}.
BSTOPRE	The number of clock cycles to maintain a page open after an access. The page open duration counter is reloaded with BSTOPRE each time the page is accessed (including page hits). When the counter expires, the open page is closed with a SDRAM precharge bank command as soon as possible.
CASLAT	Used in conjunction with additive latency to obtain the READ latency. The number of clock cycles between the registration of a READ command by the SDRAM and the availability of the first piece of output data. If a READ command is registered at clock edge n, and the read latency is m clocks, the data is available nominally coincident with clock edge $n + m$.
PRETOACT	The number of clock cycles from a precharge command until an activate or a refresh command is allowed. This interval is listed in the AC specifications of the SDRAM as t_{RP}.
REFINT	Refresh interval. Represents the number of memory bus clock cycles between refresh cycles. Depending on DDR_SDRAM_CFG_2[NUM_PR], some number of rows are refreshed in each SDRAM bank during each refresh cycle. The value of REFINT depends on the specific SDRAMs used and the frequency of the interface as t_{RP}.

Table 12-9. DDR SDRAM Interface Timing Intervals (Continued)

Timing Intervals	Definition
REFREC	The number of clock cycles from the refresh command until an activate command is allowed. This can be calculated by referring to the AC specification of the SDRAM device. The AC specification indicates a maximum refresh to activate interval in nanoseconds. This field is also combined with TIMING_CFG_3[EXT_REFREC]
WR_DATA_DELAY	Provides different options for the timing between a write command and the write data strobe. This allows write data to be sent later than the nominal time to meet the SDRAM timing requirement between the registration of a write command and the reception of a data strobe associated with the write command. The specification dictates that the data strobe may not be received earlier than 75% of a cycle, or later than 125% of a cycle, from the registration of a write command. This parameter is not defined in the SDRAM specification. It is implementation-specific, defined for the DDR memory controller in TIMING_CFG_2.
WRREC	The number of clock cycles from the last beat of a write until a precharge command is allowed. This interval, write recovery time, is listed in the AC specifications of the SDRAM as t_{WR}.
WRTORD	Last write pair to read command. Controls the number of clock cycles from the last write data pair to the subsequent read command to the same bank as t_{WTR}.

The value of the parameters listed in **Table 12-9** (in whole clock cycles) must be configured by boot code at system start-up (in the TIMING_CFG_0, TIMING_CFG_1, TIMING_CFG_2, and TIMING_CFG_3 registers as described in **Section 12.5.5**, *DDR SDRAM Timing Configuration Register 0 (TIMING_CFG_0)*, **Section 12.5.6**, *DDR SDRAM Timing Configuration Register 1 (TIMING_CFG_1)*, **Section 12.5.7**, *DDR SDRAM Timing Configuration Register 2 (TIMING_CFG_2)*, and **Section 12.5.4**, *DDR SDRAM Timing Configuration 3 Register (TIMING_CFG_3)*) and be kept in the DDR memory controller configuration register space.

The following figures show SDRAM timing for various types of accesses. System software is responsible (at reset) for optimally configuring SDRAM timing parameters. The programmable timing parameters apply to both read and write timing configuration. The configuration process must be completed and the DDR SDRAM initialized before any accesses to SDRAM are attempted.

Figure 12-6 through **Figure 12-8** show DDR SDRAM timing for various types of accesses; see **Figure 12-6** for a single-beat read operation, **Figure 12-7** for a single-beat write operation, and **Figure 12-8** for a burst-write operation. Note that all signal transitions occur on the rising edge of the memory bus clock and that single-beat read operations are identical to burst-reads. These figures assume the CLK_ADJUST is set to 1/2 DRAM cycle, an additive latency of 0 DRAM cycles is used, and the write latency is 1 DRAM cycle.

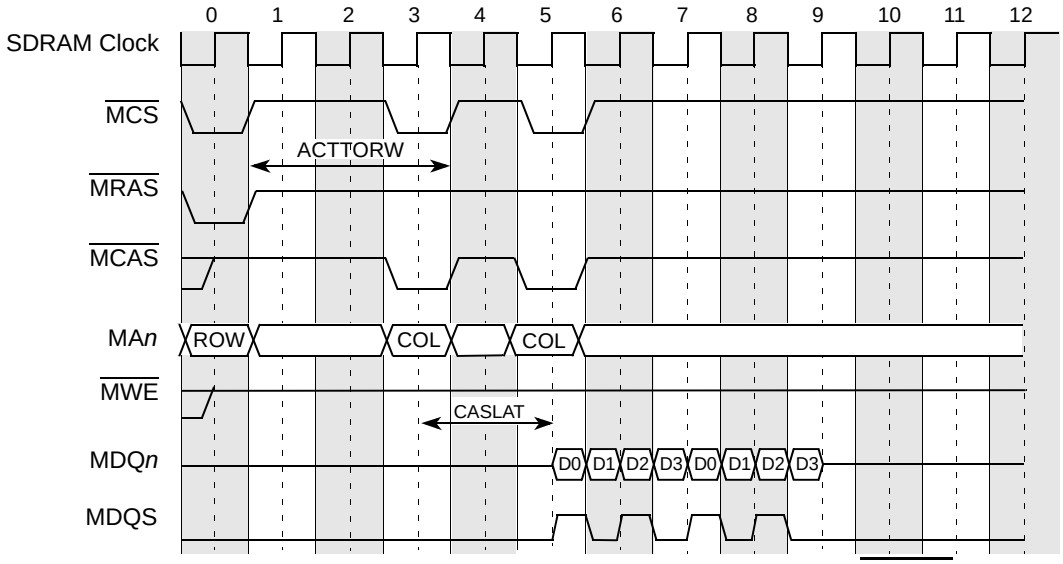

Figure 12-6. DDR SDRAM Burst Read Timing—ACTTORW = 3, MCAS Latency = 2

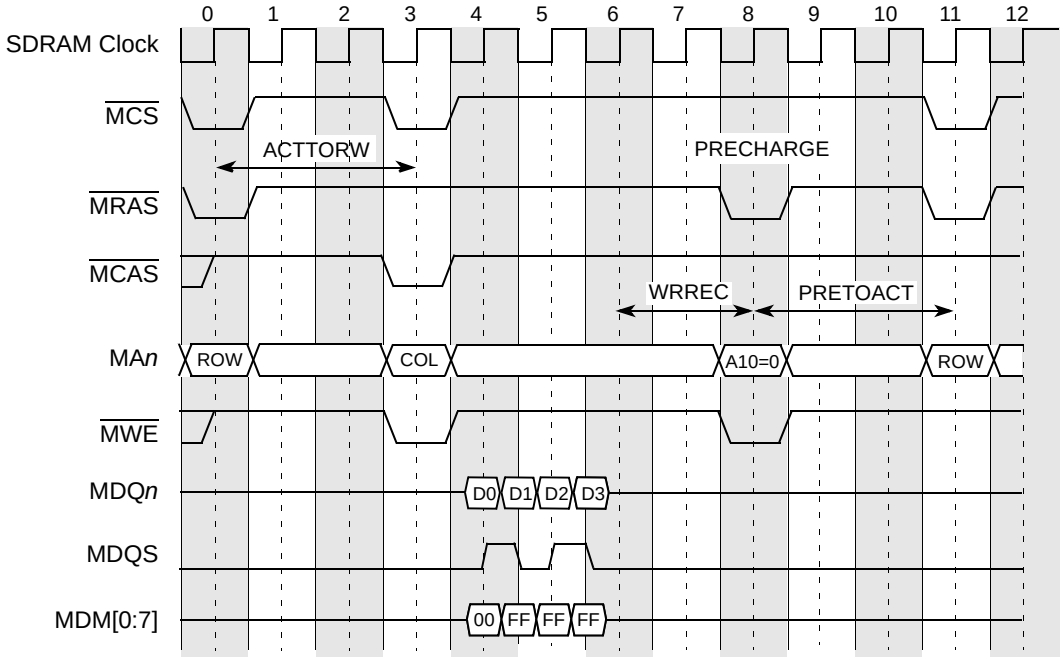

Figure 12-7. DDR SDRAM Single-Beat (64 bit) Write Timing—ACTTORW = 3

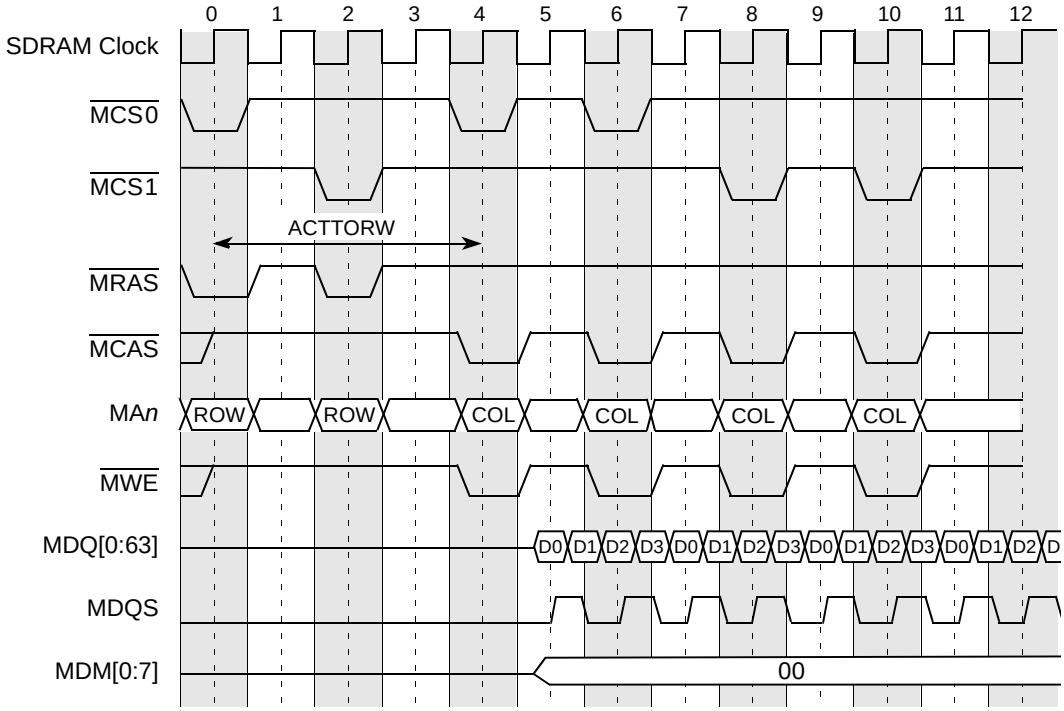

Figure 12-8. DDR SDRAM 4-Beat Burst Write Timing—ACTTORW = 4

12.3.6 Clock Distribution

Use the following recommendations for clock distribution:

- If running with many devices, zero-delay PLL clock buffers, JEDEC-JESD82 standard, should be used. These buffers were designed for DDR applications.
- A 72 bit × 2 Gbytes DDR bank has 9-byte-wide DDR chips, In this case, each MCK/$\overline{\text{MCK}}$ signal pair should drive exactly three devices.
- PCB traces for DDR clock signals should be short, all on the same layer, and of equal length and loading.
- DDR SDRAM manufacturers provide detailed information on PCB layout and termination issues.

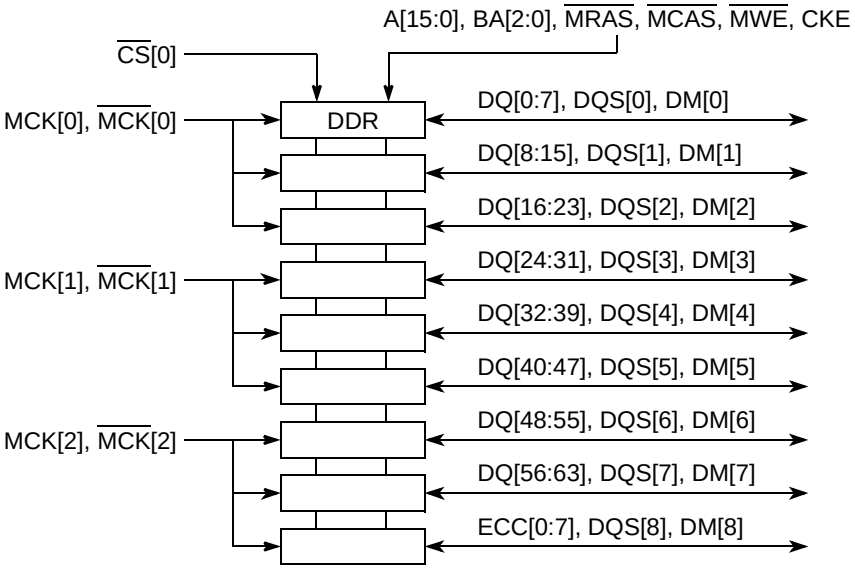

Figure 12-9. DDR SDRAM Clock Distribution Example for x8 DDR SDRAMs

12.3.7 DDR SDRAM Mode-Set Command Timing

The DDR memory controller transfers the mode register set commands to the SDRAM array, and it uses the setting of TIMING_CFG_0[MRS_CYC] for the Mode Register Set cycle time.

Figure 12-10 shows the timing of the mode-set command. The first transfer corresponds to the ESDMODE code; the second corresponds to SDMODE. The Mode Register Set cycle time is set to 2 DRAM cycles.

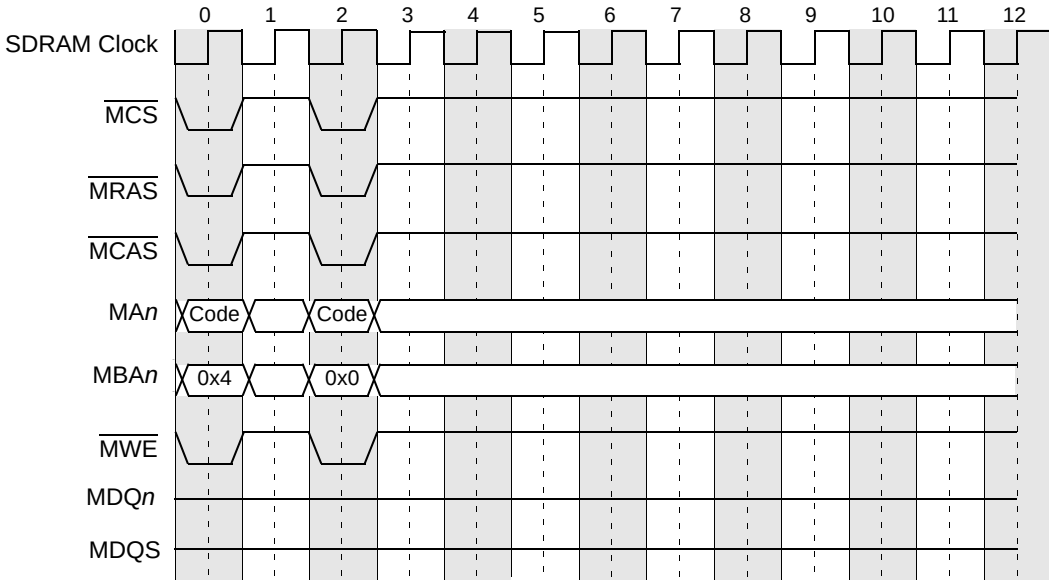

Figure 12-10. DDR SDRAM Mode-Set Command Timing

12.3.8 DDR SDRAM Registered DIMM Mode

To reduce loading, registered DIMMs latch the DDR SDRAM control signals internally before using them to access the array. Setting DDR_SDRAM_CFG[RD_EN] compensates for this delay on the DIMM control bus by delaying the data and data mask writes (on SDRAM buses) by an extra SDRAM clock cycle.

Note: Application system board must assert the reset signal on DDR memory devices until software is able to program the DDR memory controller configuration registers, and must deassert the reset signal on DDR memory devices before DDR_SDRAM_CFG[MEM_EN] is set. This ensures that the DDR memory devices are held in reset until a stable clock is provided and, further, that a stable clock is provided before memory devices are released from reset.

Figure 12-11 shows the registered DDR SDRAM DIMM single-beat write timing.

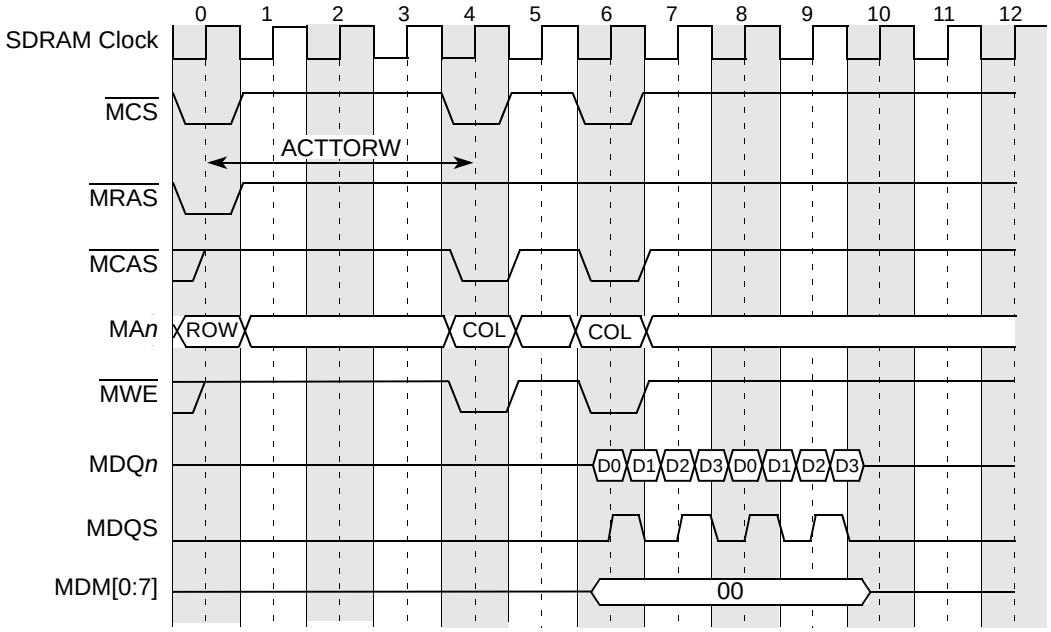

Figure 12-11. Registered DDR SDRAM DIMM Burst Write Timing

Use the following steps if RC10 must be modified to allow higher frequency operation for registered DIMMS (RDIMMs). These steps replace the Automatic DIMM Register Control Word update sequence enabled by DDR_SDRAM_CFG_2[RCW_EN]. The Automatic DIMM Register Control Word update sequence can be used if RC10 does not require an update.

1. Write all DDR registers, but leave DDR_SDRAM_CFG[MEM_EN] cleared. Note that address parity should also be enabled if writing to the RCWs.
2. Disable automatic CPO by ensuring that TIMING_CFG_2[CPO] is not set to all 1s.
3. Write 0x00000400 to the register at address 0xFFF20F08.
4. Disable ZQ calibration by clearing DDR_ZQ_CNTL[ZQ_EN].

5. Disable write levelling by clearing DDR_WRLVL_CNTL[WRLVL_EN].
6. Disable the automatic RCW sequence by clearing DDR_SDRAM_CFG_2[RCW_EN].
7. Ensure that DDR_SDRAM_CFG_2[D_INIT] is cleared and the memory test is disabled (DDR_MTCR[MT_EN] is cleared).
8. Write 0x00000015 to the register at address 0xFFF20F30.
9. Write 0x24000000 to the register at address 0xFFF20F54.
10. Disable refreshes by clearing DDR_SDRAM_INTERVAL[REFINT].
11. Set DDR_SDRAM_CFG[BI].
12. Enable the DDR controller by setting DDR_SDRAM_CFG[MEM_EN].
13. Poll until bit 1 of the register at address 0xFFF20F04 is asserted by hardware. This indicates that the controller is idle.
14. Use the DDR_SDRAM_MD_CNTL register to write RC10 for any DIMMs that are used. Note that if two registered DIMM modules are used, this requires two separate writes to the DDR_SDRAM_MD_CNTL register. Ensure that either a decoding of 0b100 or 0b101 is used for the CS_SEL field, and WRCW should be set by the controller. After each write to the DDR_SDRAM_MD_CNTL register, DDR_SDRAM_MD_CNTL[MD_EN] should be polled until it is cleared by hardware.
15. Wait for t_{STAB} as defined by the register specifications.
16. Clear DDR_SDRAM_CFG[MEM_EN].
17. Clear DDR_SDRAM_CFG[MEM_EN].
18. Restore all registers back to the original settings. This may also include enabling DDR_SDRAM_CFG_2[RCW_EN] if more RCWs will be modified. If this bit is set, ensure that DDR_SDRAM_RCW_2[RCW10] is programmed to provide the same value as that programmed via the DDR_SDRAM_MD_CNTL register in step 14.
19. Set DDR_SDRAM_CFG[MEM_EN].
20. The DDR controller should now be operational.

12.3.9 DDR SDRAM Write Timing Adjustments

The DDR memory controller facilitates system design flexibility by providing a write timing adjustment parameter, write data delay, (TIMING_CFG_2[WR_DATA_DELAY]) for data and DQS. The DDR SDRAM specification requires DQS be received no sooner than 75% of an SDRAM clock period—and no later than 125% of a clock period—from the capturing clock edge of the command/address at the SDRAM. The WR_DATA_DELAY parameter may be used to meet this timing requirement for a variety of system configurations, ranging from a system with one DIMM to a fully populated system with two DIMMs.
TIMING_CFG_2[WR_DATA_DELAY] specifies how much to delay the launching of DQS and

data from the first clock edge occurring one SDRAM clock cycle after the command is launched. The delay increment step sizes are in 1/4 SDRAM clock periods starting with the default value of 0. **Figure 12-12** shows the use of the WR_DATA_DELAY parameter.

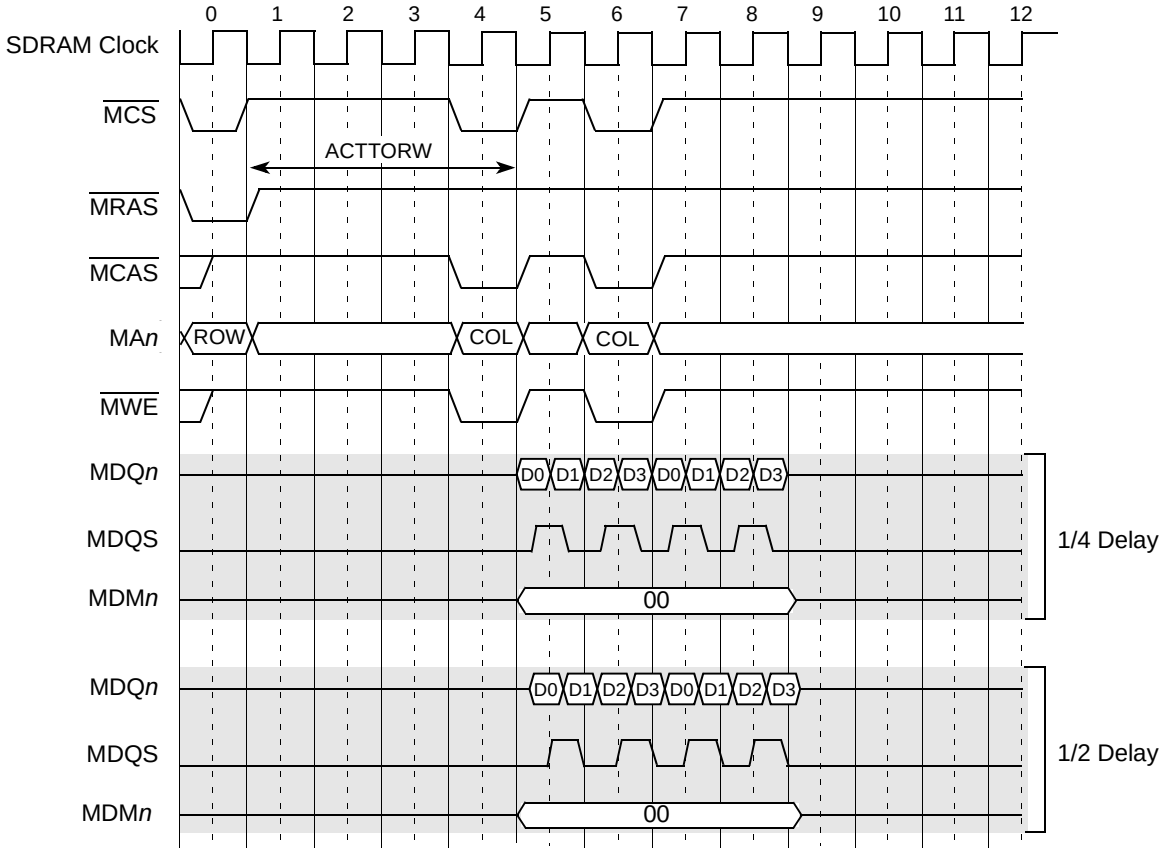

Figure 12-12. Write Timing Adjustments Example for Write Latency = 1

12.3.10 DDR SDRAM Refresh

The DDR memory controller supports auto-refresh and self-refresh. Auto refresh is used during normal operation and is controlled by the DDR_SDRAM_INTERVAL[REFINT] value; self-refresh is used only when the DDR memory controller is set to enter a sleep power management state. The REFINT value, which represents the number of memory bus clock cycles between refresh cycles, must allow for possible outstanding transactions to complete before a refresh request is sent to the memory after the REFINT value is reached. If a memory transaction is in progress when the refresh interval is reached, the refresh cycle waits for the transaction to complete. In the worst case, the refresh cycle must wait the number of bus clock cycles required by the longest programmed access. To ensure that the latency caused by a memory transaction does not violate the device refresh period, it is recommended that the programmed value of REFINT be less than that required by the SDRAM.

When a refresh cycle is required, the DDR memory controller does the following:

1. Completes all current memory requests.
2. Closes all open pages with a PRECHARGE-ALL command to each DDR SDRAM bank with an open page (as indicated by the row open table).
3. Issues one or more auto-refresh commands to each DDR SDRAM bank (as identified by its chip select) to refresh one row in each logical bank of the selected physical bank.

The auto-refresh commands are staggered across the two possible banks to reduce the system instantaneous power requirements. Two sets of auto refresh commands will be issued on consecutive cycles when the memory is fully populated with two DIMMs. The initial PRECHARGE-ALL commands are also staggered in two groups for convenience. It is important to note that when entering self-refresh mode, only one refresh command is issued simultaneously to all physical banks. For this entire refresh sequence, no cycle optimization occurs. After the refresh sequence completes, any pending memory request is initiated after an inactive period specified by TIMING_CFG_1 [REFREC] and TIMING_CFG_3[EXT_REFREC]. In addition, posted refreshes are supported to allow the refresh interval to be set to a larger value.

12.3.10.1 DDR SDRAM Refresh Timing

Refresh timing for the DDR SDRAM is controlled by the programmable timing parameter TIMING_CFG_1 [REFREC], which specifies the number of memory bus clock cycles from the refresh command until a logical bank activate command is allowed. The DDR memory controller implements bank staggering for refreshes, as shown in **Figure 12-13** (TIMING_CFG_1 [REFREC] = 10 in this example).

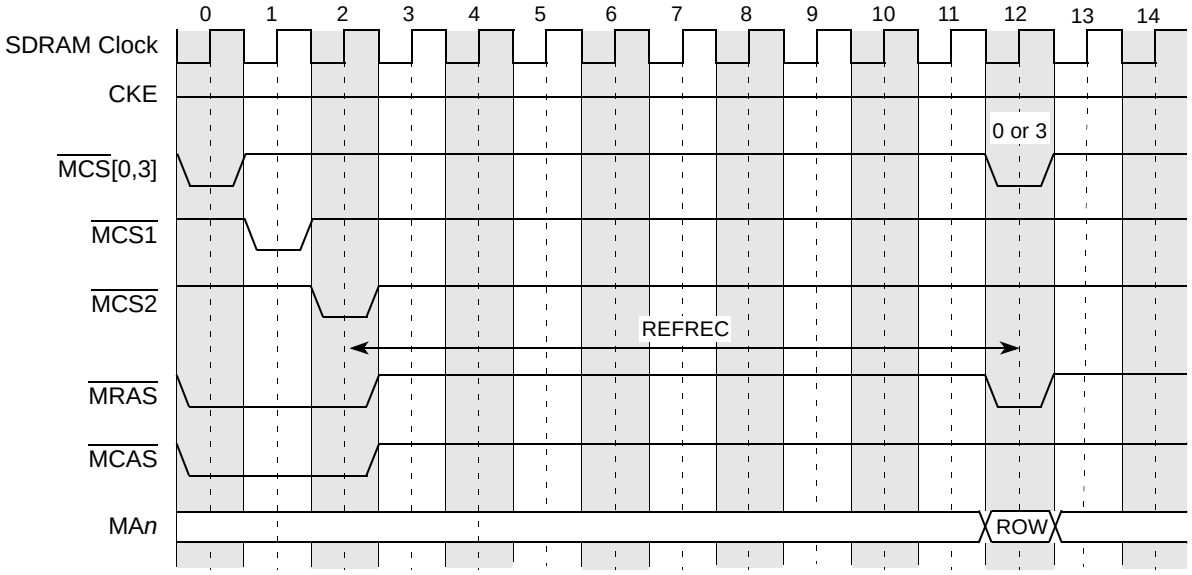

Figure 12-13. DDR SDRAM Bank Staggered Auto Refresh Timing

System software is responsible for optimal configuration of TIMING_CFG_1 [REFREC] and TIMING_CFG_3[EXT_REFREC] at reset. Configuration must be completed before DDR SDRAM accesses are attempted.

12.3.10.2 DDR SDRAM Refresh and Power-Saving Modes

In full-on mode, the DDR memory controller supplies the normal auto refresh to SDRAM. In sleep mode, the DDR memory controller can be configured to take advantage of self-refreshing SDRAMs or to provide no refresh support. Self-refresh support is enabled with the SREN memory control parameter.

Table 12-10 summarizes the refresh types available in each power-saving mode.

Table 12-10. DDR SDRAM Power-Saving Modes Refresh Configuration

Power Saving Mode	Refresh Type	SREN
Sleep	Self	1
	None	—

Note that in the absence of refresh support, system software must preserve DDR SDRAM data (such as by copying the data to disk) before entering the power-saving mode.

The dynamic power-saving mode uses the CKE DDR SDRAM pin to dynamically power down when there is no system memory activity. The CKE pin is negated when both of the following conditions are met:

- No memory refreshes are scheduled
- No memory accesses are scheduled

CKE is reasserted when a new access or refresh is scheduled or the dynamic power mode is disabled. This mode is controlled with DDR_SDRAM_CFG[DYN_PWR_MGMT].

Dynamic power management mode offers tight control of the memory system's power consumption by trading power for performance through the use of CKE. Powering up the DDR SDRAM when a new memory reference is scheduled causes an access latency penalty, depending on whether active or precharge powerdown is used, along with the settings of TIMING_CFG_0[ACT_PD_EXIT] and TIMING_CFG_0[PRE_PD_EXIT]. A penalty of 1 cycle is shown in **Figure 12-14**.

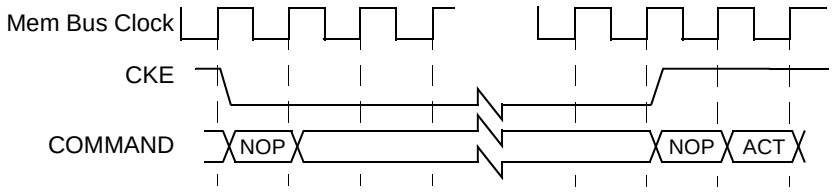

Figure 12-14. DDR SDRAM Power-Down Mode

12.3.10.3 Self-Refresh in Sleep Mode

The entry and exit timing for self-refreshing SDRAMs is shown in **Figure 12-15** and **Figure 12-16**.

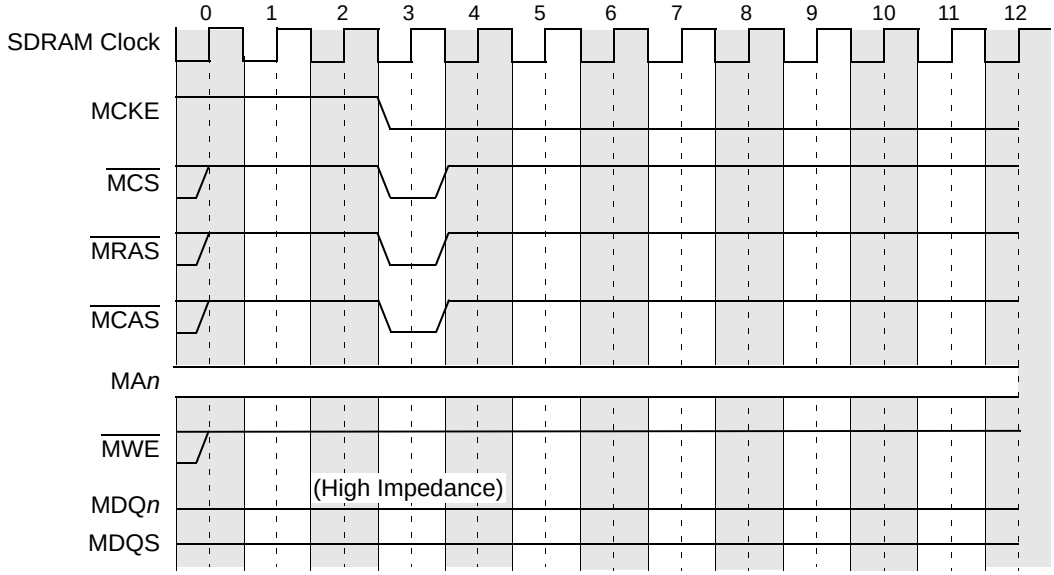

Figure 12-15. DDR SDRAM Self-Refresh Entry Timing

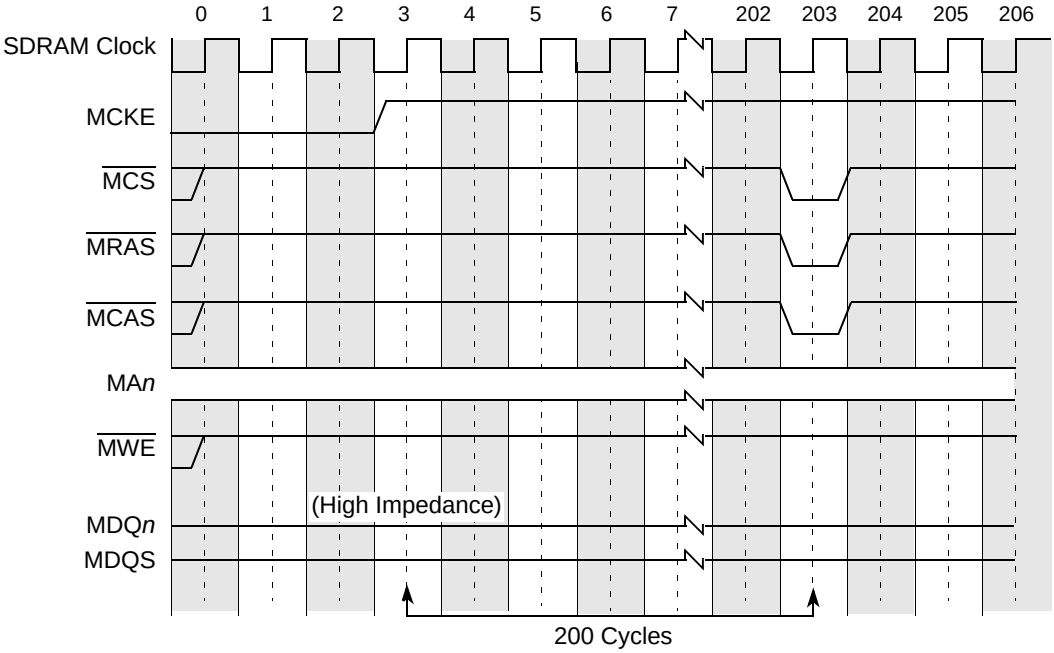

Figure 12-16. DDR SDRAM Self-Refresh Exit Timing

12.3.11 DDR Data Beat Ordering

Transfers to and from memory are always performed in eight-beat bursts (eight beats = 64 bytes when a 64-bit bus is used). For transfer sizes other than eight beats, the data transfers are still operated as eight-beat bursts. If ECC is enabled and either the access is not 64-bit aligned or the size is not a multiple of a 64 bits, a full read-modify-write is performed for a write to SDRAM. If ECC is disabled or both the access is 64-bit aligned with a size that is a multiple of a 64-bits, the data masks (MDM[0:8] (MDM[0:4] for 32-bit bus) can be used to prevent the writing of unwanted data to SDRAM. The DDR memory controller also uses data masks to prevent all unintended full 64 bits from writing to SDRAM. For example, if a write transaction is desired with a size of 64 bits (8 bytes), then the second to seventh beats of data are not written to DRAM.

All writes for DDR3 mode are aligned to beat 0 of the DRAM.

12.3.12 Page Mode and Logical Bank Retention

The DDR memory controller supports an open/closed page mode with an allowable open page for each logical bank of DRAM used. In closed page mode for DDR SDRAMs, the DDR memory controller uses the SDRAM auto-precharge feature, which allows the controller to indicate that the page must be automatically closed by the DDR SDRAM after the READ or WRITE access. This is performed by using MA[10] of the address during the COMMAND phase of the access to enable auto-precharge. Auto-precharge is non-persistent in that it is either enabled or disabled for each individual READ or WRITE command. It can, however, be enabled or disabled separately for each chip select.

When the DDR memory controller operates in open page mode, it retains the currently active SDRAM page by not issuing a precharge command. The page remains opens until one of the following conditions occurs:

- Refresh interval is met.
- The user-programmable DDR_SDRAM_INTERVAL[BSTOPRE] value is exceeded.
- There is a logical bank row collision with another transaction that must be issued.

Page mode can dramatically reduce access latencies for page hits. Depending on the memory system design and timing parameters, using page mode can save two to three clock cycles for subsequent burst accesses that hit in an active page. Also, better performance can be obtained by using more banks, especially in systems which use many different channels. Page mode is disabled by clearing DDR_SDRAM_INTERVAL[BSTOPRE] or setting CSn_CONFIG[AP_nEN].

12.3.13 Error Checking and Correcting (ECC)

The DDR memory controller supports error checking and correcting (ECC) for the data path between the core master and system memory. The memory detects all double-bit errors, detects

all multi-bit errors within a nibble, and corrects all single-bit errors. Other errors may be detected, but are not guaranteed to be corrected or detected. Double-bit errors are always reported when error reporting is enabled. When a single-bit error occurs, the single-bit error counter register is incremented, and its value compared to the single-bit error trigger register. An error is reported when these values are equal. The single-bit error registers can be programmed such that minor memory faults are corrected and ignored, but a catastrophic memory failure generates an interrupt.

For writes that are smaller than 64 bits, the DDR memory controller performs a double-word read from system memory of the address for the write (checking for errors), and merges the write data with the data read from memory. Then, a new ECC code is generated for the merged 64 bits. The data and ECC code is then written to memory. If a multi-bit error is detected on the read, the transaction completes the read-modify-write to keep the DDR memory controller from hanging. However, the corrupt data is masked on the write, so the original contents in SDRAM remain unchanged.

The syndrome encodings for the ECC code are shown in **Table 12-11** and **Table 12-12**.

Table 12-11. DDR SDRAM ECC Syndrome Encoding

12.3.14 Error Management

The DDR memory controller detects four different kinds of errors: training, single-bit, multi-bit, and memory select errors. The following discussion assumes all the relevant error detection, correction, and reporting functions are enabled as described in **Section 12.5.43**, *DDR SDRAM Memory Error Detect Register (ERR_DETECT)*, **Section 12.5.44**, *DDR SDRAM Memory Error Disable Register (ERR_DISABLE)*, and **Section 12.5.45**, *DDR SDRAM Memory Error Interrupt Enable Register (ERR_INT_EN)*.

Single-bit errors are counted and reported based on the ERR_SBE value. When a single-bit error is detected, the DDR memory controller does the following:

- Corrects the data
- Increments the single-bit error counter ERR_SBE[SBEC]

- Generates a critical interrupt if the counter value ERR_SBE[SBEC] equals the programmable threshold ERR_SBE[SBET]
- Completes the transaction normally

If a multi-bit error is detected for a read, the DDR memory controller logs the error and generates the machine check or critical interrupt (if enabled, as described in **Section 12.5.44**, *DDR SDRAM Memory Error Disable Register (ERR_DISABLE)*). Another error the DDR memory controller detects is a memory select error, which causes the DDR memory controller to log the error and generate a critical interrupt (if enabled, as described in **Section 12.5.43**, *DDR SDRAM Memory Error Detect Register (ERR_DETECT)*). This error is detected if the address from the memory request does not fall into any of the enabled, programmed chip select address ranges. For all memory select errors, the DDR memory controller does not issue any transactions onto the pins after the first read has returned data strobes. If the DDR memory controller is not using sample points, then a dummy transaction is issued to DDR SDRAM with the first enabled chip select. In this case, the source port on the pins is forced to 0x1F to show the transaction is not real. **Table 12-13** shows the errors with their descriptions. The final error the memory controller detects is the automatic calibration error. This error is set if the memory controller detects an error during its training sequence.

Table 12-13. Memory Controller Errors

Category	Error	Descriptions	Action	Detect Register
Notification	Single-bit ECC threshold	The number of ECC errors has reached the threshold specified in the ERR_SBE.	The error is reported via machine check or critical interrupt if enabled.	The error control register only logs read versus write, not full type
Access Error	Multi-bit ECC error	A multi-bit ECC error is detected during a read, or read-modify-write memory operation.		
	Memory select error	Read, or write, address does not fall within the address range of any of the memory banks.		

12.4 Initialization/Application Information

System software must configure the DDR memory controller, using a memory polling algorithm at system start-up, to correctly map the size of each bank in memory. Then, the DDR memory controller uses its bank map to assert the appropriate $\overline{\text{MCS}n}$ signal for memory accesses according to the provided bank depths. System software must also configure the DDR memory controller at system start-up to appropriately multiplex the row and column address bits for each bank. Refer to row-address configuration in **Section 12.5.2**, *Chip-Select x Configuration Register (CSx_CONFIG)*. Address multiplexing occurs according to these configuration bits.

At system reset, initialization software (boot code) must set up the programmable parameters in the memory interface configuration registers. See **Section 12.5**, *Memory Controller Programming Model*, on page 12-33 for detailed descriptions of the configuration registers. These parameters are shown in **Table 12-14**.

Table 12-14. Memory Interface Configuration Register Initialization Parameters

Name	Description	Parameter	Section/Page
CSn_BNDS	Chip select memory bounds	SAn EAn	12.5.1/12-35
CSn_CONFIG	Chip select configuration	CS_n_EN AP_n_EN ODT_RD_CFG ODT_WR_CFG BA_BITS_CS_n ROW_BITS_CS_n COL_BITS_CS_n	12.5.2/12-36

12.4.1 Programming Summary

Depending on the memory type used, certain fields must be programmed differently. **Table 12-15** illustrates the differences in certain fields for different memory types. Note: This table does not list all fields that must be programmed.

Table 12-15. DDR3 Programming Summary

Parameter	Description	Summary	Section/page
AP*n*_EN	Chip Select *n* Auto Precharge Enable	Can be used to place chip select *n* in auto precharge mode	12.5.2/12-36
ODT_RD_CFG	Chip Select ODT Read Configuration	Can be enabled to assert ODT if desired. This could be set differently depending on system topology. However, systems with only 1 chip select will typically not use ODT when issuing reads to the memory.	12.5.2/12-36
ODT_WR_CFG	Chip Select ODT Write Configuration	Can be enabled to assert ODT if desired. This could be set differently depending on system topology. However, ODT will typically be set to assert for the chip select that is getting written to (value would be set to 001).	12.5.2/12-36
ODT_PD_EXIT	ODT Powerdown Exit	Should be set to 0001 for DDR3. The powerdown times (t_{XP} and t_{XPDLL}) required for DDR3 are controlled via TIMING_CFG_0[ACT_PD_EXIT] and TIMING_CFG_0[PRE_PD_EXIT].	12.5.5/12-42
PRETOACT	Precharge to Activate Timing	Should be set according to the specifications for the memory used (t_{RP})	12.5.6/12-45
ACTTOPRE	Activate to Precharge Timing	Should be set, along with the Extended Activate to Precharge Timing, according to the specifications for the memory used (t_{RAS})	12.5.6/12-45
ACTTORW	Activate to Read/Write Timing	Should be set according to the specifications for the memory used (t_{RCD})	12.5.6/12-45
CASLAT	CAS Latency	Should be set, along with the Extended CAS Latency, to the desired CAS latency	12.5.6/12-45
REFREC	Refresh Recovery	Should be set, along with the Extended Refresh Recovery, to the specifications for the memory used (T_{RFC})	12.5.6/12-45
WRREC	Write Recovery	Should be set according to the specifications for the memory used (t_{WR}).	12.5.6/12-45
ACTTOACT	Activate *A* to Activate *B*	Should be set according to the specifications for the memory used (t_{RRD})	12.5.6/12-45

Table 12-15. DDR3 Programming Summary (Continued)

Parameter	Description	Summary	Section/page
WRTORD	Write to Read Timing	Should be set according to the specifications for the memory used (t_{WTR})	12.5.6/12-45
ADD_LAT	Additive Latency	Should be set to the desired additive latency. This must be set to a value less than TIMING_CFG_1[ACTTORW]	12.5.7/12-48
WR_LAT	Write Latency	Should be set to the desired write latency. Note that DDR3 SDRAMs do not necessarily require the write latency to equal the CAS latency minus 1 cycle. The minimum WR_LAT that can be used in 1T timing mode is 5 cycles if DDR_RATE=0	12.5.7/12-48
RD_TO_PRE	Read to Precharge Timing	Should be set according to the specifications for the memory used (t_{RTP}). Time between read and precharge for non-zero value of additive latency (AL) is a minimum of AL + t_{RTP} cycles.	12.5.7/12-48
CKE_PLS	Minimum CKE Pulse Width	Should be set according to the specifications for the memory used (t_{CKE})	12.5.7/12-48
FOUR_ACT	Four Activate Window	Should be set according to the specifications for the memory used (t_{FAW}).	12.5.7/12-48
RD_EN	Registered DIMM Enable	If registered DIMMs are used, then this field should be set to 1	12.5.8/12-51
8_BE	8-beat burst enable	If a 64-bit bus is used, this should be set to 0. Otherwise, this should be set to 1. If this is set to 0, then other requirements in TIMING_CFG_4 will be needed to ensure t_{CCD} is met.	12.5.8/12-51
2T_EN	2T Timing Enable	In heavily loaded systems, this can be set to 1 to gain extra timing margin on the interface at the cost of address/command bandwidth.	12.5.8/12-51
DLL_RST_DIS	DLL Reset Disable	Should be set to 1	12.5.9/12-54
DQS_CFG	DQS Configuration	Should be set to 01	12.5.9/12-54
ODT_CFG	ODT Configuration	Can be set for termination at the IOs according to system topology. Typically, if ODT is enabled, then the internal IOs should be set up for termination only during reads to DRAM.	12.5.9/12-54
RWT	Read-to-write turnaround for same chip select (in TIMING_CFG_4)	This can be used to force a longer read-to-write turnaround time when accessing the same chip select. This is useful for burst chop mode, as there are some timing requirements to the same chip select that still must be met.	12.5.18/12-66
WRT	Write-to-read turnaround for same chip select (in TIMING_CFG_4)	This could be used to force a certain turnaround time between a write and read to the same chip select. This is useful for burst chop mode. However, it is expected that TIMING_CFG_1[WRTORD] will be programmed appropriately such that TIMING_CFG_4[WRT] can be set to 0000.	12.5.18/12-66
RRT	Read-to-read turnaround for same chip select (in TIMING_CFG_4)	Should typically be set to 0100 in burst chop mode (on-the-fly or fixed).	12.5.18/12-66
WWT	Write-to-write turnaround for same chip select (in TIMING_CFG_4)	Should typically be set to 0100 in burst chop mode (on-the-fly or fixed).	12.5.18/12-66

Table 12-15. DDR3 Programming Summary (Continued)

Parameter	Description	Summary	Section/page
ZQ_EN	ZQ Calibration Enable	Should be set to 1. The other fields in DDR_ZQ_CNTL should also be programmed appropriately based on the DRAM specifications.	12.5.20/12-70
WRLVL_EN	Write Leveling Enable	Can be set to 1 if write leveling is desired. Otherwise the value used in TIMING_CFG_2[WR_DATA_DELAY] will be used to shift all bytes during writes to DRAM. If write leveling will be used, all other fields in DDR_WRLVL_CNTL should be programmed appropriately based on the DRAM specifications.	12.5.21/12-72
BSTOPRE	Burst To Precharge Interval	Can be set to any value, depending on the application. Auto precharge can be enabled by setting this field to all 0s.	12.5.13/12-61

12.4.2 DDR SDRAM Initialization Sequence

After configuration of all parameters is complete, system software must set DDR_SDRAM_CFG[MEM_EN] to enable the memory interface. Note that 200 µs (500 µs for DDR3) must elapse after DRAM clocks are stable (DDR_SDRAM_CLK_CNTL[CLK_ADJUST] is set and any chip select is enabled) before MEM_EN can be set, so a delay loop in the initialization code may be necessary if software is enabling the memory controller. If DDR_SDRAM_CFG[BI] is not set, the DDR memory controller will conduct an automatic initialization sequence to the memory, which will follow the memory specifications. If the bypass initialization mode is used, then software can initialize the memory through the DDR_SDRAM_MD_CNTL register.

Note: The DDR controller has an internal adjustment circuit use for automatic calibration. To prevent degradation of DDR transfer performance, disable this circuit before enabling the DDR memory using the following steps:

1. Write a value of 0x00000015 to the register at address 0xFFF20F30.
2. Write a value of 0x24000000 to the register at address 0xFFF20F54.

12.4.3 Self-Refresh Mode Usage

This section describes the options offered by this device to support battery-backed main memory.

12.4.3.1 Software Based Self-Refresh Scheme

The DDR controller also has a software-programmable bit, DDR_SDRAM_CFG_2[FRC_SR], that immediately puts main memory into self-refresh mode. See **Section 12.5.11, *DDR SDRAM Mode Configuration 2 Register (DDR_SDRAM_MODE_2)*** for a description of this register.

It is expected that a critical interrupt routine triggered by an external voltage sensing device will have time to set this bit.

12.4.3.2 Bypassing Re-initialization During Battery-Backed Operation

The DDR controller offers an initialization bypass feature (DDR_SDRAM_CFG[BI]), which system designers may use to prevent re-initialization of main memory during system power-on following an abnormal shutdown. See **Section 12.5.8**, *DDR SDRAM Control Configuration Register (DDR_SDRAM_CFG),*" for information on this bit and **Section 12.5.16**, *DDR SDRAM Initialization Address Register (DDR_INIT_ADDR)* for a discussion about avoiding possible ECC errors in this mode.

Note that the DDR controller will automatically wait 200 DRAM cycles before issuing any command after the assertion of MCKE[0:1] when this mode is used.

12.5 Memory Controller Programming Model

In the register figures and field descriptions, the following access definitions apply:

- Reserved fields are always ignored for the purposes of determining access type.
- Read/write, read only, and write only (R/W, R, and W, respectively) indicate that all the non-reserved fields in a register have the same access type.
- Non-reserved fields that are cleared by writing 1s to them are indicated by w1c.
- Mixed indicates a combination of access types.
- Special is used when no other category applies. For special access registers, read the figure and field descriptions very carefully.

The DDR memory controller registers are as follows:

- Chip-Select Memory Bounds Register (CSx_BNDS), **page 12-35**.
- Chip-Select Configuration Register (CSx_CONFIG), **page 12-36**.
- Chip-Select Configuration Register 2 (CSx_CONFIG_2), **page 12-38**
- DDR SDRAM Timing Configuration 3 Register (TIMING_CFG_3), **page 12-39**.
- DDR SDRAM Timing Configuration 0 Register (TIMING_CFG_0), **page 12-42**.
- DDR SDRAM Timing Configuration 1 Register (TIMING_CFG_1), **page 12-45**.
- DDR SDRAM Timing Configuration 2 Register (TIMING_CFG_2), **page 12-48**.
- DDR SDRAM Control Configuration Register (DDR_SDRAM_CFG), **page 12-51**.
- DDR SDRAM Control Configuration 2 Register (DDR_SDRAM_CFG_2), **page 12-54**.
- DDR SDRAM Mode Configuration Register (DDR_SDRAM_MODE), **page 12-57**.
- DDR SDRAM Mode Configuration 2 Register (DDR_SDRAM_MODE_2), **page 12-58**.
- DDR SDRAM Mode Control Register (DDR_SDRAM_MD_CNTL), **page 12-58**.
- DDR SDRAM Interval Configuration Register (DDR_SDRAM_INTERVAL), **page 12-61**.

- DDR SDRAM Data Initialization Register (DDR_DATA_INIT), **page 12-62**.
- DDR SDRAM Clock Control Configuration Register (DDR_SDRAM_CLK_CNTL), **page 12-63**.
- DDR Initialization Address Register (DDR_INIT_ADDRESS), **page 12-64**.
- DDR Initialization Enable Register (DDR_INIT_EN), **page 12-65**
- DDR SDRAM Timing Configuration 4 Register (TIMING_CFG_4), **page 12-66**
- DDR SDRAM Timing Configuration 5 Register (TIMING_CFG_5), **page 12-68**
- DDR ZQ Calibration Control Register (DDR_ZQ_CNTL), **page 12-70**
- DDR Write Levelling Control Register (DDR_WRLVL_CNTL), **page 12-72**
- DDR Write Levelling Control 2 Register (DDR_WRLVL_CNTL_2), **page 12-75**
- DDR Write Levelling Control 3 Register (DDR_WRLVL_CNTL_3), **page 12-78**
- DDR SDRAM Self Refresh Counter Register (DDR_SR_CNTR), **page 12-81**
- DDR SDRAM Register Control Words 1 Register (DDR_SDRAM_RCW_1), **page 12-82**
- DDR SDRAM Register Control Words 2 Register (DDR_SDRAM_RCW_2), **page 12-83**
- DDR Debug Status Register 1 (DDRDSR_1), **page 12-86**
- DDR Debug Status Register 2 (DDRDSR_2), **page 12-87**
- DDR Control Driver Register 1 (DDRCDR_1), **page 12-87**
- DDR Control Driver Register 2 (DDRCDR_2), **page 12-91**
- DDR IP Block Revision 1 Register (DDR_IP_REV1), **page 12-92**.
- DDR IP Block Revision 2 Register (DDR_IP_REV2), **page 12-92**.
- Memory Data Path Error Injection Mask High Register (DDR_ERR_INJECT_HI), **page 12-95**.
- Memory Data Path Error Injection Mask Low Register (DDR_ERR_INJECT_LO), **page 12-96**.
- Memory Data Path Error Injection Mask ECC Register (DDR_ERR_INJECT), **page 12-97**
- Memory Data Path Read Capture High Register (CAPTURE_DATA_HI), **page 12-98**.
- Memory Data Path Read Capture Low Register (CAPTURE_DATA_LO), **page 12-98**.
- Memory Data Path Read Capture ECC Register (CAPTURE_ECC), **page 12-99**.
- Memory Error Detect Register (ERR_DETECT), **page 12-99**.
- Memory Error Disable Register (ERR_DISABLE), **page 12-101**.
- Memory Error Interrupt Enable Register (ERR_INT_EN), **page 12-102**.
- Memory Error Attributes Capture Register (CAPTURE_ATTRIBUTES), **page 12-103**.
- Memory Error Address Capture Register (CAPTURE_ADDRESS), **page 12-104**.
- Single-Bit ECC Memory Error Management Register (ERR_SBE), **page 12-105**.

Note: DDR controller 1 (M1 registers) uses base address: 0xFFF20000

12.5.1 Chip-Select x Bounds Register (CSx_BNDS)

CS0_BNDS Chip-Select Bounds Register Offset 0x0000
CS1_BNDS 0x0008

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—								SAx							
Type	R/W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSx_BNDS define the starting and ending address of the memory space that corresponds to the individual chip selects.

Note: The size specified in CSx_BNDS should equal the size of physical DRAM. Also, note that EA*x* must be greater than or equal to SA*x*.

If chip select interleaving is enabled, all fields in the lower interleaved chip select are used, and the other chip select bounds registers are not used. For example, if chip selects 0 and 1 are interleaved, all fields in CS0_BNDS are used, and all fields in CS1_BNDS are not used.

Table 12-16. CSx_BNDS Field Descriptions

Bit	Reset	Description
— 31–24	0	Reserved. Cleared to zero for future compatibility.
SAx 23–16	0	**Starting Address** Specifies the starting address for chip-select (bank) *x.* This value is compared against the 8 MSBs of the 32-bit address.
— 15–8	0	Reserved. Cleared to zero for future compatibility.
EA*x* 7–0	*0*	**Ending Address** Specifies the ending address for chip select (bank) *x.* This value is compared against the 8 MSBs of the 32-bit address.

12.5.2 Chip-Select x Configuration Register (CSx_CONFIG)

CS0_CONFIG Chip-Select 0 Configuration Register Offset 0x0080
CS1_CONFIG Chip-Select 1 Configuration Register Offset 0x0084

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CS_x_EN	—							AP_x_EN	ODT_RD_CFG			—	ODT_WR_CFG		
Type	R/W	R/W		R	R/W								R	R/W		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	BA_BITS_CS_x	—			ROW_BITS_CS_x				—					COL_BITS_CS_x		
Type	R/W	R			R/W				R					R/W		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The CSx_CONFIG registers enable the DDR chip selects x and set the number of row and column bits used for each chip select. Load these registers with the correct number of row and column bits for each SDRAM. Because the ROW_BITS_CS_x and COL_BITS_CS_x fields establish address multiplexing, it is essential to set these values correctly.

If chip select interleaving is enabled, then all fields in the lower interleaved chip select is used and the other register fields are not used, with the exception of the ODT_RD_CFG and ODT_WR_CFG fields. For example, if chip selects 0 and 1 are interleaved, all fields in CS0_CONFIG are used, but only the ODT_RD_CFG and ODT_WR_CFG fields in CS1_CONFIG are used.

Table 12-17. CSx_CONFIG Field Descriptions

Bit	Reset	Description	Settings
CS_x_EN 31	0	**Chip Select *x* Enable** Enables/disables chip select.	0 Chip select x is not active. 1 Chip select x is active and assumes the state set in CSx_BNDS.
— 30-24	0	Reserved. Write to zero for future compatibility.	
AP_x_EN 23	0	**Chip Select x Auto-Precharge Enable** Specifies when auto-precharged is enabled for chip select x.	0 Chip select x is auto-precharged only if global auto-precharge mode is enabled (DDR_SDRAM_INTERVAL[BSTOPRE] = 0). 1 Chip select always issues an auto-precharge for read and write transactions.
ODT_RD_CFG 22–20	0	**On-Die Termination (ODT) for Reads** Specifies when ODT is to be asserted for read accesses. Note that $\overline{\text{CAS}}$ latency plus additive latency must be at least 3 cycles for ODT_RD_CFG to be enabled.	000 Never assert ODT for reads. 001 Assert ODT only during reads to CSx. 010 Assert ODT only during reads to other chip selects. 011 Reserved. 100 Assert ODT for all reads. 101–111 Reserved.

Table 12-17. CSx_CONFIG Field Descriptions (Continued)

Bit	Reset	Description	Settings
— 19	0	Reserved. Write to zero for future compatibility.	
ODT_WR_CFG 18–16	0	**ODT for Writes Configuration** Specifies when ODT is to be asserted for write accesses. Note that write latency plus additive latency must be at least 3 cycles for ODT_WR_CFG to be enabled.	000 Never assert ODT for writes. 001 Assert ODT only during writes to CSx. 010 Assert ODT only during writes to other chip selects. 011 Reserved. 100 Assert ODT for all writes. 101–111 Reserved.
BA_BITS_CS_x 15–14	0	**Number of Bank Bits for Chip Select x** Specifies the number of logical bank bits MBA[2–0] for SDRAM on chip select x. See **Table 12-7** and **Table 12-8** for details	00 2 logical bank bits. 01 3 logical bank bits. 10–11 Reserved
— 13–11	0	Reserved. Write to zero for future compatibility.	
ROW_BITS_CS_x 10–8	0	**Number of Row Bits for Chip Select x** Specifies the number of row bits for SDRAM on chip select x. See **Table 12-7** and **Table 12-8** for details	000 12 row bits 001 13 row bits 010 14 row bits 011 15 row bits 100 16 row bits 101–111 Reserved
— 7–3	0	Reserved. Write to zero for future compatibility.	
COL_BITS_CS_x 2–0	0	**Number of Column Bits for SDRAM on Chip Select x** Specifies the number of column bits for SDRAM on chip select x. See **Table 12-7** and **Table 12-8** for details.	000 8 column bits. 001 9 column bits. 010 10 column bits. 011 11 column bits. 100–111 Reserved.

12.5.3 Chip-Select x Configuration Register 2 (CSx_CONFIG_2)

CS0_CONFIG_2 Chip-Select x Configuration Register 2 Offset 0x00C0
CS1_CONFIG_2 0x00C4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—					PASR_CFG			—							
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CSx_CONFIG_2 registers enable the partial array self refresh address decode in each chip select If chip select interleaving is enabled, then all fields in the lower interleaved chip select are used, and the other register fields are unused. **Table 12-18** describes the CSx_CONFIG_2 fields.

Table 12-18. CSx_CONFIG_2 Field Descriptions

Bit	Reset	Description	Settings	
— 31–27	0	Reserved. Write to zero for future compatibility.		
PASR_CFG 26–24	0	**Partial Array Self Refresh Configuration** Controls the bits that are placed on MA[2:0] during the write to the EMRS(2) register when the automatic hardware DRAM initialization is used (DDR_SDRAM_CFG[BI] is cleared when DDR_SDRAM_CFG[MEM_EN] is set). If this field is a non-zero value, then it overrides the least significant 3 bits in DDR_SDRAM_MODE_2[ESDMODE2] during the automatic initialization for chip select *x*. In addition, if a non-zero value is programmed in this field, then the address decode for chip select *x* is optimized for partial array self refresh (see **Section 12.5.11**),	000 001–111	Partial array self refresh is disabled Partial array self refresh is enabled per JEDEC specifications. Overriding the least significant 3 bits of EMRS or EMRS2 is only supported for DDR3 memory types.
— 23–0	0	Reserved. Write to zero for future compatibility.		

12.5.4 DDR SDRAM Timing Configuration 3 Register (TIMING_CFG_3)

TIMING_CFG_3 DDR SDRAM Timing Configuration 3 Register Offset 0x0100

TIMING_CFG_3 register sets the extended values for the refresh recovery time, activate-to-precharge, CAS latency, and control adjust fields, which are combined with the corresponding TIMING_CFG_1 fields to determine the total required time. **Table 12-19** describes the TIMING_CF3_3 fields.

Table 12-19. TIMING_CFG_3 Bit Descriptions

Bits	Reset	Description	Setting
— 31–25	0	Reserved. Write to zero for future compatibility.	
EXT_ACTTOPRE 24	0	Extended Activate to precharge interval (t_{RAS}). Determines the number of clock cycles from an activate command until a precharge command is allowed. This field is concatenated with TIMING_CFG_1[ACTTOPRE] to obtain a 5-bit value for the total activate to precharge. Note that a 5-bit value of 0_0000 is the same as a 5-bit value of 1_0000. Both values represent 16 cycles.	0 0 clocks 1 16 clocks
— 23–21	0	Reserved. Write to zero for future compatibility.	

Table 12-19. TIMING_CFG_3 Bit Descriptions (Continued)

Bits	Reset	Description	Setting
EXT_ REFREC 20–16	0	**Extended Refresh Recovery Time (t_{RFC})** Controls the number of clock cycles from a refresh command until an activate command is allowed. This field is combined with TIMING_CFG_1[REFREC] to obtain the total refresh recovery time. t_{RFC} = {REFREC | + | EXT_REFREC}	00000 0 clock cycles. 00001 16 clock cycles. 00010 32 clock cycles. 00011 48 clock cycles. 00100 64 clock cycles. 00101 80 clock cycles. 00110 96 clock cycles. 00111 112 clock cycles 01000 128 clock cycles 01001 144 clock cycles 01010 160 clock cycles 01011 176 clock cycles 01100 192 clock cycles 01101 208 clock cycles 01110 224 clock cycles 01111 240 clock cycles 10000 256 clock cycles. 10001 272 clock cycles. 10010 288 clock cycles. 10011 304 clock cycles. 10100 320 clock cycles. 10101 336 clock cycles. 10110 352 clock cycles. 10111 368 clock cycles 11000 384 clock cycles 11001 400 clock cycles 11010 416 clock cycles 11011 432 clock cycles 11100 448 clock cycles 11101 464 clock cycles 11110 480 clock cycles 11111 496 clock cycles
— 15–13	0	Reserved. Write to zero for future compatibility.	
EXT_CASLAT **12**	0	Extended $\overline{\text{MCAS}}$ latency from READ command. Number of clock cycles between registration of a READ command by the SDRAM and the availability of the first output data. If a READ command is registered at clock edge n and the latency is m clocks, data is available nominally coincident with clock edge $n + m$. This field is concatenated with TIMING_CFG_1[CASLAT] to obtain a 5-bit value for the total CAS latency. Note that if this bit is set, then 8 clocks are added to the programmed value in TIMING_CFG_1[CASLAT].	0 0 clocks 1 8 clocks
— 11–3	0	Reserved. Write to zero for future compatibility.	

Table 12-19. TIMING_CFG_3 Bit Descriptions (Continued)

Bits	Reset	Description	Setting
CNTL_ADJ 2-0	0	Control Adjust. Controls the amount of delay to add to the lightly loaded control signals w/ respect to all other DRAM address and command signals. The signals affected by this field are MODT[0:1], $\overline{\text{MCS}}$[0:1], and MCKE[0:1]	000 MODT[0:1], $\overline{\text{MCS}}$[0:1], and MCKE[0:1] will be launched aligned with the other DRAM address and control signals. 001 MODT[0:1], $\overline{\text{MCS}}$[0:1], and MCKE[0:1] will be launched 1/2 platform cycle later than the other DRAM address and control signals. 010 MODT[0:1], $\overline{\text{MCS}}$[0:1], and MCKE[0:1] will be launched 1 platform cycle later than the other DRAM address and control signals. 011 MODT[0:1], $\overline{\text{MCS}}$[0:1], and MCKE[0:1] will be launched 3/2 platform cycles later than the other DRAM address and control signals. 100 MODT[0:1], $\overline{\text{MCS}}$[0:1], and MCKE[0:1] will be launched 2 platform cycles later than the other DRAM address and control signals. 101 MODT[0:1], $\overline{\text{MCS}}$[0:1], and MCKE[0:1] will be launched 5/2 platform cycles later than the other DRAM address and control signals. 110– 111 Reserved

TIMING_CFG_0 register sets the number of clock cycles between various SDRAM control commands.

Table 12-20. TIMING_CFG_0 Field Descriptions

Bit	Reset	Description	Settings
RWT 31–30	0	**Read-to-Write Turn-Around (t_{RTW})** Specifies how many extra cycles to add between a read-to-write turn-around. For 0 clock cycles, the DDR controller uses a fixed number based on the $\overline{CAS}$ latency and write latency. A value other than 0 adds extra cycles to this default calculation. By default, the DDR controller determines the read-to-write turn-around as CL – WL + BL/2 + 2. CL is the $\overline{CAS}$ latency rounded up to the next integer, WL is the programmed write latency, and BL is the burst length.	00 0 clock cycles. 01 1 clock cycle. 10 2 clock cycles. 11 3 clock cycles.
WRT 29–28	0	**Write-to-Read Turn-Around** Specifies how many extra cycles to add between a write-to-read turn-around. For 0 clock cycles, the DDR controller uses a fixed number based on the read latency and write latency. A value other than 0 adds extra cycles to this default calculation. By default, the DDR controller determines the write-to-read turn-around as WL – CL + BL/2 + 1. CL is the $\overline{CAS}$ latency rounded down to the next integer, WL is the programmed write latency, and BL is the burst length.	00 0 clock cycles. 01 1 clock cycle. 10 2 clock cycles. 11 3 clock cycles.
RRT 27–26	0	**Read-to-Read Turn-Around** Specifies how many extra cycles to add between reads to different chip selects. By default, 3 cycles are required between read commands to different chip selects. If 00 is selected the DDR Controller will use a predefined value of 3 clocks for the turnaround. Selecting a value other than 00 adds extra cycles to this predefined value according to the selection When DDR works in 8 beat burst the default is 5 clock cycles.	00 0 clock cycles. 01 1 clock cycle. 10 2 clock cycles. 11 3 clock cycles.

Table 12-20. TIMING_CFG_0 Field Descriptions (Continued)

Bit	Reset	Description	Settings
WWT 25–24	0	**Write-to-Write Turn-Around** Specifies how many extra cycles to add between writes to different chip selects. By default, 2 cycles are required between write commands to different chip selects. If 00 is selected the DDR Controller will use a predefined value of 2 clocks for the turnaround, selecting a value other than 00 adds extra cycles to this predefined value according to the selection When DDR works in 8 beat burst the default is 4 clock cycles.	00 0 clock cycles. 01 1 clock cycle. 10 2 clock cycles. 11 3 clock cycles.
ACT_PD_EXIT 23–20	0b0001	**Active Power-Down Exit Timing (t_{XP})** Specifies how many clock cycles to wait between exit from active power-down and issuing a command. The default is one clock cycle.	0000 Reserved 0001 1 clock 0010 2 clocks 0011 3 clocks 0100 4 clocks 0101 5 clocks 0110 6 clocks 0111 7 clocks 1100 8 clocks 1101 9 clocks 1110 10 clocks 1111 11 clocks 1100 12 clocks 1101 13 clocks 1110 14 clocks 1111 15 clocks
PRE_PD_EXIT 19–15	0b00010	**Precharge Power-Down Exit Timing (t_{xp})** Specifies how many clock cycles to wait after exiting precharge power down before issuing any command. **Note:** The decoding for this field requires the least significant bit to be set to add 16 clocks.	00000 Reserved 00001 16 clocks 00010 1 clock 00011 17 clocks 00100 2 clocks 00101 18 clocks 00110 3 clocks 00111 19 clocks 01000 4 clocks 01001 20 clocks 01010 5 clocks 01011 21 clocks 01100 6 clocks 01101 22 clocks 01110 7 clocks 01111 23 clocks 11000 8 clocks 10001 24 clocks 11010 9 clocks 10011 25 clocks 11100 10 clocks 10101 26 clocks 11110 11 clocks 10111 27 clocks 11000 12 clocks 11001 28 clocks 11010 13 clocks 11011 29 clocks 11100 14 clocks 11101 30 clocks 11110 15 clocks 11111 31 clocks

Table 12-20. TIMING_CFG_0 Field Descriptions (Continued)

Bit	Reset	Description	Settings
— 14–12	0	Reserved. Write to zero for future compatibility.	
ODT_PD_EXIT 11–8	0b0001	**ODT Power-Down Exit Timing (t_{AXPD})** Specifies how many clock cycles must pass after exit from power-down before ODT can be asserted. The default is 1 clock cycle. **Note:** ODT_PD_EXIT must be greater than TIMING_CFG_5[RODT_ON] when using RODT_ON overrides and must be grater than TIMING_CFG_5[WODT_ON] when using WODT_ON overrides.	0000 0 clock 0001 1 clock 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycles. 0110 6 clock cycles. 0111 7 clock cycles. 1000 8 clock cycles. 1001 9 clock cycles. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 15 clock cycles.
— 7–4	0	Reserved. Write to zero for future compatibility.	
MRS_CYC 3–0	0b0101	**Mode Register Set Cycle Time (t_{MRD})** Specifies the number of clock cycles that must pass between a Mode Register Set command and another command. The default is 5 clock cycles.	0000 Reserved 0001 1 clock 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycles. 0110 6 clock cycles. 0111 7 clock cycles. 1000 8 clock cycles. 1001 9 clock cycles. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 15 clock cycles.

TIMING_CFG_1 sets the number of clock cycles between various SDRAM control commands.

Table 12-21. TIMING_CFG_1 Field Descriptions

Bits	Reset	Description	Settings
PRETOACT 31–28	0	**Precharge-to-Activate Interval (t_{RP})** Specifies the minimum number of clock cycles between a precharge command and an activate or refresh command. This number is calculated from the AC specifications of the SDRAM. This field must be programmed for proper operation of the DDR Controller.	0000 Reserved. 0001 1 clock 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycles. 0110 6 clock cycles. 0111 7 clock cycles 1000 8 clock cycles. 1001 9 clock cycles. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 15 clock cycles.
ACTTOPRE 27–24	0	**Activate to Precharge Interval (t_{RAS})** Specifies the minimum number of clock cycles between an activate command and a precharge command. This number is calculated from the AC specifications of the SDRAM. This field is concatenated with TIMING_CFG_3[EXT_ACTTOPRE] to obtain a 5-bit value for the total activate to precharge time. **Note:** The decode of 0000–0011 is equal to 16–19 clocks when TIMING_CFG_3[EXT_ACTTOPRE] = 0, but it is equal to 0-3 clocks when TIMING_CFG_3[EXT_ACTTOPRE] = 1. This field must be programmed for proper operation of the DDR Controller.	*If TIMING_CFG_3 [EXT_ACTTOPRE] = 1:* 0000 0 clock cycles. 0001 1 clock cycles. 0010 2 clock cycles. 0011 3 clock cycles. *If TIMING_CFG_3 [EXT_ACTTOPRE] = 0:* 0000 16 clock cycles. 0001 17 clock cycles. 0010 18 clock cycles. 0011 19 clock cycles. *For any value of TIMING_CFG_3 [EXT_ACTTOPRE]:* 0100 4 clock cycles. 0101 5 clock cycles. 0110 6 clock cycles. 0111 7 clock cycles. ... 1111 15 clock cycles.

Table 12-21. TIMING_CFG_1 Field Descriptions (Continued)

Bits	Reset	Description	Settings
ACTTORW 23–20	0	**Activate to Read/Write Interval for SDRAM (t_{RCD})** Specifies the minimum number of clock cycles between an activate command and a read or write command. This interval is calculated from the AC specifications of the SDRAM. This field must be programmed for proper operation of the DDR Controller.	0000 Reserved. 0001 1 clock cycle. 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycles. 0110 6 clock cycles. 0111 7 clock cycles 1000 8 clock cycles. 1001 9 clock cycles. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 15 clock cycles.
CASLAT 19–16	0	**$\overline{\text{MCAS}}$ Latency from READ Command** Specifies the number of clock cycles between the time the SDRAM registers a READ command and the availability of the first output data. If a READ command is registered at clock edge n and the latency is m clock cycles., data is available nominally coincident with clock edge $n + m$. This field is concatenated with TIMING_CFG_3[EXT_CASLAT] to obtain a 5-bit value for the total CAS latency. This value must be programmed at initialization as described in **Section 12.5.10**, *DDR SDRAM Mode Configuration Register (DDR_SDRAM_MODE)* on **page 12-57**. This field must be programmed at initialization for proper operation of the DDR Controller, as indicated in **Section 12.5.9**, *DDR SDRAM Control Configuration Register 2 (DDR_SDRAM_CFG_2)*.	0000 Reserved. 0001 1 clock cycle. 0010 1.5 clock cycles. 0011 2 clock cycles. 0100 2.5 clock cycles 0101 3 clock cycles. 0110 3.5 clock cycles 0111 4 clock cycles. 1000 4.5 clock cycles 1001 5 clock cycles. 1010 5.5 clock cycles 1011 6 clock cycles. 1100 6.5 clock cycles 1101 7 clock cycles. 1110 7.5 clock cycles 1111 8 clock cycles.
REFREC 15–12	0	**Refresh Recovery Time (t_{RFC})** Controls the number of clock cycles from a refresh command until an activate command is allowed. This field is combined with TIMING_CFG_3[EXT_REFREC] to obtain the total refresh recovery time. t_{RFC} = {REFREC | + | EXT_REFREC} **Note:** The minimum value for REFREC is 8 clock cycles. This required value can be calculated by referring to the AC specification of the SDRAM device. The AC specification indicates a maximum refresh to activate interval in ns.	0000 8 clock cycles. 0001 9 clock cycles. 0010 10 clock cycles. 0011 11 clock cycles. 0100 12 clock cycles. 0101 13 clock cycles. 0110 14 clock cycles. 0111 15 clock cycles. 1000 16 clock cycles. 1001 17 clock cycles. 1010 18 clock cycles. 1011 19 clock cycles. 1100 20 clock cycles. 1101 21 clock cycles. 1110 22 clock cycles. 1111 23 clock cycles.

Table 12-21. TIMING_CFG_1 Field Descriptions (Continued)

Bits	Reset	Description	Settings
WRREC 11–8	0	**Write Recovery (t_{WR})** Specifies the minimum number of clock cycles between the last data associated with a write command and a precharge command. This interval, write recovery time, is calculated from the AC specifications of the SDRAM.	0000 reserved. 0001 1 clock cycle. 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycles. 0110 6 clock cycles. 0111 7 clock cycles 1000 8 clock cycles. 1001 9 clock cycles. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 15 clock cycles.
ACTTOACT 7–4	0	**Activate-to-Activate Interval (t_{RRD})** Specifies the minimum number of clock cycles between an activate command and another activate command for a different logical bank in the same physical bank (chip select). The default is one clock cycle. This interval is calculated from the AC specifications of the SDRAM.	0000 Reserved. 0001 1 clock cycle. 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycles. 0110 6 clock cycles. 0111 7 clock cycles. 1000 8 clock cycles 1001 9 clock cycle. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 15 clock cycles
WRTORD 3–0	0	**Last Write Data Pair to Read Command Interval (t_{WTR})** Specifies the minimum number of clock cycles between the last write data pair and the subsequent read command to the same physical bank.	0000 Reserved. 0001 1 clock cycle. 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycles. 0110 6 clock cycles. 0111 7 clock cycles. 1000 8 clock cycles 1001 9 clock cycle. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 15 clock cycles

TIMING_CFG_2 register sets the clock delay to data for writes and should be defined according to the system timing. **Table 12-23** describes the TIMING_CFG_2 fields.

Table 12-22. TIMING_CFG_2 Field Descriptions

Bit	Reset	Description	Settings
ADD_LAT 31–28	0	**Additive Latency** Specifies the number of clock cycles from the Posted CAS operation until the registered read/write command is issued inside the SDRAM as defined in the JEDEC DDR2 and DDR3 standards. The additive latency must be set to a value less than TIMING_CFG_1[ACTTORW].	0000 0 clock cycles. 0001 1 clock cycle. 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycles 0110 6 clock cycles 0111 7 clock cycles 1000 8 clock cycles. 1001 9 clock cycles. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 Reserved.

Table 12-22. TIMING_CFG_2 Field Descriptions (Continued)

Bit	Reset	Description	Settings
CPO 27–23	0	**$\overline{\text{MCAS}}$-to-Preamble Override** Defines the number of DRAM cycles between a read command and the time the corresponding DQS preamble is valid for the memory controller. For these decodings, read latency (RL) is equal to the $\overline{\text{CAS}}$ latency plus the additive latency. **Note:** For CPO decodings other than 00000 and 11111, read latency is rounded up to the next integer value. In other words, CPO timing decides when the DDR controller starts to wait for the first DQS rising edge from DDR memory during the DQS preamble for read access. The DQS rising edge should occur within 1 clock cycle from the timing defined by this parameter.	00000 RL + 1 00001 Reserved 00010 RL 00011 RL + 1/4 00100 RL + 1/2 00101 RL + 3/4 00110 RL + 1 00111 RL + 5/4 01000 RL + 3/2 01001 RL + 7/4 01010 RL + 2 01011 RL + 9/4 01100 RL + 5/2 01101 RL + 11/4 01110 RL + 3 01111 RL + 13/4 10000 RL + 7/2 10001 RL + 15/4 10010 RL + 4 10011 RL + 17/4 10100 RL + 9/2 10101 RL + 19/4 10110 RL + 5 10111 RL + 21/4 11000 RL + 11/2 11001 RL + 23/4 11010 RL + 6 11011 RL + 25/4 11100 RL + 13/2 11101 RL + 27/4 11110 RL + 7 11111 Automatic Calibration (recommended)
WR_LAT 22–19	0	**Write Latency** Specifies the number of clock cycles between the write command and the first data write when AL = 0. **Note:** Total write latency for DDR3 is equal to WR_LAT + ADD_LAT. If a write latency of 1 is required, then the additive latency must also be configured to at least 1 cycle.	0000 Reserved. 0001 1 clock cycle. 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles 0101 5 clock cycles 0110 6 clock cycles 0111 7 clock cycles 1000 8 clock cycles. 1001 9 clock cycles. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycles. 1110 14 clock cycles. 1111 15 clock cycles.
— 18–17	0	Reserved. Write to zero for future compatibility.	

Table 12-22. TIMING_CFG_2 Field Descriptions (Continued)

Bit	Reset	Description	Settings
RD_TO_PRE 16–13	0	**Read to Precharge (t_{RTP})** Specifies the number of clock cycles between the read command and the precharge command. .	0000 Reserved. 0001 1 clock cycle. 0010 2 clock cycles. 0011 3 clock cycles. 0100 4 clock cycles. 0101 5 clock cycle. 0110 6 clock cycles. 0111 7 clock cycles. 1000 8 clock cycles. 1001 9 clock cycles. 1010 10 clock cycles. 1011 11 clock cycles. 1100 12 clock cycles. 1101 13 clock cycle. 1110 14 clock cycles. 1111 15 clock cycles.
WR_ DATA_ DELAY 12–9	0	**Write Command to Write Data Strobe Delay** Controls the amount of delay applied to the data and data strobes for writes. See **Section 12.3.9**, *DDR SDRAM Write Timing Adjustments* for details. The write preamble is typically driven high for 1/2 DRAM cycle, and then it is driven low for 1/2 DRAM cycle. However for WR_DATA_DELAY settings of 0 clocks and 1/4 clocks, the write preamble is driven low for the entire DRAM cycle. If the preamble needs to switch high first to meet DDR3 requirements, do no use these values.	0000 0 clock delay 0001 2 clock delay 0010 1/4 clock delay 0011 9/4 clock delay 0100 1/2 clock delay 0101 5/2 clock delay 0110 3/4 clock delay 0111 Reserved 1000 1 clock delay 1001 Reserved 1010 5/4 clock delay 1011 Reserved 1100 3/2 clock delay 1101 Reserved. 1110 7/4 clock delay 1111 Reserved
CKE_PLS 8–6	0	**Minimum CKE Pulse Width (t_{CKE})** Specifies the minimum clock cycles t_{CKE}.	000 Reserved. 001 1 clock cycle. 010 2 clock cycles. 011 3 clock cycles. 100 4 clock cycles. 101 5 clock cycle. 110 6 clock cycles. 111 7 clock cycles.
FOUR_ACT 5–0	0	**Window for Four Activates (t_{FAW}).** Specifies the t_{FAW} timing. **Note:** This is applied to DDR3 with eight logical banks only.	000000 Reserved. 000001 1 clock cycle. 000010 2 clock cycles. 000011 3 clock cycles. 000100 4 clock cycles. ... 011110 30 clock cycles. 011111 31 clock cycles. 100000 32 clock cycles. 100001– 111111 Reserved.

12.5.8 DDR SDRAM Control Configuration Register (DDR_SDRAM_CFG)

DDR_SDRAM_CFG DDR SDRAM Control Configuration Register Offset 0x0110

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDR_SDRAM_CFG register enables the interface logic and specifies certain operating features such as self refreshing, error checking and correcting, registered DIMMs, and dynamic power management.

Table 12-23. DDR_SDRAM_CFG Field Descriptions

Bits	Reset	Description	Settings
MEM_EN 31	0	**DDR SDRAM Interface Logic Enable** Enables/disables SDRAM interface logic. This bit must not be set until the initialization code has appropriately configured all other memory configuration parameters.	0 SDRAM interface logic is disabled. 1 SDRAM interface logic is enabled.
SREN 30	0	**Self Refresh Enable** Enables/disables self refresh during sleep. When self refresh is disabled, the system is responsible for preserving the integrity of SDRAM during sleep.	0 SDRAM self refresh is disabled during sleep. 1 SDRAM self refresh is enabled during sleep
ECC_EN 29	0	**ECC Enable** Enables/disables ECC protection mechanism including error reporting and interrupts.	0 No ECC errors are reported. No ECC interrupts are generated. 1 ECC is enabled.
RD_EN 28	0	**Registered DIMM Enable** Specifies the type of DIMM used in the system. **Note:** RD_EN and 2T_EN must not be both set at the same time.	0 Unbuffered DIMM. 1 Registered DIMM.
— 27	0	Reserved. Write to zero for future compatibility.	
SDRAM_TYPE 26–24	011	**Type of SDRAM Device** Specifies the type of device.	011 Reserved 111 DDR3 SDRAM. All other values reserved.
— 23–22	0	Reserved. Write to zero for future compatibility.	
DYN_PWR 21	0	**Dynamic Power Management Mode** Enabled/disables dynamic power management mode. When this bit is set and there is no on-going memory activity, the SDRAM CKE signal is deasserted.	0 Dynamic power management mode is disabled. 1 Dynamic power management mode is enabled.

Table 12-23. DDR_SDRAM_CFG Field Descriptions (Continued)

Bits	Reset	Description	Settings
DBW 20–19	0	**DRAM Data Bus Width** Selects bus size.	00 64-bit bus is used. 01 32-bit bus is used. 10 Reserved. 11 Reserved.
8_BE 18	0	**8-Beat Burst Enable** **Note:** DDR3 (SDRAM_TYPE = 111) must use 8-beat bursts when using 32-bit bus mode.	0 4-beat burst. 1 8-beat burst.
NCAP 17	0	**Non-Concurrent Auto-Precharge** Some older DDR DRAMs do not support concurrent auto precharge. If one of these devices is used, this bit must be set if auto precharge is used.	0 DRAMs in system support concurrent auto-precharge. 1 DRAMs in system do not support concurrent auto-precharge.
3T_EN 16	0	**3T Timing Enable** Enables/disabled 3T timing. **Note:** This field cannot be set if DDR_SDRAM_CFG[2T_EN] is also set. **Note:** This field may not be used with 4-beat bursts.	0 1T timing is enabled if 2T_EN is cleared. The DRAM command/address are held for only 1 cycle on the DRAM bus. 1 3T timing is enabled. The DRAM command/address are held for 3 full cycles on the DRAM bus for every DRAM transaction. However, the chip select is only held for the third cycle
2T_EN 15	0	**2T Timing Enable** Enables/disabled 2T timing. **Note:** This field cannot be set if DDR_SDRAM_CFG[3T_EN] is also set. **Note:** RD_EN and 2T_EN cannot be set simultaneously	0 1T timing is used if 3T_EN is cleared (0). The DRAM command/address are held for only 1 cycle on the DRAM bus. 1 2T timing is enabled. The DRAM command/address are held for 2 full cycles on the DRAM bus for every DRAM transaction. The chip select is only held for the second cycle.
BA_INTLV_CTL 14	0	**Bank (CS) Interleaving Control** Specifies whether to use bank interleaving.	0 No external banks are interleaved. 1 External memory banks 0 and 1 are interleaved.
— 13–4	0	Reserved. Write to zero for future compatibility.	
HSE 3	0	**Global Half-Strength Override** Specifies whether the I/O drivers are configured to full strength or half strength. The half strength impedance is used by the MDIC, address/command, data, and clock, but only if automatic hardware calibration is disabled and the corresponding group software override is disabled in the DDR control driver registers **Section 12.5.31**, *DDR Control Driver Register 1 (DDRCDR_1)* and **Section 12.5.32**, *DDR Control Driver Register 2 (DDRCDR_2)*. Clear this bit if using automatic hardware calibration.	0 I/O drivers are configured to full-strength. 1 IO drivers are configured to half-strength.
— 2	0	Reserved. Write to zero for future compatibility.	

Table 12-23. DDR_SDRAM_CFG Field Descriptions (Continued)

Bits	Reset	Description	Settings
MEM_HALT 1	0	**DDR Memory Controller Halt** When this bit is set, the memory controller does not accept any new transactions until the bit is cleared. This bit can be used when bypassing initialization and forcing the MODE REGISTER SET commands through software. This bit should be used carefully. Using this MEM_HALT option can create congestion on the system interconnection and can cause hangs of the cores and other initiator.	0 DDR controller accepts new transactions. 1 DDR controller finishes any remaining transactions and then halts until software clears this bit.
BI 0	0	**Bypass Initialization** Specifies the conditions for initialization. When this bit is set, software must initialize memory through the DDR_SDRAM_MD_CTR register. If software is initializing memory, the MEM_HALT bit can be set to prevent the DDR controller from issuing transactions during the initialization sequence. **Note:** The DDR controller does not issue a DDL reset to the DRAMs when bypassing the initialization routine, regardless of the value of DDR_SDRAM_CFG[DLL_RST_DIS]. If a DLL reset is required, then you must force the controller to enter and exit self refresh after the controller is enabled. For details on avoiding ECC errors in this mode, see the discussion of the DDR SDRAM Initialization Address Register on **page 12-64**.	0 DDR controller cycles through the initialization routine based on the value of SDRAM_TYPE. 1 Initialization routine is bypassed.

12.5.9 DDR SDRAM Control Configuration Register 2 (DDR_SDRAM_CFG_2)

DDR_SDRAM_CFG_2 DDR SDRAM Control Configuration Register 2 Offset 0x0114

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDR_SDRAM_CFG_2 register provides control configuration for the DDR controller in addition to that provided by DDR_SDRAM_CFG.

Table 12-24. DDR_SDRAM_CFG_2 Field Descriptions

Bit	Reset	Description	
FRC_SR 31	0	**Force Self Refresh**	0 Normal operating mode. 1 Enter Self Refresh mode.
— 30	0	Reserved. Write to zero for future compatibility.	
DLL_RST_DIS 29	0	**DLL Reset Disable** The DDR controller typically issues a DLL reset to the DRAMs when it exists self refresh. However, you can disable this function by setting this bit during initialization.	0 DDR controller issues a DLL reset when exiting self refresh. 1 DDR controller does not issue a DLL reset when exiting self refresh.
— 28	0	Reserved. Write to zero for future compatibility.	
DQS_CFG 27–26	0	**DQS Configuration**	00 Reserved. 01 Differential DQS signals used. 10 Reserved. 11 Reserved.
— 25–23	0	Reserved. Write to zero for future compatibility.	
ODT_CFG 22–21	0	**ODT Configuration** Defines how ODT is driven to the on-chip I/O. See **Table 12-47** and **Table 12-48** for the definition of the impedance value that will be used.	00 Never assert ODT to internal I/O. 01 Assert ODT to internal I/O only during writes to DRAM. 10 Assert ODT to internal I/O only during reads to DRAM. 11 Always keep ODT asserted to internal I/O.
— 20–16	0	Reserved. Write to zero for future compatibility.	

Table 12-24. DDR_SDRAM_CFG_2 Field Descriptions (Continued)

Bit	Reset	Description	
NUM_PR 15–12	0	**Number of Posted Refreshes** Determines how many posted refreshes, if any, can be issued at one time. If posted refreshes are used, this field, along with DDR_SDRAM_INTERVAL[REFINT], must be programmed so that the maximum t_{ras} specification cannot be violated.	0000 Reserved. 0001 1 refresh at a time. 0010 2 refreshes at a time. 0011 3 refreshes at a time. ... 1000 8 refreshes at a time. 1001 - 1111 Reserved.
— 11–9	0	Reserved. Write to zero for future compatibility.	
UNQ_MRS_EN 8	0	**Unique MRS Enable.** Determines if the DDR_SDRAM_MODE_{3,4} registers will be used when initializing the memories for chip selects 1. These can be used to provide unique values to the Mode Registers of the DRAM to allow different termination values for each rank.	0 Unique MRS disabled DDR_SDRAM_MODE and DDR_SDRAM_MODE_2 are used for all chip selects 1 Unique MRS Enabled DDR_SDRAM_MODE, DDR_SDRAM_MODE_2 are used for chip select 0. FFR_SDRAM_MODE_3 and DDR_SDRAM_MODE_4 are used for chip select 1.
— 7–6	0	Reserved. Write to zero for future compatibility.	
AP_EN 5	0	**Address Parity Enable** Determines whether to generate and check address parity for the address and control signals when using registered DIMMs. If address parity is used, the MAPAR_OUT and MAPAR_IN pins are used to drive the parity bit and to receive errors from the open-drain parity error signal. Even parity are used, and parity is generated for the MA[15–0], MBA[2–0], $\overline{\text{MRAS}}$, $\overline{\text{MCAS}}$, $\overline{\text{MWE}}$ signals. Parity is not generated for the MCKE[0–3], MODT[0–3], or $\overline{\text{MCS}}$[0–3] signals. **Note:** Address parity should not be used for non-zero values of TIMING_CFG_3[CNTL_ADJ].	0 Address parity not used 1 Address parity used
D_INIT 4	0	**DRAM Data Initialization** This bit is set by software, and it is cleared by hardware. If software sets this bit before the memory controller is enabled, the controller will automatically initialize DRAM after it is enabled. This bit will be automatically cleared by hardware once the initialization is completed. This data initialization bit should only be set when the controller is idle. The value in DDR_DATA_INIT register will be used to initialize memory	0 No data initialization, and no data initialization is scheduled. 1 The memory controller initializes memory when it is enabled.
— 3	0	Reserved. Write to zero for future compatibility.	

Table 12-24. DDR_SDRAM_CFG_2 Field Descriptions (Continued)

Bit	Reset	Description	
RCW_EN 2	0	**Register Control Word Enable** If DDR3 registered DIMMs are used, it may be necessary to write the register control words before issuing commands to DRAM. If this bit is set, the controller writes the register control words after DDR_SDRAM_CFG[MEM_EN] is set, unless DDR_SDRAM_CFG[BI] is set. The register control words are written with the values in DDR_SDRAM_RCW_1 and DDR_SDRAM_RCW_2.	0 Register control words are not automatically written during DRAM initialization. 1 Register control words are automatically written during DRAM initialization. This bit should only be set if DDR3 registered DIMMs are used, and the default settings need to be modified.
CD_DIS 1	0	**Corrupted Data Disable** If this bit is set, then the corrupted data feature is disabled. When the corrupted data feature is enabled, the DDR controller inverts the generated ECC code for any beat of data that is known to have corrupted data. When a read to the corrupted data is generated later, the ERR_DETECT[CDE] error bit is set and generates an error interrupt if error reporting is enabled.	0 Corrupted data is enabled. 1 Corrupted data is disabled.
MD_EN 0	0	**Mirrored DIMM Enable** Some DDR3 DIMMs are mirrored, where certain MA and MBA pins are mirrored on one side of the DIMM. When this bit is set, the controller knows to swap these signals before transmitting to the DRAM. The controller assumes that CS1 and CS3 are the ‘mirrored’ ranks of memory. The following signals are mirrored (MBA0 versus MBA1; MA3 versus MA4; MA5 versus MA6; MA7 versus MA8).	0 Mirrored DIMMs are not used. 1 Mirrored DIMMs are used.

12.5.10 DDR SDRAM Mode Configuration Register (DDR_SDRAM_MODE)

DDR_SDRAM_MODE DDR SDRAM Mode Configuration Register Offset 0x0118

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ESDMODE															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**

DDR_SDRAM_MODE register sets the values loaded into the DDR mode registers.

Table 12-25. DDR_SDRAM_MODE Bit Descriptions

Bit	Refresh	Description
ESDMODE 31–16 MR1	0	**Extended SDRAM Mode** Specifies the initial value loaded into the DDR SDRAM extended mode register. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus during DDR SDRAM initialization, MA0 presents the LSB of ESDMODE, which corresponds to DDR_SDRAM_MODE bit 16. The MSB of the SDRAM extended mode register value must be stored at DDR_SDRAM_MODE bit 31 The value programmed into this field is also used for writing MR1 during write leveling for DDR3, although the bits specifically related to the write leveling scheme are handled automatically by the DDR controller. Even if DDR_SDRAM_CFG[BI] is set, this field is still used during write leveling. The write leveling enable bit should be cleared by software in this field
SDMODE 15–0 MR0	0	**SDRAM Mode** Specifies the initial value loaded into the DDR SDRAM mode register. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus during DDR SDRAM initialization, MA0 presents the LSB of SDMODE, which, corresponds to DDR_SDRAM_MODE bit 0. The MSB of the SDRAM mode register value must be stored at DDR_SDRAM_MODE bit 15. Because the memory controller forces SDMODE[8] to certain values depending upon the state of the initialization sequence (for resetting the SDRAM DLL) which is mapped to MA8; the memory controller ignores the corresponding bits of this field.

12.5.11 DDR SDRAM Mode Configuration 2 Register (DDR_SDRAM_MODE_2)

DDR_SDRAM_MODE_2 DDR SDRAM Mode Configuration 2 Register — Offset 0x011C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDR_SDRAM_MODE_2 register sets the values loaded into the DDR extended mode 2 and 3 registers.

Table 12-26. DDR_SDRAM_MODE_2 Bit Descriptions

Bit	Reset	Description
ESDMODE2 31–16 MR2	0	**Extended SDRAM Mode 2** Specifies the initial value loaded into the DDR SDRAM Extended 2 Mode Register. The range and meaning of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus during the DDR SDRAM initialization sequence, MA0 presents the LSB bit of ESDMODE2, which corresponds to DDR_SDRAM_MODE_2 bit 16. The MSB of the SDRAM extended mode 2 register value must be stored at DDR_SDRAM_MODE_2 bit 31.
ESDMODE3 15–0 MR3	0	**Extended SDRAM Mode 3** Specifies the initial value loaded into the DDR SDRAM Extended 3 Mode Register. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus during DDR SDRAM initialization, MA0 presents the LSB of ESDMODE3, which corresponds to DDR_SDRAM_MODE_2 bit 0. The MSB of the SDRAM extended mode 3 register value must be stored at DDR_SDRAM_MODE_2 bit 15.

12.5.12 DDR SDRAM Mode Control Register (DDR_SDRAM_MD_CNTL)

DDR_SDRAM_MD_CNTL DDR SDRAM Mode Control Register — Offset 0x0120

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MD_EN	CS_ SEL			—	MD_SEL			SET_REF	SET_PRE	CKE_CNTL		WRCW	—		
Type	R/W

	MD_VALUE															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDR_SDRAM_MD_CNTL register allows software to initiate the following tasks:

- Issue a MODE REGISTER SET command to a particular chip select
- Issue an immediate REFRESH to a particular chip select
- Issue an immediate PRECHARGE or PRECHARGE ALL command to a particular chip select
- Force the CKE signals to a specific value

Note: Each command initiated through the DDR_SDRAM_MD_CNTL register should be initiated separately in the order required by the DDR SDRAM. If multiple commands are initiated simultaneously, the execution order is not guaranteed and can cause malfunction of the DDR SDRAM. MD_EN, SET_REF, and SET_PRE are mutually exclusive; only one of these fields should be set at a time.

Table 12-27. DDR_SDRAM_MD_CNTL Bit Descriptions

Bit	Reset	Description	Settings
MD_EN 31	0	**Mode Enable** Mode enable. Setting this bit specifies that valid data in MD_VALUE is ready to be written to DRAM as one of the following commands: • MODE REGISTER SET • EXTENDED MODE REGISTER SET • EXTENDED MODE REGISTER SET 2 • EXTENDED MODE REGISTER SET 3 The specific command to be executed is selected by setting MD_SEL. In addition, the chip select must be chosen by setting CS_SEL. MD_EN is set by software and cleared by hardware once the command has been issued. **Note:** MD_SEL and CS_SEL_MD_EN are mutually exclusive and cannot be set at the same time.	0 Indicates that no MODE REGISTER SET command needs to be issued. 1 Indicates that valid data contained in the register is ready to be issued as a MODE REGISTER SET command.
CS_SEL 30–28	0	**Select for Chip Select** Specifies the chip select to drive active due to any command forced by software in DDR_SDRAM_MD_CNTL.	000 Chip select 0 is active. 001 Chip select 1 is active. 010 Reserved. 011 Reserved. 100 Chip select 0 and chip select 1 are active. 101 Reserved. 110 Reserved. 111 Reserved.
— 27	0	Reserved. Write to zero for future compatibility.	
MD_SEL 26–24	000	**Mode Register Select** MD_SEL specifies one of the following: • During a mode select command, selects the SDRAM mode register to be changed • During a precharge command, selects the SDRAM logical bank to be precharged. A precharge all command ignores this field. • During a refresh command, this field is ignored. Note that MD_SEL contains the value that is presented to the memory bank address pins (MBA*n*) of the DDR controller.	000 MR Mode register 001 EMR Extended Mode Register 010 EMR2 Extended Mode Register 2 011 EMR3 Extended Mode Register 3

Table 12-27. DDR_SDRAM_MD_CNTL Bit Descriptions (Continued)

Bit	Reset	Description	Settings
SET_REF 23	0	**Set Refresh** Forces a refresh to the chip select specified by DDR_SDRAM_MD_CNTL. Software sets this bit and hardware clears it when the command is issued. **Note:** MD_EN, SET_REF, and SET_PRE are mutually exclusive; they cannot be set at the same time	0 No REFRESH command to issue. 1 A REFRESH command is ready to issue.
SET_PRE 22	0	**Set Precharge** Forces a precharge command or precharge all command to be issued to the chip select specified by DDR_SDRAM_MD_CNTL. Software sets this bit, and hardware clears it when the command is issued. **Note:** MD_EN, SET_REF, and SET_PRE are mutually exclusive; they cannot be set at the same time	0 No PRECHARGE ALL command to issue. 1 Issue a PRECHARGE or PRECHARGE ALL command.
CKE_CNTL 21–20	0	**Clock Enable Control** Software uses these bits to set or clear all CKE signals issued to DRAM. When software forces the value driven on CKE, that value continues to be forced until software clears the CKE_CNTL bits. The DDR controller continues to drive the CKE signals to the value forced by software until another event causes the CKE signals to change (that is, self refresh entry/exit, power down entry/exit).	00 Software does not force the CKE signals. 01 Software forces the CKE signals to a low value. 10 Software forces the CKE signals to a high value. 11 Reserved.
WRCW 19	0	**Write Register Control Word** If software sets this bit, then a register control word is written by asserting the selected chip selects while providing the programmed data on the MA and MBA signals. $\overline{RAS}$, $\overline{CAS}$, and $\overline{WE}$ remain deasserted during this write The MD_EN field should also be set to force a register control word write. This should only be set if DDR3 registered DIMMs are used and the register needs to be configured. If DDR_SDRAM_MD_CNTL is used to write RCW2 specifically, then software must guarantee that the timing parameter, *t-STAB*, is met before future accesses to the controller are allowed. In addition, DDR_SDRAM_MD_CNTL register cannot be used to write the RCWs if write leveling will be used, since write leveling is run automatically before DDR_SDRAM_MD_CNTL can be used to force RCW writes.	0 Indicates that a register control word write is not issued if MD_EN is set. 1 Indicates that a register control word write is issued if MD_EN is set.
— 18–16	0	Reserved. Write to zero for future compatibility.	
MD_ VALUE 15–0	0	**Mode Register Value** This field specifies the value that is presented on the memory address pins of the DDR controller during a MODE REGISTER SET command. This bit is significant only when this register is used to issue a MODE REGISTER SET command or a PRECHARGE or PRECHARGE ALL command.	For a MODE REGISTER SET command, this field contains the data to be written to the selected mode register. For a PRECHARGE command, MD_VALUE10 is mapped to MA10 to distinguish between a PRECHARGE command and a PRECHARGE ALL command, as follows: 0 Issue a PRECHARGE command; MD_SEL selects the logical bank to be precharged 1 Issue a PRECHARGE ALL command; all logical banks are precharged All other values are not valid.

Table 12-28 shows how DDR_SDRAM_MD_CNTL fields should be set for each of the tasks described in **Table 12-27**.

Table 12-28. Settings of DDR_SDRAM_MD_CNTL Fields

Field	Mode Register Set	Refresh	Precharge	Clock Enable Signals Control
MD_EN	1	0	0	—
SET_REF	0	1	0	—
SET_PRE	0	0	1	—
CS_SEL	Chooses chip select (CS)			—
MD_SEL	Select mode register. See **Table 12-27.**	—	Selects logical bank	—
MD_VALUE	Value written to mode register	—	Only MD_VALUE10 is significant. See **Table 12-27.**	—
CKE_CNTL	0	0	0	See **Table 12-27.**

DDR_SDRAM_INTERVAL register sets the number of DRAM clock cycles between bank refreshes issued to the DDR SDRAMs. In addition, it specifies the number of DRAM cycles that a page is maintained open after it is accessed.

Table 12-29. DDR_SDRAM_INTERVAL Bit Descriptions

Bit	Reset	Description
REFINT 31–16	0	**Refresh Interval** Represents the number of memory bus clock cycles between refresh cycles. Depending on DDR_SDRAM_CFG_2 [NUM_PR], some number of rows are refreshed in each DDR SDRAM physical bank during each refresh cycle. The value for REFINT depends on the specific SDRAMs used and the interface clock frequency. Refreshes are not issued when REFINT is cleared to all 0s.

Table 12-29. DDR_SDRAM_INTERVAL Bit Descriptions (Continued)

Bit	Reset	Description
— 15–14	0	Reserved. Write to zero for future compatibility.
BSTOPRE 13–0	0	**Precharge Interval** Specifies the duration (in memory bus clock cycles) that a page is retained after a DDR SDRAM access. If BSTOPRE has a value of zero, the DDR memory controller uses auto-precharge read and write commands rather than operating in page mode. This is called global auto-precharge mode.

12.5.14 DDR SDRAM Data Initialization Register (DDR_DATA_INIT)

DDR_DATA_INIT DDR SDRAM Data Initialization Register Offset 0x0128

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INIT_VALUE															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	INIT_VALUE															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDR_DATA_INIT register provides the value to initialize memory if DDR_SDRAM_CFG_2[D_INIT] is set.

Table 12-30. DDR_DATA_INIT Bit Descriptions

Bits	Reset	Description
INIT_VALUE 31–0	0	**Initialization Value** Specifies the initialization value for the DRAM if DDR_SDRAM_CFG_2[D_INIT] is set.

12.5.15 DDR SDRAM Clock Control Configuration Register (DDR_SDRAM_CLK_CNTL)

DDR_SDRAM_CLK_CNTL DDR SDRAM Clock Control Configuration Register — Offset 0x0130

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—					CLK_ADJUST				—

	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDR_SDRAM_CLK_CNTL register provides a 1/8 cycle clock adjustment.

Table 12-31. DDR_SDRAM_CLK_CNTL Bit Descriptions

Bit	Reset	Description	Settings
— 31–27	0	Reserved. Write to zero for future compatibility.	
CLK_ADJUST 26–23	0100	**Clock Adjust** Specifies when the clock is launched in relationship to the address/command. Set delay from address/command start timing to MCK rising edge.	0000 Clock launched and aligned with address/command. 0001 Clock launched 1/8 applied cycle after address/command. 0010 Clock launched 1/4 applied cycle after address/command. 0011 Clock launched 3/8 applied cycle after address/command. 0100 Clock launched 1/2 applied cycle after address/command. 0101 Clock launched 5/8 applied cycle after address/command. 0110 Clock launched 3/4 applied cycle after address/command. 0111 Clock launched 7/8 applied cycle after address/command. 1000 Clock launched 1 applied cycle after address/command. 1001–1111 Reserved.
— 22–0	0	Reserved. Write to zero for future compatibility.	

12.5.16 DDR SDRAM Initialization Address Register (DDR_INIT_ADDR)

DDR_INIT_ADDR DDR SDRAM Initialization Address Register Offset 0x0148

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	INIT_ADDR															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	INIT_ADDR															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDR_INIT_ADDR register provides the address for the data strobe to data skew adjustment and automatic CAS to preamble calibration after setting DDR_SDRAM_CFG[MEM_EN].

Note: After the skew adjustment, this address contains bad ECC data, which is not important at power-on reset because all memory should subsequently be initialized if ECC is enabled either through software or through the use of the DDR_SDRAM_CFG_2[D_INIT] bit. However, if the $\overline{\text{HRESET}}$ is asserted after the DRAM enters Self-Refresh mode, memory is not initialized. Therefore, this address should be written using an 8- or 32-bit transaction to avoid possible ECC errors when this address is accessed later.

Table 12-32. DDR_INIT_ADDR Bit Descriptions

Bit	Reset	Description	Settings
INIT_ADDR 31–0	0	**Initialization Address** Provides the address used for the data strobe to data skew adjustment and automatic CAS to preamble calibration after setting DDR_SDRAM_CFG[MEM_EN]. This address is written during the initialization sequence.	

12.5.17 DDR Initialization Enable Register (DDR_INIT_EN)

DDR_INIT_EN DDR SDRAM Initialization Enable Offset 0x014C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	UIA	—														
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—															
Type	R/W

The DDR SDRAM timing configuration 4 register provides additional timing fields required to support DDR3 memories. **Table 12-34** describes the TIMING_CFG_4 fields.

Table 12-34. TIMING_CFG_4 Field Descriptions

Bits	Reset	Description	Settings
RWT 31–28	0	**Read-to-Write Turnaround for Same Chip Select** Specifies how many cycles will be added between a read to write turnaround for transactions to the same chip select. If a value of 0000 is chosen, then the DDR controller will use the value used for transactions to different chip selects, as defined in TIMING_CFG_0[RWT]. This field can be used to improve performance when operating in burst-chop mode by forcing transactions to the same chip select to use extra cycles, while transaction to different chip selects can utilize the tri-state time on the DRAM interface. Regardless of the value that is set in this field, the value defined by TIMING_CFG_0[RWT] will also be met before issuing a write command.	0000 Default 0001 1 clock 0010 2 clocks 0011 3 clocks 0100 4 clocks 0101 5 clocks 0110 6 clocks 0111 7 clocks 1000 8 clocks 1001 9 clocks 1010 10 clocks 1011 11 clocks 1100 12 clocks 1101 13 clocks 1110 14 clocks 1111 15 clocks
WRT 27–24	0	**Write-to-Read Turnaround for Same Chip Select** Specifies how many cycles will be added between a write to read turnaround for transactions to the same chip select. If a value of 0000 is chosen, then the DDR controller will use the value used for transactions to different chip selects, as defined in TIMING_CFG_0[WRT]. This field can be used to improve performance when operating in burst-chop mode by forcing transactions to the same chip select to use extra cycles, while transaction to different chip selects can utilize the tri-state time on the DRAM interface. Regardless of the value that is set in this field, the value defined by TIMING_CFG_0[WRT] will also be met before issuing a read command.	0000 Default 0001 1 clock 0010 2 clocks 0011 3 clocks 0100 4 clocks 0101 5 clocks 0110 6 clocks 0111 7 clocks 1000 8 clocks 1001 9 clocks 1010 10 clocks 1011 11 clocks 1100 12 clocks 1101 13 clocks 1110 14 clocks 1111 15 clocks

Table 12-34. TIMING_CFG_4 Field Descriptions (Continued)

Bits	Reset	Description	Settings
RRT 23–20	0	**Read-to-Read Turnaround for Same Chip Select** Specifies how many cycles will be added between reads to the same chip select. If a value of 0000 is chosen, then 2 cycles will be required between read commands to the same chip select if 4-beat bursts are used (4 cycles will be required if 8-beat bursts are used). Note that DDR3 does not support 4-beat bursts. However, this field may be used to add extra cycles when burst-chop mode is used, and the DDR controller must wait 4 cycles for read-to-read transactions to the same chip select.	0000 BL/2 clocks 0001 BL/2 + 1 clock 0010 BL/2 + 2 clocks 0011 BL/2 + 3 clocks 0100 BL/2 + 4 clocks 0101 BL/2 + 5 clocks 0110 BL/2 + 6 clocks 0111 BL/2 + 7 clocks 1000 BL/2 + 8 clocks 1001 BL/2 + 9 clocks 1010 BL/2 + 10 clocks 1011 BL/2 + 11 clocks 1100 BL/2 + 12 clocks 1101 BL/2 + 13 clocks 1110 BL/2 + 14 clocks 1111 BL/2 + 15 clocks
WWT 19–16	0	**Write-to-Write Turnaround for Same Chip Select** Specifies how many cycles will be added between writes to the same chip select. If a value of 0000 is chosen, then 2 cycles will be required between write commands to the same chip select if 4-beat bursts are used (4 cycles will be required if 8-beat bursts are used). Note that DDR3 does not support 4-beat bursts. However, this field may be used to add extra cycles when burst-chop mode is used, and the DDR controller must wait 4 cycles for write-to-write transactions to the same chip select.	0000 BL/2 clocks 0001 BL/2 + 1 clock 0010 BL/2 + 2 clocks 0011 BL/2 + 3 clocks 0100 BL/2 + 4 clocks 0101 BL/2 + 5 clocks 0110 BL/2 + 6 clocks 0111 BL/2 + 7 clocks 1000 BL/2 + 8 clocks 1001 BL/2 + 9 clocks 1010 BL/2 + 10 clocks 1011 BL/2 + 11 clocks 1100 BL/2 + 12 clocks 1101 BL/2 + 13 clocks 1110 BL/2 + 14 clocks 1111 BL/2 + 15 clocks
— 25–2	0	Reserved. Write to zero for future compatibility.	
DLL_LOCK 1–0	0	**DDR SDRAM DLL Lock Time** This provides the number of cycles that it will take for the DRAMs DLL to lock at power-on reset and after exiting self refresh. The controller will wait the specified number of cycles before issuing any commands after exiting POR or self refresh.	00 200 clocks 01 512 clocks 10 Reserved 11 Reserved

12.5.19 DDR SDRAM Timing Configuration 5 Register (TIMING_CFG_5)

TIMING_CFG_5 DDR SDRAM Timing Con figuration 5 Offset 0x0164

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

12.5.20 DDR ZQ Calibration Control Register (DDR_ZQ_CNTL)

DDR_ZQ_ CNTL DDR ZQ Calibration Control Offset 0x0170

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ZQ_EN	—			ZQINIT				—				ZQOPER			
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—				ZQCS				—							
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DDR ZQ Calibration Control register provides the enable and controls required for ZQ calibration when using DDR3 SDRAM devices. There is a limitation for various DRAM timing parameters when ZQ calibration is used. The factors involved in this limitation are DDR_ZQ_CNTL[ZQOPER], DDR_ZQ_CNTL[ZQCS], TIMING_CFG_1[PRETOACT], TIMING_CFG_1[REFREC], DDR_SDRAM_INTERVAL[REFINT], and the number of chip selects enabled. If the following condition is true:

```
[((DDR_ZQ_CNTL[ZQOPER] + DDR_ZQ_CNTL[ZQCS])* (# enabled chip selects)) +
TIMING_CFG_1[PRETOACT] + TIMING_CFG_1[REFREC] + 2t_CK] > (DDR_SDRAM_INTERVAL[REFINT])
```

it is possible that one refresh will be skipped when the controller exits self refresh. If this is an issue, then posted refreshes can be used to extend the refresh interval. Another alternative is to use the DDR_SDRAM_MD_CNTL register to force an extra refresh to each chip select after exiting self refresh mode. However, DDR3 timing parameters for most devices/frequencies do not allow missed refresh cycles. **Table 12-36** describes the DDR_ZQ_CNTL fields.

Table 12-36. DDR_ZQ_CNTL Field Descriptions

Bit	Reset	Description	Settings
ZQ_EN 31	0	**ZQ Calibration Enable** This bit determines whether ZQ calibration is used. This bit should be set only if DDR3 memory is used (DDR_SDRAM_CFG[SDRAM_TYPE] = 0b111).	0 ZQ Calibration is not used. 1 ZQ Calibration is used. A ZQCL command is issued by the DDR controller after power-on reset and anytime the DDR controller exits self refresh. A ZQCS command is issued every 32 refresh sequences to account for VT variations.
— 30–28	0	Reserved. Write to zero for future compatibility.	

Table 12-36. DDR_ZQ_CNTL Field Descriptions (Continued)

Bit	Reset	Description	Settings
ZQ_INIT 27–24	0	**Power-on Reset ZQ Calibration Time (t_{ZQinit})** Determines the number of cycles that must be allowed for DRAM ZQ calibration at power-on reset. Each chip select is calibrated separately, and this time must elapse after the ZQCL command is issued for each chip select before a separate command can be issued.	0111 128 clocks 1000 256 clocks 1001 512 clocks 1010 1024 clocks All other values reserved.
— 23–20	0	Reserved. Write to zero for future compatibility.	
ZQOPER 19–16	0	**Normal Operation Full Calibration Time (t_{ZQoper})** Determines the number of cycles that must be allowed for DRAM ZQ calibration when exiting self refresh. Each chip select is calibrated separately, and this time must elapse after the ZQCL command is issued for each chip select before a separate command may be issued.	0111 128 clocks 1000 256 clocks 1001 512 clocks 1010 1024 clocks All other values reserved.
— 15–12	0	Reserved. Write to zero for future compatibility.	
ZQCS 11–8	0	**Normal Operation Short Calibration Time (t_{ZQCS})** Determines the number of cycles that must be allowed for DRAM ZQ calibration during dynamic calibration which is issued every 32 refresh cycles. Each chip select will be calibrated separately, and this time must elapse after the ZQCS command is issued for each chip select before a separate command may be issued.	0000 1 clocks 0001 2 clocks 0010 4 clocks 0011 8 clocks 0100 16 clocks 0101 32 clocks 0110 64 clocks 0111 128 clocks 1000 256 clocks 1001 512 clocks All other values reserved.

DDR_SR_CNTR Register can be programmed to force the DDR controller to enter self refresh after a predefined period of idle time.

Table 12-40. DDR_SR_CNTR Bit Descriptions

Bit	Reset	Description	Settings	
— 31–20	0	Reserved. Write to zero for future compatibility.		
SR_IT 19–16	0	**Self Refresh Idle Threshold** Defines the number of DRAM cycles that must pass while the DDR controller is idle before it will enter self refresh. Anytime a transaction is issued to the DDR controller, it will reset its internal counter. When a new transaction is received by the DDR controller, it will exit self refresh and reset its internal counter. If this field is zero, then the described power savings feature will be disabled. In addition, if a non-zero value is programmed into this field, then the DDR controller will exit self refresh anytime a transaction is issued to the DDR controller, regardless of the reason self refresh was initially entered.	0000 0001 0010 0011 0100 0101 0110 0111 1000 1001 1010 1011 1100-1111	Automatic self refresh entry disabled 2^{10} DRAM clocks 2^{12} DRAM clocks 2^{14} DRAM clocks 2^{16} DRAM clocks 2^{18} DRAM clocks 2^{20} DRAM clocks 2^{22} DRAM clocks 2^{24} DRAM clocks 2^{26} DRAM clocks 2^{28} DRAM clocks 2^{30} DRAM clocks Reserved

DDR_SDRAM_MODE_3 Register sets the values loaded into the DDR mode registers. This register is used specifically for chip select 1 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set.

Table 12-43. DDR_SDRAM_MODE 3 Bit Descriptions

Bit	Refresh	Description
ESDMODE 31–16 MR1	0	**Extended SDRAM Mode** Specifies the initial value loaded into the DDR SDRAM extended mode register. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus during DDR SDRAM initialization, MA0 presents the LSB of ESDMODE, which corresponds to DDR_SDRAM_MODE_3 bit 16. The MSB of the SDRAM extended mode register value must be stored at DDR_SDRAM_MODE_3 bit 31 The value programmed into this field is also used for writing MR1 during write leveling for DDR3, although the bits specifically related to the write leveling scheme are handled automatically by the DDR controller. Even if DDR_SDRAM_CFG[BI] is set, this field is still used during write leveling. The write leveling enable bit should be cleared by software in this field
SDMODE 15–0 MR0	0	**SDRAM Mode** Specifies the initial value loaded into the DDR SDRAM mode register. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus during DDR SDRAM initialization, MA0 presents the LSB of SDMODE, which, corresponds to DDR_SDRAM_MODE_3 bit 0. The MSB of the SDRAM mode register value must be stored at DDR_SDRAM_MODE_3 bit 15. Because the memory controller forces SDMODE[8] to certain values depending upon the state of the initialization sequence (for resetting the SDRAM DLL) which is mapped to MA8; the memory controller ignores the corresponding bits of this field.

12.5.28 DDR SDRAM Mode Configuration 4 Register (DDR_SDRAM_MODE_4)

DDR_SDRAM_MODE_4 DDR SDRAM Mode Configuration 4 Register — Offset 0x0204

DDR_SDDR_SDRAM_MODE_4 register sets the values loaded into the DDR extended mode 2 and 3 registers. This register is used specifically for chip select 1 if DDR_SDRAM_CFG_2[UNQ_MRS_EN] is set.

Table 12-44. DDR_SDRAM_MODE_4 Bit Descriptions

Bit	Reset	Description
ESDMODE2 31–16 MR2	0	**Extended SDRAM Mode 2** Specifies the initial value loaded into the DDR SDRAM Extended 2 Mode Register. The range and meaning of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus during the DDR SDRAM initialization sequence, MA0 presents the LSB bit of ESDMODE2, which corresponds to DDR_SDRAM_MODE_4 bit 16. The MSB of the SDRAM extended mode 2 register value must be stored at DDR_SDRAM_MODE_4 bit 31.
ESDMODE3 15–0 MR3	0	**Extended SDRAM Mode 3** Specifies the initial value loaded into the DDR SDRAM Extended 3 Mode Register. The range of legal values is specified by the DDR SDRAM manufacturer. When this value is driven onto the address bus during DDR SDRAM initialization, MA0 presents the LSB of ESDMODE3, which corresponds to DDR_SDRAM_MODE_4 bit 0. The MSB of the SDRAM extended mode 3 register value must be stored at DDR_SDRAM_MODE_4 bit 15.

12.5.29 DDR Debug Status Register 1 (DDRDSR_1)

DDRDSR_1 DDR Debug Status Register 1 Offset 0x0B20

Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRCDR_1 register sets the driver hardware compensation enable, the DDR MDIC driver P/N impedance, ODT termination value for I/Os, driver software override enable for MDIC, driver software override enable for address/command, driver software override enable for data, the DDR address/command driver P/N impedance, and the DDR data driver P/N impedance.

The fields in DDRCDR_1, except DDRCDR_1[ODT], are used to enable driver calibration with the MDIC pins. This can be used to calibrate the DDR drivers to 36 Ω; however, this should only

be used for full-strength driver applications. If half-strength drivers are used, disable this calibration. Hardware DDR driver calibration is enabled by setting DDRCDR_1[DHC_EN].

Note: All driver calibration (hardware and software) must be done before the DDR controller is enabled (that is, before setting DDR_SDRAM_CFG[MEM_EN]).

Table 12-47. DDRCDR_1 Bit Descriptions

Bit	Reset	Description	Settings
DHC_EN 31	0	**DDR Driver Hardware Compensation Enable**	0 Hardware compensation disabled. 1 Hardware compensation enabled.
DSO_MDIC_EN 30	0	**Driver Software Override Enable for MDIC**	0 Software override for MDIC disabled. 1 Software override for MDIC enabled.
DSO_MDICPZ 29–26	0	**Driver Software Override Value for MDIC P-Impedance**	
DSO_MDICNZ 25–22	0	**Driver Software Override Value for MDIC N-Impedance**	
DSO_MDIC_PZ_OE 21	0	**Driver Software Override for P-Impedance Output Enable**	0 Output override disabled. 1 Output override enabled.
DSO_MDIC_NZ_OE 20	0	**Driver Software Override for N-Impedance Output Enable**	0 Output override disabled. 1 Output override enabled.
ODT 19–18	0	**ODT Termination Value for I/Os** This is combined with DDRCDR_2[ODT] to determine the termination value. The termination value is based on concatenating these 2 fields (DDRCDR_1[ODT]|DDRCDR_2[ODT])	000 75 Ω 001 55 Ω 010 60 Ω 011 50 Ω 100 150 Ω 101 43 Ω 110 120 Ω 111 Reserved
DSO_C_EN 17	0	**Driver Software Override Enable for Address/Command**	0 Override disabled. 1 Override enabled.
DSO_D_EN 16	0	**Driver Software Override Enable for Data**	0 Override disabled. 1 Override enabled.
DSO_CPZ 15–12	0	**DDR Driver Software Override Value for Command P-Impedance Override**	
DSO_CNZ 11–8	0	**DDR Driver Software Override Value for Command N-Impedance Override**	
DSO_DPZ 7–4	0	**DDR Driver Software Override Value for Data P-Impedance Override**	
DSO_DNZ 3–0	0	**DDR Driver Software Override value for Data N-Impedance Override**	

Software can be used to calibrate the drivers instead of the automatic hardware calibration. If software calibration is required, use the following steps:

1. Set DDRCDR_1[DSO_MDIC_EN] and ensure that DDRCDR_1[DHC_EN] is cleared
2. Set the highest impedance (value 0000) for DDRCDR_1[DSO_MDICPZ]
3. Set DDRCDR_1[DSO_MDIC_PZ_OE] to enable the output enable for MDIC[0]

4. After at least 4 cycles, read DDRDSR_1[0]. If the value is 0, then use the next lowest impedance, and read DDRDSR_1[0] again. Once a value of 1 is detected, then leave DDRCDR_1[DSO_MDICPZ] at the calibrated value
5. Clear DDRCDR_1[DSO_MDIC_PZ_OE]
6. After DDRCDR_1[DSO_MDICPZ] is calibrated, set a value of 0000 for DDRCDR_1[DSO_MDICNZ]
7. Set DDRCDR_1[DSO_MDIC_NZ_OE] to enable the output enable for MDIC[1]
8. After at least 4 cycles, read DDRDSR_1[1]. If the value is 1, then use the next lowest impedance, and read DDRDSR_1[1] again. Once a value of 0 is detected, then leave DDRCDR_1[DSO_MDICNZ] at the calibrated value
9. Clear DDRCDR_1[DSO_MDIC_NZ_OE]

The legal impedance values (from highest impedance to lowest impedance) for DDR3 (1.5 V) are:

- 0000 lowest strength/highest impedance
- 0001
- 0011
- 0010
- 0110
- 0111 half strength
- 0101
- 0100
- 1100
- 1101
- 1111
- 1110
- 1010
- 1011
- 1001
- 1000 highest strength/lowest impedance

Reset	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

DDR_MTCR provides enable and control for an automatic memory test.

Table 12-51. DDR_MTCR Bit Descriptions

Bit	Reset	Description	Settings
MT_EN 31	0	**Memory Test Enable** This bit can be set by software to enable memory testing. Based on the value of MT_TYP, the controller either performs only writes, only reads, or reads and writes. The controller issues transactions throughout memory, as defined by the CSx_CONFIG and CSx_BNDS registers. The memory controller checks the data during the test. In addition, if ECC is enabled, the software should read the ERR_DETECT register to ensure there are no ECC errors. If an ECC error is detected, the error capture registers hold the address, data, and attributes captured for the first failure. If no ECC error occurs and the test fails for a data miscompare, the registers hold the data for the first miscompare. Transactions with ECC errors take precedent over data miscompare errors. Hardware clears the MT_EN bit after the test completes. This bit can be set before or after the controller is enabled.	0 Memory test disabled. 1 Memory test enabled.
— 30–26	0	Reserved. Write to zero for future compatibility.	
MT_TYP 25–24	0	**Memory Test Type** This field determines the type of test: write only, read only, or read/write. Do not use the read-only test unless memory is already initialized.	00 Read/write 01 Write only. 10 Read only 11 Reserved.
— 23–20	0	Reserved. Write to zero for future compatibility.	

Table 12-51. DDR_MTCR Bit Descriptions (Continued)

Bit	Reset	Description	Settings
MT_TRNARND 19–16	0	**Memory Test Turnaround** This field determines how many writes to issue during the memory test before the reads to the same addresses are issued. This can be used both to allow longer streams of reads/writes and to test the write-to-read and read-to-write turnarounds in a stressed setting. The field is only used if MT_TYP = 00.	0000 Entire memory is written before read transactions are issued. 0001 Total read/write streams = 1 transaction each. 0010 Total read/write streams = 2 transactions each. 0011 Total read/write streams = 4 transactions each.
— 15–1	0	Reserved. Write to zero for future compatibility.	
MT_STAT 0	0	**Memory Test Status** After hardware clears MT_EN, this bit sets is a failure occurred. If the failure occurred during the memory test (data miscompare), this bit sets at the same time MT_EN is cleared. Software can clear this bit after it is set.	0 No failure detected. 1 Data miscompare detected.

CAPTURE_ECC register stores the ECC syndrome bits on the data bus when an error is detected.

Table 12-58. CAPTURE_ECC Bit Descriptions

Bit	Reset	Description
— 31–16	0	Reserved. Write to zero for future compatibility.
ECE 15–0	0	**Error Capture ECC** Captures the ECC bits on the data path when errors are detected. The high order byte represents the 8-bit ECC code for the first 32 bits and the low order byte represents the 8-bit ECC code for the second 32 bits.

12.5.43 DDR SDRAM Memory Error Detect Register (ERR_DETECT)

ERR_DETECT DDR SDRAM Memory Error Detect Register Offset 0x0E40

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: W1C - Write 0b1 to clear the bit, writing 0b0 as no effect.

ERR_DETECT register stores the detection bits for multiple memory errors, single- and multiple-bit ECC errors, calibration error, and memory select errors. Each bit is cleared when software writes a value of 1 to it. System software can determine the type of memory error by examining the contents of this register. If an error is disabled with ERR_DISABLE, the corresponding error is never detected or captured in ERR_DETECT.

Table 12-59. ERR_DETECT Bit Descriptions

Bit	Reset	Description	Settings
MME 31	0	**Multiple Memory Errors** Indicates whether multiple memory errors of the same type were detected. This bit is cleared by software writing a 1 to it.	0 Multiple memory errors not detected. 1 Multiple memory errors detected.
— 30–9	0	Reserved. Write to zero for future compatibility.	
APE 8	0	Address parity error. Indicates whether an address parity error was detected. This bit is cleared by software writing a 1 to it.	0 An address parity error has not been detected. 1 An address parity error has been detected
ACE 7	0	**Automatic Calibration Error** Indicates whether an automatic calibration error was detected. This bit is cleared by software writing a 1 to it.	0 Error not detected. 1 Error detected.
— 6–5	0	Reserved. Write to zero for future compatibility.	
CDE 4	0	**Corrupted Data Error** This bit is set if the actual ECC value is inverted compared to the expected value.during a read command. The memory controller inverts the ECC code if the DDR_SDRAM_CFG2[CD_DIS] bit is cleared when corrupted data is written to memory. The ERR_DETECT[MBE] bit is also set when a corrupted data error is detected. It is possible for a 2-bit data error to cause the ECC code to become inverted, which would either mask a corrupted data error or cause a normal multi-bit error to also appear as a corrupted data error.	0 Corrupted data error not detected. 1 Corrupted data error detected.
MBE 3	0	**Multiple-Bit Error** Indicates whether a multiple-bit error was detected. This bit is cleared by software writing a 1 to it.	0 Multiple-bit error not detected. 1 Multiple-bit error detected.
SBE 2		**Single-Bit ECC Error** Indicates whether the number of single-bit ECC errors detected is greater than the threshold set in ERR_SBE[SBET]. This bit is cleared by software writing a 1 to it.	0 The number of errors has not crossed the threshold. 1 The number of errors has crossed the threshold.
— 1	0	Reserved. Write to zero for future compatibility.	
MSE 0	0	**Memory Select Error** Indicates whether a memory select error has been detected. This bit is cleared by software writing a 1 to it.	0 Memory select error not detected. 1 Memory select error detected.

12.5.44 DDR SDRAM Memory Error Disable Register (ERR_DISABLE)

ERR_DISABLE DDR SDRAM Memory Error Disable Register Offset 0x0E44

ERR_DISABLE register selectively disables the DDR controller error detection circuitry. Disabled errors are not detected or reported.

Table 12-60. ERR_DISABLE Bit Descriptions

Bit	Reset	Description	Settings
— 31–9	0	Reserved. Write to zero for future compatibility.	
APED 8	0	**Address Parity Error Disable** Enables/disables address parity errors.	0 Address parity errors are enabled. 1 Address parity errors are disabled.
ACED 7	0	**Automatic Calibration Error Disable** Enables/disables automatic calibration errors detection	0 Calibration errors enabled. 1 Calibration errors disabled.
— 6–5	0	Reserved. Write to zero for future compatibility.	
CDED 4	0	**Corrupted Data Error Disable** Enables/disables corrupted data error detection.	0 Corrupted data error checking is enabled. 1 Corrupted data error checking is disabled.
MBED 3	0	**Multiple-Bit ECC Error Disable** Enables/disables multiple-bit ECC errors detection. When this bit is cleared, multiple-bit errors are detected if DDR_SDRAM_CFG[ECC_EN] is set. They are reported if ERR_INT_EN[MBEE] is set.	0 Multiple-bit ECC errors detected 1 Multiple-bit ECC errors not detected or reported.
SBED 2	0	**Single-Bit ECC Error Disable** Enables/disables single-bit ECC errors detection.	0 Single-bit ECC errors detection is enabled. 1 Single-bit ECC errors detection is disabled.
1	0	Reserved. Write to zero for future compatibility.	
MSED 0	0	**Memory Select Error Disable** Enables/disables memory select errors detection.	0 Memory select errors detection is enabled. 1 Memory select errors detection is disabled.

12.5.45 DDR SDRAM Memory Error Interrupt Enable Register (ERR_INT_EN)

ERR_INT_EN DDR SDRAM Memory Error Interrupt Enable Register Offset 0x0E48

ERR_INT_EN register enables ECC interrupts, calibration error, address/command parity error or memory select error interrupts. When an enabled interrupt condition occurs, the DDR Controller interrupt request signal is asserted to the embedded programmable interrupt controller (EPIC).

Table 12-61. ERR_INT_EN Bit Descriptions

Bit	Reset	Description	Settings
— 31–9	0	Reserved. Write to zero for future compatibility.	
APEE 8	0	Address parity error interrupt enable	0 Address parity errors cannot generate interrupts. 1 Address parity errors generate interrupts.
ACEE 7	0	**Automatic Calibration Error Interrupt Enable** Specifies whether automatic calibration errors generate interrupts.	0 Calibration errors cannot generate interrupts. 1 Calibration errors generate interrupts.
— 6–5	0	Reserved. Write to zero for future compatibility.	
CDEE 4	0	**Corrupted Data Error Interrupt Enable** Specifies whether corrupted data errors generate interrupts.	0 Corrupted data errors cannot generate interrupts. 1 Corrupted data errors generate interrupts.
MBEE 3	0	**Multiple-Bit ECC Error Interrupt Enable** Specifies whether multiple-bit ECC errors generate interrupts.	0 Multiple-bit ECC errors cannot generate interrupts. 1 Multiple-bit ECC errors generate interrupts.
SBEE 2	0	**Single-Bit ECC Error Interrupt Enable** Specifies whether single-bit ECC errors generate interrupts.	0 Single-bit ECC errors cannot generate interrupts. 1 Single-bit ECC errors generate interrupts.
— 1	0	Reserved. Write to zero for future compatibility.	
MSEE 0		**Memory Select Error Interrupt Enable** Specifies whether memory select errors generate interrupts.	0 Memory select errors do not generate interrupts. 1 Memory select errors generate interrupts.

12.5.46 DDR SDRAM Memory Error Attributes Capture Register (CAPTURE_ATTRIBUTES)

CAPTURE_ATTRIBUTES DDR SDRAM Memory Error Attributes Capture Register — Offset 0x0E4C

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CAPTURE_ATTRIBUTES register sets attributes for errors including type, size, source, and so on.

Table 12-62. CAPTURE_ATTRIBUTES Bit Descriptions

Bit	Reset	Description	Settings
— 31	0	Reserved. Write to zero for future compatibility.	
BNUM 30–28	0	**Data Beat Number** Captures the data beat number for the detected error. This bit is relevant only for ECC errors.	
— 27	0	Reserved. Write to zero for future compatibility.	
TSIZ 26–24	0	**Transaction Size for Error** Captures the transaction size in 64-bit increments.	000 8 beats. 001 1 beat. 010 2 beats. 011 3 beats. 100 4 beats. 101 5 beats. 110 6 beats. 111 7 beats.
— 23–14	0	Reserved. Write to zero for future compatibility.	
TTYP 13–12	0	**Transaction Type for Error** Specifies the access type that generates the error.	00 Reserved. 01 Write. 10 Read. 11 Read-modify-write.
— 11–1	0	Reserved. Write to zero for future compatibility.	
VLD 0	0	**Valid** Set as soon as valid information is captured in the error capture registers.	0 No valid information captured 1 Valid information captured

12.5.47 DDR SDRAM Memory Error Address Capture Register (CAPTURE_ADDRESS)

CAPTURE_ADDRESS DDR SDRAM Memory Error Address Capture Register — Offset 0x0E50

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ERR_SBE register stores the threshold value for reporting single-bit errors and the number of single-bit errors counted since the last error report. When the counter field reaches the threshold, it wraps back to the reset value (0). If necessary, software must clear the counter after it has managed the error.

Table 12-64. ERR_SBE Bit Descriptions

Bit	Reset	Description
— 31–24	0	Reserved. Write to zero for future compatibility.
SBET 23–16	0	**Single-Bit Error Threshold** Establishes the number of single-bit errors that must be detected before an error condition is reported.
— 15–8	0	Reserved. Write to zero for future compatibility.
SBEC 7–0	0	**Single-Bit Error Counter** Indicates the number of single-bit errors detected and corrected since the last error report. If single-bit error reporting is enabled, an error is reported when this value cross the SBET value. SBEC is automatically cleared when the threshold value is reached.

13 Interrupt Handling

This chapter describes interrupt handling at the device level. All interrupts that are connected to the different processing cores in the system (SC3850 DSP cores and QUICC Engine and MAPLE RISC cores) and/or to different I/O pins (external events) are included in this chapter along with the device level interrupt programming model and functionality.

Note: Detailed explanations and descriptions of the different interrupts are not provided in this chapter. Refer to the chapter for the specific module that is the interrupt source. For example, for details about CPRI interrupts, refer to **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.

The MSC8157E interrupt system is optimized for a multi-processing environment, routing each interrupt source to each of the SC3850 cores with programmable masking by core, which allows the following:

- Flexible resource allocation as well as a symmetrical or a non-symmetrical application architecture.
- Core-to-core full interrupt mesh.
- External host-to-core signalling mechanism through virtual interrupt generation.

In addition to the SC3850 core interrupt capability, the MSC8157E also includes the following:

- Routes CPRI interrupts to the MAPLE-B block with programmable masking of each interrupt source for the MAPLE block.
- Routes SEC and Serial RapidIO interrupts directly to the QUICC Engine processors with programmable masking of the each interrupt source for the QUICC Engine processors.

The MSC8157E supports both internal and external interrupt sources as well as allowing for the generation of an interrupt to external devices.

There are five device level interrupt handlers in the MSC8157E:

1. *Global interrupt controller*. Allows for the generation of virtual interrupt requests (VIRQ) as well as virtual non-maskable interrupts (VNMI) towards the cores as well as generates interrupts to external devices.
2. *General configuration block*. Concentrates and routes rare and debug interrupts to the SC3850 cores.
3. *Embedded programmable interrupt controller (EPIC)*. Concentrates all the interrupt directed at the associated core and dispatches the highest priority interrupt to the SC3850 core. Although there are various interrupts in the system designated as non-maskable interrupts (NMIs), you must program them to be non-maskable in the EPIC. This is typically done by the boot program. See the *SC3850 DSP Core Subsystem Reference Manual* for details about the EPIC. The manual is available with a signed non-disclosure agreement. Contact your local Freescale dealer or sales representative for more information.
4. *QUICC Engine interrupt controller*. The QUICC Engine module includes an interrupt controller that handles interrupts within the module for the dual-RISC processor system. The user can configure this controller, using general configuration registers, to receive either the SEC primary interrupt or the Serial RapidIO eMSG Queue Manager Receive/Transmit interrupts. The Serial RapidIO eMSG Queue Manager Receive/Transmit interrupts are doorbells, and used for messaging filtering or offloading the core. The SEC interrupt is also used for offloading work from the core. For details about that interrupt controller and how to program it, refer to **Chapter 19**, *QUICC Engine Subsystem* and the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM).
5. *MAPLE-B2 interrupt controller*. The MAPLE-B2 includes an interrupt controller that handles interrupts within the module for the quad-RISC processor system. The interrupts from the CPRI controllers that indicate start of frame are connected to the Chip Rate Processing Element Down Link module for synchronization between the CPRI and CRPE modules. For details about that interrupt controller and how to program it, refer to **Chapter 26**, *Multi Accelerator Platform Engine, Baseband 2 (MAPLE-B2)*.

Part of the device interrupts are directed to the performance monitor module for counting and used in debug scenarios. For details about these use cases and connectivity, refer to **Chapter 25**, *Debugging, Profiling, and Performance Monitoring*.

13.1 Global Interrupt Controller (GIC)

The GIC generates 16 VIRQs and 8 VNMIs to the DSP cores by writing to registers in the GIC memory map. The GIC also uses two additional VIRQ slots to generate a non-maskable interrupt $\overline{\text{NMI\_OUT}}$ and a maskable interrupt $\overline{\text{INT\_OUT}}$ to external devices. A virtual interrupt/VNMI is generated via a write access to the Virtual Interrupt Generation Register (VIGR) by one of the SC3850 cores or an external host CPU. **Table 13-1** describes the destination of the supported VIRQs.

Table 13-1. VIRQ Description

VIRQ Num	Destination
VIRQ_0	Connected to Virtual Interrupt 0 at SC3850
VIRQ_1	Connected to Virtual Interrupt 1 at SC3850
VIRQ_2	Connected to Virtual Interrupt 2 at SC3850
VIRQ_3	Connected to Virtual Interrupt 3 at SC3850
VIRQ_4	Connected to Virtual Interrupt 4 at SC3850
VIRQ_5	Connected to Virtual Interrupt 5 at SC3850
VIRQ_6	Connected to Virtual Interrupt 6 at SC3850
VIRQ_7	Connected to Virtual Interrupt 7 at SC3850
VIRQ_8	Connected to Virtual Interrupt 8 at SC3850
VIRQ_9	Connected to Virtual Interrupt 9 at SC3850
VIRQ_10	Connected to Virtual Interrupt 10 at SC3850
VIRQ_11	Connected to Virtual Interrupt 11 at SC3850
VIRQ_12	Connected to Virtual Interrupt 12 at SC3850
VIRQ_13	Connected to Virtual Interrupt 13 at SC3850
VIRQ_14	Connected to Virtual Interrupt 14 at SC3850
VIRQ_15	Connected to Virtual Interrupt 15 at SC3850
VIRQ_16	Connected to VNMI_0
VIRQ_17	Connected to VNMI_1
VIRQ_18	Connected to VNMI_2
VIRQ_19	Connected to VNMI_3
VIRQ_20	Connected to VNMI_4
VIRQ_21	Connected to VNMI_5
VIRQ_22	Connected to VNMI_6
VIRQ_23	Connected to VNMI_7
VIRQ_24	Use to generate $\overline{\text{INT\_OUT}}$ (see **13.2.3**, *External Interrupts*)
VIRQ_25	Use to generate $\overline{\text{NMI\_OUT}}$ (see **13.2.3**, *External Interrupts*)

The GIC has a status register to indicate whether a virtual interrupt was generated at least once, while not preventing the generation of another interrupt. The core that services the interrupt may clear this status bit by writing a value of one to it, or it may ignore this bit and work locally.

13.2 General Configuration Block

The general configuration block performs services for rare and debug interrupts generated throughout the MSC8157E before they reach the SC3850 EPICs. These services include:

- Generating ORed interrupt signals towards the SC3850 cores (see **Section 13.2.1**).
- Providing an interrupt enable bit for each interrupt source for each SC3850 core (see **Section 13.5.2**, *General Interrupt Configuration*, on page 13-29).
- Providing a status bit for each interrupt source. These bits are shared for all the SC3850 cores (see **Section 13.5.2**, *General Interrupt Configuration*, on page 13-29).

The general configuration block also performs services for interrupts generated by the CPRI controllers before they reach the MAPLE-B2 engine. These services include:

- Providing an interrupt enable bit for each interrupt source.
- Providing a status bit for each interrupt source.

The general configuration block also performs services for interrupts generated by the Serial RapidIO controllers and SEC before they reach the QUICC Engine processors. These services include:

- Generating an ORed interrupt signal towards the QUICC Engine dual-RISC processor system.
- Providing an interrupt enable bit for each interrupt source.
- Providing a status bit for each interrupt source.

13.2.1 Interrupt Groups Toward the SC3850 Cores

The general configuration block generates 11 interrupts based on the groups of ORed interrupts described in **Table 13-2**.

Table 13-2. SC3850 Core General Configuration Block Interrupt Sources

CPRI Rx Ctl	CPRI TX Ctl	CPRI Rx Frame Timing	CPRI Tx Frame Timing	Debug	SRIO eMSG Buffer Mgr	SRIO eMSG Rx Queue Mgr	SRIO eMSG Tx Queue Mgr	General	MAPLE-B2	Watch Dog Timer
CPRI1	CPRI1	CPRI1	CPRI1	CLASS0 overrun	BM0	QM0	QM0	CPRI	MAPLE general error	Watch Dog Timer 0
CPRI2	CPRI2	CPRI2	CPRI2	CLASS0 watch point	BM1	QM1	QM1	SRIO/ eMSG		Watch Dog Timer 1
CPRI3	CPRI3	CPRI3	CPRI3	CLASS0 error	BM2	QM2	QM2	BM		Watch Dog Timer 2
CPRI4	CPRI4	CPRI4	CPRI4	CLASS1 overrun	BM3	QM3	QM3	QM		Watch Dog Timer 3
CPRI5	CPRI5	CPRI5	CPRI5	CLASS1 watch point	BM4	QM4	QM4	eMSG multi-bit error		Watch Dog Timer 4
CPRI6	CPRI6	CPRI6	CPRI6	CLASS1 error	BM5	QM5	QM5	SRIO1 multi-bit error		Watch Dog Timer 5

				Core0–1 MEX addr error	BM7	QM7	QM7	PCI Exp multi-bit error		Watch Dog Timer 7
				Core2–3 MEX addr error				PCI Exp internal multi-bit error		
				Core4–5 MEX addr error				QUICC Engine IMEM multi-bit error		
								DMA		
								OCN0 to MBus		
								OCN1 to MBus		
								MAPLE multi-bit error		
								DDR		
								OCN0 DMA multi-bit error		
								OCN1 DMA double error		

13.2.2 Interrupt Groups Toward QUICC Engine Processors

The general configuration block generates 4 interrupts based on the groups of ORed interrupts described in **Table 13-3**. These interrupts are multiplexed with the SEC primary interrupt. The multiplexer is controlled by General Configuration Registers CPCE1R to CPCE4R (see **Section 8.2.16**, *QUICC Engine First External Request Multiplex Register (CPCE1R)*, on page 8-27.and the following three subsections).

Table 13-3. QUICC Engine General Configuration Block Interrupt Sources

SRIO eMSG Rx Interrupt Source #1	SRIO eMSG Rx Interrupt Source #2	SRIO eMSG Tx Interrupt Source #1	SRIO eMSG Tx Interrupt Source #2
QM0	QM0	QM0	QM0
QM1	QM1	QM1	QM1
QM2	QM2	QM2	QM2
QM3	QM3	QM3	QM3
QM4	QM4	QM4	QM4
QM5	QM5	QM5	QM5
QM6	QM6	QM6	QM6
QM7	QM7	QM7	QM7

Note: The provided redundancy allows the user to configure which Queue Manager Interrupt to receive. For example, the general SRIO eMSG Rx Interrupt Source #1 can be configured to pass on only the interrupt for Queue Manager 2, while SRIO eMSG Rx Interrupt Source #2 can be configured to pass on only the interrupt for Queue Manager 4.

13.2.3 External Interrupts

The MSC8157E allows a number of external interrupt inputs to be multiplexed with the GPIO signals to enable external devices to interrupt the cores (see **Chapter 21**, *GPIO*). There are also dedicated external interrupt pins.

Note: All external $\overline{\text{IRQ}}$ signals are multiplexed options of the associated GPIO ports.

Table 13-4 summarizes all the external interrupt inputs in the MSC8157E.

Table 13-4. MSC8157E External Interrupt Pins

Name	GPIO	Direction
$\overline{\text{NMI}}$	N/A	In
$\overline{\text{NMI\_OUT}}/\overline{\text{CP\_RX\_INT}}$	N/A	Out
$\overline{\text{INT\_OUT}}/\overline{\text{CP\_TX\_INT}}$	N/A	Out
$\overline{\text{IRQ0}}$	GPIO0	In
$\overline{\text{IRQ1}}$	GPIO1	In

Table 13-4. MSC8157E External Interrupt Pins (Continued)

Name	GPIO	Direction
$\overline{\text{IRQ2}}$	GPIO2	In
$\overline{\text{IRQ3}}$	GPIO3	In
$\overline{\text{IRQ4}}$	GPIO4	In
$\overline{\text{IRQ5}}$	GPIO5	In
$\overline{\text{IRQ6}}$	GPIO6	In
$\overline{\text{IRQ7}}$	GPIO7	In
$\overline{\text{IRQ8}}$	GPIO8	In
$\overline{\text{IRQ9}}$	GPIO9	In
$\overline{\text{IRQ10}}$	GPIO10	In
$\overline{\text{IRQ11}}$	GPIO11	In
$\overline{\text{IRQ12}}$	GPIO12	In
$\overline{\text{IRQ13}}$	GPIO13	In
$\overline{\text{IRQ14}}$	GPIO14	In
$\overline{\text{IRQ15}}$	GPIO15	In

$\overline{\text{INT\_OUT}}$ is asserted when VIRQ_24 is asserted. $\overline{\text{NMI\_OUT}}$ is asserted when VIRQ_25 is asserted. $\overline{\text{CP\_RX\_INT}}$ is a CPRI Receive Interrupt asserted by the CPRI controller that is constantly ORed with $\overline{\text{NMI\_OUT}}$. $\overline{\text{CP\_TX\_INT}}$ is a CPRI Transmit Interrupt asserted by the CPRI controller that is constantly ORed with $\overline{\text{INT\_OUT}}$. See **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*for details.

13.2.4 Interrupt Groups Directed Toward MAPLE-B2

The general configuration block generates three interrupts based on the CPRI interrupts 1 to 3. Each interrupt is sampled and can be masked separately through GIR8 and MAPLE_EXT_REQ_EN_1 (see **Chapter 8**, *General Configuration Registers*). There are three interrupts that connect directly to the MAPLE CRPE, as follows:

- CPRI1 indicates a sub-slot (256 chips).
- CPRI2 indicates a frame.
- CPRI3 indicates a chunk (16 chips).

The use of these interrupts is described in detail in **Chapter 26**, *Multi Accelerator Platform Engine, Baseband 2 (MAPLE-B2)*. These are the same three interrupts that connect directly between the CPRI and the SC3850 cores, as described in **Section 13.3**, *Interrupt Mapping*, on page 13-9.

13.2.5 Interrupt Handling

The MSC8157E interrupts sources can be grouped in to four basic types:

1. Interrupts that represent a single interrupt source and are routed directly to the cores (for example, the DMA channel 0 EOB interrupt).
2. Interrupts that represent multiple interrupt sources and are routed directly to the cores (for example, all I^2C interrupts).
3. Interrupts that represent a single interrupt source and are routed to the cores via the general configuration block (for example, MAPLE general error interrupt).
4. Interrupts that represent multiple interrupt sources and are routed to the cores via the General Configuration Block (for example, a serial RapidIO eMSG Buffer Manager Interrupt).

Figure 13-1 outlines the flow for handling the various types of interrupts.

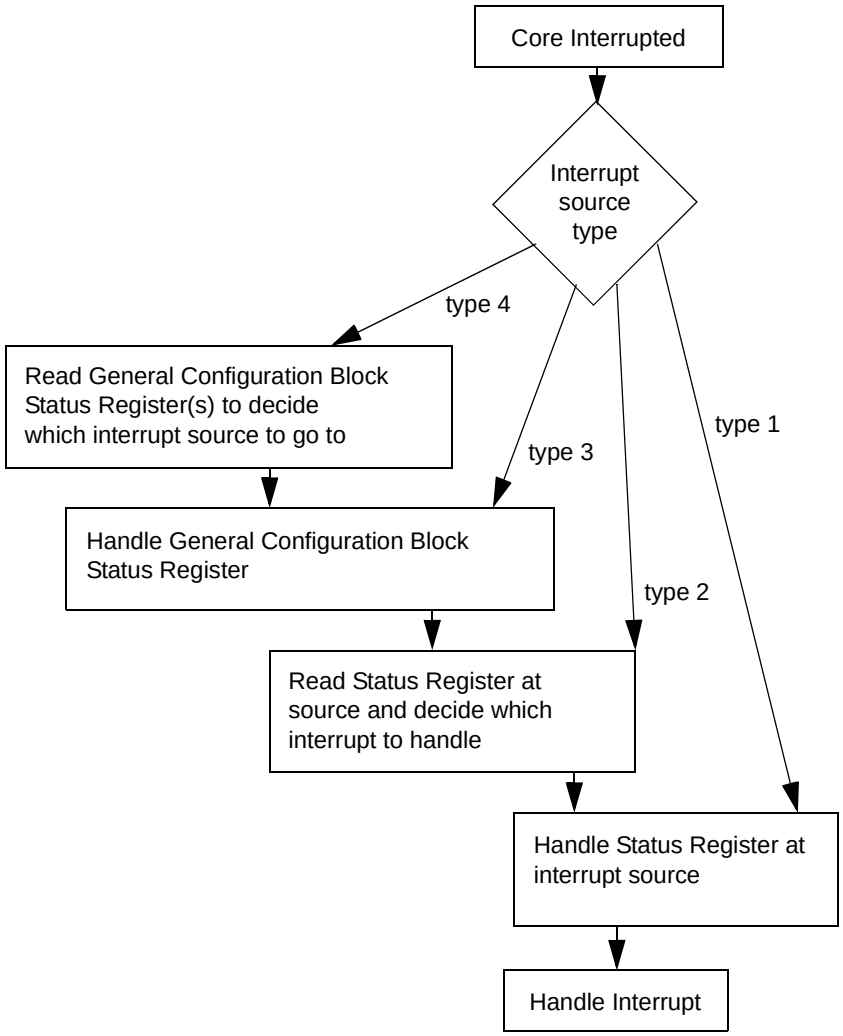

Figure 13-1. Interrupt Handling Flow

As an example of handling a type 4 interrupt, processing of a QUICC Engine interrupt is provided. In **Table 13-2**, there are two types of QUICC Engine interrupts that are routed through the GCRs:

- DRAM multi-bit error
- IMEM multi-bit error

When enabled and unmasked, both interrupts are concentrated to the GCR general interrupt which is routed to all cores. The GIER1_[0–5] registers allow the user to mask/unmask the interrupts for any or all of the cores.

If the general interrupt from the GCR is received by a core (index 245), the ISR should read GIR1 (GCR offset 0x80) to identify the origin of the general interrupt. Bits 18 and 19 in the register represent DRAM multi-bit error and IMEM multi-bit error, respectively. After identifying that the interrupt is coming from the QUICC Engine subsystem, the cores can handle the interrupt in the same way as other QUICC Engine interrupts that are directed to the DSP core subsystems.

There are nine other QUICC Engine interrupts that use indexes 132–141 as indicated in **Table 13-5**. Details about the QUICC Engine interrupt controller and how to use this interrupts is provided in **Section 19.5** and the *QUICC Engine Block Reference Manual with Interworking* (QEIWRM).

13.3 Interrupt Mapping

The EPIC can support up to 256 interrupt sources that can be level-, edge-, or double-edge triggered. The interrupts can have an assigned priority from 1(lowest) to 31 (highest) as well as non-maskable (priority 32). The first 34 interrupt sources are used internally by the SC3850 DSP cores. The core-to-core interrupt mesh uses another 12 interrupts for core-to-core communication. All other interrupts are used by the MSC8157E device. The MSC8157E does not implement all of these possible sources.

Table 13-5 describes the interrupt capabilities (level/edge) and index for each interrupt source. The interrupt default priority at wake up is 0 (all interrupts are ignored). Interrupt sources routed via the general configuration block do not appear in the table because their function is set by the GCR.

13.4 Core Interrupt Mesh

To enhance communication between the six SC3850 DSP core subsystems, the MSC8157E has a core interrupt mesh. This mesh is built by connecting two interrupts from each of the SC3850 core subsystems to each of the DSP core subsystems (including itself). **Table 13-7** describes the interrupt names connecting the DSP core subsystems:

Table 13-7. Core Interrupt Mesh

From/To	Core Subsystem 0	Core Subsystem 1	Core Subsystem 2	Core Subsystem 3	Core Subsystem 4	Core Subsystem 5
Core Subsystem 0	M_GPR0[1:0]	M_GPR0[3:2]	M_GPR0[5:4]	M_GPR0[7:6]	M_GPR0[9:8]	M_GPR0[11:10]
Core Subsystem 1	M_GPR0[1:0]	M_GPR0[3:2]	M_GPR0[5:4]	M_GPR0[7:6]	M_GPR0[9:8]	M_GPR0[11:10]
Core Subsystem 2	M_GPR0[1:0]	M_GPR0[3:2]	M_GPR0[5:4]	M_GPR0[7:6]	M_GPR0[9:8]	M_GPR0[11:10]
Core Subsystem 3	M_GPR0[1:0]	M_GPR0[3:2]	M_GPR0[5:4]	M_GPR0[7:6]	M_GPR0[9:8]	M_GPR0[11:10]
Core Subsystem 4	M_GPR0[1:0]	M_GPR0[3:2]	M_GPR0[5:4]	M_GPR0[7:6]	M_GPR0[9:8]	M_GPR0[11:10]
Core Subsystem 5	M_GPR0[1:0]	M_GPR0[3:2]	M_GPR0[5:4]	M_GPR0[7:6]	M_GPR0[9:8]	M_GPR0[11:10]

Note: See the *SC3850 DSP Core Subsystem Reference Manual* for assertion/deassertion of the smmu_gpr signals. As an example of how to use this information, to assert an interrupt from core 1 to core 2, set bit 5 or 4 in M_GPR0 in the core 1 subsystem, which is the sending core.

13.5 Programming Model

The MSC8157E interrupt program model includes configuration of the global interrupt controller and the general configuration block interrupt registers.

Note: See the *SC3850 DSP Core Subsystem Reference Manual* for configuration and programming of the EPIC registers.

13.5.1 Global Interrupt Controller

The virtual interrupt registers reside in a 256-byte address space (for more information see **Chapter 9**, *Memory Map*) and include:

- Virtual Interrupt Generation Register (VIGR)
- Virtual Interrupt status register (VISR)

Note: The GIC registers use a base address of: 0xFFF27000.

13.5.1.1 Virtual Interrupt Generation Register (VIGR)

VIGR Virtual Interrupt Generation Register Offset 0x00

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Type	W															

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	—	—	—	—	—	VIRQNUM_H		—	—	—	—	—	VIRQNUM_L		
Type	W															

VIGR generates virtual interrupts according to the written data. The VIRQ generated corresponds to the combination of {VIRQNUM_H, VIRQNUM_L}. A read from VIGR returns all zeros. Notice that the supported values of {VIRQNUM_H, VIRQNUM_L} are 0 to 25.

Table 13-8. VIGR Bit Descriptions

Name	Description	Settings
— 31–10	Reserved. Write to zero for future compatibility.	
VIRQNUM_H 9–8	**Virtual Interrupt Number (High)** The high bits of the virtual interrupt index number.	00 to 11
— 7–3	Reserved. Write to zero for future compatibility.	
VIRQNUM_L 2–0	**Virtual Interrupt Number (Low)** The low bits of the virtual interrupt index number.	000 to 111

13.5.1.2 Virtual Interrupt Status Register (VISR)

VISR Virtual Interrupt Status Register ‘Offset 0x08

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	—	—	—	—	—	VS25	VS24	VS23	VS22	VS21	VS20	VS19	VS18	VS17	VS16
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	VS15	VS14	VS13	VS12	VS11	VS10	VS9	VS8	VS7	VS6	VS5	VS4	VS3	VS2	VS1	VS0
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each bit in the VISR corresponds to one virtual interrupt source, selected by proper write access to the VIGR. When the interrupt is generated by this write access, the GIC sets the corresponding status bit. It is the responsibility of the interrupt service routine (ISR) of the destination to clear only the correct status bits by writing ones to them. Writing zeros to status bits has no effect on their status. A set status bit does not block the generation of another virtual interrupt pulse by additional writes to VIGR.

Table 13-9. VISR Bit Descriptions

Name	Description	Settings
— 31–26	Reserved. Write to zero for future compatibility.	
VS25 25	**Virtual Interrupt 25 Status** Reflects the status of $\overline{\text{NMI\_OUT}}$/$\overline{\text{CP\_RX\_INT}}$.	0 Interrupt not asserted 1 Interrupt asserted
VS24 24	**Virtual Interrupt 24 Status** Reflects the status of $\overline{\text{INT\_OUT}}$/$\overline{\text{CP\_TX\_INT}}$.	0 Interrupt not asserted 1 Interrupt asserted
VS23 23	**Virtual Interrupt 23 Status** Reflects the status of VNMI_7.	0 Interrupt not asserted 1 Interrupt asserted
VS22 22	**Virtual Interrupt 22 Status** Reflects the status of VNMI_6.	0 Interrupt not asserted 1 Interrupt asserted
VS21 21	**Virtual Interrupt 21 Status** Reflects the status of tVNMI_5.	0 Interrupt not asserted 1 Interrupt asserted
VS20 20	**Virtual Interrupt 20 Status** Reflects the status of VNMI_4.	0 Interrupt not asserted 1 Interrupt asserted
VS19 19	**Virtual Interrupt 19 Status** Reflects the status of VNMI_3.	0 Interrupt not asserted 1 Interrupt asserted
VS18 18	**Virtual Interrupt 18 Status** Reflects the status of VNMI_2.	0 Interrupt not asserted 1 Interrupt asserted
VS17 17	**Virtual Interrupt 17 Status** Reflects the status of VNMI_1.	0 Interrupt not asserted 1 Interrupt asserted

Table 13-9. VISR Bit Descriptions (Continued)

Name	Description	Settings
VS16 16	**Virtual Interrupt 16 Status** Reflects the status of VNMI_0.	0 Interrupt not asserted 1 Interrupt asserted
VS15 15	**Virtual Interrupt 15 Status** Reflects the status of the core virtual interrupt 15.	0 Interrupt not asserted 1 Interrupt asserted
VS14 14	**Virtual Interrupt 14 Status** Reflects the status of the core virtual interrupt 14.	0 Interrupt not asserted 1 Interrupt asserted
VS13 13	**Virtual Interrupt 13 Status** Reflects the status of the core virtual interrupt 13.	0 Interrupt not asserted 1 Interrupt asserted
VS12 12	**Virtual Interrupt 12 Status** Reflects the status of the core virtual interrupt 12.	0 Interrupt not asserted 1 Interrupt asserted
VS11 11	**Virtual Interrupt 11 Status** Reflects the status of the core virtual interrupt 11.	0 Interrupt not asserted 1 Interrupt asserted
VS10 10	**Virtual Interrupt 10 Status** Reflects the status of the core virtual interrupt 10.	0 Interrupt not asserted 1 Interrupt asserted
VS9 9	**Virtual Interrupt 9 Status** Reflects the status of the core virtual interrupt 9.	0 Interrupt not asserted 1 Interrupt asserted
VS8 8	**Virtual Interrupt 8 Status** Reflects the status of the core virtual interrupt 8.	0 Interrupt not asserted 1 Interrupt asserted
VS7 7	**Virtual Interrupt 7 Status** Reflects the status of the core virtual interrupt 7.	0 Interrupt not asserted 1 Interrupt asserted
VS6 6	**Virtual Interrupt 6 Status** Reflects the status of the core virtual interrupt 6.	0 Interrupt not asserted 1 Interrupt asserted
VS5 5	**Virtual Interrupt 5 Status** Reflects the status of the core virtual interrupt 5.	0 Interrupt not asserted 1 Interrupt asserted
VS4 4	**Virtual Interrupt 4 Status** Reflects the status of the core virtual interrupt 4.	0 Interrupt not asserted 1 Interrupt asserted
VS3 3	**Virtual Interrupt 3 Status** Reflects the status of the core virtual interrupt 3.	0 Interrupt not asserted 1 Interrupt asserted
VS2 2	**Virtual Interrupt 2 Status** Reflects the status of the core virtual interrupt 2.	0 Interrupt not asserted 1 Interrupt asserted
VS1 1	**Virtual Interrupt 2 Status** Reflects the status of the core virtual interrupt 1.	0 Interrupt not asserted 1 Interrupt asserted
VS0 0	**Virtual Interrupt 0 Status** Reflects the status of the core virtual interrupt 0.	0 Interrupt not asserted 1 Interrupt asserted

13.5.2 General Interrupt Configuration

The general configuration block resides in a 128-byte address space (see **Chapter 9**, *Memory Map*). These registers are described in detail in **Chapter 8**, *General Configuration Registers*. The registers that concentrate and route rare and debug interrupts to the SC3850 cores are:

- General Interrupt Register 1 (GIR1), see **page 8-41**
- General Interrupt Enable Registers 1 for Cores 0–5 (GIER1_[0–5]), see **page 8-41**
- General Interrupt Register 3 (GIR3), see **page 8-42**
- General Interrupt Enable Registers 3 for Cores 0–5 (GIER3_[0–5]), see **page 8-44**
- General Interrupt Register 5 (GIR5), see **page 8-46**
- General Interrupt Enable Registers 5 for Cores 0–5 (GIER5_[0–5]), see **page 8-48**
- General Interrupt Register 6 (GIR6), see **page 8-71**
- General Interrupt Enable Registers 6 for Cores 0–5 (GIER6_[0–5], see **page 8-74**
- General Interrupt Register 7 (GIR7), see **page 8-77**
- General Interrupt Enable Registers 7 for Cores 0–5 (GIER7_[0–5], see **page 8-79**

The registers that route CPRI interrupts to the MAPLE-B2 are:

- General Interrupt Register 8 (GIR8), see **page 8-91**
- CPRI Interrupt to MAPLE External Request Enable (MAPLE_EXT_REQ_EN_1), see **page 8-95**

The registers that concentrate, multiplex, and route CPRI interrupts to the QUICC Engine module are:

- General Interrupt Register 7 (GIR7), see **page 8-77**
- eMSG to QUICC Engine External Request Enable (CPCEER), see **page 8-84**
- QUICC Engine First External Request Multiplex Register (CPCE1R), see **page 8-27**
- QUICC Engine Second External Request Multiplex Register (CPCE2R), see **page 8-28**
- QUICC Engine Third External Request Multiplex Register (CPCE3R), see **page 8-29**
- QUICC Engine Fourth External Request Multiplex Register (CPCE4R), see **page 8-30**

Note: The general interrupt configuration registers use a base address of: 0xFFF28000.

13.5.3 Programming Restrictions

If a precise interrupt occurs in the SC3850 subsystem, the cause of the interrupt must be resolved before returning from the interrupt handler to normal code execution. If the interrupt is not resolved and cleared, an endless loop can occur and cause a deadlock. For details, see the *SC3850 DSP Subsystem Reference Manual*, **Appendix C**: *Error Handling*.

14 Direct Memory Access (DMA) Controller

The DMA controller enables data movement and rearrangement while the DSP cores work independently. It can transfer blocks of data to and from the M2 memory, M3 memory, and the DDR SDRAM controllers via the CLASS. It has 16 high-speed bidirectional channels and can be commanded from each of the DSP subsystems, as well as from up to two external initiators through the RapidIO or PCI Express interfaces using buffer descriptors (BDs). All channels are capable of complex data movement and advanced transaction chaining. Operations such as descriptor fetches and block transfers are initiated by each of the sixteen channels. Full duplex operation allows the DMA controller to read data from one target and store it in its internal memory while concurrently writing another buffer to another target. This capability can be used extensively when data is read from the M3 memory and written into the M2 memory. The bidirectional DMA controller reads from one of the CLASS target ports while writing to the second one. The DMA controller supports smart arbitration algorithms such as round-robin and a timer-based mechanism using an earliest deadline first (EDF) algorithm. The DMA controller also supports a Debug mode and profiling for application development and testing. **Figure 14-1** shows the DMAC block diagram.

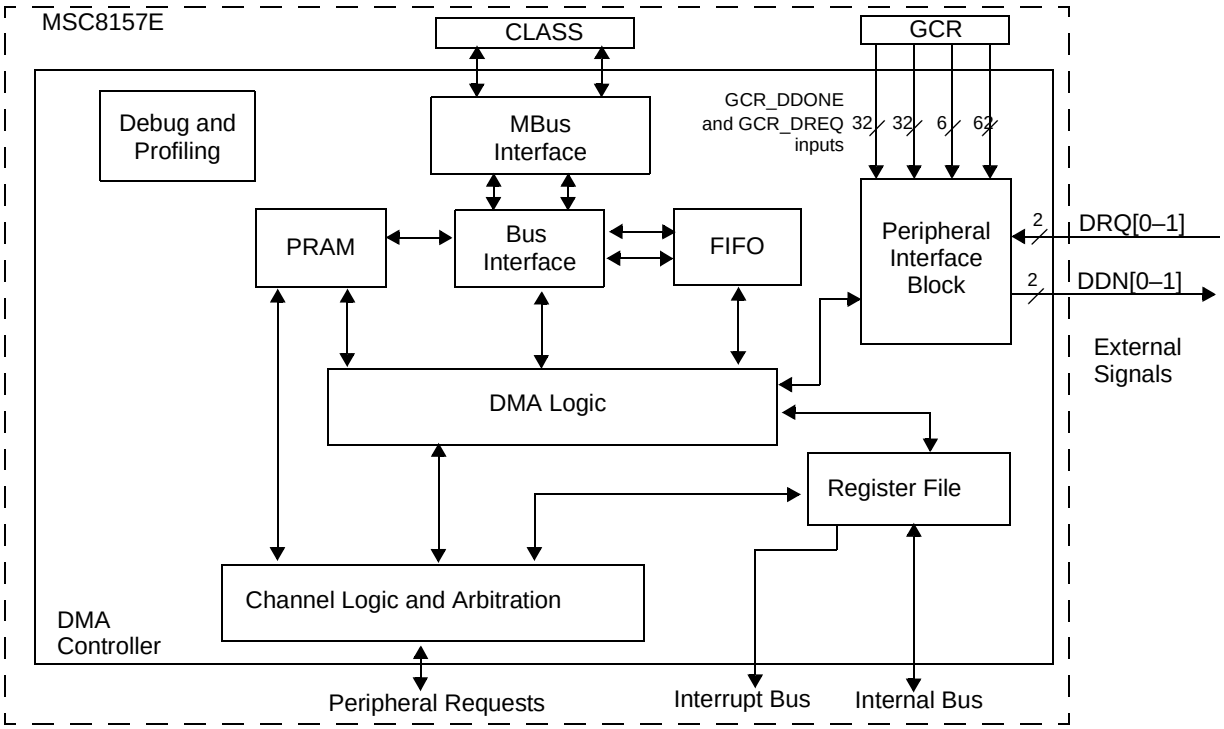

Figure 14-1. DMA Controller Block Diagram

14.1 Operating Modes

The DMA controller supports to modes of operation:

- *Functional mode*. Each of the data transactions can be executed on each of the MBus ports. The DMAC supports memory to memory data transfers.
- *Debug mode*. The DMAC enters the debug by external debug request. Once the DMAC enters the debug mode, it holds its requests to the MBus ports. The internal logic in the DMAC masks the channels.
  - MBus is in debug mode and each of its ports gracefully stops its transaction.
  - Channel logic in debug mode. The arbitration mechanism masks all channels requests. The last serviced channel gets is fully serviced.

14.2 Buffer Types

The DMA channel parameter RAM (PRAM) is accessible to the DMA controller and the port interface and includes a parity mechanism. Each channel has one dedicated PRAM line. The external BD is fetched into the PRAM the first time the channel wins during arbitration.

When a buffer is activated, the DMA controller generates a bus transaction with a maximum size as described in the buffer descriptor BTSZ field and decrements BD_SIZE accordingly. The address can increment or freeze. When BD_SIZE reaches zero, the channel takes one of the following actions:

- Shuts down (simple buffer)
- Reinitializes itself (cyclic buffer)
- Reinstalls its size (incremental buffer)
- Switches to another buffer (chained-buffers)
- Any combination of the preceding
- Updates the multi-dimension parameters (multi dimension-buffers)

The sections that follow provide examples of several types of buffers. The BD_ATTR fields listed for each example are only those that do not have zero values.

14.2.1 One-Dimensional Simple Buffer

A simple channel is a buffer that closes when BD_SIZE reaches zero. It is defined by clearing the BD_ATTR[CONT] field to zero (see **Table 14-28*BD_ATTR Field Descriptions,*** on page 14>-48). **Figure 14-2** shows an example simple buffer.

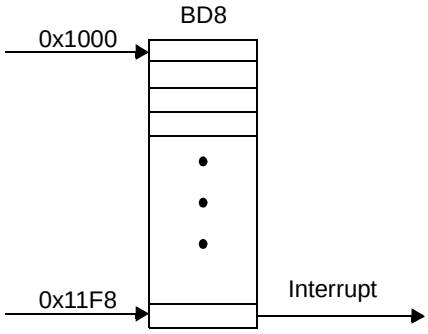

Figure 14-2. One-Dimensional Simple Buffer

Table 14-1 shows how a simple buffer, designated as BD8, is configured. A 0x200 byte block is read from address 0x1000. The channel closes when the data transfer is complete, and an interrupt is generated. Burst transactions are used on the bus.

Table 14-1. Channel Parameter Values for a Simple Buffer

BD	BD Parameters		Value	Description
8	BD_ADDR		0x1000	External memory buffer current address.
	BD_SIZE		0x200	Size of transfer left for this buffer.
	BD_BSIZE		—	Buffer base size of cyclic buffer.
	BD_ATTR	SST	0x1	Generate interrupt when buffer ends.
		CONT	0x0	Non-continuous mode: the buffer closes when the size reaches zero.
		CYC	0x0	Increment BD_ADDR when the size reaches zero.
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes.

14.2.2 One-Dimensional Cyclic Buffer

A cyclic buffer is a continuous buffer. When the buffer current address reaches zero, the pointer jumps back to the base address and the buffer executes again. **Figure 14-3** shows an example of a cyclic buffer.

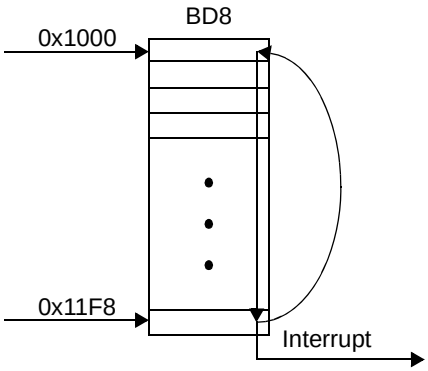

Figure 14-3. One-Dimensional Cyclic Buffer

Table 14-2 lists the channel parameters values for channel BD8 when a 0x200 byte block is read from address 0x1000. An interrupt is generated when the buffer size reaches zero, and the transfer restarts from the base address 0x1000.

Table 14-2. Channel Parameter Values for a Cyclic Buffer

BD	BD Parameters		Value	Description
8	BD_ADDR		0x1000	External memory buffer current address.
	BD_SIZE		0x200	Size of transfer left for this buffer.
	BD_BSIZE		0x200	Buffer base size of cyclic buffer.
	BD_ATTR	SST	0x1	Generate interrupt when buffer ends.
		CONT	0x1	Continuous mode: the buffer is not closed when the size reaches zero.
		CYC	0x1	Reinitialize BD_ADDR to original value when the size reaches zero.
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes.

14.2.3 One-Dimensional Chained Buffer

In a chained buffer scheme, when the size of the first buffer reaches zero, the read jumps to the address of the next buffer, which may be another chained buffer or another buffer type (simple, cyclic, or incremental)). **Figure 14-4** shows a buffer chained to a simple buffer.

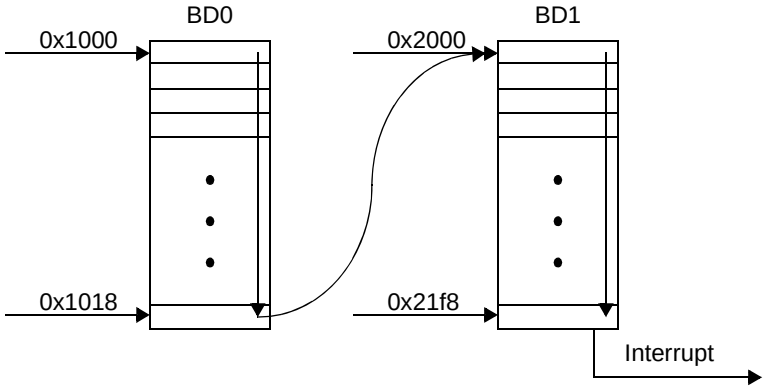

Figure 14-4. One-Dimensional Chained Buffer

There is no constraint on the port used by each chained buffer. However, if the buffers use different ports, the DMA controller masks requests until data is out of the source or in the destination. This operation prevents out-of-sequence transactions at the ports. **Table 14-3** lists the channel parameter values associated with a chained buffer (BD0) and a simple buffer (BD1). A 0x20 byte block is read starting from address 0x1000 (buffer 0). When the buffer size is zero, there is a jump to address 0x2000 (buffer 1). 0x200 byte blocks are read and an interrupt is generated.

Table 14-3. Channel Parameter Values for a Chained Buffer and a Simple Buffer

BD	BD Parameters		Value	Description
0	BD_ADDR		0x1000	External memory buffer current address.
	BD_SIZE		0x20	Size of transfer left for this buffer.
	BD_BSIZE		0x20	Buffer base size of cyclic buffer.
	BD_ATTR	CONT	0x1	Continuous mode. Do not close the buffer when size reaches zero.
		CYC	0x0	Non-cyclic.
		NBD	0x1	When size reaches zero, the next request calls buffer 1.
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes.
1	BD_ADDR		0x2000	External memory buffer current address.
	BD_SIZE		0x200	Size of transfer left for this buffer.
	BD_BSIZE		0x200	Buffer base size of cyclic buffer.
	BD_ATTR	SST	0x1	Generate interrupt when buffer ends.
		CONT	0x0	Non-continuous mode. Close the buffer when size reaches zero.
		CYC	0x0	Non-cyclic mode.
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes.

14.2.4 One-Dimensional Incremental Buffer

In an incremental buffer, a data transfer starts at the buffer base address and continues until all data is transferred. An interrupt is generated each time BD_SIZE reaches zero. BD_ATTR[CONT] = 1, so the channel does not close when BD_SIZE reaches zero. BD_ATTR[CYC] = 0, signifying sequential addressing. NBD points to the buffer itself. **Figure 14-5** shows an example incremental buffer.

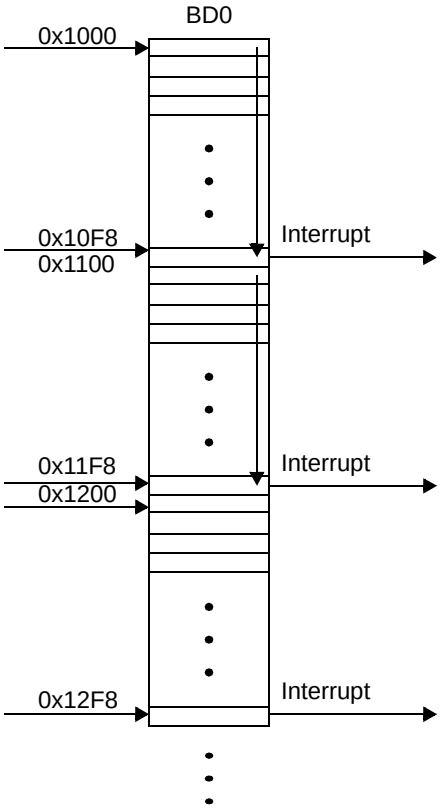

Figure 14-5. One-Dimensional Incremental Buffer

Table 14-4 lists the channel parameter values for an incremental buffer (BD0). Blocks of 0x100 bytes are read, starting at address 0x1000, and an interrupt is generated every 0x100 bytes. The mode is continuous and addressing is sequential. Be aware that in an incremental buffer, memory can be corrupted because of overwriting.

Table 14-4. Channel Parameter Values for an Incremental Buffer

BD	BD Parameters		Value	Description
0	BD_ADDR		0x1000	External memory buffer current address.
	BD_SIZE		0x100	Size of transfer left for this buffer.
	BD_BSIZE		0x100	Buffer base size of cyclic buffer.
	BD_ATTR	SST	0x1	Generate interrupt when buffer ends.
		CONT	0x1	Continuous mode. Do not close the buffer when size reaches zero.
		CYC	0x0	Increment BD_ADDRESS when size reaches zero.
		NBD	0x0	Next request calls buffer 0 when size reaches zero.

14.2.5 One-Dimensional Complex Buffers With Dual Cyclic Buffers

Any combination of the previously described buffers can be used. Dual cyclic buffers, which use two areas in memory to store data, constitute a useful combination of buffer types. While one area of memory is processed, the other receives new data, as shown in **Figure 14-6**.

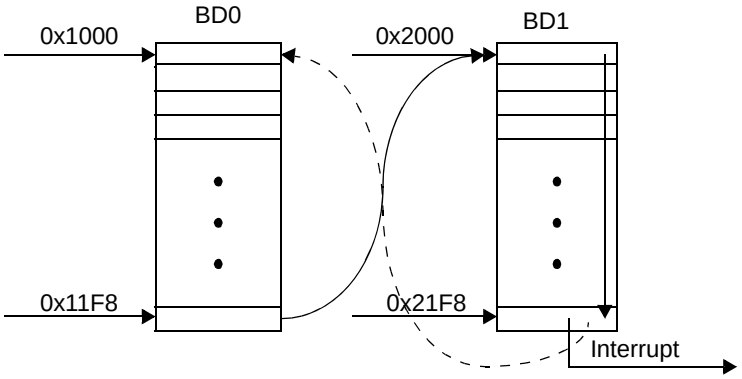

Figure 14-6. Dual Cyclic Buffers

Buffer 0 starts at address 0x1000, and transfers 0x200 byte-blocks. Buffer 1 starts at address 0x2000 and transfer size is also 0x200 bytes. **Table 14-5** lists the channel parameter values corresponding to dual cyclic buffers.

Table 14-5. Channel Parameter Values for Dual Cyclic Buffers

BD	BD Parameters		Value	Description
0	BD_ADDR		0x1000	External memory buffer current address.
	BD_SIZE		0x200	Size of transfer left for this buffer.
	BD_BSIZE		0x200	Buffer base size of cyclic buffer.
	BD_ATTR	CONT	0x1	Continuous mode. Do not shut down the channel when size reaches zero.
		CYC	0x1	Reinitialize BD_ADDRESS to original value when size reaches zero.
		NBD	0x1	When size reaches zero, next request calls buffer 1.
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes.
1	BD_ADDR		0x2000	External memory buffer current address.
	BD_SIZE		0x200	Size of transfer left for this buffer.
	BD_BSIZE		0x200	Buffer base size of cyclic buffer.
	BD_ATTR	SST	0x1	Generate interrupt when buffer ends
		CONT	0x1	Continuous mode. Do not shut down the channel when size reaches zero
		CYC	0x1	Reinitialize BD_ADDRESS to original value when size reaches zero
		NBD	0x0	When size reaches zero, the next request calls buffer 0
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes

14.2.6 Two-Dimensional Simple Buffer

A two-dimensional simple channel is a buffer that closes when BD_SIZE and M2D_COUNT reach zero. This buffer is defined as follows:

- BD_ATTR[CONT] = 0
- BD_MD_ATTR[BD] = 1
- DMACHCR[xMDC] = 1

M2D_COUNT must be set to the two-dimensional parameter and the M2D_OFFSET is set to the next address offset for each two-dimensional loop. The M2D_OFFSET is written in two's complement. The parameters of the third and fourth dimensions must be set to zero. **Figure 14-7** shows an example of a two-dimensional simple buffer.

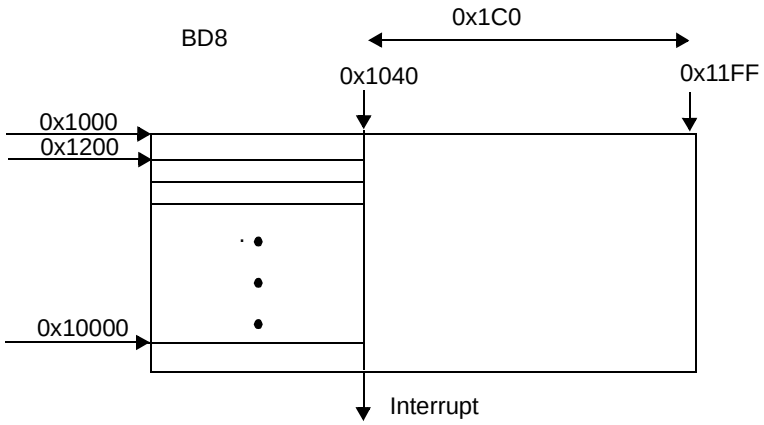

Figure 14-7. Two-Dimensional Simple Buffer

Table 14-6 lists the configuration of a simple buffer designated as channel BD8. A 0x2000 (0x80 × 0x40) byte two-dimensional block is read from address 0x1000. The first dimension is a line of 0x40 bytes. The second dimension is composed of 0x80 lines of 0x40 bytes each. The offset between each 0x40 byte transaction is 0x1c0. The channel closes when the transfer completes after 0x80 iterations, and an interrupt is generated. Burst transactions are used on the bus.

Table 14-6. Channel Parameter Values for a Two-Dimensional Simple Buffer

BD	BD Parameters		Value	Description
8	BD_ADDR		0x1000	External memory buffer current address.
	BD_MD_SIZE		0x40	Size of transfer left for this buffer.
	BD_MD_BSIZE		0x40	Buffer base size of continuous buffer.
	BD_MD_ATTR	SST	0x1	Generate interrupt when buffer ends.
		CONT	0x0	Non-continuous mode: the channel closes when the size reaches zero.
		CYC	0x0	Increment BD_ADDR when the size reaches zero.
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes.
		BD	0x1	Buffer dimension is 2.
		SSTD	0x1	Interrupt issued at the end of the second dimension.
		CONTD	0x0	Simple buffer.
	BD_MD_2D	M2D_COUNT	0x80	Second dimension iterations left.
		M2D_BCOUNT	—	Second dimension base number of iterations.
		M2D_OFFSET	0x1C0	Second dimension offset between two consecutive iterations.
	BD_MD_3D	M3D_COUNT	0	Third dimension iterations left.
		M3D_BCOUNT	0	Third dimension base number of iterations.
		M3D_OFFSET	0	Third dimension offset between two consecutive iterations.
	BD_MD_4D	M4D_COUNT	0	Fourth dimension iterations left.
		M4D_OFFSET	0	Fourth dimension offset between two consecutive iterations.

14.2.7 Three-Dimensional Simple Buffer

A three-dimensional simple channel is a buffer that closes when BD_SIZE, M2D_COUNT, and M3D_COUNT reach zero. It is defined as follows:

- BD_ATTR[CONT] = 0
- BD_MD_ATTR[BD] = 2
- DMACHCR[xMDC] = 1

The M2D_COUNT and M3D_COUNT must be set to each dimension parameter. The M2D_OFFSET and M3D_OFFSET must be set to the next address offset for each dimension loop. The MxD_OFFSET is written in twos-complement form. The parameters of the fourth dimension must be cleared to zero. **Figure 14-8** shows a three-dimensional simple buffer.

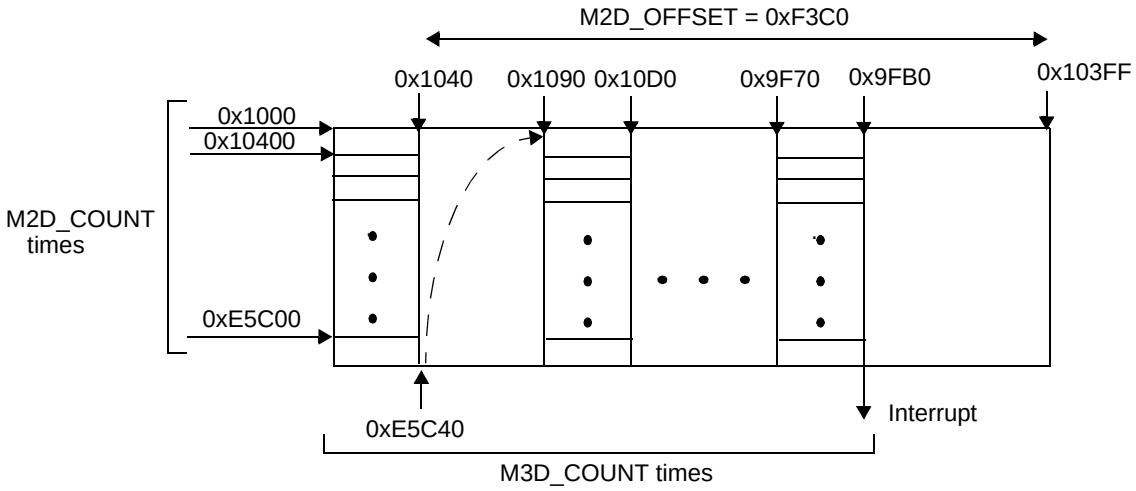

Figure 14-8. Three-Dimensional Simple Buffer

Table 14-7 shows the configuration of a simple buffer designated as channel BD8. A 0x40000 ($0x100 \times 10 \times 40$) three-dimensional block is read from address 0x1000. The basic buffer is 0x40 byte. The offset between each 0x40 byte transaction is 0xF3C0 (0x10400 – 0x1040). The second dimension parameter is 0x10. The offset between each two-dimensional buffers is –0xF4BB0 (0x1090 – 0xE5040). The channel closes when the transfer completes after 0x100 executions of the two-dimensional buffers, and an interrupt is generated. Burst transactions are used on the bus.

Table 14-7. Channel Parameter Values for a Three-Dimensional Simple Buffer

BD	BD Parameters		Value	Description
8	BD_ADDR		0x1000	External memory buffer current address.
	BD_MD_SIZE		0x40	Size of transfer left for this buffer.
	BD_MD_BSIZE		0x40	Buffer base size of continuous buffer.
	BD_MD_ATTR	SST	0x1	Generate interrupt when buffer ends.
		CONT	0x0	Non-continuous mode: the channel is closed when the size reaches zero.
		CYC	0x0	Increment BD_ADDR when the size reaches zero.
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes
		BD	0x2	Buffer dimension is 3.
		SSTD	0x2	Interrupt issued at the end of the third dimension.
		CONTD	0x0	Simple buffer.
	BD_MD_2D	M2D_COUNT	0x10	Second dimension iterations left.
		M2D_BCOUNT	0x10	Second dimension base number of iterations.
		M2D_OFFSET	0xF3C0	Second dimension offset between two consecutive iterations.
	BD_MD_3D	M3D_COUNT	0x100	Third dimension iterations left.
		M3D_BCOUNT	—	Third dimension base number of iterations.
		M3D_OFFSET	–0xE4BB0	Third dimension offset between two consecutive iterations of two-dimensional buffers.
	BD_MD_4D	M4D_COUNT	0	Fourth dimension iterations left.
		M4D_OFFSET	0	Fourth dimension offset between two consecutive iterations.

14.2.8 Four-Dimensional Simple Buffer

A four-dimensional simple channel is a buffer that closes when BD_SIZE and all MxD_COUNT reach zero. It is defined as follows:

- BD_ATTR[CONT] = 0
- BD_MD_ATTR[BD] = 3
- DMACHCR[xMDC] = 1

All MxD_COUNT must be set to their corresponding dimension parameter. All MxD_OFFSET must be set to the next address offset for the corresponding dimension loop. The MxD_OFFSET is written in twos-complement form. **Figure 14-9** shows an example four-dimensional simple buffer.

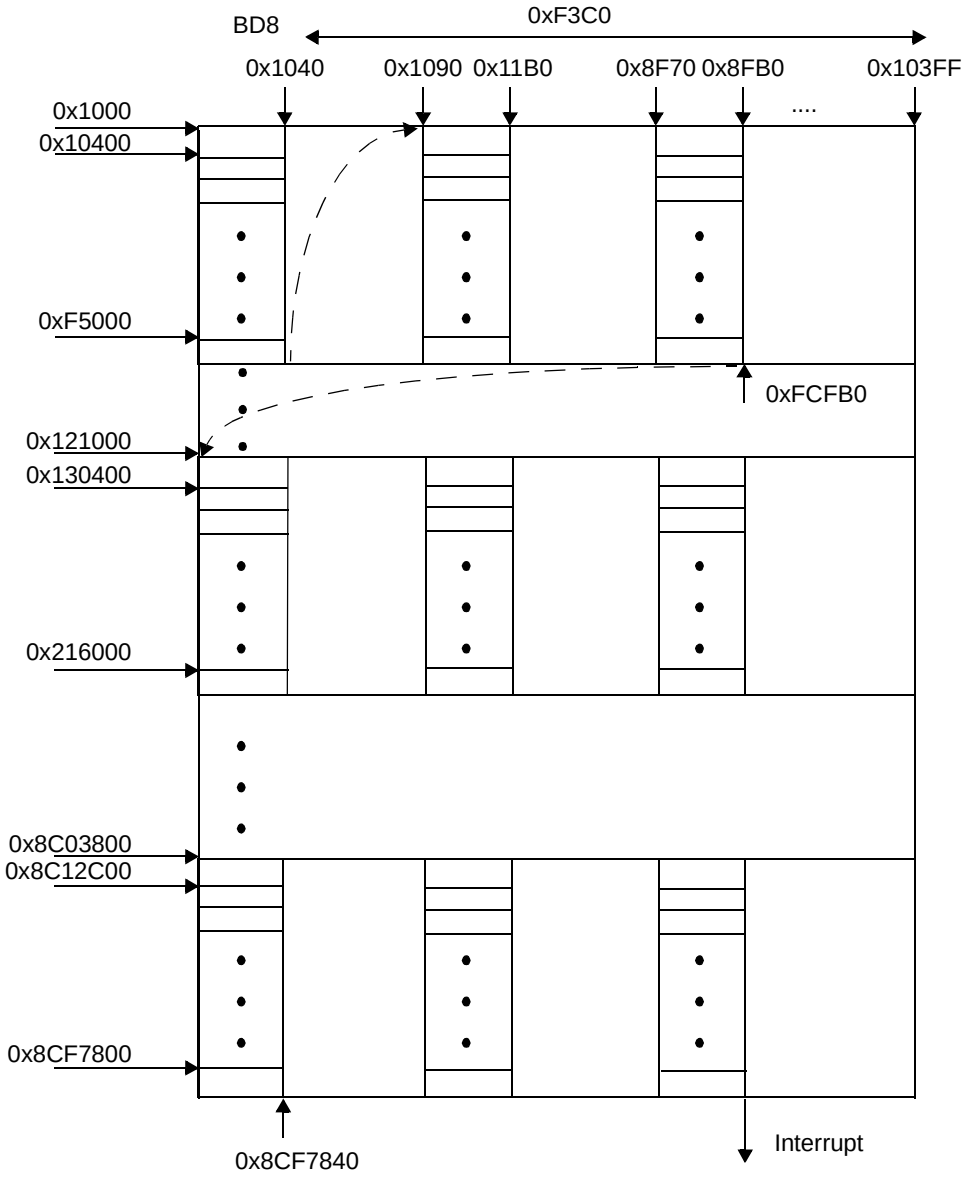

Figure 14-9. Four-Dimensional Simple Buffer

Table 14-8 lists the configuration of a simple buffer designated as channel BD8. A 0x2000000 (0x80 × 0x100 × 0x10 × 0x40) byte block is read from address 0x1000. The first dimension is a 0x40 byte buffer. The offset between each 0x40 bytes transaction is 0xF3C0. The two-dimensional buffers execute 0x100 times for each fourth dimension iteration. The offset between each two-dimensional buffers is –0xF3FB0 (0x1090 – 0xF5040). The channel closes when the transfer completes after 0x80 iterations of the three-dimensional buffer, and an interrupt is generated. Burst transactions are used on the bus.

Table 14-8. Channel Parameter Values for a Four Dimensional Simple Buffer

BD	BD Parameters		Value	Description
8	BD_ADDR		0x1000	External memory buffer current address.
	BD_MD_SIZE		0x40	Size of transfer left for this buffer.
	BD_MD_BSIZE		0x40	Buffer base size of continuous buffer.
	BD_MD_ATTR	SST	0x1	Generate interrupt when buffer ends.
		CONT	0x0	Non-continuous mode: the channel closes when the size reaches zero.
		CYC	0x0	Increment BD_ADDR when the size reaches zero.
		BTSZ	0x7	Maximum transfer size is one burst of 64 bytes.
		BD	0x3	Buffer dimension is 4.
		SSTD	0x3	Interrupt issued at the end of the fourth dimension.
		CONTD	0x0	Simple buffer.
	BD_MD_2D	M2D_COUNT	0x10	Second dimension iterations left.
		M2D_BCOUNT	0x10	Second dimension base number of iterations.
		M2D_OFFSET	0xF3C0	Second dimension offset between two consecutive iterations.
	BD_MD_3D	M3D_COUNT	0x100	Third dimension iterations left.
		M3D_BCOUNT	0x100	Third dimension base number of iterations.
		M3D_OFFSET	0xF3FB0	Third dimension offset between two consecutive iterations.
	BD_MD_4D	M4D_COUNT	0x80	Fourth dimension iterations left.
		M4D_OFFSET	0x24050	Fourth dimension offset between two consecutive iterations.

14.2.9 Multi-Dimensional Chained Buffer

A multi-dimensional chained buffer has two or more multi-dimensional buffers. When the size of the first buffer and all its dimension counters reaches zero, the read jumps to the address of the next buffer, which may be another multi-chained buffer or another type of multi-dimensional buffer types (simple, cyclic, or incremental). The chained multi-dimensional buffers can be of any dimension. **Figure 14-10** shows a three-dimensional buffer chained to a four-dimensional simple buffer.

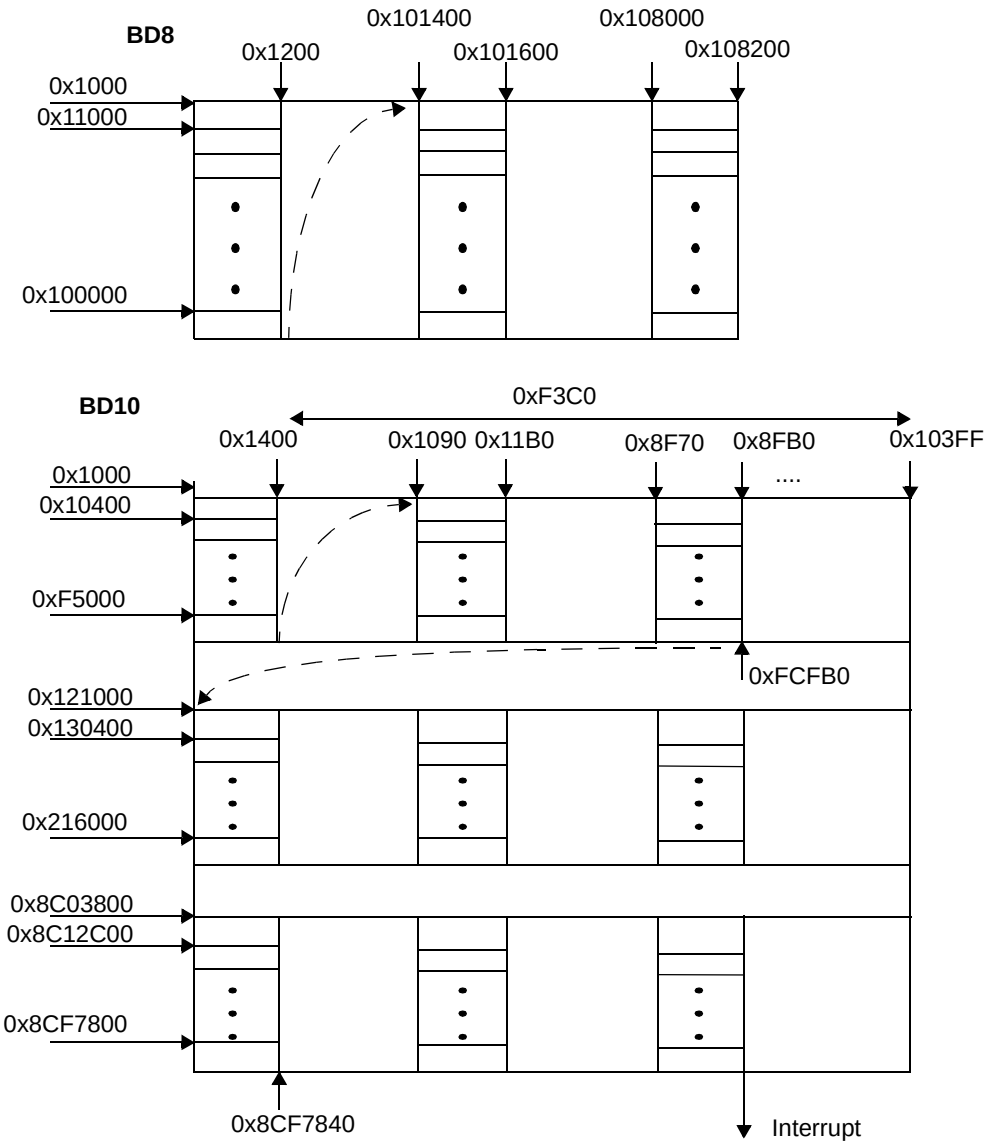

Figure 14-10. Multi-Dimensional Chained Buffer

There is no constraint on the port used by each chained buffer. However, if the buffers use different ports, the DMA logic masks requests until data is out of the source or in the destination. This operation prevents out-of-sequence transactions at the ports. **Table 14-9** shows the channel

parameter values associated with a three-dimensional chained buffer (BD8) and a four-dimensional simple buffer (BD10).

Table 14-9. Parameter Values for Multi-Dimensional Chained and Simple Buffers

BD	DCPRAM Parameters		Value	Description
8	BD_ADDR		0x1000	External memory buffer current address.
	BD_MD_SIZE		0x200	Size of transfer left for this buffer.
	BD_MD_BSIZE		0x200	Buffer base size of continuous buffer.
	BD_MD_ATTR	BTSZ	0x5	Basic transfer size is 16 bytes.
		NBD	0xA	Next Buffer descriptor is 10.
		SST	0x0	Do not generate interrupt when buffer ends.
		CONT	0x1	Continuous mode: the channel continues when the size and third dimension counter reach zero. See the CONTD field of the BD_MD_ATTR.
		CYC	0x0	Increment BD_ADDR when the size reaches zero.
		BD	0x2	Buffer dimension is 3.
		SSTD	0x0	No interrupt issued.
		CONTD	0x2	Continuous buffer when size reaches zero at the end of the third dimension.
	BD_MD_2D	M2D_COUNT	0x10	Second dimension iterations left.
		M2D_BCOUNT	0x10	Second dimension base number of iterations.
		M2D_OFFSET	0xFE00	Second dimension offset between two consecutive iterations.
	BD_MD_3D	M3D_COUNT	0x8	Third dimension iterations left.
		M3D_BCOUNT	-	Third dimension base number of iterations.
		M3D_OFFSET	0x1200	Third dimension offset between two consecutive iterations.
	BD_MD_4D	M4D_COUNT	0	Fourth dimension iterations left.
		M4D_OFFSET	0	Fourth dimension offset between two consecutive iterations.
10	BD_ADDR		0x1000	External memory buffer current address.
	BD_MD_SIZE		0x40	Size of transfer left for this buffer.
	BD_MD_BSIZE		0x40	Buffer base size of cyclic buffer.
	BD_ATTR	BTSZ	0x5	Basic transfer size is 16 bytes.
		SST	0x1	Generate interrupt when buffer ends.
		CONT	0x0	Non-continuous mode: the channel closes when the size reaches zero.
		CYC	0x0	Increment BD_ADDR when the size reaches zero.
	BD_MD_ATTR	BD	0x3	Buffer dimension is 4.
		SSTD	0x3	Interrupt issued at the end of the fourth dimension.
		CONTD	0x0	Simple buffer.
	BD_MD_2D	M2D_COUNT	0x10	Second dimension iterations left.
		M2D_BCOUNT	0x10	Second dimension base number of iterations.
		M2D_OFFSET	0xF3C0	Second dimension offset between two consecutive iterations.
	BD_MD_3D	M3D_COUNT	0x100	Third dimension iterations left.
		M3D_BCOUNT	0x100	Third dimension base number of iterations.
		M3D_OFFSET	–0xF3FB0	Third dimension offset between two consecutive iterations.
	BD_MD_4D	M4D_COUNT	0x80	Fourth dimension iterations left.
		M4D_OFFSET	0x24050	Fourth dimension offset between two consecutive iterations.

14.2.10 Two-Dimensional Cyclic Buffer

A two-dimensional cyclic buffer is a two-dimensional continuous buffer. When the size of the current buffer reaches zero, the pointer jumps back to the base address and the buffer executes again. The third and fourth dimension counters must be cleared to zero. The M3D_OFFSET must be set to the offset between the base address and the last transaction address. **Figure 14-11** shows an example cyclic buffer.

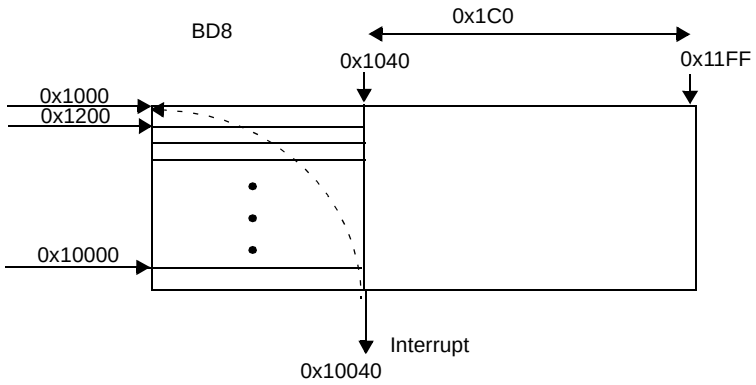

Figure 14-11. Two-Dimensional Cyclic Buffer

Table 14-10 lists the configuration of a two-dimensional cyclic buffer, designated as channel BD8 in this example. A 0x2000 (0x80 × 0x40) byte two dimension block is read from address 0x1000. The first dimension is a line of 0x40 bytes. The second dimension is a 0x80 lines of 0x40 bytes each. The offset between each 0x40 bytes transaction is 0x1C0. The base address is restored when the transfer is complete after 0x80 iterations.

Table 14-10. Channel Parameters Values for a Two Dimensions Cyclic Buffer

BD	BD Parameters		Value	Description
8	BD_MD_ADDR		0x1000	External memory buffer current address.
	BD_MD_SIZE		0x40	Size of transfer left for this buffer.
	BD_MD_BSIZE		0x40	Buffer base size of continuous buffer.
	BD_MD_ATTR	SST	0x0	Do not generate interrupt when buffer ends.
		CYC	0x1	Cyclic two-dimensional buffer; the third dimension offset is used to restore the base address.
		CONT	0x1	Continuous mode. The buffer does not close when BD_MD_BSIZE and M2D_COUNT reach zero.
		BTSZ	0x5	Basic transfer size is 16 bytes.
		BD	0x1	Buffer dimension is 2.
		CONTD	0x1	Second dimension continuous.
	BD_MD_2D	M2D_COUNT	0x80	Second dimension iterations left.
		M2D_BCOUNT	0x80	Second dimension base number of iterations.
		M2D_OFFSET	0x1C0	Second dimension offset between two consecutive iterations.
	BD_MD_3D	M3D_COUNT	0	Third dimension iterations left.
		M3D_BCOUNT	0	Third dimension base number of iterations.
		M3D_OFFSET	–0xF040	Third dimension offset between two consecutive iterations.
	BD_MD_4D	M4D_COUNT	0	Fourth dimension iterations left.
		M4D_OFFSET	0	Fourth dimension offset between two consecutive iterations.

14.2.11 Three-Dimensional Cyclic Buffer

A three-dimensional cyclic channel is a buffer that continues when BD_SIZE, M2D_COUNT, and M3D_COUNT reach zero. It is defined as follows:

- BD_ATTR[CONT] = 0
- BD_MD_ATTR[BD] = 2
- DMACHCR[xMDC] = 1

M2D_COUNT and M3D_COUNT must be set to each dimension parameter. The M2D_OFFSET and M3D_OFFSET must be set to the next address offset for each dimension loop. The M4D_OFFSET must be set to restore the base address of the channel. The MxD_OFFSET is written in two's complement. The counters of the fourth dimensions must be cleared to zero. **Figure 14-12** shows an example three-dimensional cyclic buffer.

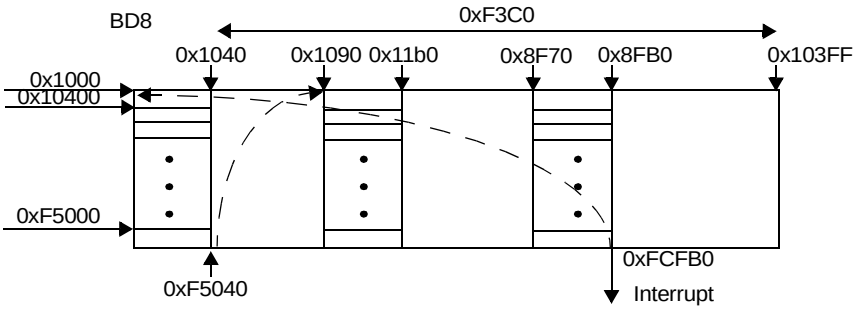

Figure 14-12. Three-Dimensional Cyclic Buffer

Table 14-11 shows the configuration of a cyclic buffer designated as channel BD8. A 0x40000 ($0x100 \times 10 \times 40$) three-dimensional block is read from address 0x1000. The basic buffer is 0x40 byte. The offset between each 0x40 byte transaction is 0xF3C0 (0x10400 – 0x1040). The two-dimensional parameter is 0x10. The offset between each two-dimensional buffer is –0xF3FB0 (0x1090 – 0xF5040). The base address of the channel is restored when the transfer completes after 0x100 executions of the two-dimensional buffers, and an interrupt is generated.

Table 14-11. Parameter Values for a Three-Dimensional Cyclic Buffer

BD	BD Parameters		Value	Description
8	BD_ADDR		0x1000	External memory buffer current address.
	BD_MD_SIZE		0x40	Size of transfer left for this buffer.
	BD_MD_BSIZE		0x40	Buffer base size of continuous buffer.
	BD_MD_ATTR	SST	0x1	Generate interrupt when buffer ends.
		CONT	0x1	Non-continuous mode: the channel closes when the size reaches zero.
		CYC	0x1	Cyclic three dimensions.
		BTSZ	0x5	Basic transfer size is 16 bytes.
		BD	0x2	Buffer dimension is 3.
		SSTD	0x2	Interrupt issued at the end of the third dimension.
		CONTD	0x2	Cyclic three-dimensional buffer.
	BD_MD_2D	M2D_COUNT	0x10	Second dimension iterations left.
		M2D_BCOUNT	0x10	Second dimension base number of iterations.
		M2D_OFFSET	0xF3C0	Second dimension offset between two consecutive iterations.
	BD_MD_3D	M3D_COUNT	0x100	Third dimension iterations left.
		M3D_BCOUNT	0x100	Third dimension base number of iterations.
		M3D_OFFSET	–0xF3FB0	Third dimension offset between two consecutive iterations of two dimension buffers.
	BD_MD_4D	M4D_COUNT	0	Fourth dimension iterations left.
		M4D_OFFSET	–0xFBFB0	Fourth dimension offset between two consecutive iterations.

14.3 Arbitration Types

There are two types of DMA arbitration: round-robin and early-deadline-serve-first (EDF). The type of arbitration is selected via the DGCR[AT] bit (see **Table 14-17*DMAGCR Field Descriptions,*** on page 14>-31).

14.3.1 Round-Robin Arbitration

The round-robin arbitration between channels is a least recently used (LRU) schema. Following is a list of the arbitration parameters according to their weight:

- *DMA port*. Each channel is assigned to one DMA port. Each time a channel request is serviced, the channels assigned to its port are masked for three clock cycles. When there are requesting channels for both ports, they are serviced intermittently.
- *Fixed-priority among round-robin groups*. Each channel is assigned to one of the four priority groups as defined by the DCHCRx[RRPG] bit. Each priority group can contain from 0 (empty) to all 16 channels. Pending requests from the highest-priority group are serviced first.

- *Bandwidth control*. Each channel has credit for maximum consecutive grants according to BD_ATTR [TSZ] and BD_ATTR[BTSZ]. If TSZ is greater than BTSZ bytes, the channel wins consecutively in BTSZ byte portions until TSZ is reached. The channel may stop requesting before it is continuously granted the maximum transfer size. The channel keeps its priority until the address is aligned. The channel priority is updated when the buffer or dimension ends.
- *Least recently used round-robin*. A linear queue defines the channel priority. After reset, each channel has a unique priority according to its number. After a channel is serviced, it gets the lowest priority. All the other channels with a priority lower than the winning priority upgrade their priority. All the channels with higher priority on this cycle keep their priority so that they are guaranteed service. Some channels may get the same priority by the time. **Table 14-12** lists the priority of the channels for two successive cycles.

Table 14-12. Round-Robin Arbitration Example

Channel Number	Channel Request	Clock n Priority		Clock n+1 Priority
1	Deasserted	0 (Highest)		0 (Highest)
8	Deasserted	1		1
3	Asserted	2	Channel 3 win	31 (Lowest)
2	Asserted	3		2
6	Asserted	4		3
5	Deasserted	5		4
4	Deasserted	6		5
7	Deasserted	7 (Lowest)		6

14.3.2 EDF Arbitration

EDF arbitration optimizes the DMA transactions in a time domain, simplifying application development. The EDF algorithm assumes that the application needs certain data to be transferred within a certain time. Every channel declares its deadline target, and the DMA controller sorts all channels into four priority groups. The deadline is the time between the current counter value (DMAEDFTDLx[CC]) to the threshold value (DMAEDFTDLx[TH]). See **page 14-34** for details. The features of EDF arbitration are as follows:

- Round-robin arbitration with channels in the same group.
- 8-bit counter and base register for each channel.
- Counter is enabled/disabled when channel is activated/deactivated.
- Two options for continued buffer:
  - *Continuous mode*. Continues the deadline counter and channel with no action by the EDF logic.
  - *Reset mode*. Reloads the counter.

- Maskable interrupt for threshold deadline crossing when an active counter crosses the threshold.
- Four optional clock sources for the counters and a DMA predivider.
- Automatic channel priority group supporting DMA based on EDF algorithm.

The EDF sorts the channels into four priority groups according to their time to deadline value. The arbitration between the groups is fixed-priority (lowest group number has the highest priority). The arbitration among the channels in the same group is round-robin. Pairs of channels with same priority in the same priority group are served according to their channel number, as illustrated in **Table 14-13** and **Table 14-14**.

Table 14-13. Channels Sorted Into Four Priority Groups

Time to Deadline	Priority Group
0–1	0
2–7	1
8–63	2
64–255	3

Table 14-14. Example of Channel Priority Sorting

Channel	Current Count	Threshold	Time to Deadline	Priority Group	Priority (n)	Priority (n+1)	Priority (n+2)	Priority (n+3)
0	100	0	100	3	1	0 (winner)	31	30
1	255	80	175	3	2	1	0 (winner)	31
2	255	80	175	3	2	1	0	0 (winner)
3	240	160	80	3	0 (winner)	31	30	29

The first priority parameter is the port, which changes each cycle. The second parameter is the time to deadline, which determines the channel group. The last parameter is the channel number, which gives higher priority to the lower channel number for channels in the same group with the same priority. After each channel is serviced, all priorities are updated on a round-robin basis.

14.3.2.1 Issuing Interrupts

The EDF logic can issue a maskable interrupt request for each counter. The EDF issues its interrupts on the error request line of the DMA controller. There is one source for EDF interrupts: the threshold violation for each counter, as specified in the DMA EDF Status Register (DMAEDFSTR) (see **page 14-38**). The EDF logic compares each counter value with the threshold value. If a counter value equals the threshold value, EDF logic sets the corresponding sticky bit in the pending register.

14.3.2.2 Counter Control

The EDF field in the source BD_ATTR of the channel defines the EDF logic behavior when source BD_SIZE reached zero.

14.3.2.3 Clock Source to the Counters

All the counters share the same clock source. There are three clock sources: 2 external (to the DMA) clock sources and the DMA clock divided by 16.

14.4 Interrupts

The DMA controller uses two types of interrupts: maskable and nonmaskable interrupts.

14.4.1 Maskable Interrupts

The DMA controller can issue one maskable interrupt per channel at the end of a buffer or end of a transfer. For multi-dimension buffers, the interrupt may be issued on any of the dimensions. For each maskable interrupt request, a bit in the DMA Status Register (DMASTR) indicates the interrupt source. The interrupt mask is configured via bits in DMA Mask Register (DMAMR). Maskable interrupts are output as 16 individual interrupts, one for each unidirectional destination channel.

Most of the maskable interrupts are issued to request service or indicate that a transfer is available. The exception is EDF threshold violation error interrupt. This interrupt can be masked for each counter.

14.4.2 Nonmaskable Interrupts

Except for the DMA counters threshold violation, nonmaskable interrupts are error interrupts and are all output by one level-error interrupt. The DMA controller issues unmasked interrupts for one of the following sources:

- EDF violation (the only maskable source of a DMA error; it can be masked per counter)
- Port 0 transfer error
- Port 1 transfer error
- Any parity error
- Buffer size of zero

Note: In some cases in which a PRAM parity error occurs, the BD size zero error may also be set.

For each error source, a bit in the DMA Error Register (DMAERR) indicates the error source. DMAERR also samples the first channel that caused the first bus error and the first channel that caused the first parity error.

14.5 DMA Peripheral Interface

The DMA peripheral interface supports the handshaking signals that permit up to 2 devices to control the DMA transfers through the RapidIO or PCI Express interfaces using buffer descriptors (BDs). For each interface, the peripheral can generate a request using the DRQ0 or DRQ1 input signal. The DMA controller generates the appropriate DDN0 or DDN1 response to the peripheral device when the transfer is completed. Channel definition is configured via the registers in the GCR block (see **Chapter 8**, *General Configuration Registers* for details). Each peripheral can connect to any DMA channel. Internally, the peripheral requests are translated to MBus transactions and the peripheral has an individual request number generated when the DMA generates the transaction on the MBus. The simple asynchronous interface supports all types of buffers and multi-dimensional channels.

14.5.1 Modes of Operation

The DMA peripheral interface supports the following combinations of data transfers:

- *Peripheral to memory*. Source transactions are controlled by the data request (DRQn). After the channel is enabled, the destination BD is fetched. Read data arbitration is sustained until DRQn is asserted. As long as the signal remains asserted, data is read from the source to the DMA internal FIFO. Destination transactions depend only on the data in the DMA internal FIFO and the destination and channel programming. If DRQn is deasserted before the end of the BD, any previously won read transaction arbitrations are executed. Write transactions are executed as long as there is a minimum of 64 bytes of data in the DMA internal FIFO or the FIFO is being flushed due to BD_ATTR[MR] or port switching. Once the channel is closed or BD_ATTR[SST] is set, the done signal is asserted.
- *Memory to peripheral*. Destination transactions are controlled by the data request (DRQn). After the channel is enabled, the source and destination BDs are fetched. Write data arbitration is sustained until the done signal is asserted. As long as the signal remains asserted, data is written from the DMA internal FIFO to the destination. Destination transactions depend on the data in the DMA internal FIFO, the state of the done signal, and the destination BD. Source data is arbitrated depending on the source BD, channel programming, and the internal DMA FIFO space. If DRQn is deasserted before the end of the BD, any previously won write transaction arbitrations are executed. Write transactions are arbitrated as long as there is a minimum of 64 bytes of data in the DMA internal FIFO or the FIFO is being flushed due to BD_ATTR[MR] or port switching and the done signal is asserted. Once the channel is closed or BD_ATTR[SST] is set and the BD is finished, the done signal is asserted.
- *Peripheral to peripheral*. Both the source and destination transactions are controlled by DRQn. They can be controlled by the same done signal or by different done signals.

— Same done signal. Do not use this mode. If the associated channel source generates a done signal, then data will be left in FIFO. If the associated channel destination generates the done signal, source data will be fetched after the done is asserted until you flush the FIFO.
— Different done signals. One data request signal is associated with the destination and a different request signal is associated with the source of the channel. This means that after the channel is enabled, the source and destination BDs are fetched. The read data arbitration operates in the same way as for the case of peripheral to memory. The write data arbitration behave in the same way as for the case of memory to peripheral. If the source data request is deasserted before the end of the BD, then previously won read transaction arbitrations are executed. If the destination request is deasserted before the end of the BD, any previously won write transaction arbitrations are executed. However, data may be left in the FIFO because no more write arbitrations can occur until the destination request is asserted again.

14.5.2 Configuration and Control Registers

The operation of DMA peripheral interface is configured using three of the General Configuration Registers:

- GCR DMA Request 0 (GCR_DREQ0)
- GCR DMA Request 1 (GCR_DREQ1)
- GCR DMA Done (GCR_DDONE)

For details about the layout and structure of these registers, see **Chapter 8**, *General Configuration Registers*.

14.5.3 Functional Description

The DMA peripheral interface block controls the operation of the request and done signals for two peripherals. The following subsections describe the how the signals are handled.

14.5.3.1 Request Signal

The request signals (initiated by the peripheral by asserting the appropriate DRQn input) are synchronized by an internal clock and control the internal associated DMA channel requests. For a source channel, once the DMA channel is enabled and the associated request signal is asserted, the channel reads data from the source. For a destination channel, once the DMA channel is enabled and the associated request signal is asserted, the channel writes data to the destination. The input signal does not enable the channel or the channel logic pulse that sets the channel bit in the DMASTR. However, deasserting the signal disables future arbitration wins for the associated channel. Previously won arbitrations continue to the end even after the request signal is pulled low.

14.5.3.2 Done Signal

The done signals are driven by an internal channel logic pulse width that sets the corresponding channel bit in the DMASTR. You must always set DMA_BD_ATTR[SST] and DMA_BD_ATTR[MR] to enable the generation of the done signal at the end of the BD (or the selected dimension for multi-dimensional channels). When enabled, the interface generates a done signal (which is expressed on the appropriate DDNn output line).

14.5.3.3 Signal Operation

The request and done signal operate under the following conditions:

- The done signal is generated when the DMA execution reaches the end of the BD or the channel is closed.
- The done signal is driven by one channel only.
- Once the done signal is asserted, it is not deasserted as long as the corresponding request signal is asserted.
- After the done signal is asserted, additional requests for the channel are ignored until the request signal is deasserted, the done signal is deasserted, and the request signal is reasserted.

14.5.4 Using the DMA Peripheral Interface Block

To use the DMA peripheral interface block features, you must configure and initialize the block using the following procedures:

1. Program the DMA_BD and other DMA registers for memory-to-memory transactions.
2. Set the corresponding DMA_BD_ATTR[SST] and DMA_BD_ATTR[MR} and, for multidimensional operation BD_MD_ATTR[SSTD] and BD_MD_ATTR[MRD], as required by the peripheral.
3. Because they are multiplexed with GPIO signals, you must configure the GPIO interface to specify the DDN[0–1] and DRQ[0–1] signals. The following list identifies the appropriate GPIO signals to configure:
   - GPIO3 must be configured as DRQ1
   - GPIO4 must be configured as DDN1
   - GPIO14 must be configured as DRQ0
   - GPIO15 must be configured as DDN0

   See **Chapter 21**, *GPIO* for details.
4. You must configure the channels to associate with the signals using GCR_DREQ0, GCR_DREQ1, and GCR_DDONE. See **Chapter 8**, *General Configuration Registers* for details.
5. Enable the channel.

After the MSC8157E has set up the DMA controller, the peripheral must perform the following steps:

1. Deassert the DRQn input signal until the peripheral is ready to initiate the transfer.
2. When ready, assert DRQn.
3. Deassert DRQn when DDNn asserts either because it is ready for the next BD or dimension or it has finished the transaction.
4. Reassert DRQn if there is more data to transmit or space to receive the next BD.
5. Continue on in this manner until all transactions are complete.

14.6 DMA Programming Model

The DMA controller uses a combination of registers used to configure and report status of the DMA transfers and the Buffer Descriptor tables that control and implement the DMA transfers.

- DMA Registers
  - DMA Buffer Descriptor Base Registers 0–15 (DMABDBR[0–15], **page 14-28**
  - DMA Controller Channel Configuration Registers 0–15 (DMACHCR[0–15]), **page 14-29**
  - DMA Controller Global Configuration Register (DMAGCR), **page 14-31**
  - DMA Channel Enable Register (DMACHER), **page 14-31**
  - DMA Channel Disable Register (DMACHDR), **page 14-32**
  - DMA Channel Freeze Register (DMACHFR),
  - DMA Channel Defrost Register (DMACHDFR),
  - DMA EDF Time-to-Dead Line Registers 0–15 (DMAEDFDL[0–15]), **page 14-34**
  - DMA EDF Control Register (DMAEDFCTRL), **page 14-35**
  - DMA EDF Mask Register (DMAEDFMR), **page 14-35**
  - DMA EDF Mask Update Register (DMAEDFMUR), **page 14-36**
  - DMA EDF Status Register (DMAEDFSTR), **page 14-38**
  - DMA Mask Register (DMAMR), **page 14-38**
  - DMA Mask Update Register (DMAMUR), **page 14-39**
  - DMA Status Register (DMASTR), **page 14-40**
  - DMA Error Register (DMAERR), **page 14-41**
  - DMA Debug Event Status Register (DMADESR), **page 14-43**
  - DMA Round-Robin Priority Group Update Register (DMARRPGUR), **page 14-43**
  - DMA Channel Active Status Register (DMACHASTR), **page 14-44**
  - DMA Channel Freeze Status Register (DMACHFSTR), **page 14-44**
- DMA Channel Buffer Descriptors
  - Buffer Attributes (BD_ATTR), **page 14-48**
  - Multi-Dimensional Buffer Attributes (BD_MD_ATTR), **page 14-51**

Note: The DMA controller registers use a base address of: 0xFFF10000.

Note: If you are using external peripherals, you must configure the DMA peripheral interface block by programming the GPIO block to enable the multiplexing of the handshaking signals and configure the associated channel information in the General Configuration Registers. See **Section 14.5.4**, *Using the DMA Peripheral Interface Block*, on page 14-26 for details.

14.6.1 DMA Buffer Descriptor Base Registers x (DMABDBRx)

DMABDBR[0–15] DMA Buffer Descriptor Base Registers 0–15 Offset 0x000 + x*0x4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—				BDTPTR											
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	BDTPTR												DESO			
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each DMABDBRx holds the user-programmable addresses of the BD tables for DMA channel x. There are two fields: BDTPTR that identifies the base address of the Buffer Descriptor Table and DESO field that identifies the location offset for the destination buffer within the table. All the channel properties should be programmed, including the relevant BD, before the channel is enabled. For more information on BD address calculation, see the discussion in **Section 14.6.21**, *DMA Channel Buffer Descriptors*, on page 14-45.

Table 14-15. DMABDBRx Field Descriptions

Bits	Reset	Description	Setting
— 31–28	0	Reserved. Write to zero for future compatibility.	
BDTPTR 27–4	0	**Buffer Descriptor Table Pointer** Holds the 24 most significant bits, out of the 32 bit Buffer Descriptors Table (BDT) address.	
DESO 3–0	0	**Destination Offset** Holds the offset of destination buffer descriptor table from the BTD base (BDTPTR × 256).	0000 Destination table offset is 0x20. 0001 Destination table offset is 0x40. 0010 Destination table offset is 0x80. 0011 Destination table offset is 0x100. 0100 Destination table offset is 0x200. 0101 Destination table offset is 0x400. 0110 Destination table offset is 0x600. 0111 Destination table offset is 0x800. 1000 Destination table offset is 0x1000. 1001 Destination table offset is 0x2000. 1010 Destination table offset is 0x3000. 1011 Destination table offset is 0x4000. 11xx Reserved.

14.6.2 DMA Controller Channel Configuration Registers x (DMACHCRx)

DMACHCR[0–15] DMA Controller Channel Configuration Registers 0–15 — Offset 0x100 + x*0x4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ACTV	SPRT	DPRT	SMDC	DMDC	—	SRCBDPT									
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	RRPG			—	DPO	—	DESBDPT									
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMACHCR[0–15] configure the connection between a VCOP requestor and the corresponding VCOP channel. All the channel properties should be programmed, including the relevant BD, before a channel is enabled. The VCOP logic can modify some fields in these registers while the channel is active. To avoid conflict with the DMA logic, never write these registers while the respective channel is active.

Table 14-16. DMACHCRx Field Descriptions

Bits	Reset	Description	Settings
ACTV 31	0	**Active VCOP Channel** While a channel is disabled, all requests are ignored and any non-serviced request is lost. The DMA controller resets ACTV when the channel task completes. Never write a 0 to this bit when the channel is active. You must use DMACHDR to disable the channel first before disabling the channel. Disabling the channel does not reset its value immediately; the value is reset only when there are no more open requests on the bus interface. See also the DMA Channel Enable Register on **page 14-31** and the DMA Channel Disable Register on **page 14-32**. **Written by:** User, DMA controller	0 Channel is disabled. 1 Channel is enabled.
SPRT 30	0	**Source Channel Port** Selects the MBus port associated with the source. **Written by:** User, DMA controller	0 Source is assigned to port 0 of the MBus interface. 1 Source is assigned to port 1 of the MBus interface.
DPRT 29	0	**Destination Channel Port** Selects the MBus interface associated with the destination. **Written by:** User, DMA controller	0 Destination is assigned to port 0 of the MBus interface. 1 Destination is assigned to port 1 of the MBus interface.
SMDC 28	0	**Source Multi-Dimensional Channel** The source can be either one-dimensional or multi-dimensional. **Written by:** User	0 Source is one-dimensional. 1 Source is multi-dimensional.
DMDC 27	0	**Destination Multi-Dimensional Channel** The destination can be either one-dimensional or multi-dimensional **Written by:** User	0 Destination is one-dimensional. 1 Destination is multi-dimensional.

Table 14-16. DMACHCRx Field Descriptions (Continued)

Bits	Reset	Description	Settings
— 26	0	Reserved. Write to zero for future compatibility.	
SRCBDPT 25–16	0	**Source Buffer Pointer** BD number in the BD table assigned to the source. The maximum number of one-dimensional BDs per source is 1024, and the maximum number of multi-dimensional BDs per source is 512. For details on BD address calculation, see **Section 14.6.21**, *DMA Channel Buffer Descriptors*, on page 14-45. **Written by:** User, DMA controller	
RRPG 15–13	0	**Channel Round-Robin Priority Group** This field is valid only for round robin arbitration.See **Table 14-17** for selecting arbitration mode. For more details about round robin, see **14.3.1**, *Round-Robin Arbitration*. To update this field while the channel is active, use the DMA_RRPGUR register (see **page 14-43**) **Written by:** User, DMA controller	000 Highest priority. 011 Lowest priority. 1xx Reserved.
— 12	0	Reserved. Write to zero for future compatibility.	
DPO 11	0	Destination Port Optimize Specifies how the destination port is to be optimized. **Written by:** User	0 Optimize for destination port requests latency. 1 Optimize for destination port requests utilization.
— 10	0	Reserved. Write to zero for future compatibility.	
DESBDPT 9-0	0	**Destination Buffer Pointer** BD number in the BD table assigned to the destination. The maximum number of one-dimensional BDs per destination is 1024. The maximum number of multi-dimensional BDs per destination is 512. For details on BD address calculation, see **Section 14.6.21**. **Written by:** User, DMA controller	

14.6.3 DMA Controller Global Configuration Register (DMAGCR)

DMAGCR DMA Controller Global Configuration Register Offset 0x200

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—													PSCB	PSCA	AT
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMAGCR defines DMA global parameters.

Table 14-17. DMAGCR Field Descriptions

Bits	Reset	Description	Register Setting
— 31–3	0	Reserved. Write to zero for future compatibility.	
PSCB 2	0	**Port 1 Slow Confirmation** For debug, the DMA supports slow confirmation for all transactions **Written by:** User	0 Fast confirmation on port 1, when possible. 1 Slow confirmation on port 1.
PSCA 1	0	**Port 0 Slow Confirmation** For debug, the DMA supports slow confirmation for all transactions **Written by:** User	0 Fast confirmation on port 0, when possible. 1 Slow confirmation on port 0.
AT 0	0	**Arbitration Type** Enables the DMA arbitration type. The DMA arbitration type is defined in the DMAGCR. See **Section 14.3**, *Arbitration Types,* on page 14-19 for details on arbitration. **Written by:** User	0 Enable round-robin arbitration. 1 Enable EDF arbitration.

14.6.4 DMA Channel Enable Register (DMACHER)

DMACHER DMA Channel Enable Register Offset 0x204

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	EN15	EN14	EN13	EN12	EN11	EN10	EN9	EN8	EN7	EN6	EN5	EN4	EN3	EN2	EN1	EN0
Type	W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each bit in DMACHER corresponds to DMACHCRx[ACTV]. When an ENx bit is set, it activates channel x. When ENx bit is cleared, it does not affect the channel. DMACHER is cleared at reset, and the user enables a channel request by setting the appropriate bit. The register allows simultaneous activation of channels after they are configured. While channel x is disabled, all requests are ignored and any non-serviced request is lost. The DMA controller logic resets the ENx bit when the channel task completes.

14.6.5 DMA Channel Disable Register (DMACHDR)

DMACHDR DMA Channel Disable Register Offset 0x20C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	DIS15	DIS14	DIS13	DIS12	DIS11	DIS10	DIS9	DIS8	DIS7	DIS6	DIS5	DIS4	DIS3	DIS2	DIS1	DIS0
Type	W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each bit in the DMACHDR corresponds to a channel. Writing a 1 to DISx disables channel x. Writing a 0 to DISx does not affect the channel. DMACHDR is cleared at reset. The register allows simultaneous deactivation of channels during normal operation. While channel x is disabled, all requests are ignored and any non-serviced request is lost. The DISx bit is reset by the DMA logic.

When the user writes either a 1 to DMACHDR[DISx] or a 0 to DMACHCRx[ACTV], the channel is shut down. If more channel requests are pending on the bus interface, the channel is not disabled. The DMACHDR[DISx] and corresponding DMACHER[ENx] and CHCRx[ACTV] are all set until the pending channel transactions are closed. When all transactions are closed, the DMA logic resets the DMACHER[ENx] and DMACHCRx[ACTV] bits. After the channel is disabled, you must poll DMACHASTR to acknowledge that the channel is disabled. The interrupt latency in the system must be considered as well. When you are sure that the channel is disabled and there is no previous pending interrupts, the channel can be activated.

14.6.6 DMA Channel Freeze Register (DMACHFR)

DMACHFR DMA Channel Freeze Register Offset 0x214

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D15	S15	D14	S14	D13	S13	D12	S12	D11	S11	D10	S10	D9	S9	D8	S8
Type	W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	D7	S7	D6	S6	D5	S5	D4	S4	D3	S3	D2	S2	D1	S1	D0	S0
Type	W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Setting an Sx bit freezes the corresponding channel source. Setting a Dx bit freezes the corresponding channel destination. When a bit is set, the corresponding channel settings remain valid and new DREQ requests are considered, but the DMA controller does not issue any transactions to the specified channel. This register is write only; writing a 1 to a bit toggles its value (that is, if the value is 0, it sets the bit and if it is 1, it clears the bit). Writing a zero to the bits has no effect. The DMACHFR bits are all cleared by reset. Activating a channel clears the corresponding DMACHFR bits (Sx and Dx). The register allows simultaneous freezing of channels during normal operation

Note: The DMA channels do not freeze immediately; therefore, after a channel freeze is set, the DMA controller can issue new transactions for the channel until its pipeline is cleared.

Note: When the DMA channel becomes frozen, data may be left in the FIFO.

14.6.7 DMA Channel Defrost Register (DMACHDFR).

DMACHDFR DMA Channel Defrost Register Offset 0x224

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D15	S15	D14	S14	D13	S13	D12	S12	D11	S11	D10	S10	D9	S9	D8	S8
Type	W															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	D7	S7	D6	S6	D5	S5	D4	S4	D3	S3	D2	S2	D1	S1	D0	S0
Type	W															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Setting an Sx bit defrosts the corresponding channel source. Setting a Dx bit defrosts the corresponding channel destination. Defrosting a channel allows it to return to normal functioning. This register is write only; writing a 1 to a bit toggles its value (that is, if the value is 0, it sets the bit and if it is 1, it clears the bit). Writing a zero to the bits has no effect. The DMACHDFR bits

are all set by reset. Activating a channel sets the corresponding DMACHDFR bits (Sx and Dx). The register allows simultaneous defrosting of channels

14.6.8 DMA Time-To-Dead Line Registers x (DMAEDFTDLx)

DMAEDFTDL[0–15] DMA Time-To-Dead Line Registers 0–15 Offset 0x234 + x*0x4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ENC	—							CURRENT_COUNT							
Type	R/W	R														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	THRESHOLD								BASE_COUNT							
Type	R/W															
Reset	0	0	0	0	0	0	1	0	1	1	1	1	1	1	1	1

Table 14-18 describes the fields of DMAEDFTDL[0–15].

Table 14-18. DMAEDFTDL[0–15] Field Descriptions

Bits	Reset	Write By	Description	Settings
ENC 31	0	User	**ENC** This field enable this counter. The counter will start counting when a task is asserted and this field set. **Note:** Enabling and disabling the channels change the counters value. Disabling channels stops the counting and enabling them reloads the counters with their base values.	0 Counter disabled 1 Counter enabled
— 30–24	0	Reserved. Write to zero for future compatibility.		
CURRENT_ COUNT 23–16	0	DMA	**Current Counter Value** This field holds the current value of the counter. Upon enabling the channel the counter is loaded with the base value. The counter counts down as long as the channel is enabled. The counter will stop counting when the channel is disabled or when counter reached zero and task is not completed yet. The counter resumes counting when the buffer ends according to the BD_ATTR[EDF].	
THRESHOLD 15–8	0x02	User	**Time to Dead Line Threshold** The threshold defines the value of the counter when the DMA task is due. The maximum threshold value is 0xff and the minimum is 2. **Note:** The DMA logic sets the priority of the channels according to counters threshold value.	
BASE_COUNT 7–0	0xFF	User	**Base Count Value** The base count value is set by the user before enabling the associated channel. When the DMA reinitializes the counter it reloads the counter with BASE_COUNT. The BASE_COUNT maximum value is 0xff and the minimum is 0. **Note:** Do not change the base count value of active channels.	

14.6.9 DMA EDF Control Register (DMAEDFCTRL)

DMAEDFCTRL DMA EDF Control Register Offset 0x334

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—														CLK_SRC	
Type	R/W															
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLK_DIV															
Type	R/W															
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Table 14-19 describes the fields of the DMAEDFCTRL registers.

Table 14-19. DMAEDFCTRL Field Descriptions

Bits	Write by	Description	Setting
— 31–18	—	Reserved. Write to zero for future compatibility.	
CLK_SRC 17–16	User	**Clock Source** There are four clock sources for the EDF counters.	00: DMA clock divided by 16 01: Source 1 10: Source 2 11: Source 3
CLK_DIV 15–0	User	**Clock Divider** Divide the clock source (selected by CLK_SRC) for the EDF counters. The DMAEDFTDLx clock frequency is EDF clock (selected by CLK_SRC) divided by CLK_DIV. The maximum CLK_DIV value is 0xFFFF and the minimum is 1.	

14.6.10 DMA EDF Mask Register (DMAEDFMR)

DMAEDFMR DMA EDF Mask Register Offset 0x338

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	M15	M14	M13	M12	M11	M10	M9	M8	M7	M6	M5	M4	M3	M2	M1	M0
Type	R/W															
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each bit in the DMAEDFMR corresponds to an interrupt request bit in the DMAEDFSTR. When a bit is set, it enables the generation of an interrupt request of the corresponding counter.

DMAEDFMR is cleared at reset, and the user enables a counter interrupt request by setting the appropriate bit.**Table 14-20** describes the fields of the DMAEDFMR.

Table 14-20. DMAEDFMR Field Descriptions

Bits	Write by	Description	Setting
— 31–16	—	Reserved. Write to zero for future compatibility.	
M[15–0] 15–0	User	**Masks 15–0** Each bit corresponds to an interrupt request bit in the DMAEDFSTR. Setting the bit enables generation of the respective interrupt request.	0 Interrupt masked. 1 Interrupt enabled.

14.6.11 DMA EDF Mask Update Register (DMAEDFMUR)

DMAEDFMUR DMA EDF Mask Update Register Offset 0x340

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MASK_CH3						NM3	EN3	MASK_CH2						NM2	EN2

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	MASK_CH1						NM1	EN1	MASK_CH0						NM0	EN0
	R/W															
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DMAEDFMUR enables modifying the DMAEDFMR registers without a read modify write operation. You can modify up to four channels with one action. **Table 14-21** describes the fields of the DMAEDFMUR.

Table 14-21. DMAEDFMUR Field Descriptions

Bits	Write by	Description	Setting
MASK_CH3 31–26	User	**Channel Number** Indicate the channel number of the DMAEDFMR to change.	000000–001111 Channel number. 01xxxx Reserved. 1xxxxx Reserved.
NM3 25	User	**New Channel Mask Value** Stores the new value of DMAEDFMR[MASK_CH3].	0 Not masked. 1 Masked.
EN3 24	User	**Enable Mask/Unmask Updating** When set, updates DMAEDFMR[MASK_CH3] according to NM3. When DMAEDFMR[MASK_CH3] is updated, the DMA controller clears this bit.	0 Update occurred. 1 Perform update.
MASK_CH2 23–18	User	**Channel Number** Indicate the channel number of the DMAEDFMR to change.	000000–001111 Channel number. 01xxxx Reserved. 1xxxxx Reserved.
NM2 17	User	**New Channel Mask Value** Stores the new value of DMAEDFMR[MASK_CH2].	0 Not masked. 1 Masked.

Table 14-21. DMAEDFMUR Field Descriptions (Continued) (Continued)

Bits	Write by	Description	Setting
EN2 16	User	**Enable Mask/Unmask Updating** When set, updates DMAEDFMR[MASK_CH2] according to NM3. When DMAEDFMR[MASK_CH2] is updated, the DMA controller clears this bit.	0 Update occurred. 1 Perform update.
MASK_CH1 15–10	User	**Channel Number** Indicate the channel number of the DMAEDFMR to change.	000000–001111 Channel number. 01xxxx Reserved. 1xxxxx Reserved.
NM1 9	User	**New Channel Mask Value** Stores the new value of DMAEDFMR[MASK_CH1].	0 Not masked. 1 Masked.
EN1 8	User	**Enable Mask/Unmask Updating** When set, updates DMAEDFMR[MASK_CH1] according to NM3. When DMAEDFMR[MASK_CH1] is updated, the DMA controller clears this bit.	0 Update occurred. 1 Perform update.
MASK_CH0 7–2	User	**Channel Number** Indicate the channel number of the DMAEDFMR to change.	000000–001111 Channel number. 01xxxx Reserved. 1xxxxx Reserved.
NM0 1	User	**New Channel Mask Value** Stores the new value of DMAEDFMR[MASK_CH0].	0 Not masked. 1 Masked.
EN0 0	User	**Enable Mask/Unmask Updating** When set, updates DMAEDFMR[MASK_CH0 according to NM3. When DMAEDFMR[MASK_CH0] is updated, the DMA controller clears this bit.	0 Update occurred. 1 Perform update.

14.6.12 DMA EDF Status Register (DMAEDFSTR)

DMAEDFSTR DMA EDF Status Register Offset 0x344

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	I15	I14	I13	I12	I11	I10	I9	I8	I7	I6	I5	I4	I3	I2	I1	I0
	W1C															
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each bit in the DMAEDFSTR corresponds to an EDF threshold violation status the corresponding channel. If set, a bit associated with a channel indicates that EDF threshold violation occurred for that channel. A bit is cleared by writing one to it. Writing zero does not affect a bit value. It is possible to clear several bits at a time. **Table 14-22** describes the fields of the DMAEDFSTR.

Table 14-22. DMAEDFSTR Field Descriptions

Bits	Write by	Description	Setting
— 31–16	—	Reserved. Write to zero for future compatibility.	
I[15–0] 15–0	User	**Interrupt for Threshold Violation 15–0** Each bit corresponds to an interrupt request bit in the DMAEDFSTR. Setting the bit enables generation of the respective interrupt request.	0 No interrupt. 1 Interrupt request issued.

Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each bit in the DMAMR corresponds to an interrupt request bit in the DMASTR. When a bit is set, it enables the generation of an interrupt request on the corresponding interrupt line. DMAMR is cleared at reset, and you enable a channel interrupt request by setting the appropriate bit.

Note: Setting the Sn bits has no effect because in the MSC8157E, only unidirectional destination channel interrupts are implemented as described in **Section 14.4.1**.

14.6.14 DMA Mask Update Register (DMAMUR)

DMAMUR DMA Mask Update Register Offset 0x35C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MASKCH3					DES3	NM3	EN3	MASKCH2					DES2	NM2	EM2
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	MASKCH1					DES1	NM1	EN1	MASKCH0					DES0	NM0	EN0
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMAMUR is a special register that allows you to modify the DMAMR registers without a read-modify-write operation.

Table 14-23. DMAMUR Field Descriptions

Bits	Reset	Description	Settings
MASKCH3 31–27	0	**Channel Number** The channel number to which DMAMR should be changed. **Written by:** User	00000–01111: Channel number. 1xxxx Reserved.
DES3 26	0	**Channel Number Destination** Destination channel number to which DMAMR should be changed. **Written by:** User	0 Channel number source. 1 Channel number destination.
NM3 25	0	**New Channel Mask value** The new value of DMAMR[MASKCH3, DES3]. **Written by:** User	0 Unmask. 1 Mask.
EN3 24	0	**Enable MASK/UNMASK Update** Updates DMAMR[MASK_CH3, DES3] according to NM3. Then the DMA controller clears this bit. **Written by:** User, DMA controller	
MASKCH2 23–19	0	**Channel Number** The channel number to which DMAMR should be changed. **Written by:** User	00000–01111: Channel number. 1xxxx: Reserved.
DES2 18	0	**Channel Number Destination** Destination channel number to which DMAMR should be changed. **Written by:** User	0 Channel number source. 1 Channel number destination.
NM2 17	0	**New Channel Mask value** The new value of DMAMR[MASKCH3, DES2]. **Written by:** User	0 Unmask. 1 Mask.
EN2 16	0	**Enable MASK/UNMASK Update** Updates the DMAMR[MASKCH2, DES2] according to NM2. Then the DMA controller clears this bit. **Written by:** User, DMA controller	
MASKCH1 15–11	0	**Channel Number** The channel number to which DMAMR should be changed. **Written by:** User	00000–01111: Channel number. 1xxxx: Reserved

Table 14-23. DMAMUR Field Descriptions (Continued)

Bits	Reset	Description	Settings
DES1 10	0	**Channel Number Destination** Destination channel number to which DMAMR should be changed. **Written by:** User	0 Channel number source. 1 Channel Number destination.
NM1 9	0	**New Channel Mask value** The new value of DMA_MR[MASK_CH1, DES1]. **Written by:** User	0 Unmask. 1 Mask.
EN1 8	0	**Enable MASK/UNMASK Update** Updates DMAMR[MASKCH0, DES0] according to NM0. Then the DMA controller clears this bit. **Written by:** User, DMA controller	
MASKCH0 7–3	0	**Channel Number** The channel number to which DMAMR should be changed. **Written by:** User	00000–01111: Channel number. 1xxxx Reserved
DES0 2	0	**Channel Number Destination** Destination channel number to which DMAMR should be changed. **Written by:** User	0 Channel number source. 1 Channel number destination.
NM0 1	0	**New Channel Mask value** The new value of DMAMR[MASKCH0, DES0]. **Written by:** User	0 Unmask. 1 Mask.
EN0 0	0	**Enable MASK/UNMASK Update** Updates DMAMR[MASKCH0, DES0] according to NM0. Then the DMA controller clears this bit. **Written by:** User, DMA controller	

14.6.15 DMA Status Register (DMASTR)

DMASTR DMA Status Register Offset 0x360

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D15	S15	D14	S14	D13	S13	D12	S12	D11	S11	D10	S10	D9	S9	D8	S8
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	D7	S7	D6	S6	D5	S5	D4	S4	D3	S3	D2	S2	D1	S1	D0	S0
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each bit in the DMASTR corresponds to a channel. The source status for each channel is controlled in the BD associated with the channel. If set, a bit associated with a channel indicates that the buffer ends when BD_ATTR[SST] is set or it is the last buffer. A bit is cleared by writing a value of one to it. Writing zero does not affect a bit value. Several bits can be cleared at one time.

Note: You must clear the Dx and Sx bits before enabling the channel.

14.6.16 DMA Error Register (DMAERR)

DMAERR DMA Error Register Offset 0x370

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	BDSZ	PACH						PADEST	—	PBCH						PBDEST
Type	R	R/W							R	R/W						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	PAE	PBE	—	THV	PRTYP	PRTYF	PRTYB	PRTY	—	PRTYCH						PRTYD
Type	R/W		R													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMAERR holds the source for the error interrupt. The error interrupt output is unmasked in the DMA controller. A bit is cleared by writing a value of one to it. Writing zero does not affect a bit value. Several bits can be cleared at one time. If a port error occurs, all channels assigned to the port enter a freeze state. You must reprogram the channel that caused the error and reactivate it. You may decide to defrost other port assigned channels and continue normally. For a BD size error or parity error, only the channel that caused the error is frozen.

Table 14-24. DMAERR Description

Bits	Reset	Description	Settings
BDSZ 31	0	**Buffer Descriptor Size** Indicates whether the buffer descriptor size is programmed to zero. See also **Table 14-27** and **Table 14-29**.	0 No BD_SIZE or MD_BD_SIZE of 0 detected. 1 BD_SIZE or MD_BD_SIZE of 0 detected.
PACH 30–25	0	**First Port 0 Channel to Cause Bus Error** Indicates which channel caused the first error on bus interface port A.	000000 - 001111: channel number 01xxxx: Reserved 10xxxx: Reserved
PADEST 24	0	**Error of Port 0 Destination Channel** Indicates whether the last error on port 0 was caused by channel source or destination.	0: Source transaction error. 1: Destination transaction error.
— 23	0	Reserved. Write to zero for future compatibility.	
PBCH 22–17	0	**First Port 1 Channel to Cause Bus Error** Indicates which channel caused the first error on bus interface port B.	000000–001111: channel number. 01xxxx Reserved 10xxxx: Reserved
PBDEST 16	0	**Error of Port 1 Destination Channel** Indicates whether the last error on port 1 was caused by a channel source or destination.	0 Source transaction error. 1 Destination transaction error.
PAE 15	0	**Port 0 Transfer Error Indication** Indicates whether there is an acknowledged transfer error on port 0.	0 No transfer error acknowledged on port 0. 1 Transfer error acknowledged on port 0.
PBE 14	0	**Port 1 Transfer Error Indication** Indicates whether there is an acknowledged transfer error on port 1.	0 No transfer error acknowledged on port 1. 1 Transfer error acknowledged on port 1.
— 13	0	**Reserved**, write zero for future compatibility.	

Table 14-24. DMAERR Description (Continued)

Bits	Reset	Description	Settings
THV 12	0	**Threshold Violation** The channel that violated the deadline is indicated in the DMA Counter Status Register (DMACNTSTR). THV is set as long as there is a set bit in DMACNTSTR. THV is automatically cleared when all bits in DMACNTSTR are cleared.	0 No deadline violation. 1 Deadline violation.
PRTYP 11	0	**Parity Error on PRAM** Indicates that the parity error occurred in the PRAM.	0 No error indication on the PRAM. 1 PRAM parity error indication.
PRTYF 10	0	**Parity Error on FIFOs** Indicates that the parity error occurred in the FIFOs.	0 No error indication in the FIFO's. 1 FIFO's parity error indication.
PRTYB 9	0	**Parity Error on Bus interface** Indicates that the parity error occurred in the BI.	0 No error indication in the BI. 1 BI parity error indication.
PRTY 8	0	**Parity Error** Indicates any parity error.	0 No error indication. 1 Error indication.
— 7	0	**Reserved**, write zero for future compatibility.	
PRTYCH 6–1	0	**Parity Channel** First channel that caused parity error Indicates by which channel the last parity error was caused.	000000–001111: Channel number. 01xxxx Reserved. 10xxxx Reserved.
PRTYD 0	0	**Parity Error Destination** Indicates whether the first parity error was caused by a channel source or destination.	0 Source transaction error. 1 Destination transaction error.

14.6.17 DMA Debug Event Status Register (DMADESR)

DMADESR DMA Debug Event Status Register Offset 0x374

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—														EXT	DBG
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DMADESCR reflects whether an external debug request was received and whether the DMA is in Debug mode. **Table 14-25** describes the fields of the DMADESR.

Table 14-25. DMADESR Field Descriptions

Bits	Write By	Description	Settings
— 31–2	—	Reserved. Write to zero for future compatibility.	
EXT 1	DMA	**External DMA Debug Request Event** Set when external debug event occurs.	0 Normal operation 1 External DMA debug request
DBG 0	DMA	**Debug Mode Status** Set when the DMA is in full Debug mode.	0 Normal operation. 1 DMA in Debug mode.

14.6.18 DMA Round-Robin Priority Group Update Register (DMARRPGUR)

DMARRPGUR DMA Round-Robin Priority Group Update Register Offset 0x37C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—						CH						NRRPG			EN
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DMARRPGR is a special register that allows you to modify the DMACHCR[RRPG] bit without a read-modify-write operation.

Note: Do not modify this register while the DMA controller is in EDF mode (DMAGCR[AT] is set—see **page 14-31**).

Table 14-26. DMARRPGUR Field Descriptions

Bits	Description	Settings
— 31–10	Reserved. Write to zero for future compatibility.	
CH 9–4	**Channel Number** The channel number to which DMACHCR[RRPG] should be changed.	000000–001111: Channel number. 01xxxx Reserved. 1xxxxx Reserved.
NRRPG 3–1	**New Channel Round-Robin Priority Group** The new value of RRPG to be written to the corresponding CHCR of the channel.	000 Highest priority. ... 011 Lowest priority. 1xx Reserved.
EN 0	**Enable RRPG Update** Enables the RRPG update. Then the DMA controller clears this bit	

14.6.19 DMA Channel Active Status Register (DMACHASTR)

DMACHASTR DMA Channel Active Status Register Offset 0x380

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	A15	A14	A13	A12	A11	A10	A9	A8	A7	A6	A5	A4	A3	A2	A1	A0
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Each bit in the DMACHASTR corresponds to the active status of the associated channel. If set, a bit associated with a channel indicates that the channel is still active. A channel can stay active even after DMACHCR[ACTV] is cleared or DMACHDR[DISx] is set. A DMACHASTR bit is reset only when its corresponding channel completes the shutdown procedure.

14.6.20 DMA Channel Freeze Status Register (DMACHFSTR)

DMACHFSTR DMA Channel Freeze Status Register Offset 0x388

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D15	S15	D14	S14	D13	S13	D12	S12	D11	S11	D10	S10	D9	S9	D8	S8
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	D7	S7	D6	S6	D5	S5	D4	S4	D3	S3	D2	S2	D1	S1	D0	S0
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

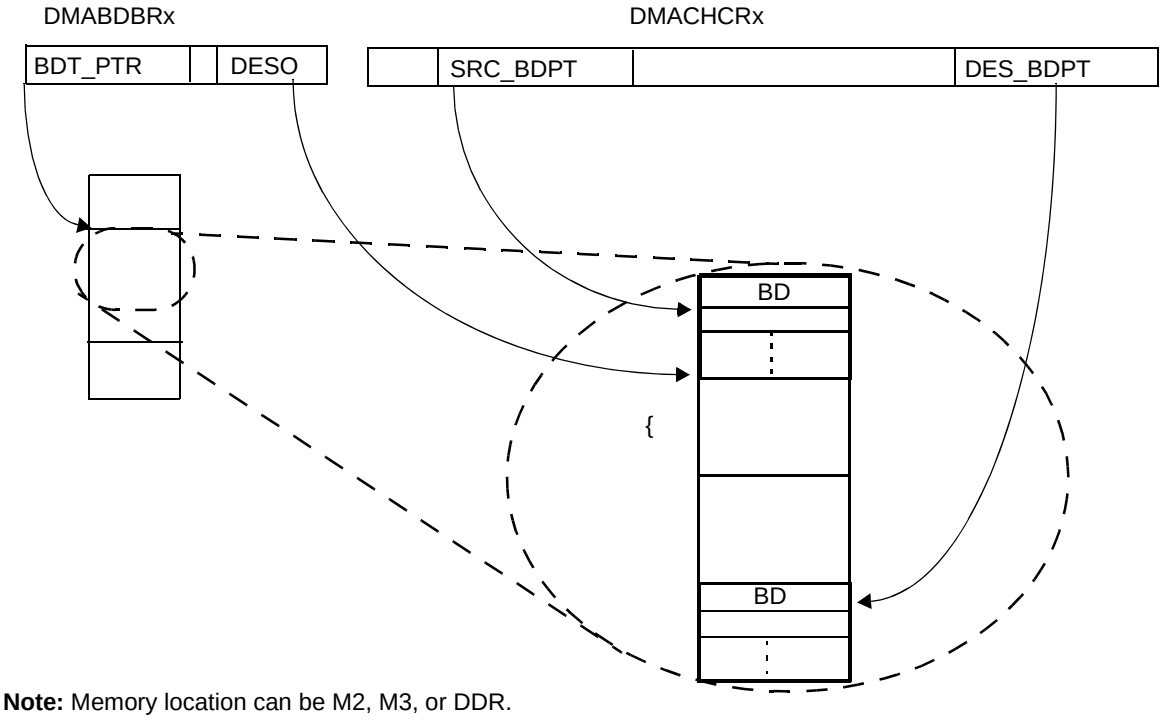
Each bit in the DMACHFSTR corresponds to the freeze status of the associated channel. If set, a bit associated with a channel indicates that the channel is still frozen.

Note: The corresponding bits are cleared when a channel is activated.

Note: When a bit is set as a result of BD_ATTR[FRZ] or BD_MD_ATTR[FRZ], it means that the DMA internal logic has finished serving the current BD and will not fetch or process the next BD until the channel is unfrozen. It does not imply that the current BD data or update has reached its destination. To guarantee that data or an updated BD is written to memory, use the interrupt mechanism or poll the channel status register.

14.6.21 DMA Channel Buffer Descriptors

Figure 14-13 shows a diagram of the BD pointer scheme.



Note: Memory location can be M2, M3, or DDR.

Figure 14-13. Buffer Descriptor Pointers

Following are the actual addresses of the source and destination BDs for any channel:

- BDT_BASE = DMABDBR[BDT_PTR] × 256
- Source BD = BDT_BASE + DMACHCR[SRCBDPT] × 16 × (DMACHCR[SMDC] + 1)
- Destination BD: BDT_BASE + offset + DMACHCR[DESBDPT] × 16 × (DMACHCR[DMDC] + 1)
- Offset is the decoded value of DMABDBR[DESO]

The VCOP channel BDs are located in memory outside the VCOP. Each channel has a BD table to hold the BDs for both source and destination buffers. All BDs of all channels must be located in memory connected to MBus interface 0. **Figure 14-14** shows the structure of one-dimensional BD, which is a 128-bit entry.

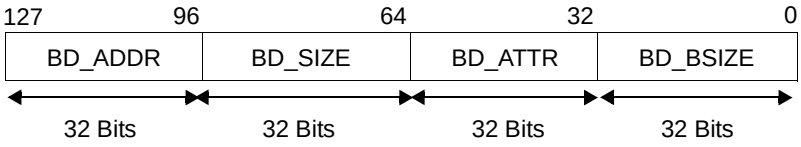


Figure 14-14. DMA Channel BD One-Dimensional Line

Figure 14-15 shows the structure of a multi-dimensional BD, which is a 256-bit entry.

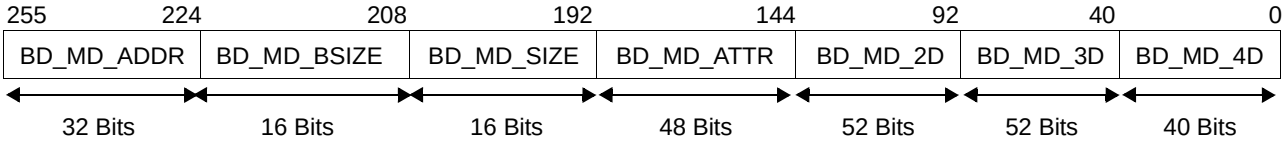

Figure 14-15. DMA Channel Multi-Dimensional Buffer Descriptor

Table 14-16 shows an example structure for a BD table that holds multi-dimensional read and one-dimensional DMA write tasks. The read channel uses 512 BDs of multi-dimensional BDs, which is the maximum available for multiple dimensions. The write channel uses 1024 one-dimensional BDs, which is the maximum available for one dimension. For details on BD address calculation.

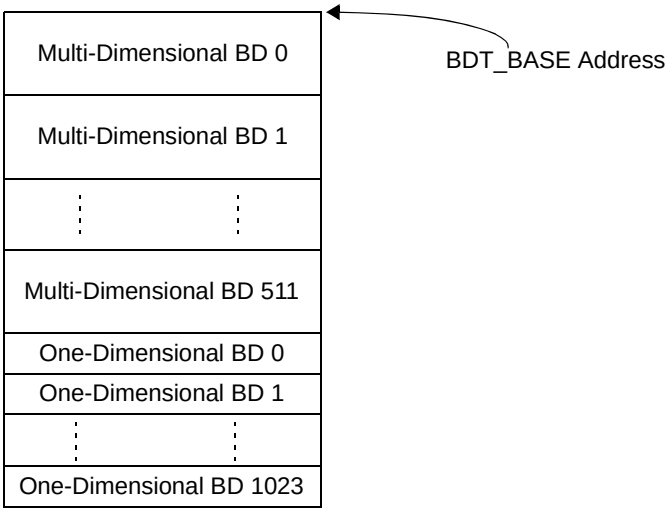

Figure 14-16. Example BD Table with a Mixed Dimensional Structure

The BDs are either one-dimensional or multi-dimensional. One-dimensional BDs are chained only to one-dimensional BDs and multi-dimensional BDs are chained only to multi-dimensional BDs. The types of source and destination BDs are defined in the DMACHCR (see **page 14-29**). **Table 14-27** lists the channel parameters for a one-dimensional BD.

Table 14-27. One-Dimensional BD Field Descriptions

Bits	Description
BD_ADDR 127–96	**Current Buffer Address** Holds the buffer address pointer. This value increments on every transaction the DMA controller issues for this buffer. If the buffer is cyclic, the original address value is restored when the BD_SIZE value reaches zero. For details, refer to **Section 14.2.2**, *One-Dimensional Cyclic Buffer,* on page 14-5.
BD_SIZE 95–64	**Size of Transfer Left for Current Buffer** Contains the remaining size of the buffer. This value decrements by the transfer size each time the DMA controller issues a transaction until it reaches zero. When BD_SIZE reaches zero, the value is restored to the value of BD_BSIZE. **Note:** The BD_SIZE must not be programmed as zero. A value of zero sets DMAERR[BDSZ] and freezes the channel. To reactivate the channel, you must disable the channel, reprogram the BDs, and reactivate the channel.
BD_ATTR 63–32	**Buffer Attributes** This 32-bit parameter describes the attributes of the channel handling this buffer. The fields of the BD_ATTR parameter are described in **Table 14-28**.
BD_BSIZE 31–0	**Buffer Base Size** Holds the base size of the buffer.

14.6.21.1 Buffer Attributes (BD_ATTR)

BD_ATTR Buffer Attributes

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SST	CYC	CONT	NPRT	NO_INC	—	NBD									
Type	R/W															
Reset	Undefined															

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNT		PP		TSZ				—	FRZ	MR	—	BTSZ			
Type	R/W															
Reset	Undefined															

Table 14-28. BD_ATTR Field Descriptions

Bits	Description	Settings
SST 31	**Set Status** Indicates whether to set the associated status bit in DMASTR when size reaches zero and the last data transaction ends. Setting this bit in the destination buffer issues a masked interrupt request.	0 Do not set status 1 Set status.
CYC 30	**Cyclic Address** Indicates the behavior of BD_ADDR when BD_SIZE reaches zero. For details on cyclic buffers, see **Section 14.2**, *Buffer Types,* on page 14-3.	0 Sequential address: BD_ADDR increments. 1 Cyclic address: BD_ADDR is restored to the original value for a one-dimensional buffer.
CONT 29	**Continuous Buffer Mode** Indicates whether buffer is to close when BD_SIZE reaches zero. **Note:** Unlike multidimensional mode, there is no *last buffer indicator* in simple mode. If your application is chaining multiple single dimension buffers, you must set this bit for all but the last BD in the chain. The cleared CONT bit in the last BD effectively becomes the last buffer indicator for the chain.	0 Buffer closes. 1 Buffer continues operating.
NPRT 28	**Next Port** When size reaches zero and CONT is set, DMACHCR[SPRT] (for source buffers) or DMACHCR[DPRT] (for destination buffers) is updated according to the NPRT field:	0 Next buffer port is MBus port 0. 1 Next buffer port is MBus port 1.
NO_INC 27	**Increment Address** Indicates the behavior of the buffer address after the request is serviced. **Note:** When this bit is set, the DMA controller always issues requests for the same address. It aligns (to the transfer size) on the first transfer as it does for any other first transaction. The DMA controller handles BD_SIZE as if it were a normal buffer, that is, it issues requests with the total byte count size as recorded in the BD_SIZE field.	0 Increment address. 1 Do not increment address.
— 26	Reserved. Write to zero for future compatibility.	
NBD 25–16	**Next Buffer** When size reaches zero and CONT is set, the next request calls the buffer to which NBD points.	

Table 14-28. BD_ATTR Field Descriptions (Continued)

Bits	Description	Settings
CNT 15–14	**Channel Counter** This field is valid only when the arbitration is time-based. It characterizes the time-based arbitration mechanism for continuous buffers when the buffer size reaches zero and applies only when switching buffers.	00 Continuous: Channel and counter continue working normally. 01 Reserved. 10 Reserved. 11 Resets the channel counter.
PP 13–12	**Port priority** Define priority for this buffer. The bus Interface will set priority for this buffer. Note that the user must map the priority in system level.	00 Priority 0 (lowest). 11 Priority 3 (highest).
TSZ 11–8	**Transfer size** Indicates the maximum transfer size that the DMA will issue when request is detected.	0000 512 bytes 0001 1 byte. 0010 2 bytes. 0011 4 bytes. 0100 8 bytes. 0101 16 bytes. 0110 32 bytes. 0111 64 bytes. 1000 128 bytes. 1001 256 bytes. 1010 512 bytes. 1011 1024 bytes. 1100 2048 bytes. 1101 4096 bytes. 111x Reserved.
— 7	Reserved. Write to zero for future compatibility.	
FRZ 6	**Freeze channel** When size reaches zero, the channel can be frozen. The already serviced requests continue normally. No further requests are issued for the associated channel until the host defrosts it.	0 Normal operation 1 Freeze channel.
MR 5	**Mask Requests Until Data Reached Destination** Indicates the behavior of the logic when BD_SIZE reaches zero. Typically, in continuous buffers, the channel should not be masked. However, there is an automatic mask when continuous buffers switch between ports. The DMA controller unmasks the requests when the last data reaches the destination.	0 Normal operation. 1 Mask requests until data reached destination.

Table 14-28. BD_ATTR Field Descriptions (Continued)

Bits	Description	Settings
— 4	Reserved. Write to zero for future compatibility.	
BTSZ 3–0	**Basic Transfer Size** The basic transfer size issued for the request. If BTSZ is greater than TSZ, the DMA controller uses TSZ for the transfer size.	0000 64 bytes 0001 1 byte 0010 2 bytes 0011 4 bytes 0100 8 bytes 0101 16 bytes 0110 32 bytes 0111 64 bytes 1000 128 bytes 1001 256 bytes 101x reserved 11xx reserved

Table 14-29 shows the DMA channel parameters for a multi-dimensional buffer.

Table 14-29. Multi-Dimensional BD Field Descriptions

Bits	Description
BD_MD_ADDR 255–224	**Current Buffer Address** Holds the buffer address pointer. This value increments on every transaction the DMA controller issues for this buffer. When BD_MD_SIZE reached zero and the next dimension is active, the next dimension offset is added to the BD_MD_ADDR. For details, see **Section 14.2**, *Buffer Types,* on page 14-3.
BD_MD_BSIZE 223–208	**First Dimension Buffer Base Size** Contains the base size for the buffer first dimension.
BD_MD_SIZE 207–192	**First Dimension Buffer Size** Holds the remaining size for the buffer first dimension. This value is incremented by the transfer size each time the DMA controller issues a transaction, until it reaches zero. When BD_MD_SIZE reaches zero, its value is restored to the value of BD_MD_BSIZE. **Note:** BD_MD_SIZE must not be programmed to zero. Programming the value to zero sets DMAERR[BDSZ] and freezes the channel. To reactivate the channel, you must disable the channel, wait for the active status bit to go to clear, reprogram the BDs, and reactivate the channel.
BD_MD_ATTR 191–144	**Multi-Dimensional Buffer Attributes** This 48-bit parameter describes the multi-dimensional attributes of the channel handling this buffer. The BD_MD_ATTR parameters are described in **Table 14-30**.
BD_MD_2D 143–92	**Two-Dimensional Buffer Offset, Bcount, and Count** This 52-bit parameter holds the two-dimensional parameters of the channel handling this buffer. It holds the base count value, current count, and address offset. The Multi Dimension fields are described in **Table 14-31*BD_MD_2D Field Descriptions,*** on page 14>-54.

Table 14-29. Multi-Dimensional BD Field Descriptions (Continued)

Bits	Description
BD_MD_3D 91–40	**Three-Dimensional Buffer Offset, Bcount, and Count** This 52-bit parameter holds the three-dimension parameters of the channel handling this buffer. It holds the base count value, current count, and address offset. The Multi Dimension fields are described in **Table 14-32*BD_MD_3D Field Descriptions,*** on page 14>-55.
BD_MD_4D 39–0	**Four-Dimensional Buffer Offset and Count** This 40-bit parameter holds the four-dimensional parameters of the channel handling this buffer. It holds the base count value and current count. The multi-dimensional fields are described in **Table 14-33*BD_MD_4D Field Descriptions,*** on page 14>-55.

Table 14-30. BD_MD_ATTR Field Descriptions

Bits	Description	Settings
SST 47	**Set Status** Indicates whether to set the associated status bit in DMASTR when size reaches zero and the last data transaction ends. Setting this bit in the destination buffer issues a masked interrupt request. See also the SSTD bit.	0 Do not set status. 1 Set status when the size of the dimension selected by SSTD reaches zero.
CYC 46	**Cyclic Address** Indicates the behavior of BD_MD_ADDR when BD dimension count reaches zero. For details on cyclic buffers, see **Section 14.2**, *Buffer Types,* on page 14-3. **Notes: 1.** This field must not be set for four dimensional buffers. **2.** This field is not valid for BD_MD_ATTR[CONTD]<BD_MD+ATTTR[BD].	0 Sequential address: BD_MD_ADDR is incremented. 1 Cyclic address: the next dimension offset is added to BD_MD_ADDR.
CONT 45	**Continuous Buffer Mode** Specifies whether the buffer closes when CONTD dimension count reaches zero.	0 Buffer closes. 1 Buffer continues operating.

Table 14-30. BD_MD_ATTR Field Descriptions (Continued)

Bits	Description	Settings
NPRT 44	**Next Port** When size reaches zero and CONT is set and the CONTD dimension count reaches zero, DMACHCR[SPRT] (for source buffers) or DMACHCR[DPRT] (for destination buffers) is updated according to the NPRT field.	0 Next buffer port is MBus port 0. 1 Next buffer port is MBus port 1.
NO_INC 43	**Increment Address** Indicates the behavior of the buffer address after a request is serviced. When a dimension is processed, the DMA adds the next dimension offset to the address, regardless of the status of NO_INC.	0 Increment address. 1 Do not increment address.
— 42	Reserved. Write to zero for future compatibility.	
NBD 41–32	**Next Buffer** When size reaches zero, CONT is set, and the CONTD dimension count reaches zero, the next request calls the buffer to which NBD points. **Note:** For four dimensional buffers, if CONT is set, NBD must be different from the current BD.	
CNT 31–30	**Channel Counter** This field is valid only for a destination buffer only when the arbitration is time-based. It characterizes the time-based arbitration mechanism for continuous buffers when the buffer size reaches zero and applies only when switching buffers.	00 Continuous: Channel and counter continue working normally. 01 Reserved. 10 Reserved. 11 Resets the channel counter.
PP 29–28	**Port Priority** Defines the priority for the designated buffer. The bus interface sets the priority for this buffer. You must map the priority at the system level.	00 Priority 0 (lowest.). 11 Priority 3 (highest).
TSZ 27–24	**Transfer Size** Indicates the maximum transfer size that the DMA controller issues when a request is detected.	0000 512 bytes 0001 1 byte. 0010 2 bytes. 0011 4 bytes. 0100 8 bytes. 0101 16 bytes. 0110 32 bytes. 0111 64 bytes. 1000 128 bytes. 1001 256 bytes. 1010 512 bytes. 1011 1024 bytes. 1100 2048 bytes. 1101 4096 bytes. 111x Reserved.
— 23	Reserved. Write to zero for future compatibility.	

Table 14-30. BD_MD_ATTR Field Descriptions (Continued)

Bits	Description	Settings
FRZ 22	**Freeze Channel** When size reached zero the channel can be freeze. The already serviced requests continue normally. No further requests are issued for the associated channel until the host defrost it. See also the FRZD field.	0 Normal operation. 1 Freeze channel when size reaches zero on the dimension selected by FRZD.
MR 21	**Mask Requests Until Data Reached Destination** Indicates the behavior of the logic when BD_MD_SIZE reaches zero. In continuous buffers, the channel is usually not masked. There is an automatic mask when ports are switched in a continuous buffer. The DMA controller unmasks the requests when last data reaches the destination. See also the MRD field.	0 Normal operation. 1 Mask requests until data reached destination on the dimension selected by MRD.
— 20	Reserved. Write to zero for future compatibility.	
BTSZ 19–16	**Basic Transfer Size** The basic transfer size issued by the request. If BTSZ is greater than TSZ, the DMA controller uses the TSZ value.	0000 64 bytes 0001 1 byte 0010 2 bytes 0011 4 bytes 0100 8 bytes 0101 16 bytes 0110 32 bytes 0111 64 bytes 1000 128 bytes 1001 256 bytes 101x reserved 11xx reserved
— 15–11	Reserved. Write to zero for future compatibility.	
LAST 10	**Last Buffer In Chain** Set this bit only to avoid an endless task condition when CONT is set and CONTD is smaller than BD.	0 Not the last buffer in the chain. 1 Last buffer in the chain.
BD 9–8	**Buffer Dimension** Indicates the dimension of the buffer.	00 1 dimension. 01 2 dimensions. 10 3 dimensions. 11 4 dimensions.
SSTD 7–6	**Set Status Dimension** When BD_MD_SIZE reaches zero and BD_MD_ATTR[SST] = 1, the status bit is set for the channel in DMASTR. For details, see **page 14-40**. The SSTD field defines the dimension on which the status bit is set.	00 BD_MD_SIZE reached zero, 1D. 01 M2D_COUNT reached zero, 2D. 10 M3D_COUNT reached zero, 3D. 11 M4D_COUNT reached zero, 4D.
FRZD 5–4	**Freeze Dimension** When the selected dimension is processed, the internal logic masks all channel requests and freezes the channel. The host must defrost the channel for further service.This field is valid only if FRZ is set in the BD_MD_ATTR.	00 Mask and freeze channel when first dimension ends. 01 Mask and freeze channel when second dimension ends. 10 Mask and freeze channel when third dimension ends. 11 Mask and freeze channel when fourth dimension ends.

Table 14-30. BD_MD_ATTR Field Descriptions (Continued)

Bits	Description	Settings
CONTD 3–2	**Continuous Buffer Mode Dimension Select** Indicates the dimension after which the channel switches to the next multi-dimensional BD. This field is valid only if CONT is set in the BD_MD_ATTR. **Notes:** **1.** The value must not be greater than BD. **2.** When NBD is equal to the current BD and CONT is set, CONTD must equal BD. **3.** If CONT is set and CONTD < BD, the BD area is updated by the DMA controller. Do not access this area until the DMA task is completed. **4.** If CONT is set, CONTD < BD, and NPRT is different from the current port, MR must be set an MRD must be equal to CONTD.	00 Switch to next BD when BD_MD_SIZE reaches zero, 1D 01 Switch to next BD when M2D_COUNT reaches zero, 2D. 10 Switch to next BD when M3D_COUNT reaches zero, 3D. 11 Switch to next BD when M4D_COUNT reaches zero, 4D.
MRD 1–0	**Mask Requests Dimension** Indicates the dimension after which the channel masks requests until the data reaches its destination. This field is valid only if MR is set in the BD_MD_ATTR.	00 Mask requests when BD_MD_SIZE reaches zero, 1D. 01 Mask requests when M2D_COUNT reaches zero, 2D. 10 Mask requests when M3D_COUNT reaches zero, 3D. 11 Mask requests when M4D_COUNT reaches zero, 4D.

Table 14-31. BD_MD_2D Field Descriptions

Bits	Description
M2D_COUNT 51–40	**Second Dimension Current Count** Decrements each time the BD_MD_SIZE reaches zero. The field is reloaded with the M2D_BCOUNT each time it reaches zero. **Note:** If the buffer is two dimensional or more, this field cannot be 0.
M2D_BCOUNT 39–28	**Second Dimension Base Count** Holds the second dimension base count. **Note:** If the buffer is more than two dimensional, this field cannot be 0.
M2D_OFFSET 27–0	**Second Dimension Offset** Written in two's complement. The offset is added to the BD_MD_ADDR each time BD_MD_SIZE reaches zero.

Table 14-32. BD_MD_3D Field Descriptions

Bits	Description
M3D_COUNT 51–40	**Third Dimension Current Count** Decrements each time the BD_MD_SIZE and M2D_COUNT reach zero. The field is reloaded with the M3D_BCOUNT each time it reaches zero. **Note:** If the buffer is three dimensional or more, this field cannot be 0.
M3D_BCOUNT 39–28	**Third Dimension Base Count** Holds the third dimension base count. **Note:** If the buffer is more than three dimensional, this field cannot be 0.
M3D_OFFSET 27–0	**Third Dimension Offset** Written in two's complement. The offset is added to the BD_MD_ADDR each time BD_MD_SIZE and M2D_COUNT reach zero.

Table 14-33. BD_MD_4D Field Descriptions

Bits	Description
M4D_COUNT 39–28	**Fourth Dimension Current Count** Decrements each time BD_MD_SIZE, M2D_COUNT, and M3D_COUNT reach zero. **Note:** If the buffer is four dimensional, then this field cannot be 0.
M4D_OFFSET 27–0	**Fourth Dimension Offset** Written in two's complement. The offset is added to the BD_MD_ADDR each time BD_MD_SIZE, M2D_COUNT, and M3D_COUNT reach zero.

15 High Speed Serial Interface (HSSI) Subsystem

The High Speed Serial Interface (HSSI) is a 10-port serial communications subsystem that supports multiplexing of the following serial interfaces:

- Two x1/x2/x4 Serial RapidIO ports
- One x1/x2/x4 PCI Express port
- Two SGMII ports
- Six x1 CPRI ports

To support these interfaces, the HSSI includes the following blocks:

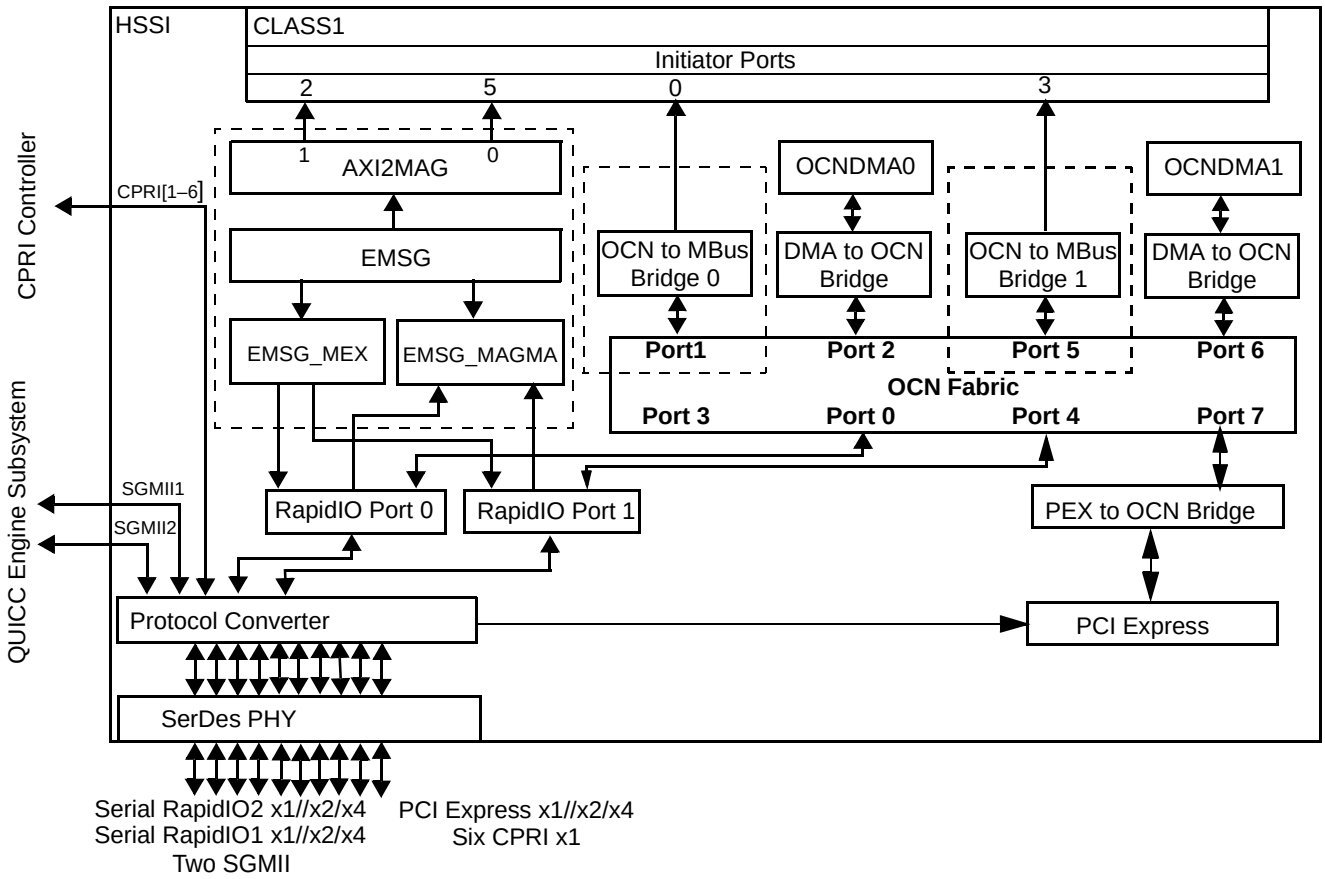
- One CLASS1 non-blocking fabric to interface between the HSSI and the system CLASS module.
- One 8-port OCN fabric with two dedicated DMA controllers and two OCN to MBus bridges to provide high-speed memory access with no core intervention for the two Serial RapidIO port controllers and the PCI Express controller. The bridges connect to the CLASS 1 module.
- Two Serial RapidIO port controllers (port 1 and 0) with enhanced messaging unit (eMSG). The RapidIO complex includes an AXI bridge to MBus to connect to the CLASS1 fabric and an eMSG MBus expander and normalizer to connect to the two Serial RapidIO port controllers. The RapidIO complex and eMSG details are provided in **Chapter 16**, *Serial RapidIO Controller and Enhanced Message Complex*.
- One PCI Express controller with a bridge to the OCN fabric. The PCI Express controller details are provided in **Chapter 17**, *PCI Express Controller*
- Six CPRI controllers, described in detail in **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.
- One Protocol Converter module to link the two Serial RapidIO ports, one PCI Express port, six CPRI ports and the two SGMII ports to the SerDes PHY.
- One 10-channel SerDes PHY that multiplexes the RapidIO, PCI Express, CPRI and SGMII signals for external connection.

These communication interfaces allow the cores to execute the data processing code and be relieved from the data transfer and handling overhead for processing serial data flow.

This chapter includes the interface component programming model, with the exception of the SerDes multiplexing programming, which is done using the SP bits in the low half of the reset configuration word (RCW), as described in **Chapter 5**, *Reset*. The communication controllers supported and eMSG unit within the block are described in **Chapter 16**, *Serial RapidIO Controller and Enhanced Message Complex***.** While the SGMII lines are multiplexed through the SerDes interfaces, they are functionally part of the QUICC Engine subsystem, as described in **Chapter 19**, *QUICC Engine Subsystem*. While the CPRI signals and multiplexed through the SerDes interfaces, the CPRI controller lies outside of HSSI complex, as described in **Chapter 18**, *Common Public Radio Interface (CPRI) Complex*.

15.1 HSSI Subsystem Block Diagram

Figure 15-1 shows a block diagram of the HSSI.



Note: The actual signal multiplexed for each channel in the PHY is determined by the SerDes configuration field contents in the lower 32 bits of the reset configuration word, which are recorded in RCWLR[SP]. See **Chapter 5**, *Reset* for details.

Figure 15-1. HSSI Block Diagram

15.2 CLASS1

Based on the same design as the system CLASS fabric, CLASS1 uses a fully pipelined low latency design and is the interconnect between the HSSI complex and the system CLASS. Like the CLASS, CLASS1 is a non-blocking, full-fabric interconnect that allows any initiator to access any target in parallel with another initiator-target couple. CLASS1 uses per-target prioritized round-robin arbitration, highly optimized to the target characteristics. CLASS1 is ready for use and does not require any special configuration to perform non-blocking pipelined transactions from any initiator to any memory. The configurable arbitration features described in this chapter are for fine-tuning the system for specific application requirements.

The Six CLASS1 initiators are:

- OCN-to-MBus bridge 0 (initiator port 0)
- OCN-to-MBus bridge 1 (initiator port 3)
- AXI-to-MBus bridge 0 (initiator port 5)
- AXI-to-MBus bridge 1 (initiator port 2)
- CPRI MBus port 0 (initiator port 4)
- CPRI MBus port 1 (initiator port 1)

The two CLASS1 targets are:

- HSSI port 0 (target port 1). Connects to CLASS0 initiator port 8.
- HSSI port 1 (target port 2). Connects to CLASS0 initiator port 12.

The CLASS initiators and targets are shown in **Figure 15-2**. The arrows indicate the address direction from initiator to target.

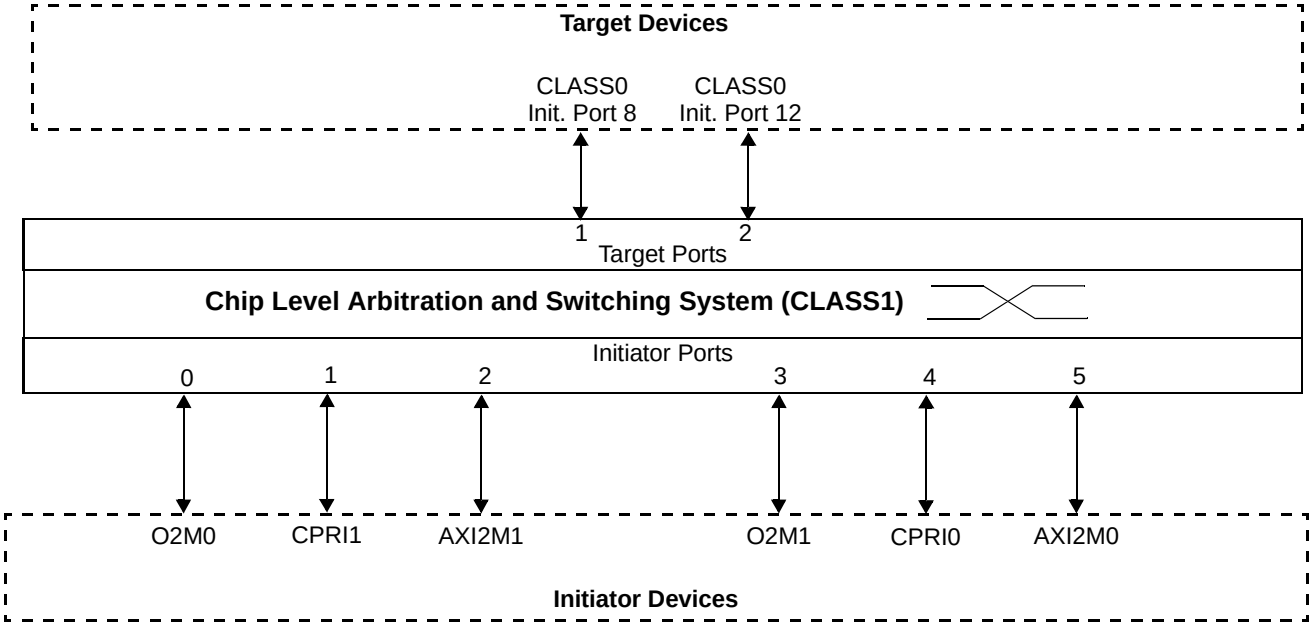


Figure 15-2. CLASS1 Initiators and Targets in the MSC8157E Device

15.2.1 Functional Description

CLASS1 is a non blocking interconnect between 6 initiators and 2 targets. The main sub-blocks of the CLASS are: expander, multiplexer and arbiter, normalizer, and the CLASS control interface (CCI) unit that implements the interface and interrupt lines and the CLASS register files. Each CLASS module also implements an inherent debug and profiling unit (CDPU).

To implement the protocol that deals with the point-to-point bus, the CLASS includes an expander module per initiator that performs address decoding and is used as sampling stage on the initiator side. Each expander module can detect an error address and generate an interrupt. For details about the expander module, see **Section 15.2.1.1**. From the target side, the CLASS includes a multiplexer and arbiter module and a normalizer module for each target. The multiplexer and arbiter module performs a pseudo round-robin (RR) arbitration algorithm between all the initiators and concentrates them toward one target. For details about multiplexer and arbiter module, see **Section 15.2.1.2**. Each multiplexer and arbiter module has a dedicated normalizer module that is used as the sampling stage on the target side. The normalizer can also be used for normalizing transactions. For details about normalizer module see **Section 15.2.1.2.3**.

15.2.1.1 Expander Module and Transaction Flow

Each expander module connects to one initiator. The expander module performs address decoding according to the configuration register settings. Each target is presented by a start address and an end address that define a window in the memory space. The address decoding is done by checking whether the transaction address hits one of the active windows. Each expander module is connected to all of the multiplexer and arbiter blocks in the CLASS to implement a full-fabric and non-blocking interconnect between any initiator to any target. If the address decoding hits in more than one window, the CLASS arbiter chooses a window by fixed priority arbitration (target 0 has the lowest priority). After detecting the requested target and the arbiter selects the target window, the expander module starts a transaction toward the associated multiplexer and arbiter module. The CLASS prevents the possibility of simultaneous accessing to more than one target by the same initiator. If there are accesses from one initiator to different targets, the expander module start the transactions to other targets only after all the open accesses to the current target are completed. The expander module is a sampling stage of transaction. For each request (address + attribute), write data is sampled from the initiator and driven to the normalizer module through multiplexer and arbiter module in the following clock cycle; read data is sampled from the normalizer module through multiplexer and arbiter module and driven to the initiator in the following clock cycle.

15.2.1.2 Multiplexer and Arbiter Module

The multiplexer and arbiter module connects to all the expander modules on one side and to a dedicated normalizer module on the other side. The multiplexer and arbiter module block is a pure logic data path design, that supports up to 16 initiators, performs an arbitration, and concentrates them towards a specific target normalizer module.

15.2.1.2.1 CLASS Arbiter

The CLASS arbiter performs weighted arbitration algorithm for requesters simultaneously using a pseudo round-robin arbitration algorithm for each of the priority levels and chooses the highest level request. The CLASS arbiter supports four priority levels, where 3 is the highest and 0 is the lowest. The arbitration operation can be done every clock cycle or delayed according to the number of datums of acknowledged transaction (Late Arbitration mode). The CLASS arbiter supports priority upgrade, so the initiator can upgrade the priority level at any clock cycle.

To eliminate starvation for initiators with low priority, the Masking Priority should be enabled. Starvation can occur when the higher priority initiators access continuously and the lower priority initiators can not perform any access (no priority upgrade ability by the initiator and auto priority upgrade in the expander module is disabled). When the Masking Priority is enabled, the arbiter dedicates slots for lower priority initiator in which the higher priority initiators are masked.

The arbiter supports the following arbitration schemes and functions:

- Weighted Arbitration. The CLASS arbiter supports limited weighted arbitration. Weighted arbitration is needed to apply non-uniform distribution of the bandwidth from all initiators toward each target. Weighted arbitration is configurable per CLASS target and gives configurable weights to each initiator. The CLASS arbiter ensures that when a weighted initiator wins the arbitration, it performs Weight + 1 consecutive transactions before transferring control to another initiator with the same or lower priority level.
- Late Arbitration. In late arbitration mode, the request is initiated by the class arbiters as late as possible. At the end of a data burst, this can give better or worse performance for the initiators. The performance depends on the bursty character of the application and the utilization to the target. In CLASS1, this mode is activated/deactivated by the appropriate bit in the C1ACR (see **15.10.29**, *CLASS1 Arbitration Control Register (C1ACR)*).
- Priority Masking. In CLASS1, when C1ACR[PME] is set, the class arbiters are configured to preserve cycle slots for low priority accesses. They reserve 1/16 of all cycles for priority 0, 2/16 of all cycles for priority 1 or 0, and 2/16 of all cycles for priority 2, 1, or 0. This mode can decrease overall performance. This is one of two approaches to eliminate starvation. The other is to use auto-priority upgrade.
- Auto Priority Upgrade. In CLASS1, this mode is activated by setting the C1PACRx[AUE] bit (see **15.10.3**, *CLASS1 Priority Auto Upgrade Control Registers (C1PACRx)*). When active, a pending request has its priority upgraded to the next higher priority after a specified number of cycles specified by C1PAVRx[AUV] (see **15.10.2**, *CLASS1 Priority Auto Upgrade Value Registers (C1PAVRx)*). The upgrade level and timing depend on the current priority value assigned, as follows:
  - For priority 0 requests, the priority is upgraded to priority 1 after AUV cycles.
  - For priority 1 requests, the priority is upgraded to priority 2 after AUV/2 cycles.
  - For priority 2 requests, the priority is upgraded to priority 3 (highest) after AUV/4 cycles.

  The upgrade process continues until the request is processed or it reaches priority 3.

15.2.1.2.2 CLASS Multiplexer

The CLASS multiplexer includes two FIFOs that connect between the appropriate initiator and the target. The FIFO depth is 16, thus enabling the multiplexer and arbiter module to deal with 16 open transactions, which received their request acknowledge and are waiting for the end-of-data or end-of-transaction signals. The CLASS multiplexer is pure logic for the data path and does not cause any latency.

15.2.1.2.3 Normalizer Module

Each normalizer module is connected to the appropriate multiplexer and arbiter module on one side and to a specific CLASS target interface on the other side. Each normalizer module is used as a sampler for full pipeline towards the target. The normalizer module is the only module within the CLASS that can manipulate the transaction (for example, splitting non-aligned transactions). An internal signal is used to indicate that optimization is needed. Only the last normalizer module on the way to the target is used for normalization. All the other normalizer modules should be used only as samplers. The normalizer module supports the fast confirm mechanism for writes.

15.2.1.3 CLASS1 Control Interface (C1CI)

The CLASS control interface (CCI) enables access to the CLASS configuration, control, and status registers. All write accesses to these registers should use supervisor mode. See **Section 15.10** for programming details.

15.2.2 CLASS Error Interrupts

CLASS can generate one error interrupt that is common for all initiators. The error interrupt is created when the CLASS receives a transaction request with an illegal address. Illegal addresses are defined as any one of the following 2 cases:

1. An address which does not belong to any of the address space windows of the enabled address decoders.
2. An address which falls within any of the address space windows of the enabled error address decoders.

When an illegal address is identified by the CLASS, the following events occur.

- The associated **AEIx** bit in the CISR is set.
- The address that was identified as illegal is stored in the associated **CEARx** and **CEEARx**. These registers are locked until the associated **AEIx** bit in the CISR is cleared either by a hardware reset or by writing 1 to this bit.

Note: If the associated **AEIx** bit in the C1ISR is already set when the illegal address is identified (due to a prior illegal address), then the new error address is not stored.

- If the corresponding **AEIEx** bit in the C1IER is set, an IRQ is issued.
- The CLASS does not initiate a transaction to any target. However, the CLASS will continue normally on the initiator side until completion, and report the error. In case of a read transaction, the CLASS delivers invalid data to the initiator.

- If, at the time of the error transaction, there are open transactions that did not receive the end-of-transaction, the expander module stalls all new transaction until all prior transactions receive the end-of-transaction, close the error transaction, report the end-of-transaction, report the error, and only then continue with subsequent transactions.
- Any subsequent requests with a legal address are serviced normally.

Note: The CLASS does not produce an error when a transaction starts inside a target address window and finishes outside of the window. This situation must be avoided by the user. If it occurs, the results are unpredictable.

The error interrupt is logically ORed with internal error interrupts. The internal error interrupts are associated with each initiator. Thus, the CLASS error interrupt is asserted when at least one internal interrupt is asserted.

15.2.3 CLASS Debug Profiling Unit

CLASS1 supports debug and profiling measurements by the CLASS1 debug and profiling unit (C1DPU).

15.2.3.1 Profiling

The user can configure the desired measurement in the C1IPCRs and C1TPCRs.

Note: For each CLASS1 module, only one PMM field among all C1IPCRx and C1TPCRx can be greater than 0 during profiling.

You can activate the C1DPU by:

- Writing a 1 to the C1PCR[PE] bit.
- Configuring a watch point event in C1PCR[WPEC] field.

The CDPU is deactivated by:

- Writing a 0 to the C1PCR[PE] bit.
- Configuring a watch point event in C1PCR[WPEC] field.
- Reaching a time-out in the C1PTOR when the C1PCR[TOE] bit is set.
- C1PRCR overflow.

After the desired profiling mode has been chosen, activate the C1DPU to perform the measurement. At the beginning of every measurement, the CLASS1 Profiling Reference Counter (C1PRCR) starts counting the clock cycles. Read the C1PISR[OVE] bit to verify that the measurement is complete and that the profiling counter values are valid. If the C1PISR[OVE] is clear, read the profiling counters C1PRCR and C1PGCR and analyze the results.

15.2.3.2 Watch Point Unit

The CLASS includes a watch point unit (WPU) for each of the initiator interfaces and for each of the target interfaces. The WPU can compare programmed values to the real transactions and generate a watch point event when a match occurs.

Note: For each CLASS1 module, only one WPEN field can be set among all C1IWPCRx and C1TWPCRx when snooping watch point events. That is, only one watch point unit can be active at a time.

Use the following steps to use the watch point unit:

1. Clear C1PCR.
2. Clear C1IPCRx and C1TPCR.
3. For the time-out mechanism, program C1PTOR and set the C1PCR[TOE] bit.
4. Define the transaction to be monitored by writing the desired configuration to C1WPCR, C1WPACR, C1WPEACR, and C1WPAMR.
5. Enable the watch point units through C1IWPCRx and C1TWPCR.
6. Set the C1WPRCR[CE] bit to enable counting of the watch point events. If you use the watch point events to enable/disable the profiling unit according to WPCE, clear this bit.
7. After the measurement are finished check the following registers:
   - Read the C1PISR[OVE] bit.
   - In time-out mode, read C1PRCR.
   - If C1PISR[OVE] is set or if C1PRCR is equal to C1PTOR, the results are not valid.
   - Read C1PGCRx to get the number of watch point events during the measurement.

15.2.3.3 Event Selection

Events are selected using a combination of the CLASS watch point and profiling registers. **Table 15-1** lists the measurement modes, the required configuration settings, and the events measured by the specific CLASS Profiling General Registers for each CLASS module. See **Section 15.10** for the register details.

Table 15-1. C1PGCRx Events Selection

Measurement Mode	Configuration Settings for Each Mode				Events Measured			
	C1WPCR [CE]	C1TPCR [TT]	C1TPCR [PMM]	C1IPCRx [PMM]	C1PGCR0	C1PGCR1	C1PGCR2	C1PGCR3
None selected	0	—	00	00000	—	—	—	—
Initiator Priority and Auto-Upgrade	0	—	00	00001	No. of Initiator Requests with Priority 1	No. of Initiator Requests with Priority 2	No. of Initiator Requests with Priority 3	No. of Initiator Auto-Upgrade
	Allows the user to profile a statistical distribution of transaction priorities. This information can be used to consider whether other arbitration methods (priority mapping, Auto-upgrade, weighted arbitration, priority mask enable) should be considered							
Initiator Access Type	0	—	00	00010	Initiator Pending Request cycles (not acknow-ledged)	No. of Initiator Read Requests	No. of Initiator Real Write Requests (not confirmed)	No. of Initiator Fast Write Requests (not confirmed)
	Real/Fast confirmation refers to the type of EOT for writes that are requested per MBus transaction. • Real means that for coherency reasons the EOT for write should be high only after the data is written to the target. • Fast means that for performance reasons the EOT can be high even before the data is written to the target. Real/Fast confirmation support is initiator dependent and the user cannot change the related settings. A summary follows below: • DSP Cores – Write through uses fast confirmation – Write through with SYNCIO generate real confirmation – Last burst in a line write-back is sent with real confirmation • DMA. Channel transfers come with fast confirm and real confirm on the last data of a transfer. • Serial RapidIO Inbound Transactions. When the transfer comes with a response (NWRITE_R), the last data uses real confirmation and fast confirm for the previous transfer. For NWRITE, data is transferred with fast confirmation • Serial RapidIO Outbound Transactions. Supports fast confirm on the last data transfer per channel transfer and fast confirm for the previous transfer. • QUICC Engine Transactions. Always uses real confirmation The resulting information can be used to redesign the code to minimize stalls related to real confirmations. Use of large transactions reduces the number of real confirmations because they are only required for the last beat of the transfer.							
Initiator Stall	0	—	00	00011	No. of Write After Read (WAR) events	No. of stall cycles due to WAR events	—	No. of stall cycles due to Target Switch (TS) events
	By managing WAR and target switching, an initiator can enhance the performance for memory accesses and thus minimize run time. **Note:** Stall at the initiator does not mean that the initiator target data phase is idle; it indicates the delay after which the next access from the initiator starts at the target after a WAR or TS event.							

Table 15-1. C1PGCRx Events Selection (Continued)

Measurement Mode	Configuration Settings for Each Mode				Events Measured			
	C1WPCR [CE]	C1TPCR [TT]	C1TPCR [PMM]	C1IPCRx [PMM]	C1PGCR0	C1PGCR1	C1PGCR2	C1PGCR3
Initiator Priority Upgrade	0	—	00	00100	Initiator Sample 0 Upgrade cycles	Initiator Sample 1 Upgrade cycles	Initiator Sample 2 Upgrade cycles	—
	Initiator Priority Upgrade measurement counts the number of cycles a low-priority transaction is upgraded because a high-priority transaction was scheduled into the CLASS pipeline. This upgrading mechanism is necessary to reduce the service latency of newly issued transactions because the CLASS is ordered in nature and does not do preemption. A high-priority transaction could otherwise be delayed by preceding lower priority accesses for long periods of time. The upgrade is to the priority level of the high-priority transaction and it is only possible if the transaction is upgradable. The upgrade attribute of a transaction is initiator dependent and it is hard-wired. The system DMA is the only initiator issuing non-upgradable transactions. The counter measurements take place in the early stages of the CLASS pipeline at different sample locations. Transactions in sample 0 are older than transactions on sample 1, and transactions in sample 1 are older than the ones in sample 2. Any type of priority upgrade, including auto-upgrade, is captured by these counters. These counters provide a good view of the starvation dynamics of the system.							
Initiator Priority Non-Upgrade	0	—	00	00101	Initiator Sample 0 No Upgrade cycles	Initiator Sample 1 No Upgrade cycles	Initiator Sample 2 No Upgrade cycles	—
	Initiator Priority No-Upgrade measurement counts the number of cycles an older low-priority transaction is not upgraded despite the fact that a newer high-priority is scheduled by the same initiator. Compare with “Initiator Priority Upgrade”. This applies only to System DMA transactions because they are not upgradable by default. All other initiator transactions can be upgraded. These counts are not very useful for performance analysis, but they provide a good view of the starvation dynamics of the system.							
Initiator Supervisor	0	—	00	00110	Request pending cycles	No. of supervisor accesses	No. of non-supervisor accesses	—
	Supervisor/user accesses can be used to profile the amount of time the OS spends running and how much time is left for the users application. Effective for evaluating the core subsystem supervisor/user mode usage. The implementation depends on the values configured in M_DSDAx[DAPU]/M_DSDAx[DAPS], and so forth. See the *SC3850 Core Subsystem Reference Manual* for configuration details.							
Initiator Bandwidth	0	—	00	00111	No. of Initiator Read Data Acknow-ledges.	No. of Initiator Write Data Acknow-ledges	—	—
	Can be used to profile the number of data reads and writes. The amount of data that passes through the initiator port = [(NumberOfReadAck + NumberOfWriteAck) × W]. where W is the port width. Note that an access may be smaller than the port width.							
Initiator-target Bandwidth	0	—	00	10000 + T	No. of Read Data Acknow-ledges between Initiator and Target T	No. of Write Data Acknow-ledges between Initiator and Target T	—	—
	Can be used to profile the number of data reads and writes. between an initiator and a specific target The amount of data that passes through the initiator port = [(NumberOfReadAck + NumberOfWriteAck) × W]. where W is the port width. Note that an access may be smaller than the port width.							

Table 15-1. C1PGCRx Events Selection (Continued)

Measurement Mode	Configuration Settings for Each Mode				Events Measured			
	C1WPCR [CE]	C1TPCR [TT]	C1TPCR [PMM]	C1IPCRx [PMM]	C1PGCR0	C1PGCR1	C1PGCR2	C1PGCR3
Arbitration Winner Priority	0	0	01	00000	No. of priority 0 trans-actions at Target T	No. of priority 1 trans-actions at Target T	No. of priority 2 trans-actions at Target T	No. of priority 3 trans-actions at Target T
	Can be used to see the priority distribution for a target port							
Target Access Splitting	0	1	01	00000	No. of M-byte accesses toward target T. M = Initiator requests (pre splitting accesses)	No. of N-byte accesses toward target T. N = Initiator requests (post splitting accesses)	—	—
	Target access splitting gives statistical information about the ratio between initiator and target accesses towards every target. It returns the number of accesses in pre and post splitting. For example, say there are only 2 types of accesses to some target #T: 64-Byte and 16-Byte, and this target only supports 16-Byte accesses. Then, if the count shows 10000 initiator accesses and 34000 target accesses, this translates to 8000 × (64-Byte accesses) + 2000 × (16-Byte accesses), and they were split into 8000 × (4 × 16-Byte accesses) + 2000 × (16-Byte access) = 32000 + 2000 = 34000 accesses							
Arbitration Collision	0	0	10	00000	Target T Pending Request cycles	—	—	—
	This represents the number of cycles with more than one request directed to Target T.							
Target Bandwidth	0	1	10	00000	No. of Target T Read Data Acknow-ledges	No. of Target T Write Data Acknow-ledges	—	—
	Can be used to profile the number of data reads and writes to Target T. The amount of data that passes through the target port = [(NumberOfReadAck + NumberOfWriteAck) × W] where W is the port width.Note that an access can be less than the port width							
Target Stall	0	—	11	00000	No. of Write after Read (WAR) events	No. of stall cycles due to WAR events	—	—
	By managing WAR event, the system designer can enhance memory access performance and thus minimize run time. **Note:** A WAR stall at the target does not mean that the target bus is idle. It indicates the delay after which the next access from the initiator starts at the target after a WAR event.							
Watch Point	1	—	00	00000	No. of Watch Point Event	—	—	—
	Watch point event scan be snooped on any initiator and any target. It can be used for debug and also for triggering profiling counts that are pre-configured, this is non-intrusive (eliminating the need to write to the registers in the middle of an application)							

15.2.3.4 Debug and Profiling Events

The CLASS generates two event interrupts:

- Watch point event (WPE)
- Overflow event (OVE)

15.2.4 CLASS Reset

The CLASS implements two kinds of reset:

- Synchronous hard reset. This reset brings all states machines to idle state and sets all CLASS registers to the reset values.
- Synchronous soft reset. This kind of reset has the following effects:
  - All the CLASS state machines return to their idle state.
  - All the CLASS operation FFs return to their idle state.
  - The CLASS configuration registers are reset as described in the table for each register in **15.10**, *HSSI Programming Model*.

15.2.5 Limitations

- The CLASS does not support split transaction between targets. A split transaction starts inside a targets address space but ends outside of this window. The CLASS does not report an error in this event and the results are unpredictable. You must avoid this situation.
- The CLASS does not support pipelined transactions between different targets by the same initiator. The pipeline is stalled until all transaction to one target are closed before issuing a transaction to a different target.
- Arbitration Fairness. Requests with the higher priority levels may cause transactions with lower priority levels not to be acknowledged, resulting in a starvation condition. This situation can be prevented by using the auto priority upgrade supported by the expander module and/or by the multiplexer and arbiter module priority mask mechanism.

15.3 OCN Fabric

The On-Chip Network (OCN) fabric is a non-blocking high speed interconnect used for embedded system devices. The MSC8157E DSP HSSI uses an 8-port OCN to connect between the Serial RapidIO Controllers, PCI Express Controller, the two OCN-to-MBus bridges (O2M[0–1]) that connect to the CLASS1 module, and the two supporting dedicated DMA controllers. The OCN requires no programming and provides a seamless interface for the HSSI.

15.4 OCN-to-MBus (O2M) Bridges

The O2M bridges provide an interface between the OCN fabric and the CLASS1 module that connects to the system CLASS. The bridges support all mandatory MBus and OCN interface protocol procedures. The bridges provide initiator interfaces to access the target CLASS ports, formats OCN packets, negotiates with the OCN arbiter, and transmits/receives associated transactions. The O2M bridges are connected to CLASS1 initiator ports 0 and 3, each 128 bits wide and connect to OCN ports 1 and 5.

Note: When using the same OCN-to-MBus (O2M) for Read and Write transactions, the write transactions may write incorrect data for specific access sequences. To preclude this scenario, use one bridge for Write transactions and the other bridge for read transactions.

15.5 DMA Controllers

The MSC8157E includes two dedicated DMA controllers that transfer blocks of data between the serial RapidIO controller/PEX Controller and the local address space independent from the DSP cores. **Figure 15-3** shows the block diagram of each dedicated DMA controller.

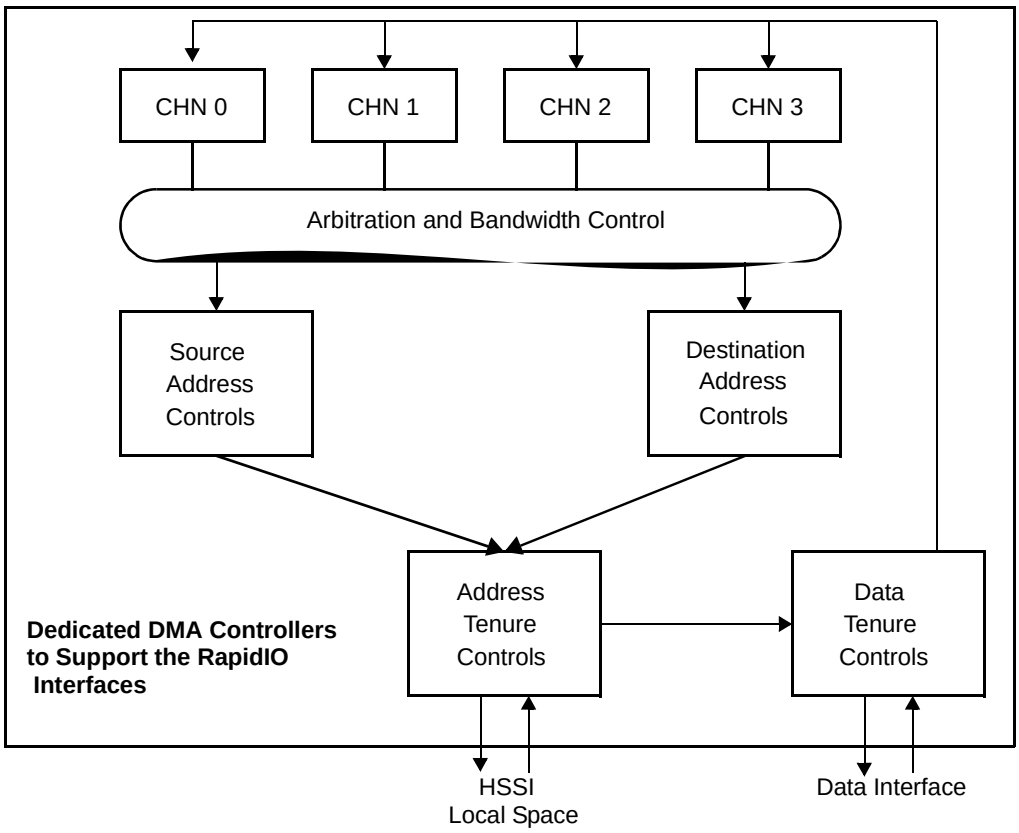

Figure 15-3. Interface Dedicated DMA Controller Block Diagram

15.5.1 Overview

Each dedicated DMA controller has four high-speed DMA channels. Each of the DSP cores can initiate DMA transfers. All channels are capable of complex data movement and advanced transaction chaining. Operations, such as descriptor fetches and block transfers, are initiated by each channel. A channel is selected by the arbitration logic and information is passed to the source and destination control blocks for processing. The source and destination blocks generate read and write requests to the address tenure engine, which manages the DMA master port address interface. After a transaction is accepted by the master port, control is transferred to the data tenure engine that manages the read and write data transfers. A channel remains active in the shared resources for the duration of the data transfer unless the allotted bandwidth per channel is reached.

15.5.2 Features

Each dedicated DMA controller offers the following features:

- Four high-speed/high-bandwidth channels accessible by local and remote masters
- Basic DMA operation modes (direct, simple chaining)
- Extended DMA operation modes (advanced chaining and stride capability)
- Cascading descriptor chains
- Misaligned transfers
- Programmable bandwidth control between channels
- Up to 256 bytes for DMA sub-block transfers to maximize performance
- Three priority levels supported for source and destination transactions
- Interrupt on error and completed segment, list, or link
- An Address Translation Management Unit (ATMU) with 10 local access address windows. The ATMU translates a request address into a logical device source/destination.

15.5.3 Modes of Operation

Each MSC8157E dedicated DMA controller has two modes of operation: basic and extended. Basic mode is the DMA legacy mode. It does not support advanced features. Extended mode supports advanced features like striding and flexible descriptor structures.

These two basic modes allow users to initiate and end DMA transfers in various ways. **Table 15-2** summarizes the relationship between the modes and the following features:

- *Direct mode*. No descriptors are involved. Software must initialize the required fields as described in **Table 15-2** before starting a transfer.
- *Chaining mode*. Software must initialize descriptors in memory and the required fields as described in **Table 15-2** before starting a transfer.

- *Single-write start mode.* The DMA process can be started by using a single-write command to either the descriptor address register in one of the chaining modes or the source/destination address registers in one of the direct modes.
- *External control capability*. This allows an external agent to start, pause, and check the status of a DMA transfer that has already been initialized.
- *Channel continue capability*. The channel continue capability allows software the flexibility of having the DMA controller start with descriptors that have already been programmed while software continues to build more descriptors in memory.
- *Channel abort capability*. The software can abort a previously initiated transfer by setting the bit MR*n*[CA]. The DMA controller terminates all outstanding transfers initiated by the channel without generating any errors before entering an idle state.

Table 15-2. Relationship of Modes and Features

Mode	Mode with One Additional Feature	Mode with Two Additional Features
B (Basic)	BD (basic direct)	BDS (BD single-write start)
	BC (basic chaining)	BCS (BC single-write start)
Ext (Extended)	ExtD (extended direct)	ExtDS (ExtD single-write start)
	ExtC (extended chaining)	ExtCS (ExtC single-write start)

Refer to **Section 15.5.4**, *DMA Channel Operation* for details on these modes. **Figure 15-4** shows the general DMA operational flow chart.

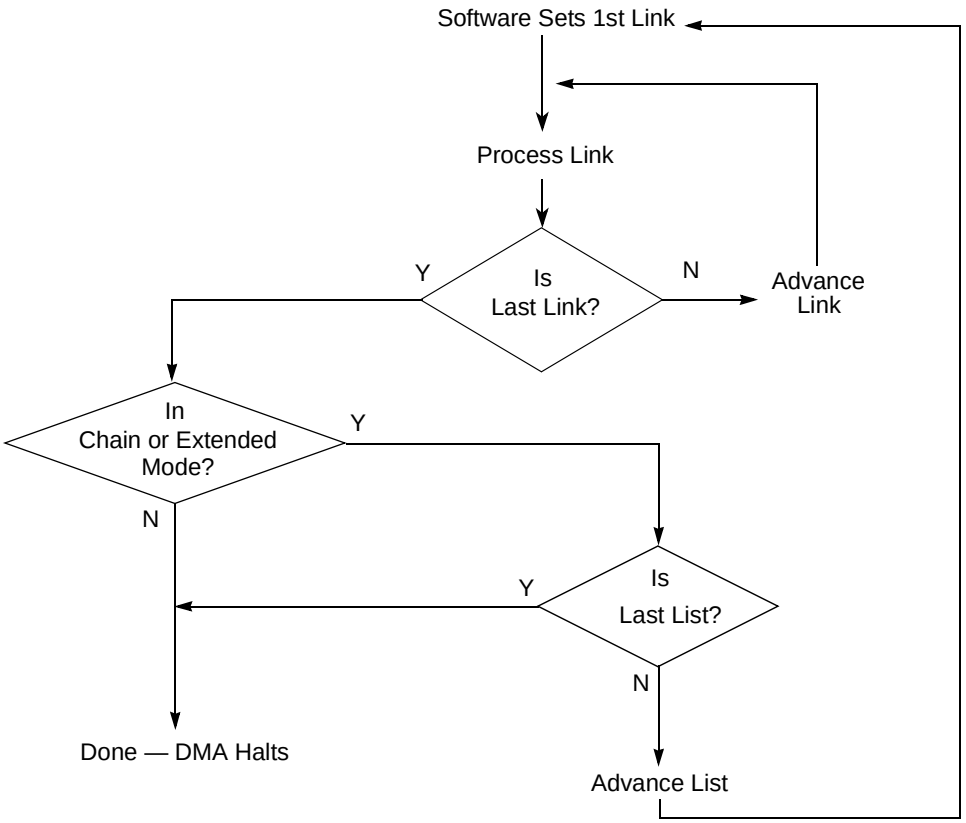

Figure 15-4. DMA Operational Flow Chart

15.5.4 DMA Channel Operation

All DMA channels support two different modes of operation, a basic mode (MRn[XFE] = 0) and an extended mode (MRn[XFE] = 1). In both modes, a channel can be activated by clearing and setting MRn[CS] or through the single-write start mode using MRn[CDSM/SWSM] and MRn[SRW].

In basic mode, the channel can be programmed in basic direct mode or basic chaining mode. In extended mode, the channel can be programmed in extended direct mode or extended chaining mode. Extended mode provides more capabilities, such as extended descriptor chaining, striding capabilities, and a more flexible descriptor structure.

The DMA controller supports misaligned transfers for both the source and destination addresses. In order to maximize performance, the source and destination engines align the source and destination addresses to a 64-byte boundary. The DMA always reads/writes the maximum number of bytes for a given transfer as described by the capability inputs of the DMA controller except for globally coherent transactions that use the size of the cache coherence granule as described by the mode select input. Using 256 bytes over the RapidIO interface reduces packet overhead that translates to increased bandwidth utilization through the interface.

The DMA controller supports bandwidth control, which prevents a channel from consuming all the data bandwidth in the controller. Each channel is allowed to consume the bandwidth of the shared resources as specified by the bandwidth control value. After the channel uses its allotted bandwidth, the arbiter grants the next channel access to the shared resources. The arbitration is round robin between the channels. This feature is also used to implement the external control pause feature. If the external control start and pause are enabled in the MR*n*, the channel enters a paused state after transferring the data described in the bandwidth control. External control can restart the channel from a paused state.

The DMA controller is designed to support RapidIO transaction types, including various priority level support. The DMA controller offers additional features from previous generations in which the reads can be mapped to non-coherent (NREAD), or maintenance reads. In addition, the writes can be mapped to non-coherent (NWRITE, NWRITE_R) writes, messages, and maintenance writes. The DMA programming model permits software to program each DMA engine independently to interrupt on completed segment, chain, or error. It also provides the capability for software to resume the DMA engine from a hardware halted condition by setting the channel continue bit, MR*n*[CC]. See **Table 15-3** for more complete descriptions of the channel states and state transitions.

15.5.4.1 Basic DMA Mode Transfer

This mode is primarily included for backward compatibility with existing DMA controllers which use a simple programming model. This is the default mode out of reset. The different modes of operation under the basic mode are explained in the following sections.

15.5.4.1.1 Basic Direct Mode

In basic direct mode, the DMA controller does not read descriptors from memory, but instead uses the current parameters programmed in the DMA registers to start the DMA transfer. Software is responsible for initializing SAR*n*, SATR*n*, DAR*n*, DATR*n*, and BCR*n* registers. The DMA transfer is started when MR*n*[CS] is set. Software is expected to program all the appropriate registers before setting MR*n*[CS] to a 1. The transfer is finished after all the bytes specified in the byte count register have been transferred or if an error condition occurs. The sequence of events to start and complete a transfer in basic direct mode is as follows:

1. Poll the channel state (see **Table 15-3**), to confirm that the specific DMA channel is idle.
2. Initialize SAR*n*, SATR*n*, DAR*n*, DATR*n* and BCR*n*.
3. Set the mode register channel transfer mode bit, MR*n*[CTM], to indicate direct mode. Other control parameters may also be initialized in the mode register.
4. Clear then set the mode register channel start bit, MR*n*[CS], to start the DMA transfer.
5. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
6. SR*n*[CB] is automatically cleared by the DMA controller after the transfer is finished, or if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if a transfer error occurs.
7. End of segment interrupt is generated if MR*n*[EOSIE] is set.

15.5.4.1.2 Basic Direct Single-Write Start Mode

In basic direct single-write start mode, the DMA controller does not read descriptors from memory, but instead uses the current parameters programmed in the DMA registers to start the DMA transfer. Software is responsible for initializing the SATR*n*, DATR*n*, and BCR*n* registers. Setting MR*n*[SRW] configures the DMA controller to begin the DMA transfer either when SAR*n* is written or when DAR*n* is written, determined by the state of MR*n*[CDSM/SWSM]. Writing to SAR*n* initiates the DMA transfer if MR*n*[CDSM/SWSM] is set. Writing to DAR*n* initiates the DMA transfer if MR*n*[CDSM/SWSM] is cleared. The DMA controller automatically sets the channel start bit, MR*n*[CS]. Software is expected to program all the appropriate registers before writing the source or destination address registers. The transfer is finished after all the bytes specified in the byte count register have been transferred or if an error condition occurs. The sequence of events to start and complete a transfer in single-write start basic direct mode is as follows:

1. Poll the channel state (see **Table 15-3**), to confirm that the specific DMA channel is idle.
2. Initialize the source attributes (SATR*n*), DATR*n*, and BCR*n* registers.

3. Set the mode register channel transfer mode bit, MR*n*[CTM], and the single-write start direct mode bit, MR*n*[SRW]. Other control parameters may also be initialized in the mode register. Set MR*n*[CDSM/SWSM] for transfers started using SAR*n*. Clear MR*n*[CDSM/SWSM] for transfers started using the DAR*n*.
4. A write to the source or destination address register starts the DMA transfer and automatically sets MR*n*[CS].
5. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
6. SR*n*[CB] is automatically cleared by the DMA controller after the transfer is finished, or if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if a transfer error occurs.
7. End of segment interrupt is generated if MR*n*[EOSIE] is set.

15.5.4.1.3 Basic Chaining Mode

In basic chaining mode, software must first build link descriptor segments in memory. Then the current link descriptor address register must be initialized to point to the first descriptor in memory. The DMA controller loads descriptors from memory prior to a DMA transfer. The DMA controller begins the transfer according to the link descriptor information loaded for the segment. After the current segment is finished, the DMA controller reads the next link descriptor from memory and begins another DMA transfer. The transfer is finished if the current link descriptor is the last one in memory or if an error condition occurs. The sequence of events to start and complete a transfer in chaining mode is as follows:

1. Build link descriptor segments in memory.
2. Poll the channel state (see **Table 15-3**), to confirm that the specific DMA channel is idle.
3. Initialize CLNDAR*n* to point to the first link descriptor in memory.
4. Clear the mode register channel transfer mode bit, MR*n*[CTM], as well as MR*n*[XFE], to indicate basic chaining mode. Other control parameters may also be initialized in the mode register.
5. Clear, then set the mode register channel start bit, MR*n*[CS], to start the DMA transfer.
6. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
7. SR*n*[CB] is automatically cleared by the DMA controller after finishing the transfer of the last descriptor segment, or if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if an error occurs during any of the transfers.

15.5.4.1.4 Basic Chaining Single-Write Start Mode

Basic chaining single-write start mode allows a chain to be started by writing the current link descriptor address register (CLNDAR*n*). Setting MR*n*[CDSM/SWSM] in the mode register causes MR*n*[CS] to be automatically set when the current link descriptor address register is

written. The sequence of events to start and complete a chain using single-write start mode is as follows:

1. Set the mode register current descriptor start mode bit MRn[CDSM/SWSM]. Clear the extended features enable bit MRn[XFE] and the channel transfer mode bit, MRn[CTM]. This initialization indicates basic chaining and single-write start mode. Also other control parameters may be initialized in the mode register.
2. Build link descriptor segments in memory.
3. Poll the channel state (see **Table 15-3**), to confirm that the specific DMA channel is idle.
4. Initialize CLNDAR*n* to point to the first descriptor segment in memory. This write automatically causes the DMA controller to begin the link descriptor fetch and set MR*n*[CS].
5. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
6. SR*n*[CB] is automatically cleared by the DMA controller after finishing the transfer of the last descriptor segment, or if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if an error occurs during any of the transfers.

15.5.4.1.5 Extended DMA Mode Transfer

The extended DMA mode also operates in chaining and direct mode. It offers additional capability over the basic mode by supporting striding and a more flexible descriptor structure. This additional functionality also requires a new and more complex programming model. The extended DMA mode is activated by setting MR*n*[XFE].

15.5.4.1.5.1 Extended Direct Mode

Extended direct mode has the same functionality as basic direct mode with the addition of stride capabilities. The bit settings are the same as in direct mode with the exception of the MR*n*[XFE] being set. Striding on the source address can be accomplished by setting SATR*n*[SSME] and setting the desired stride size and distance in SSR*n*. Striding on the destination address can be accomplished by setting DATR*n*[DSME] and setting the desired stride size and distance in DSR*n*.

15.5.4.1.5.2 Extended Direct Single-Write Start Mode

Extended direct single-write start mode has the same functionality as the basic direct single-write start mode with the addition of stride capabilities. The bit settings are also the same with the exception of MR*n*[XFE] being set. Striding on the source address can be accomplished by setting SATR*n*[SSME] and setting the desired stride size and distance in SSR*n*. Striding on the destination address can be accomplished by setting DATR*n*[DSME] and setting the desired stride size and distance in DSR*n*.

15.5.4.1.5.3 Extended Chaining Mode

In extended chaining mode, the software must first build list and link descriptor segments in memory. Then CLSDAR*n* must be initialized to point to the first list descriptor in memory. The DMA controller loads list descriptors and link descriptors from memory prior to a DMA transfer. The DMA controller begins the transfer according to the link descriptor information loaded. Once the current link descriptor is finished, the DMA controller reads the next link descriptor from memory and begins another DMA transfer. If the current link descriptor is the last in the list, the DMA controller reads the next list descriptor in memory. The transfer is finished if the current link descriptor is the last one in the last list in memory or if an error condition occurs. The sequence of events to start and complete a transfer in extended chaining mode is as follows:

1. Build link and list descriptor segments in memory.
2. Poll the channel state (see **Table 15-3**), to confirm that the specific DMA channel is idle.
3. Initialize CLSDAR*n* to point to the first list descriptor in memory.
4. Clear the mode register channel transfer mode bit, MR*n*[CTM], to indicate chaining mode. MR*n*[XFE] must be set to indicate extended DMA mode. Other control parameters may also be initialized in the mode register.
5. Clear, then set the mode register channel start bit, MR*n*[CS], to start the DMA transfer.
6. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
7. SR*n*[CB] is automatically cleared by the DMA controller after finishing the transfer of the last descriptor segment, or if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if an error occurs during any of the transfers.

15.5.4.1.5.4 Extended Chaining Single-Write Start Mode

In the extended mode, the single-write start feature allows a chain to be started by writing the current list descriptor pointer. Setting MR*n*[CDSM/SWSM] causes MR*n*[CS] to be set automatically when CLSDAR*n* is written. The sequence of events to start and complete an extended chain using single-write start mode is as follows:

1. Set MR*n*[CDSM/SWSM], MR*n*[CTM], and MR*n*[XFE] to indicate extended chaining and single-write start mode. Also other control parameters may be initialized in the mode register.
2. Build list and link descriptor segments in local memory.
3. Poll the channel state (see **Table 15-3**), to confirm that the specific DMA channel is idle.
4. Initialize the current list descriptor address register to point to the first list descriptor segment in memory. This write automatically causes the DMA controller to begin the list descriptor fetch and set MR*n*[CS].
5. SR*n*[CB] is set by the DMA controller to indicate the DMA transfer is in progress.
6. SR*n*[CB] is automatically cleared by the DMA controller after finishing the transfer of the last descriptor segment, or if the transfer is aborted (MR*n*[CA] transitions from a 0 to 1), or if an error occurs during any of the transfers.

15.5.4.2 Channel Continue Mode for Cascading Transfer Chains

The channel continue mode (enabled when MR*n*[CC] is set) offers software the flexibility of having the DMA controller get started on descriptors that have already been programmed while software continues to build more descriptors in memory. Software can set the end-of-links descriptor (EOLND) in basic mode, or end-of-lists descriptor (EOLSD) in extended mode, to cause the channel to go into a halted state while software continues to build other descriptors in memory. Software can then set CC to force hardware to continue where it left off. channel continue is only meaningful for chaining modes, not direct mode.

If CC is set by software while the channel is busy with a transfer, the DMA controller finishes all transfers until it reaches the EOLND in basic mode or EOLSD in extended mode. The DMA controller then refetches the last link descriptor in basic mode, or the last list descriptor in extended mode and clears the channel continue bit. If EOLND or EOLSD is still set for their respective modes, the DMA controller remains in the idle state. If EOLND or EOLSD is not set, the DMA controller continues the transfer by refetching the new descriptor.

If CC is set by software while the channel is not busy with a transfer, the DMA controller refetches the last link descriptor in basic mode, or the last list descriptor in extended mode and clears the channel continue bit. If EOLND or EOLSD is still set for their respective modes, the DMA controller remains in the idle state. If the EOLND or EOLSD bits are not set, the DMA controller continues the transfer by refetching the new descriptor.

15.5.4.2.1 Basic Mode

On a channel continue, the descriptor at the current link descriptor address register (CLNDAR*n*) is refetched to get the next link descriptor address field as updated by software. The channel halts if NLNDAR*n*[EOLND] is still set. If EOLND is zero, the next link descriptor address is copied into CLNDAR*n* and the channel continues with another descriptor fetch of the current link descriptor address. As a result, two link descriptor fetches always exist after channel continue before starting the first transfer.

15.5.4.2.2 Extended Mode

On a channel continue, the descriptor at the current list descriptor (CLSDAR*n*) address register is refetched to get the next list descriptor address field as updated by software. The channel halts if NLSDAR*n*[EOLSD] is still set. If not, the next list descriptor address is copied into the CLSDAR*n* register and the channel continues with another descriptor fetch of the current list descriptor address. As a result, two list descriptor fetches always exist after channel continue before the first link descriptor fetch and the first transfer.

15.5.4.3 Channel Abort

Software can abort a previously initiated transfer by setting MR*n*[CA]. Once the DMA channel controller detects a zero-to-one transition of MR*n*[CA], it finishes the current sub-block transfer and halts all further activity. The controller then waits for all previously initiated transfers from the specified channel to drain and clears SR*n*[CB]. Successful completion of a software initiated abort request can be recognized by MR*n*[CA] being set and SR*n*[CB] being cleared. Obviously, if the controller was already halted because of an error condition (SR*n*[TE] is set), or the channel has completed all transfers, then SR*n*[CB] being cleared may not signify that the controller entered a halt state due to the abort request.

15.5.4.4 Bandwidth Control

MR*n*[BWC] specifies how much data to allow a specific channel to transfer before allowing the next channel to use the shared data transfer hardware. This promotes equitable bandwidth allocation between channels. However, if only one channel is busy, hardware overrides the specified bandwidth control size value. The DMA controller allows a channel to transfer up to 1 Kbyte at a time when no other channel is active.

15.5.4.5 Channel State

Table 15-3 defines the state of a channel based on the values of the channel start (MR*n*[CS]), channel busy (SR*n*[CB]), transfer error (SR*n*[TE]), and channel continue (MR*n*[CC]) bits.

Table 15-3. Channel State Table

MR*n*[CS]	SR*n*[CB]	SR*n*[TE]	MR*n*[CC]	Channel State
0	0	0	0	Idle state. This is the state of the bits out of reset.
0	0	0	1	Channel continue unexpected. Channel remains idle
0	0	1	0	Error occurred after software halted the channel.
0	0	1	1	Channel Continue unexpected. Channel remains in error halt state
0	1	0	0	Software halted channel. The channel was busy and software cleared MR*n*[CS].
0	1	0	1	Channel remains in halt state.
—	1	1	—	The channel has encountered an error condition and it is trying to halt.
1	0	0	0	Ready to start a transfer, or transfer completed
1	0	0	1	Continue transfer (only meaningful in chaining mode, not direct mode). In direct mode, the channel continue has no effect.
1	0	1	0	Error occurred during transfer
1	0	1	1	Channel remains in error halt state
1	1	0	0	Transfer in progress
1	1	0	1	Continue after reaching the end of list/link, or the first descriptor fetch after channel continue

15.5.4.6 Illustration of Stride Size and Stride Distance

If operating in stride mode, the stride size defines the amount of data to transfer before jumping to the next quantity of data as specified by the stride distance. The stride distance is added to the current base address to point to the next quantity of data to be transferred. **Figure 15-5** illustrates the stride size and distance parameters. As shown, each time the stride distance is added to the base address, the resulting address becomes the new base address. This sequence repeats until the amount of data transferred equals the transfer size.

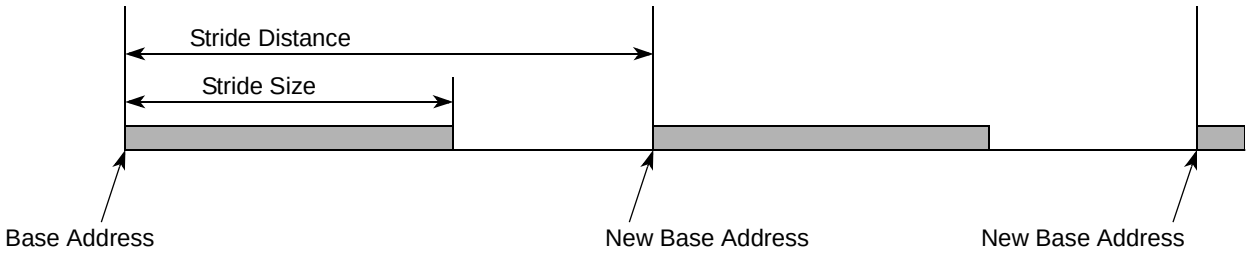

Figure 15-5. Stride Size and Stride Distance

15.5.5 DMA Transfer Interfaces

The DMA can be used to achieve data transfers across the entire memory map.

15.5.6 DMA Errors

On a transfer error (uncorrectable ECC errors on memory accesses, parity errors on MBus, address mapping errors, for example), the DMA halts by setting SR*n*[TE] and generates an interrupt if MR*n*[EIE] is set. On a programming error, the DMA sets SR*n*[PE] and generates an interrupt if MR*n*[EIE] is set. The DMA controller detects the following programming errors:

- Transfer started with a byte count of zero
- Stride transfer started with a stride size of zero
- Transfer started with a priority of three
- Illegal type, defined by SATR*n*[SREADTTYPE] and DATR*n*[DWRITETTYPE], used for the transfer.

15.5.7 DMA Descriptors

The DMA engine recognizes list descriptors and link descriptors. List descriptors connect lists of link descriptors. Link descriptors describe the DMA activity that is to take place. DMA descriptors are built in either local or remote memory and are connected by the next descriptor fields. Only link descriptors contain information for the DMA controller to transfer data. Software must ensure that each descriptor is 32-byte aligned. The last link descriptor in the last list in memory sets the EOLND bit in the next link descriptor; the next list descriptor fields indicating that these are the last descriptors in memory. Software initializes the current list descriptor address register to point to the first list descriptor in memory. The DMA controller traverses through the descriptor lists until the last link descriptor is met. For each link descriptor in the chain, the DMA controller starts a new DMA transfer with the control parameters specified by that descriptor. Link and list descriptor fetches always snoop the local memory space.

Note: Software must ensure that each descriptor is aligned on a 32-byte boundary.

The last link descriptor in the last list in memory sets NLNDAR*n*[EOLND] in the next link descriptor and NLSDAR*n*[EOLSD] in the next list descriptor fields indicating that these are the last descriptors in memory. Software initializes the current list descriptor address register to point to the first list descriptor in memory. The DMA controller traverses through the descriptor lists until the last link descriptor is met as shown in. For each link descriptor in the chain, the DMA controller starts a new DMA transfer with the control parameters specified by that descriptor.

Table 15-4 summarizes the DMA list descriptors.

Table 15-4. List DMA Descriptor Summary

Descriptor Field	Description
Next list descriptor extended address	Points to the next list descriptor in memory. After the DMA controller reads the descriptor from memory, this field is loaded into the next list descriptor extended address registers.
Next list descriptor address	Points to the next list descriptor in memory. After the DMA controller reads the descriptor from memory, this field is loaded into the next list descriptor address registers.
First link descriptor extended address	Points to the first link descriptor in memory for this list. After the DMA controller reads the descriptor from memory, this field is loaded into the current link descriptor extended address registers.
First link descriptor address	Points to the first link descriptor in memory for this list. After the DMA controller reads the descriptor from memory, this field is loaded into the current link descriptor address registers.
Source stride	Contains the stride information used for the data source if striding is enabled for a link in the list
Destination stride	Contains the stride information used for the data destination if striding is enabled for a link in the list

Table 15-5 summarizes the DMA link descriptors.

Table 15-5. Link DMA Descriptor Summary

Descriptor Field	Description
Source attributes register	Contains source transaction attributes
Source address	Contains the source address of the DMA transfer. After the DMA controller reads the descriptor from memory, this field is loaded into the Source address register.
Destination attributes register	Contains destination transaction attributes
Destination address	Contains the destination address of the DMA transfer. After the DMA controller reads the descriptor from memory, this field is loaded into the destination address register.
Next link descriptor extended address	Points to the next link descriptor in memory. After the DMA controller reads the link descriptor from memory, this field is loaded into the extended next link descriptor address registers
Next link descriptor address	Points to the next link descriptor in memory. After the DMA controller reads the link descriptor from memory, this field is loaded into the next link descriptor address registers.
Byte count	Contains the number of bytes to transfer. After the DMA controller reads the descriptor from memory, this field is loaded into the byte count register.

Figure 15-6 shows the format of the list descriptors for 32-bit devices.

Offset	Field
0x00	Reserved
0x04	Next List Descriptor Address
0x08	Reserved
0x0c	First Link Descriptor Address
0x10	Source Stride
0x14	Destination Stride
0x18	Reserved
0x1c	Reserved

Figure 15-6. List Descriptor Format (Used for 32-bit devices)

Figure 15-7 shows the format of the list descriptors for 36-bit devices.

Offset	Field
0x00	Next List Descriptor Extended Address
0x04	Next List Descriptor Address
0x08	First Link Descriptor Extended Address
0x0c	First Link Descriptor Address
0x10	Source Stride
0x14	Destination Stride
0x18	Reserved
0x1c	Reserved

Figure 15-7. List Descriptor Format (Used for 36-bit devices)

Note: For each channel (DMA controller 0 or 1, channels 0–3), the values written to the mode register determine how the DMA controller executes the data transfers, such as a simple direct transfer, a chain of direct transfers specified by a set of links, or a complex chain involving chained lists, each of which contains pointers to chained link sets (as indicated by **Table 15-4** and **Table 15-5**). **Table 15-6** and **Table 15-7** show the order in which data should be stored in memory (for 32-bit or 36-bit devices, respectively); the name listed for each field indicates the register format to use for the data written to the specified offset. For example, *Next List Descriptor Address* refers to the **Next List Descriptor Address Register (DnNLSDARx)** for the specified DMA controller (n = 0 or 1) and the specific channel (x = 0–3). See the specified register description in **Section 15.10**, *HSSI Programming Model* for details.

Figure 15-6 shows the format of the link descriptors for 32-bit devices.

Offset	Field
0x00	Source Attributes
0x04	Source Address
0x08	Destination Attributes
0x0c	Destination Address
0x10	Reserved
0x14	Next Link Descriptor Address
0x18	Byte Count
0x1c	Reserved

Figure 15-9. Link Descriptor Format (Used for 36-bit devices)

15.5.8 Local Access ATMU Registers

The local access ATMU has ten address windows that can map a DMA request to a programmable transaction interface (logical device). The user set up the ATMU windows correctly before enabling translation through the ATMU. In a multiple hit scenario, the first matching window is used. If no hit is detected or if mapping is to a reserved transaction interface, the source/target defaults to local address space.

Note: See **Section 15.10.48**, *Local Access Window Base Address Registers 0–9 (DnLAWBAR[0–9])*, on page 15-90 and **Section 15.10.49**, *Local Access Window Attributes Registers 0–9 (DnLAWAR[0–9])*, on page 15-91 for details.

15.5.9 Limitations and Restrictions

This section addresses some of the limitations and restrictions of the dedicated DMA controller and is intended to help software maximize the DMA performance and avoid DMA programming errors.

The DMA controller restrictions are as follows:

- Due to the limited number of buffers that the DMA controller can use, stride sizes less than 64 bytes should be avoided. Maximum utilization is obtained from strides greater than or equal to 256 bytes. However, small stride sizes can be used for scatter-gather functions.
- Coherent reads or writes are broken up into cache line accesses in the DMA.
- All interface capabilities from where descriptors are being fetched must support read sizes of 32 bytes or greater.
- If MR*n*[SAHE] is set, the source interface transfer size capability must be greater than or equal to MR*n*[SAHTS]. The source address must be aligned to a size specified by SAHTS.

- If MR*n*[DAHE] is set, the destination interface transfer size capability must be greater than or equal to MR*n*[DAHTS]. The destination address must be aligned to the size specified by DAHTS.
- Destination striding is not supported if MR*n*[DAHE] is set and source striding is not supported if MR*n*[SAHE] is set.
- If the DMA is programmed to send SWRITEs over RapidIO, the programmer must ensure that the destination address is double-word aligned and that the byte count is a double-word multiple.
- Striding does not work if the destination transaction type is MESSAGE (DATR[DWRITETTYPE] = 0x0110) because messages have no memory addresses. As well, destination address hold should be disabled (MR*n*[DAHE] is cleared) unless the destination address hold transfer size indicates an 8-byte message (MR*n*[DAHTS] = 0x11). Software is responsible for disabling striding and DAHE, in this case, and for ensuring that the bandwidth control is large enough to support the desired message size. Failure to adhere to these restrictions results in undefined behavior.
- A single DMA transfer in any of the direct or chaining modes must not cross a 16 GB (34-bit) address boundary.

15.6 Serial RapidIO Complex

The Serial RapidIO complex includes two ports (SRIO0 and SRIO1) that perform the serial data transfers between the SerDes PHY and the DSP system, an enhanced messaging unit (eMSG), and the interface bridges that connect between SRIO0 and SRIO1, the eMSG module, and the CLASS1 module. Configuration and functional details for this complex are provided in **Chapter 16**, *Serial RapidIO Controller and Enhanced Message Complex*. Transfers through the SRIO modules can be tracked by the performance monitor. See **Section 25.3**, *Performance Monitor* in **Chapter 25**, *Debugging, Profiling, and Performance Monitoring* for details.

15.7 PCI Express Controller

HSSI includes one PCI Express controller that supports x1/x2/x4 link configuration. It is interfaced to the SerDes Phy through Protocol converter module and connects to the OCN fabric through PEX to OCN bridge. The functional and configuration details are provided in **Chapter 17**, *PCI Express Controller***.**

15.8 Protocol Converter

The protocol converter interfaces the Serial RapidIO, PCI Express, CPRI, and SGMII signals to the SerDes PHY. It is programmed internally by selections make in the General Configuration Registers and the power-on reset configuration (see **Section 15.9**, *SerDes PHY Interfaces*). Two of the register sets provide SerDes delay information used by the CPRI modules.

15.9 SerDes PHY Interfaces

The HSSI includes one 10-port SerDes PHY interface that is multiplexed between the two Serial RapidIO ports, one PCI Express port, six CPRI lanes, and the two SGMII ports from the QUICC Engine subsystem. Multiplexing configuration is done using the RCWLR[SP] field (see **Section 5.3.1**, *Reset Configuration Word Low Register (RCWLR)*, on page 5-16) and the HSSI general configuration registers (see **Section 8.2.6** and **Section 8.2.7** in **Chapter 8**, *General Configuration Registers*). Control of the individual lanes is done through the SRDS Control Registers described in **Section 15.10.56** through **Section 15.10.59**.

The SerDes block is designed to accept system parallel data, perform 8b/10b encoding, convert the parallel data to serial data, and, using the selected rate, transmit the data via high speed differential outputs. The block is also designed to receive serial data and, using the selected rate, convert the data to a 10b/8b decoded parallel format and present it to the system interface.

Note: For CPRI, the 8b/10b encoding-decoding is done inside CPRI controller block and does not use SerDes 8b/10b encoders-decoders. The SerDes transparently sends/receives 10b data to the CPRI controller.

15.9.1 Serdes Banks and PLL

The Serdes block is composed of two banks. Each Bank consists of a controlling PLL and SerDes Lanes. The SerDes lanes within a bank are independent from each other and can be run using any combination of protocols provided that all of the protocols within a bank operate using the same base PLL full rate frequency.

It is very important to remember that any and all SerDes lanes connected to a given PLL must have the same base full rate. For example, only 1.25 Gbps, 2.5 Gbps, and 5 Gbps protocols can be run from a PLL running at 5 GHz. The same PLL can not be used simultaneously on two SerDes lanes running 5 Gbps and 3.125 Gbps.

A bank with a PLL VCO frequency of 5 GHz can run any combination of PCI Express/Serial RapidIO lanes at 5 Gbps, PCI Express/Serial RapidIO lanes at 2.5 Gbps, and/or Serial RapidIO/SGMII lanes at 1.25Gbps. A bank with a PLL/VCO Frequency of 6.25 Gbps can only run combinations of SRIO at 3.125 Gbps. CPRI can be used when the PLL VCO frequency is either 4.9152 GHz or 6.144 GHz, but no other protocols can be used with them. The banks are completely independent of each other and have no restrictions on which PLL/VCO frequencies can run on a given bank. There is one restriction, however, when both the PLL banks are used together: both banks cannot have same PLL VCO frequency. For example, if the PLL1 VCO frequency is 5 GHz, the PLL2 VCO frequency can not be 5 GHz; instead, PLL2 must be one of 6.125 GHz, 6.144 GHz, or 4.9152 GHz.

15.9.2 SerDes PLL Reference Clocks

The PLL is used to generate the required top-bit rate frequencies needed by the SerDes lanes.

For each PLL a reference clocks must be supplied. The reference clock frequencies should be such that the PLL VCO frequency is a multiple of the PLL reference clock frequency. Three PLL reference clock frequencies can generate any data-rate supported by the device-

- 100 MHz /5 GHz supports PCI Express/Serial RapidIO lanes at 5Gbps and 2.5Gbps and/or Serial RapidIO/SGMII lanes at 1.25 Gbps.
- 125 MHz/6.125 GHz supports Serial RapidIO lanes at 3.125 Gbps.
- 122.88 MHz/6.144 GHz supports CPRI lanes at 6.144Gbps and 3.072Gbps.
- 122.88 MHz /4.9152 GHz supports CPRI at 4.9152 Gbps, 2.4576 Gbps, and 1.2288Gbps.

15.9.3 Serdes PLL Multiplexing

Each of the 10 Serdes lanes (A–J) can be sourced from either of the two PLLs. Based on the PLL source of each of the banks, there are four PLL multiplexing options

- 10×0 = Lanes A–J sourced by PLL1 and PLL2 is off
- 8×2 = Lanes A–H sourced by PLL1 and Lanes I–J sourced by PLL2
- 6×4 = Lanes A–F sourced by PLL1 and Lanes G–J sourced by PLL2
- 4×6 = Lanes A–D sourced by PLL1 and Lanes E–J sourced by PLL2

The sequence of figures below show the PLL multiplexing options. A–J indicate each of the 10 SerDes ports The BLUE lines indicate PLL1 support and the RED lines indicate PLL2 support. In case of 10×0 configuration, PLL2 is off.

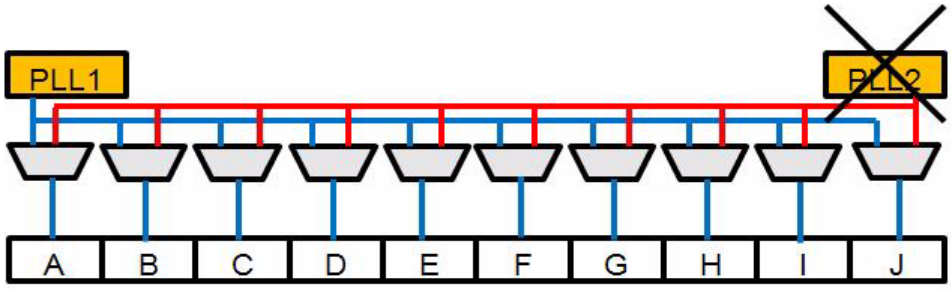

Figure 15-10. 10×0 PLL Multiplexing

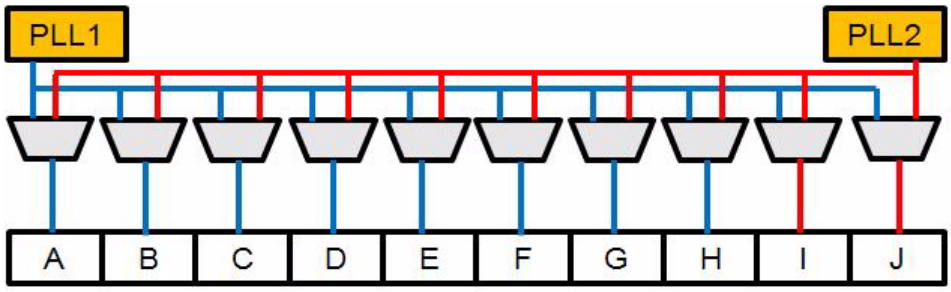

Figure 15-11. 8 × 2 PLL Multiplexing

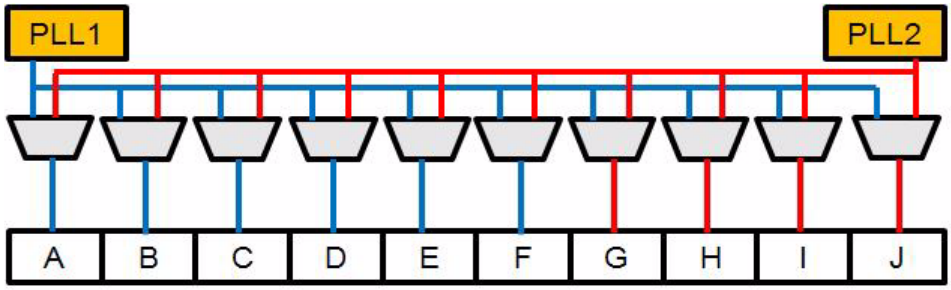

Figure 15-12. 6 × 4 PLL Multiplexing

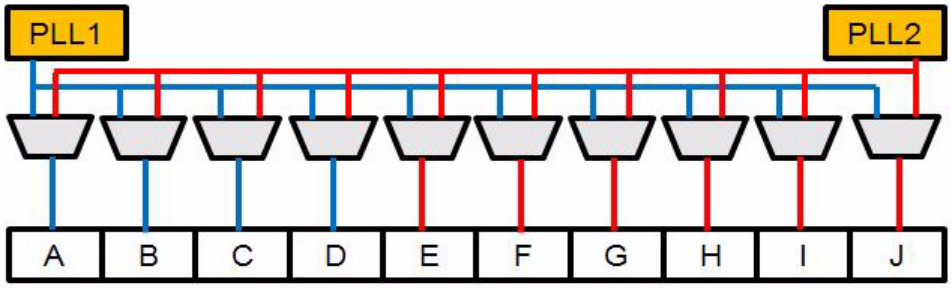

Figure 15-13. 4 × 6 PLL Multiplexing

The CPRI lanes are always sourced from PLL2 and always use some of or all of Lanes E–J. Based on the number of lanes CPRI is using, the following PLL multiplexing options exist:

- CPRI on 2 Lanes (I–J) uses 8 × 2
- CPRI on 4 Lanes (G–J) uses 6 × 4
- CPRI on 6 Lanes (E–J) uses 4 × 6

15.9.4 SerDes Clocks

Each of the 10 lanes have a pair (transmit and receive) of Ten-Bit Interface clocks. **Table 15-6** lists the Transmit/Receive clock frequencies for the different data rates.

Table 15-6. SerDes Clocks to Controllers

Data Rate (Gbps)	TBI Clock (MHz)
1.2500	125.00
2.5000	250.00
3.1250	312.50
5.0000	500.00
6.1440	614.40
4.9152	491.52
3.0720	307.20
2.4576	245.76
1.2288	122.88

15.10 HSSI Programming Model

The HSSI includes configuration, control, and status registers for the following modules:

- CLASS1 Registers use a base address of 0xFFFBA000.
  - CLASS1 Priority Mapping Registers (see **page 15-36**)
  - CLASS1 Priority Auto Upgrade Value Registers (see **page 15-37**)
  - CLASS1 Priority Auto Upgrade Control Registers (see **page 15-38**)
  - CLASS1 Error Address Registers (see **page 15-39**)
  - CLASS1 Error Extended Address Registers (see **page 15-40**)
  - CLASS1 Initiator Profiling Configuration Registers (see **page 15-41**)
  - CLASS1 Initiator Watch Point Control Registers (see **page 15-42**)
  - CLASS1 Arbitration Weight Registers (see **page 15-43**)
  - CLASS1 Start Address Decoder 1 (see **page 15-44**)
  - CLASS1 End Address Decoder 1 (see **page 15-46**)
  - CLASS1 Attributes Decoder 1 (see **page 15-48**)
  - CLASS1 Start Address Decoder 2 (see **page 15-44**)
  - CLASS1 End Address Decoder 2 (see **page 15-46**)
  - CLASS1 Attributes Decoder 2 (see **page 15-48**)
  - CLASS1 IRQ Status Register (see **page 15-51**)
  - CLASS1 IRQ Enable Register (see **page 15-53**)
  - CLASS1 Target Profiling Configuration Register (see **page 15-54**)

- CLASS1 Profiling Control Register (see **page 15-55**)
- CLASS1 Watch Point Control Register (see **page 15-56**)
- CLASS1 Watch Point Access Configuration Register (**page 15-58**)
- CLASS1 Watch Point Extended Access Configuration Register (see **page 15-59**)
- CLASS1 Watch Point Address Mask Register (see **page 15-60**)
- CLASS1 Profiling Time Out Register (see **page 15-61**)
- CLASS1 Target Watch Point Control Register (see **page 15-62**)
- CLASS1 Profiling IRQ Status Register (see **page 15-63**)
- CLASS1 Profiling IRQ Enable Register (see **page 15-64**)
- CLASS1 Profiling Reference Counter Register (see **page 15-65**)
- CLASS1 Profiling General Counter Registers (see **page 15-66**)
- CLASS1 Arbitration Control Register (see **page 15-67**)

- DMA Controller Registers. Dedicated DMA Controller 0 (D0) registers use a base address of 0xFFFA8000. Dedicated DMA Controller 1 (D1) registers use a base address of 0xFFFAA000.
  - Dn DMA 0–3 Mode Registers (DnMR[0–3]), **page 15-68**
  - Dn DMA 0–3 Status Registers (DnSR[0–3]), **page 15-71**
  - Dn DMA 0–3 Current Link Descriptor Extended Address Registers (DnECLNDAR[0–3], **page 15-73**
  - Dn DMA 0–3 Current Link Descriptor Address Registers (DnCLNDAR[0–3]), **page 15-74**
  - Dn DMA 0–3 Source Attributes Registers (DnSATR[0–3]), **page 15-75**
  - Dn DMA 0–3 Source Address Registers (DnSAR[0–3]), **page 15-76**
  - Dn DMA 0–3 Destination Attributes Registers (DnDATR[0–3]), **page 15-77**
  - Dn DMA 0–3 Destination Address Registers (DnDAR[0–3]), **page 15-78**
  - Dn DMA 0–3 Byte Count Registers (DnBCR[0–3], **page 15-79**
  - Dn DMA 1–3 Next Link Descriptor Extended Address Registers (DnENLNDAR[0–3], **page 15-80**
  - Dn DMA 0–3 Next Link Descriptor Address Registers (DnNLNDAR[0–3]), **page 15-81**
  - Dn DMA 1–3 Current List Descriptor Extended Address Registers (DnECLSDAR[0–3], **page 15-82**
  - Dn DMA 0–3 Current List Descriptor Address Registers (DnCLSDAR[0–3]), **page 15-83**
  - Dn DMA 0–3 Next List Descriptor Extended Address Registers (DnENLSDAR[0–3], **page 15-84**
  - Dn DMA 0–3 Next List Descriptor Address Registers (DnNLSDAR[0–3]), **page 15-85**
  - Dn DMA 0–3 Source Stride Registers (DnSSR[0–3]), **page 15-86**
  - Dn DMA 0–3 Destination Stride Registers (DnDSR[0–3]), **page 15-87**
  - Dn DMA General Status Register (DnDGSR), **page 15-88**

  - Dn Local Access Window Base Address Registers 0–9 (DnLAWBAR[0–9]), **page 15-90**
  - Dn Local Access Window Attributes Registers 0–9 (DnLAWAR[0–9]), **page 15-91**
- Protocol Converter Registers use a base address of 0xFFFAD000:
  - CPRI[1–6] Protocol Converter Control Register 0 (PCVTRCPRI[1–6]CR0), **page 15-93**
  - CPRI[1–6] Protocol Converter Control Register 1 (PCVTRCPRI[1–6]CR1), **page 15-94**

- SerDes PHY Interface Registers. SerDes Port uses a base address of 0xFFFAD000.
  - SRDS Bank 1–2 Reset Control Register (SRDSB[1–2]RSTCTL), **page 15-95**
  - SRDS Bank 1–2 PLL Control Register 0 (SRDSB[1–2]PLLCR0), **page 15-97**
  - SRDS Bank 1–2 PLL Control Register 1 (SRDSB[1–2]PLLCR1), **page 15-97**
  - Lane A–J General Control Register 0 (L[A–J]GCR0), **page 15-98**
  - Lane A–J Receive Equalization Control Register 0 (L[A–J]RECR0), **page 15-101**
  - Lane A–J Transmit Equalization Control Register 0 (L[A–J]TECR0), **page 15-104**

There are also several general configuration registers (base address 0xFFF28000) used to control and monitor HSSI operation (see **Chapter 8**, *General Configuration Registers* for details. These include the following:

- General Control Register 2 (GCR2), **page 8-4**
- High Speed Serial Interface Status Register (HSSI_SR), **page 8-8**
- High Speed Serial Interface Control Register 1 (HSSI_CR1), **page 8-12**
- High Speed Serial Interface Control Register 2 (HSSI_CR2), **page 8-15**
- General Control Register 5 (GCR5), **page 8-22**
- General Status Register 2 (GSR2), **page 8-24**
- General Status Register 3 (GSR3), **page 8-27**
- General Interrupt Register 5 (GIR5), **page 8-42**
- General Interrupt Enable Register 5 (GIER5_[0–5]), **page 8-44**
- General Interrupt Register 7 (GIR7), **page 8-74**
- General Interrupt Enable Register 7 (GIER7_[0–5]), **page 8-76**

15.10.1 CLASS1 Priority Mapping Registers (C1PMRx)

C1PMR[0–5] CLASS1 Priority Mapping Registers Offset 0x800 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															PB
Type	R/W

Type	R/W															
Reset	0	0	1	1	0	0	1	0	0	0	0	1	0	0	0	0

C1PMRx is used as a look-up table for mapping the priority received from the initiator. By default the input priority is mapped to an identical value on the output. This register also enables/disables the priority derivation feature.

Note: You cannot write to this register while there are open CLASS1 transactions.

Table 15-7 lists the C1PMRx bit field descriptions.

Table 15-7. C1PMRx Bit Descriptions

Name	Reset	Description	Settings
— 31–17	0	Reserved. Write to 0 for future compatibility.	
PB 16	0	**Priority Bypass** Enables/disables the priority derivation mechanism.	0 Filter the mapped priority with the priority derivation mechanism. 1 Pass the mapped priority from initiator to target with no filtering.
— 15–14	0	Reserved. Write to 0 for future compatibility.	
PM3 13–12	11	**Priority Mapping 3** Holds the priority value assigned to transactions that arrive with a value of 3.	00 Priority 0 01 Priority 1 10 Priority 2 11 Priority 3
— 11–10	0	Reserved. Write to 0 for future compatibility.	
PM2 9–8	10	**Priority Mapping 2** Holds the priority value assigned to transactions that arrive with a value of 2.	00 Priority 0 01 Priority 1 10 Priority 2 11 Priority 3
— 7–6	0	Reserved. Write to 0 for future compatibility.	
PM1 5–4	01	**Priority Mapping 1** Holds the priority value assigned to transactions that arrive with a value of 1.	00 Priority 0 01 Priority 1 10 Priority 2 11 Priority 3

Table 15-7. C1PMRx Bit Descriptions (Continued)

Name	Reset	Description	Settings
— 3–2	0	Reserved. Write to 0 for future compatibility.	
PM0 1–0	0	**Priority Mapping 0** Holds the priority value assigned to transactions that arrive with a value of 0.	00 Priority 0 01 Priority 1 10 Priority 2 11 Priority 3

15.10.2 CLASS1 Priority Auto Upgrade Value Registers (C1PAVRx)

C1PAVR[0–5] CLASS1 Priority Auto Upgrade Value Registers Offset 0x840 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	AUV															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1PAVRx holds the value loaded to the priority auto-upgrade counter.

Note: You can write to this register while there are open CLASS1 transactions. The AUV field is loaded into the auto-upgrade counter only when you set the AUE bit in C1PACRx. Therefore, always update the AUV field in the C1PAVRx before you set the AUE bit.

Table 15-8 lists the C1PAVRx bit field descriptions.

Table 15-8. C1PAVRx Bit Descriptions

Name	Reset	Description
— 31–16	0	Reserved. Write to 0 for future compatibility.
AUV 15—0	0	**Auto-Upgrade Value** The value loaded into the auto-upgrade counter. The priority of the access determines which bits of this value are used, as follows: • Priority 0: All 16 bits are loaded into the counter. • Priority 1: Bits 15–1 are loaded into bit 14–0 of the counter and a 0 into bit 15. • Priority 2: Bits 15–2 are loaded into bits 13–0 of the counter and 0 into bits 15 and 14.

15.10.3 CLASS1 Priority Auto Upgrade Control Registers (C1PACRx)

C1PACR[0–5] CLASS1 Priority Auto Upgrade Control Registers Offset 0x880 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—															AUE
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1PACRx controls the priority auto-upgrade mechanism.

Note: You can write to this register while there are open CLASS1 transactions.

Table 15-9 lists the C1PACRx bit field descriptions.

Table 15-9. C1PACRx Bit Descriptions

Name	Reset	Description	Settings
— 31–1	0	Reserved. Write to 0 for future compatibility.	
AUE 0	0	**Auto-Upgrade Enable** Enables/disables the auto-upgrade mechanism. **Note:** This bit can only be cleared by a hardware reset.	0 Auto-upgrade mechanism disabled. 1 Auto-upgrade mechanism enabled.

15.10.4 CLASS1 Error Address Registers (C1EARx)

C1EAR[0–5] CLASS1 Error Address Registers Offset 0x980 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ERR_ADD															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	ERR_ADD															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The C1EAR is used to store the address (32 least significant bits) of the internal transaction when an error has been identified by the CLASS. When an error occurs and an error bit is set in the C1ISR, the internal transaction address is stored and the C1EARx is locked and does not update even if another error with a different transactions address occurs. Only when the AEIx bit in the C1ISR is cleared (either by a hardware reset or by writing a 1 to it) is C1EARx unlocked.

Table 15-10 lists the C1EARx bit field descriptions.

Table 15-10. C1EARx Bit Descriptions

Name	Reset	Description
ERR_ADD 31–0	0	**Error Address** This field stores the 32 lsbs of the address of the internal transaction that caused the error.

Note: The generated interrupts correspond to the following sources:

— C1EAR0 = Address generated by OCN-to-MBus port 0 (O2M0).
— C1EAR1 = Address generated by CPRI MBus port 1 — CPRI read
— C1EAR2 = Address generated by AXI-to-MBus port 1 (AXI2M1)—eMSG read.
— C1EAR3 = Address generated by OCN-to-MBus port 1 (O2M1)
— C1EAR4 = Address generated by CPRI MBus port 0 — CPRI write
— C1EAR5 = Address generated by AXI-to-MBus port 0 (AXI2M0)—eMSG write.

15.10.5 CLASS1 Error Extended Address Registers (C1EEARx)

C1EEAR[0-5] CLASS1 Extended Error Address Registers Offset 0x9C0 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															RW
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—	SA	—					SRC_ID					ERR_ADD			
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The C1EEAR stores the most significant 4 bits of the address of the internal transaction when an error has been identified by the CLASS. This register also stores the attributes and the source ID of this transaction. When an error occurs and an error bit is set in the C1ISR, the internal transaction address is stored and the C1EEAR is locked and is not updated even if another error with a different transactions address/attributes occurs. Only when the AEI bit in the CISR is cleared (either by a hardware reset or by writing a 1 to it) is C1EEAR unlocked.

Table 15-11 lists the C1EEARx bit field descriptions.

Table 15-11. C1EEARx Bit Descriptions

Name	Reset	Description	Settings
— 31–17	0	Reserved. Write to 0 for future compatibility.	
RW 16	0	**Read/Write** This field indicates whether the transaction that caused the error was a read or a write.	0 Write. 1 Read.
— 15	0	Reserved. Write to 0 for future compatibility.	
SA 14	0	**Supervisor Access** This field indicates whether the transaction that caused the error was in supervisor mode.	0 Not supervisor. 1 Supervisor.
— 13–9	0	Reserved. Write to 0 for future compatibility.	
SRC_ID 8–4	0	**Source ID** Identifies the source ID of the initiator that caused the error.	01100 OCN-to-MBus Port (O2M0) 10001 CPRI MBus Port 1—CPRI read 10011 AXI-to-MBus port 1 (AXI2M1)—eMSG read 01101 OCN-to-MBus Port 1 (O2M1) 10010 CPRI MBus Port 0 — CPRI write 10100 AXI-to-MBus port 0 (AXI2M0)—eMSG write
ERR_ADD 3–0	0	**Error Address** This field stores the 4 msbs of the address of the internal transaction that caused the error.	

15.10.6 CLASS1 Initiator Profiling Configuration Registers (C1IPCRx)

C1IPCR[0–5] CLASS1 Initiator Profiling Configuration Registers‘Offset 0xA00 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—											PMM				
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1IPCRx controls the CLASS1 initiator profiling measurements. Each initiator has a dedicated C1IPCR which is numbered according to the initiator number within each CLASS1 module. The CLASS1 can perform only one measurement for a specific module at a time. Select the desired measurement for the initiator, enter the PMM value in the associated C1IPCR and make sure all the other C1IPCR and the C1TPCR for that CLASS1 are cleared.

Note: Only one PMM field among all C1IPCRx and C1TPCR can be > 0 during profiling.

Table 15-12 lists the C1IPCRx bit field descriptions.

Table 15-12. C1IPCRx Bit Descriptions

Name	Reset	Description	Settings
— 31–5	0	Reserved. Write to 0 for future compatibility.	
PMM 4–0	0	**Profiling Measurement Mode** Determines the profiling measurement mode for the matching initiator. **Note:** This register can only be cleared by a hardware reset.	00000 No measurement. 00001 Initiator priority and auto-upgrade. 00010 Initiator access type. 00011 Initiator stall. 00100 Initiator priority upgrade. 00101 Initiator priority non-upgrade. 00110 Initiator supervisor. 00111 Initiator bandwidth. 01000–01111 reserved 10000 Target 0 bandwidth. 10001 Target 1 bandwidth. 10010–11111 reserved

Table 15-13. Initiator Numbers

Initiator Number	Initiator Module
0	OCN-to-MBus Port 0 (O2M0)
1	CPRI MBus Port 1— CPRI read
2	AXI-to-MBus port 1 (AXI2M1)—eMSG read
3	OCN-to-MBus Port 1 (O2M1)

Table 15-13. Initiator Numbers

Initiator Number	Initiator Module
4	CPRI MBus Port 0 — CPRI write
5	AXI-to-MBus port 0 (AXI2M0)—eMSG write

15.10.7 CLASS1 Initiator Watch Point Control Registers (C1IWPCRx)

C1IWPCR[0–5] CLASS1 Initiator Watch Point Control Registers Offset 0xA40 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—															WPEN
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1IWPCRx controls the Watch Point Unit operation for the associated initiator. The Watch Point Unit monitors a specific access defined by the C1WPCRx, C1WPACRx, C1WPEACRx, and C1WPAMR. Each initiator can be enabled/disabled to monitor the selected access. You can write to this register while there are open CLASS1 transactions.

Note: Only one WPEN field can be set among all C1IWPCRx and C1TWPCRx when snooping watch point events.

Table 15-14 lists the C1IWPCRx bit field descriptions.

Table 15-14. C1IWPCRx Bit Descriptions

Name	Reset	Description	Settings
— 31–1	0	Reserved. Write to 0 for future compatibility.	
WPEN 0	0	**Watch Point Enable** Enables/disables the auto-upgrade mechanism. **Note:** This bit can only be cleared by a hardware reset.	0 The watch point is disabled. 1 The watch point is enabled.

15.10.8 CLASS1 Arbitration Weight Registers (C1AWRx)

C1AWR[0–5] CLASS1 Arbitration Weight Registers Offset 0xA80 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Boot	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—												WEIGHT			
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Boot	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The value in C1AWRx determines the arbitration weight for the associated initiator. An initiator with arbitration weight of W is allowed to initiate up to W+1 consecutive transactions.

Note: When another initiator requests for access with higher priority level, the CLASS1 Arbiter chooses the higher priority request instead of the weighted winner.

Table 15-15 lists the C1AWRx bit field descriptions.

Table 15-15. C1AWRx Bit Descriptions

Name	Reset	Description	Settings
— 31–4	0	Reserved. Write to 0 for future compatibility.	
WEIGHT 3–0	0	**Weight** Contains the arbitration weight assigned to the associated initiator. **Note:** This register can only be cleared by a hardware reset.	**Recommended Values:** 0011 Use this value.

Using the reset values can result in poor initial system performance. **Table 15-15** lists the recommended initial arbitration weight settings to apply after reset to increase initial performance levels during application development. These are just initial recommendations and can be changed by the designer according to the application requirements. However, the recommended settings will yield much higher performance than using the hardware default values. As a general rule, these recommended settings select a weighted arbitration of 3. Also, see **Table 15-37** for recommended initial settings for the CLASS1 Arbitration Control Register (C1ACR).

15.10.9 CLASS1 Start Address Decoder 1 (C1SAD1)

C1SAD1 CLASS1 Start Address Decoder 1 Offset 0xC04

	—											SPRW	—			DEN
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

C1ATD1 controls the functionality of the decoder for CLASS1 toward the CLASS0 initiator port 8. The register contains the bit that enables/disables the specific port. In addition to containing the bit that enables/disables the port 1, this register also contains a bit to determine whether the access between CLASS1 and CLASS0 uses direct connections or uses split read/write access. If a decoder is disabled, it never indicates a hit, even if the address corresponds to the decoder address window. In this case, the CLASS1 treats the space as if it is not assigned to any port. However, any transaction that was acknowledged up to and including the cycle in which DEN is cleared continues normally until completed.

Note: To ensure proper operation, do not enable the specific decoder before the start and end addresses are specified in the associated C1SAD1 and C1EAD1.

This register is reset by a hardware reset only. **Table 15-20** lists the C1ATD1 bit field descriptions.

Table 15-20. C1ATD1 Bit Descriptions

Name	Reset	Description	Settings
— 31–5	0	Reserved. Write to 0 for future compatibility.	
SPRW 4	1	**Split Read/Write** Determines whether reads and writes both occur on a port or they are split between two ports. **Note:** **Table 15-21** summarizes the split access configuration options.	0 Read and write accesses use both target ports 0 and 1. Address decoding for each port is done by the respective register sets: C1SAD1/C1EAD1 are used for port 1 and C1SAD2/C1EAD2 are used for port 0. Use of this mode may improve performance for applications with an unbalanced proportion of HSSI reads and writes, or it can be used to allocate memory accesses to reduce collisions between the HSSI initiators. In this mode, you must configure the start/end registers so that all desired memory space (including M2 banks, M3, DDR, and MAPLE slave ports) is split between the two ports to optimize the specific application access needs. 1 Reads and writes go through different ports (Reads use target 1 and writes use target 0). The start and end addresses for both ports are controlled by C1SAD1 and C1EAD1.
— 31–1	0	Reserved. Write to 0 for future compatibility.	
DEN 0	1	**Decoder Enable** Enables/disables the specified decoder.	0 Disables the decoder. 1 Enables the decoder.

Note: Never write to this register when there are open transactions being handled by the CLASS1 to the specified target controlled by the register.

Table 15-21. Split HSSI Access Configurations

Scenario	C1ATD1[DEN]	C1ATD2[DEN]	C1ATD1[SPRW]	Result
1	0	0	x	No accesses can be made by the HSSI
2	0	1	x	All HSSI accesses use Target0 as defined by C1SAD2/C1EAD2. (no benefit)
3	1	0	0	All HSSI accesses use Target1 as defined by C1SAD1/C1EAD1. (no benefit)
4	1	x	1	Writes from the HSSI use Target 1. Reads to HSSI use Target 0. Both ports are defined by C1SAD1/C1EAD1.
5	1	1	0	Some accesses use Target 1 (defined by C1SAD1/C1EAD1). Some accesses use Target 0 (defined by C0SAD2/C0EAD2). Use for cases of unbalanced reads/writes or to split address space among different HSSI masters. **Note:** A hit in C1SAD2/C1EAD2 has a higher priority than a hit in C1SAD1/C1EAD1 window.

15.10.14 CLASS1 Attributes Decoder 1 (C1ATD2)

C1ATD2 CLASS0 Attributes Decoders Offset 0xC88

The C1IER is used to enable/disable the generation of interrupts that have occurred. There is a dedicated bit for each initiator. If a C1IER bit is cleared the corresponding bit in the C1ISR is masked. This register is reset by the hardware reset only.

Table 15-24 lists the C1IER bit field descriptions.

Table 15-24. C1IER Bit Descriptions

Name	Reset	Description	Settings
— 31–6	0	Reserved. Write to 0 for future compatibility.	
AEIE5 5	0	**Address Error5 Interrupt Enable** Used to enable/disable the address error interrupt for an initiator.	0 Interrupt masked. 1 Interrupt enabled.
AEI4 4	0	**Address Error4 Interrupt Enable** Used to enable/disable the address error interrupt for an initiator.	0 Interrupt masked. 1 Interrupt enabled.
AEIE3 3	0	**Address Error3 Interrupt Enable** Used to enable/disable the address error interrupt for an initiator.	0 Interrupt masked. 1 Interrupt enabled.
AEIE2 2	0	**Address Error2 Interrupt Enable** Used to enable/disable the address error interrupt for an initiator.	0 Interrupt masked. 1 Interrupt enabled.
AEI1 1	0	**Address Error1 Interrupt Enable** Used to enable/disable the address error interrupt for an initiator.	0 Interrupt masked. 1 Interrupt enabled.
AEI0 0	0	**Address Error0 Interrupt Enable** Used to enable/disable the address error interrupt for an initiator.	0 Interrupt masked. 1 Interrupt enabled.

15.10.17 CLASS1 Target Profiling Configuration Register (C1TPCR)

C1TPCR CLASS1 Target Profiling Configuration Register Offset 0xE00

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—			TT	TN				—						PMM	
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1TPCR is used to control the CLASS1 target profiling measurements. Each CLASS1 module can perform only one measurement for a specific module at a time. Use the values of TT and TN to select the module. Use the PMM value to select the measurement. Only write the PMM value to this register when all the C1IPCRx are cleared.

Note: For each CLASS1 module, you can only monitor one transaction. Therefore, only one PMM field in C1IPCRx and C1TPCR can be greater than 0 during profiling.

Table 15-25 lists the C1TPCR bit field descriptions.

Table 15-25. C1TPCR Bit Descriptions

Name	Reset	Description	Settings
— 31–13	0	Reserved. Write to 0 for future compatibility.	
TT 12	0	**Target Type** Selects the module used for target profiling. Used with PMM. See PMM settings.	0 Arbiter. 1 Normalizer.
TN 11–8	0	**Target Number** Indicates the number of selected target.	0010 HSSI Port 0 (CLASS Init. 8) 0001 HSSI Port 1 (CLASS Init. 12) All other values reserved.
— 7–2	0	Reserved. Write to 0 for future compatibility.	
PMM 1–0	0	**Profiling Measurement Mode** Selects the profiling measurement for the selected target.	If TT = 0: 00 No profiling measurement. 01 Arbitration winner priority measurement. 10 Collisions measurement. 11 reserved. If TT = 1: 00 No profiling measurement. 01 Transaction splitting measurement. 10 Bandwidth measurement. 11 Stall measurement.

15.10.18 CLASS1 Profiling Control Register (C1PCR)

C1PCR CLASS1 Profiling Control Register Offset 0xE04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	ADDR															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1WPACR, along with C1WPEACR, configures the selected access to monitor. The watch point monitoring occurs only if the respective function is enabled in the C1WPCR. The register is reset only by a hardware reset. **Table 15-28** lists the C1WPACR bit field descriptions.

Table 15-28. C1WPACR Bit Descriptions

Name	Reset	Description	Settings
ATR 31	0	**Atomic Result** Defines the atomic result type to monitor.	0 Atomic access failed. 1 Atomic access succeeded.
ATA 30	0	**Atomic Access** Defines the atomic access type to monitor.	0 Non-atomic access. 1 Atomic access.
RS 29	0	**Read-Safe Access** Defines the read-safe access type to monitor.	0 Non-read-safe access. 1 Read-safe access.
SN 28	0	**Snoop Access** Defines the snoop access type to monitor.	0 Non-snoop access. 1 Snoop access.
OP 27	0	**Optimize Access** Defines the optimize access type to monitor.	0 Non-optimized access. 1 Optimized access.
TST 26	0	**Test Access** Defines the test access type to monitor.	0 Non-test access. 1 Test access.
SPV 25	0	**Supervisor Access** Defines the supervisor access type to monitor.	0 Non-supervisor access. 1 Supervisor access.
RW 24	0	**Read/Write Access** Defines the access type to monitor.	0 Write. 1 Read.
ADDR 23–0	0	**Address[35–12]** This field, along with the ADDM field in C1WPAWMR, defines the start and range of the addresses the watch point unit monitors. **Note:** For every bit in C1WPAMR[ADDM] that is cleared, make sure the corresponding bit is cleared in the ADDR. The bit location in ADDM (b) corresponds to the b + 12 bit location in ADDR.	

15.10.21 CLASS1 Watch Point Extended Access Configuration Register (C1WPEACR)

C1WPEACR CLASS1 Watch Point Extended Access Configuration Registers Offset 0xE10

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1WPEACR, along with C1WPACR, configures the selected access to monitor. The watch point monitoring occurs only if the respective function is enabled in the C1WPCR. The register is reset only by a hardware reset. **Table 15-29** lists the C1WPEACR bit field descriptions.

Table 15-29. C1WPEACR Bit Descriptions

Name	Reset	Description	Settings
UP 31	0	**Upgradeable Access** Defines the upgradeable access type to monitor.	0 Non-upgradeable access. 1 Upgradeable access.
WC 30	0	**Write-with-Confirm Access** Defines the write-with-confirm access type to monitor.	0 Fast confirm access. 1 Write-with-confirm access.
— 29–28	0	Reserved. Write to 0 for future compatibility.	
EATTR 27–24	0	**EOT Attributes** Defines the EOT attributes to monitor.	0x9 Target port 1 CLASS initiator port 8 0xA Target port 2 CLASS initiator port 12 All other values reserved.
— 23–16	0	Reserved. Write to 0 for future compatibility.	
SI 15–11	0	**Source** Defines the source ID to monitor.	0x00 O2M0 (OCN to MBus port 0) 0x01 CPRI MBus read port 0x02 AXI2M1 (eMSG read) 0x03 O2M1 (OCN to MBus port 1) 0x04 CPRI Mbus write port 0x05 AXI2M1 (eMSG write) All others reserved.
PR 10–9	0	**Priority** Defines the priority level to monitor.	00 Priority 0 (highest) 01 Priority 1 10 Priority 2 11 Priority 3 (lowest)
BC 8–0	0	**Byte Count** This field defines the value of the byte count that the watch point unit monitors.	The byte count to monitor can be from 1 to 511 bytes.

15.10.22 CLASS1 Watch Point Address Mask Registers (C1WPAMR)

C1WPAMR CLASS1 Watch Point Address Mask Registers Offset 0xE14

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—								ADDM							
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1WPAMR controls the address range monitored by the watch point unit. The register is reset only by a hardware reset. **Table 15-30** lists the C1WPAMR bit field descriptions.

Table 15-30. C1WPAMR Bit Descriptions

Name	Reset	Description	Settings
— 31–8	0	Reserved. Write to 0 for future compatibility.	
ADDM 7–0	0	**Address Mask** Defines the range and alignment of the address to monitor if address monitoring is enabled. The start address is defined in C1WPACR[ADDR]. **Note:** For every bit in ADDM that is cleared, make sure the corresponding bit is cleared in the C1WPACR.	00000000 Aligned with a range of 1 MB. 10000000 Aligned with a range of 512 KB. 11000000 Aligned with a range of 256 KB. 11100000 Aligned with a range of 128 KB. 11110000 Aligned with a range of 64 KB. 11111000 Aligned with a range of 32 KB. 11111100 Aligned with a range of 16 KB. 11111110 Aligned with a range of 8 KB. 11111111 Aligned with a range of 4 KB. All other values are reserved.

15.10.23 CLASS1 Profiling Time-Out Register (C1PTOR)

C1PTOR CLASS1 Profiling Time-Out Register Offset 0xE18

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TO															
Type	R/W															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TO															
Type	R/W															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

C1PTOR is used to stop the profiling unit operation. When the C1PRCR reaches the value stored in C1PTOR and C1PCR[TOE] is set, the CLASS1 clears the C1PCR[PE] bit to disable the profiling unit. When C1PCR[PE] clears, the CLASS1 stops all profiling counters. The register is reset only by a hardware reset. **Table 15-31** lists the C1PTOR bit field descriptions.

Table 15-31. C1PTOR Bit Descriptions

Name	Reset	Description
TO 31–0	0xFFFFFFFF	**Time-Out** Holds the time-out value used to stop the profiling unit when the time-out function is enabled.

15.10.24 CLASS1 Target Watch Point Control Register (C1TWPCR)

C1TWPCR CLASS1 Target Watch Point Control Register Offset 0xE1C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—													WPEN2	WPEN1	—
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The C1TWPCR controls the watch point unit operation for CLASS1 targets. The watch point unit monitors a specific access defined in C1WPCR, C1WPACR, C1WPEACR, and C1WPAMR. Each target can be enabled/disabled for monitoring the specified access type. The register is reset by a hard reset only.

Note: Only one WPEN field can be set among all the C1IWPCRx and C1TWPCR. That is, only one watch point unit can be active at a time.

Table 15-23 lists the C1TWPCR bit field descriptions.

Table 15-32. C1TWPCR Bit Descriptions

Name	Reset	Description	Settings
— 31–3	0	Reserved. Write to 0 for future compatibility.	
WPEN[2–1] 2–1	0	**Watch Point Enable 2–1** Each bit enables monitoring of access by the associated target.	0 The watch point unit for the associated target is disabled. 1 The watch point unit for the associated target is enabled.
— 0	0	Reserved. Write to 0 for future compatibility.	

15.10.25 CLASS1 Profiling IRQ Status Register (C1PISR)

C1PISR CLASS1 Profiling IRQ Status Registers Offset 0xE20

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—														WPE	OVE
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1PISR indicates that a watch point event occurred or that the C1PRCR overflowed. An interrupt is generated if the status bit is set and the corresponding bit in C1PIERx is set to enable the interrupt. You can write to or read the register at any time. Write a 1 to a bit to clear it; writing a 0 has no effect. The register is reset by a hard or soft reset. **Table 15-33** lists the C1PISR bit field descriptions.

Table 15-33. C1PISR Bit Descriptions

Name	Reset	Description	Settings
— 31–2	0	Reserved. Write to 0 for future compatibility.	
WPE **1**	0	**Watch Point Event** Enables monitoring of access by the associated target.	0 No watch point event occurred. 1 Watch point event captured.
OVE **0**	0	**Overflow Event** Enables monitoring of access by the associated target.	0 No overflow occurred. 1 C1PRCR overflowed (reached 0xFFFFFFFF) during the last measurement.

15.10.26 CLASS1 Profiling IRQ Enable Register (C1PIER)

C1PIER CLASS1 Profiling IRQ Enable Registers Offset 0xE24

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—														WPEE	OVEE
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1PIER enables/disables the generation of interrupts by the debug profiling unit. You can write to the register at any time. The register is reset by a hard reset only. **Table 15-34** lists the C1PIER bit field descriptions.

Table 15-34. C1PIER Bit Descriptions

Name	Reset	Description	Settings
— 31–2	0	Reserved. Write to 0 for future compatibility.	
WPEE **1**	0	**Watch Point Event Enable** Enables/disables a watch point interrupt.	0 Watch point interrupt is masked. 1 Watch point interrupt is enabled.
OVEE **0**	0	**Overflow Event Enable** Enables/disables an overflow interrupt.	0 Overflow interrupt is masked. 1 Overflow interrupt is enabled.

15.10.27 CLASS1 Profiling Reference Counter Register (C1PRCR)

C1PRCR CLASS1 Profiling Reference Counter Registers Offset 0xE40

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNT															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNT															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1PRCR is the reference counter for all profiling measurements. This read-only register counts the number of cycles occurring during the profiling measurement or during the watch point unit operation. The counter starts counting from zero when the profiling unit is enabled. The C1PRCR stops when the profiling unit is disabled, or when the C1PRCR reaches the value stored in C1PTOR and TOE is set, which causes the CLASS1 to clear the PE bit to disable the profiling unit. When PE clears, the CLASS1 stops all profiling counters. The register is reset only by a hardware reset only. **Table 15-35** lists the C1PRCR bit field descriptions.

Table 15-35. C1PRCR Bit Descriptions

Name	Reset	Description
CNT 31–0	0	**Counter** Holds the reference counter for the profilers.

15.10.28 CLASS1 Profiling General Counter Registers (C1PGCRx)

C1PGCR[0–3] CLASS1 Profiling General Counter Registers Offset 0xE44 + x*0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CNT															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CNT															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

C1PGCRx is used to count profiling unit or watch point unit events. This read-only register counts the number of cycles occurring during the profiling measurement or during the watch point unit operation. The counter starts counting from zero when the profiling unit is enabled. The C1PRCR stops when the profiling unit is disabled, or when the C1PRCR reaches the value stored in C1PTOR and TOE is set, which causes the CLASS1 to clear the PE bit to disable the profiling unit. When PE clears, the CLASS1 stops all profiling counters. The register is reset only by a hardware reset. **Table 15-36** lists the C1PGCR bit field descriptions.

Table 15-36. C1PGCR Bit Descriptions

Name	Reset	Description
CNT 31–0	0	**Counter** Holds the counter value of the selected measurement. **Table 15-1** lists the measurements counted by each counter for each configuration combination.

15.10.29 CLASS1 Arbitration Control Register (C1ACR)

C1ACR CLASS1 Arbitration Control Registers Offset 0xFC0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—			PME	—											
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Boot	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—													LA2	LA1	—
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Boot	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

The C1ACR controls the CLASS1 arbiters. There is a dedicated bit for each arbiter that controls the Late Arbitration mode of the associated arbiter. When Late Arbitration mode is enabled, the arbiter delays the decision about the winner according to the MDBW parameter and the byte count of the winner access. When Late Arbitration mode is disabled, the arbiter makes a decision every clock cycle.The register is reset by a hard reset only. **Table 15-37** lists the C1ACR bit field descriptions.

Table 15-37. C1ACR Bit Descriptions

Name	Reset	Description	Settings
— 31–29	0	Reserved. Write to 0 for future compatibility.	
PME **28**	0	**Priority Mask Enable** Enables/disables the operation of the priority mask unit for starvation elimination.	0 Priority mask disabled. 1 Priority mask enabled.
— 27–3	0	Reserved. Write to 0 for future compatibility.	
LA[2–1] 2–1	0	**Late Arbitration 2–1** Enables/disables late arbitration mode for the associated arbiter. **Note:** As with the arbitration weight (see **Section 15.10.8**, *CLASS1 Arbitration Weight Registers (C1AWRx)*, on page 15-43), the default value for this field does not yield optimal performance. Freescale recommends that after reset, write a value of 0b11 to this field. This value assigns late arbitration to system CLASS accesses. This is just an initial value, and can be changed according to the application requirements and system traffic.	0 Late arbitration disabled. 1 Late arbitration enabled.
— 0	0	Reserved. Write to 0 for future compatibility.	

15.10.30 Mode Registers 0–3 (DnMR[0–3]).

DnMR0 Mode Registers 0–3 Offset 0x100
DnMR1 Offset 0x180

The mode register allows software to start a DMA transfer and to control various DMA transfer characteristics. **Table 15-38** describes the fields of the DnMR.

Table 15-38. DnMR Field Descriptions

Bits	Reset	Description	Setting
— 31–28	0	Reserved. Write to zero for future compatibility.	
BWC 27–24	1000	**Bandwidth Control** If multiple channels are executing transfers concurrently, this value determines how many bytes a channel can transfer before the DMA controller shifts to the next channel. If a single channel is executing, configure this field as 1111 for the channel.	0000 1 byte 0001 2 bytes 0010 4 bytes 0011 8 bytes 0100 16 bytes 0101 32 bytes 0110 64 bytes 0111 128 bytes 1000 256 bytes 1001 512 bytes 1010 1024 bytes 1011–1110 reserved. 1111 Bandwidth sharing disabled; allows uninterrupted transfers from each channel.
— 23–18	0	Reserved. Write to zero for future compatibility.	
DAHTS 17–16	0	**Destination Address Hold Transfer Size** Indicates the transfer size to use while MR[DAHE} is set. The byte count must be in multiples of the size and the destination address must be aligned based on the size. The defined size must be equal to or small than the value of MR[BWC] to avoid undefined behavior.	00 1 byte. 01 2 bytes. 10 4 bytes. 11 8 bytes.

Table 15-38. DnMR Field Descriptions (Continued)

Bits	Reset	Description	Setting
SATHS 15–14	0	**Source Address Hold Transfer Size** Indicates the transfer size to use while MR[SAHE} is set. The byte count must be in multiples of the size and the destination address must be aligned based on the size. The defined size must be equal to or small than the value of MR[BWC] to avoid undefined behavior.	00 1 byte. 01 2 bytes. 10 4 bytes. 11 8 bytes.
DAHE 13	0	**Destination Address Hold Enable** When set, allows the DMA controller to hold the destination address of a transfer to the size specified by DATHS. This hardware feature only supports aligned transfers.	0 Destination address hold disabled. 1 Destination address hold enabled.
SAHE 12	0	**Source Address Hold Enable** When set, allows the DMA controller to hold the destination address of a transfer to the size specified by SATHS. This hardware feature only supports aligned transfers.	0 Source address hold disabled. 1 Source address hold enabled.
— 11	0	Reserved. Write to zero for future compatibility.	
SRW 10	0	**Single Register Write (CTM = 1 only)** The effect of setting this bit in direct mode depends on the value of CDSM/SWSM. **Note:** This bit is reserved for CTM = 0 (chaining mode).	*CDSM/SWSM = 0* 0 Normal operation. 1 A write to the destination address register sets MR[CS] to initiate a DMA transfer. *CDSM/SWSM = 1* 0 Normal operation. 1 A write to the source address register sets MR[CS] to initiate a DMA transfer.
EOSIE 9	0	**End-of-Segments interrupt Enable** When set, generates an interrupt to indicate the completion of a data transfer. **Note:** When set, the value of this bit overrides the value of CLNDAR[EOSIE] on a link descriptor basis.	0 No end-of-transfer interrupt generated. 1 End-of-transfer interrupt generated.
EOLNIE 8	0	**End-of-Links Interrupt Enable** When set, generates an interrupt at the completion of a list of DMA transfers (that is, sets NLNDAR[EOLND]).	0 No end-of-list interrupt generated. 1 End-of-list interrupt generated.
EOLSIE 7	0	**End-of-Lists Interrupt Enable** When set, generates an interrupt at the completion of all DMA transfers (that is, sets NLNDAR[EOLND] and NLSDAR[EOLSD]).	0 No end of all transfers interrupt generated. 1 End of all transfers interrupt generated.
EIE 6	0	**Error Interrupt Enable** When set, generates an interrupt if a programming or transfer error is detected.	0 No error interrupt generated. 1 Error interrupt generated.
XFE 5	0	**Extended Chaining Enable (CTM = 0 only)** When set, enables extended chaining mode. **Note:** This bit is reserved in direct mode.	0 Extended chaining disabled. 1 Extended chaining enabled.

Table 15-38. DnMR Field Descriptions (Continued)

Bits	Reset	Description	Setting
CDSM/SWSM 4	0	**Current Descriptor Start Mode/Single-Write Start Mode** The function of this bit varies depending on the setting of XFE, CTM, and SRW. **Note:** This bit must be cleared when SRW is cleared.	CTM = 0 and XFE = 0 0 Normal operation. 1 Single-write start mode in which a write to the current link descriptor address register sets MR[CS] to start the DMA transfer. CTM = 0 and XFE = 1 0 Normal operation. 1 Single-write start mode in which a write to the current list descriptor address register sets MR[CS] to start the DMA transfer. *CTM = 1 and SRW = 0* 0 Normal operation. 1 A write to the current link descriptor address register sets MR[CS] to initiate a DMA transfer. *CTM = 1 and SRW = 1* 0 A write to the destination address register sets MR[CS] to initiate a DMA transfer. 1 A write to the source address register sets MR[CS] to initiate a DMA transfer.
CA 3	0	**Channel Abort** When set, causes the channel to abort the transfer and clear CB. The channel then remains idle until a new transfer is programmed.	0 No effect. 1 Abort current transfer.
CTM 2	0	**Channel Transfer Mode** When set, configures the controller in direct mode, which means that software must place all the required parameters into the necessary registers to start the DMA transfer.	0 Chaining mode. 1 Direct mode.
CC 1	0	**Channel Continue (chaining mode only)** When set, restarts the transferring process starting at the current descriptor address. This bit is reserved in external master mode. The bit is cleared automatically by hardware after the first descriptor read when continuing a transfer.	0 No effect. 1 Restarts the DMA transfer at the current descriptor address.
CS 0	0	**Channel Start** Stops or starts the DMA transfer. This bit is set automatically by hardware during single-write start mode and external master start enable mode.	0 Stops the DMA transfer if the channel is busy (SR[CB] is set), no effect if the channel is idle. 1 Starts the DMA process if the channel is idle (SR[CB] is cleared). Setting the bit while the channel is busy continues the current transfer from the point at which it stopped.

15.10.31 Status Registers (DnSR*n*)

DnSR0 Status Registers 0–3 Offset 0x104
DnSR1 Offset 0x184
DnSR2 Offset 0x204
DnSR3 Offset 0x284

The status registers report various DMA conditions during and after a DMA transfer. **Table 15-39** describes the fields of the DnSR.

Table 15-39. DnSR Field Descriptions

Bits	Reset	Description	Setting
— 31–8	0	Reserved. Write to zero for future compatibility.	
TE 7	0	**Transfer Error** Indicates whether an error occurred during the DMA transfer. See **Section 15.5.6**, *DMA Errors,* on page 15-25 for details. **Note:** Write a 1 to this bit to clear it.	0 No error during the DMA transfer. 1 Error condition during the DMA transfer.
— 6	0	Reserved. Write to zero for future compatibility.	
CH 5	0	**Channel Halted** Indicates whether the transfer is halted. Attempts to halt a channel that is idle have no effect. If the bit is set, the channel was successfully halted by software and can be restarted.	0 Channel is not halted. 1 DMA successfully halted by software.
PE 4	0	**Programming Error** Indicates whether a programming error was detected that prevented the DMA transfer. **Note:** Write a 1 to this bit to clear it.	0 No programming error detected. 1 Programming error detected.
EOLNI 3	0	**End-of-Links Interrupt** After transferring the last block of data in the last link descriptor. if MR[EOLSIE] is set, then this bit is set and an interrupt is generated. **Note:** Write a 1 to this bit to clear it.	0 No end-of-links interrupt. 1 End-of-links interrupt.
CB 2	0	**Channel Busy** Indicates the current status of the channel.	0 Channel is idle, DMA transfer completed, error occurred, or a channel abort occurred. 1 DMA transfer is in progress.

Table 15-39. DnSR Field Descriptions (Continued)

Bits	Reset	Description	Setting
EOSI 1	0	**End-of-Segment Interrupt** In chaining mode, after finishing a data transfer, if MR[EOLSIE] is set or if CLNDAR[EOSIE} is set, then this bit is set and an interrupt is generated. In direct mode, if MR[EOSIE] is set, then this bit is set and an interrupt is generated. **Note:** Write a 1 to this bit to clear it.	0 No end-of-segment interrupt. 1 End-of-segment interrupt.
EOLSI 0	0	**End-of-List Interrupt** After transferring the last block of data in the last list descriptor, if MR[EOLSIE] is set, then this bit is set and an interrupt is generated. **Note:** Write a 1 to this bit to clear it.	0 No end-of-list interrupt. 1 End-of-list interrupt.

15.10.32 Current Link Descriptor Extended Address Registers (DnECLNDAR*n*)

DnECLNDAR0 Current Link Descriptor Extended Address Registers 0–3 Offset 0x108
DnECLNDAR1 Offset 0x188
DnECLNDAR2 Offset 0x208
DnECLNDAR3 Offset 0x288

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—												ECLNDA			
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnECLNDAR contains the extended address of the current link descriptor for the specified channel.

Note: These registers are only used for RapidIO transactions. They are not used for accesses to the internal RapidIO address space.

For RapidIO transactions in basic chaining mode, software must initialize this register and the Current Link Descriptor Address Register (DnCLNDAR) to point to the first link descriptor in memory. After the current descriptor is processed, the DnECLNDAR and DnCLNDAR are loaded from the Next Link Descriptor Extended Address Register (DnENLNDAR) and the Next Link Descriptor Address Register (DnNLNDAR). Then the controller evaluates the DnNLNDAR*n*[EOLND] field. If EOLND is cleared (0), the DMA controller reads in the new current link descriptor for processing. If EOLND is set (1), the last descriptor of the list has completed. If extended chaining mode is not enabled, all DMA transfers are complete and the DMA controller halts.

If extended chaining mode is enabled, the DMA controller examines the state of the EOLSD bit in the next list descriptor address register (DnNLSDAR). If EOLSD is clear, the controller loads the contents of the DnENLSDAR into the Current List Descriptor Extended Address Register (DnECLSDAR) and the contents of the DnNLSDAR into the DnCLSDAR and reads the new list descriptor from memory. If EOLSD is set, all DMA transfers are complete and the DMA controller halts. **Table 15-40** describes the DnECLNDAR fields.

Table 15-40. DnECLNDAR Field Descriptions

Bits	Reset	Description	Setting
— 31–4	0	Reserved. Write to zero for future compatibility.	

Table 15-40. DnECLNDAR Field Descriptions (Continued)

Bits	Reset	Description	Setting
ECLNDA 3–0	0	**Current Link Descriptor Extended Address** Contains the most significant 4 bits of the 36-bit address used with RapidIO transactions only. **Note:** This field is not used for local transactions.	

15.10.33 Current Link Descriptor Address Registers (DnCLNDAR*n*):

DnCLNDAR0 Current Link Descriptor Address Registers 0–3 Offset 0x10C
DnCLNDAR1 Offset 0x18C
DnCLNDAR2 Offset 0x20C
DnCLNDAR3 Offset 0x28C

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnCLNDAR contains the address of the current link descriptor for the specified channel. In basic chaining mode, software must initialize this register to point to the first link descriptors in memory. After the current descriptor is processed, the CLDAR is loaded from the NLNDAR and the NLNDAR*n*[EOLND] field in the DnNLNDAR is examined. If EOLND is zero, the DMA controller reads in the new current link descriptor for processing. If EOLND is set, the last descriptor of the list was just completed. If extended chaining mode is not enabled, all DMA transfers are complete and the DMA controller halts. If extended chaining mode is enabled, the DMA controller examines the state of DnNLSDAR*n*[EOLSD] in the DnNLSDAR. If EOLSD is clear, the controller loads the contents of the DnNLSDAR into the DnCLNDAR and reads the new list descriptor from memory. If EOLSD is set, all DMA transfers are complete and the DMA controller halts. **Table 15-41** describes the DnCLNDAR fields.

Table 15-41. DnCLNDAR Field Descriptions

Bits	Reset	Description	Setting
CLNDA 31–4	0	**Current Link Descriptor Address** Holds the current descriptor address of the buffer descriptor in memory. The descriptor must be 32-byte aligned. **Note:** This field is used for all transfers. For RapidIO transactions, it is the lower portion of the 36-bit address formed by combining with the ECLNDA for use with RapidIO transaction types.	

Table 15-41. DnCLNDAR Field Descriptions (Continued)

Bits	Reset	Description	Setting
EOSIE 3	0	**End-of-Segment Interrupt Enable** Enables/disables the end-of-segment interrupt at the completion of the current DMA transfer for the current link descriptor.	0 Do not generate end-of-segment interrupt. 1 Generate end-of-segment interrupt when transfer is complete.
— 2–0	0	Reserved. Write to zero for future compatibility.	

15.10.34 Source Attributes Registers (DnSATR*n*)

DnSATR0 Source Attributes Registers 0–3 Offset 0x110
DnSATR1 Offset 0x190
DnSATR2 Offset 0x210
DnSATR3 Offset 0x290

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnATR contains the transaction attributes to be used for the DMA operation on the specified channel. Stride mode is enabled by setting DnSATR[SSME]. Source read transaction type is specified using DnSATR[SREADTTYPE]. Attributes are derived from local access windows and outbound ATMU registers according to the transaction address.

Table 15-42 describes the fields of the DnSATR.

Table 15-42. DnSATR Field Descriptions

Bits	Reset	Description	Setting
— 31–25	0	Reserved. Write to zero for future compatibility.	
SSME 24	0	**Source Stride Mode Enable** Enables/disables source stride mode. When enabled, you must set the required stride size and distance in the Source Stride Register (SSR) for the specified channel. **Note:** This bit is ignored in basic mode (MR[EFE] is cleared (0).	0 Stride mode disabled. 1 Stride mode enabled.
— 23–20	0	Reserved. Write to zero for future compatibility.	
SREADTTYPE 19–16	0	**DMA Source Transaction Type** Specifies the source transaction type. **Note:** Writing a reserved value to this field causes a programming error to be detected and indicated in SR[PE] for the specified channel.	0100 Read, do not snoop local processor. All other values reserved.

Table 15-42. DnSATR Field Descriptions (Continued)

Bits	Reset	Description	Setting
— 15–4	0	Reserved. Write to zero for future compatibility.	
ESAD 3–0	0	**Extended Source Address** Represents the most significant 4 bits of the 36-bit source address of the DMA transfer with SARx.	

15.10.35 Source Address Registers (DnSAR*n*)

DnSAR0 Source Address Registers 0–3 Offset 0x114
DnSAR1 Offset 0x194
DnSAR2 Offset 0x214

The SAR contains the address from which the DMA controller reads data for the specified channel. In direct mode, if DnMR[CDSM/SWSM] and DnMR[SRW] are set, a write to this register simultaneously sets DnMR[CS], starting a DMA transfer. Software must ensure that this is a valid address. **Table 15-43** describes the DnSAR fields.

Table 15-43. DnSAR Field Descriptions

Bits	Reset	Description
Local Source		
SAD 31–0	0	**Source Address** Contains least significant 32 bits of the 36-bit source address of the DMA transfer. The contents are updated after every DMA write operation unless the final stride of a striding operation is less than the stride size, it which case it remains equal to the address from with the last stride began.

15.10.36 Destination Attributes Registers (DnDATR*n*).

DnDATR0 Destination Attributes Registers 0–3 Offset 0x118
DnDATR1 Offset 0x198
DnDATR2 Offset 0x218
DnDATR3 Offset 0x298

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	NLWR	—					DSME	—				DWRITETTYPE

The destination attributes registers contain the transaction attributes for the DMA operation. Stride mode is enabled by setting DnDATR[DSME] for the specified channel. Destination write transaction type is specified using the DnDATR[DWRITETTYPE] field.

The target interface is derived from the local access ATMU mapping and the transaction is obtained from the value specified in DnDATR[DWRITETTYPE] using the local address space category.

Table 15-44 describes the fields of the DATR.

Table 15-44. DnDATR Field Descriptions

Bits	Reset	Description	Setting
— 31	0	Reserved. Write to zero for future compatibility.	
NLWR 30	0	**No Last Write With Response** Used to indicate whether the last write requires a target response. The ROWARx[WRTYP] value selects the write transaction type. If NLWR is cleared, then the last write transaction is NWRITE_R instead of SWRITE or NWRITE, depending on the value of ROWARx[WRTYP]. If NLWR is set, the last write transaction is performed as specified by the value of ROWARx[WRTYP].	0 Last write transfer is a write with target response. 1 Last write transfer is a write without target response.
— 20–25	0	Reserved. Write to zero for future compatibility.	
DSME 24	0	**Destination Stride Mode Enable** Enables/disables destination stride mode. When enabled, you must set the required stride size and distance in the Destination Stride Register (DSR) for the specified channel. **Note:** This bit is ignored in basic mode (MR[EFE] is cleared (0).	0 Stride mode disabled. 1 Stride mode enabled.
— 23–20	0	Reserved. Write to zero for future compatibility.	

Table 15-44. DnDATR Field Descriptions (Continued)

Bits	Reset	Description	Setting
DWRITETTYPE 19–16	0	**DMA Destination Transaction Type** Specifies the destination transaction type. **Note:** Writing a reserved value to this field causes a programming error to be detected and indicated in SR[PE] for the specified channel.	0100 Write. All other values reserved.
— 15–4	0	Reserved. Write to zero for future compatibility.	
EDAD 3–0	0	**Extended Destination Address** Represents the most significant 4 bits of the 36-bit destination address of the DMA transfer with DARx.	

15.10.37 Destination Address Registers (DnDAR*n*)

DnDAR0 Destination Address Registers 0–3 Offset 0x11C
DnDAR1 Offset 0x19C

The DnENLNDAR contains the extended address of the next link descriptor for the specified channel.

Note: These registers are only used for RapidIO transactions. They are not used for accesses to the internal RapidIO address space.

For RapidIO transactions in basic chaining mode, software must initialize this register and the NLNDAR to point to the next link descriptor in memory. After the current descriptor is processed, the ECLNDAR and CLNDAR are loaded from the ENLNDAR and the NLNDAR. Then the controller evaluates the NLNDAR*n*[EOLND] field. If EOLND is cleared (0), the DMA controller reads in the new current link descriptor for processing. If EOLND is set (1), the last descriptor of the list has completed. If extended chaining mode is not enabled, all DMA transfers are complete and the DMA controller halts.

If extended chaining mode is enabled, the DMA controller examines the state of the EOLSD bit in the next list descriptor address register (NLSDAR). If EOLSD is clear, the controller loads the contents of the ENLSDAR into the ECLSDAR and the contents of the NLSDAR into the CLSDAR and reads the new list descriptor from memory. If EOLSD is set, all DMA transfers are complete and the DMA controller halts. **Table 15-47** describes the ENLNDAR fields.

Table 15-47. DnENLNDAR Field Descriptions

Bits	Reset	Description	Setting
— 31–4	0	Reserved. Write to zero for future compatibility.	
ENLNDA 3–0	0	**Next Link Descriptor Extended Address** Contains the most significant 4 bits of the 36-bit address used with RapidIO transactions only. **Note:** This field is not used for local transactions.	

15.10.40 Next Link Descriptor Address Registers (DnNLNDAR*n*)

DnNLNDAR0 Next Link Descriptor Address Registers 0–3 Offset 0x128
DnNLNDAR1 Offset 0x1A8
DnNLNDAR2 Offset 0x228
DnNLNDAR3 Offset 0x2A8

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	NLNDA															
Type	R/W

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	NLNDA											—	NDEOSIE	—		EOLND
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnNLNDAR contains the address of the next link descriptor for the specified channel. In basic chaining mode, software must initialize this register to point to the first link descriptors in memory. After the current descriptor is processed, the CLDAR is loaded from the DnNLNDAR and the DnNLNDAR*n*[EOLND] field in the DnNLNDAR is examined. If EOLND is zero, the DMA controller reads in the new current link descriptor for processing. If EOLND is set, the last descriptor of the list was just completed. If extended chaining mode is not enabled, all DMA transfers are complete and the DMA controller halts. If extended chaining mode is enabled, the DMA controller examines the state of DnNLSDAR*n*[EOLSD] in the DnNLSDAR. If EOLSD is clear, the controller loads the contents of the NLSDAR into the CLNDAR and reads the new list descriptor from memory. If EOLSD is set, all DMA transfers are complete and the DMA controller halts. **Table 15-48** describes the DnNLNDAR fields.

Table 15-48. DnNLNDAR Field Descriptions

Bits	Reset	Description	Setting
NLNDA 31–5	0	**Next Link Descriptor Address** Holds the descriptor address of the next buffer descriptor in memory. The descriptor must be 32-byte aligned. **Note:** This field is used for all transfers. For RapidIO transactions, it is the lower portion of the 36-bit address formed by combining with the ENLNDA for use with RapidIO transaction types.	
— 4	0	Reserved. Write to zero for future compatibility.	
NDEOSIE 3	0	**Next Descriptor End-of-Segment Interrupt Enable** Enables/disables the next descriptor end-of-segment interrupt when the current DMA transfer for the current link descriptor completes.	0 Do not generate next descriptor end-of-segment interrupt. 1 Generate next descriptor end-of-segment interrupt when transfer is complete.
— 2–1	0	Reserved. Write to zero for future compatibility.	

Table 15-48. DnNLNDAR Field Descriptions (Continued)

Bits	Reset	Description	Setting
EOLND 0	0	**End-of-Links Descriptor** Indicates whether the descriptor is the last descriptor in memory for this list. **Note:** This bit is ignored in direct mode.	0 Not the last descriptor for this list. 1 Last descriptor for this list.

15.10.41 Extended Current List Descriptor Address Registers (DnECLSDAR*n*)

DnECLSDAR1 Extended Current List Descriptor Address Registers 0–3 Offset 0x1B0
DnECLSDAR2 Offset 0x230
DnECLSDAR3 Offset 0x2B0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—												ECLSDA			
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnECLSDAR contains the extended address of the current address of the list descriptor in memory in extended chaining mode for the specified channel.

Note: These registers are only used for RapidIO transaction types. They are not used for accesses to the internal RapidIO address space.

In extended chaining mode, software must initialize this register and DnCLSDAR to point to the first list descriptor in memory. After finishing the last link descriptor in the current list, the DMA controller loads the contents of the DnENLNDAR and the DnNLNDAR. Then the controller evaluates the DnNLSDAR*n*[EOLSD] field. If EOLSD is cleared (0), the DMA controller reads in the new current list descriptor for processing. If EOLND is set (1) and the last link of the current list is finished, all DMA transfers are complete. **Table 15-49** describes the DnECLSDAR fields.

Table 15-49. DnECLSDAR Field Descriptions

Bits	Reset	Description	Setting
— 31–4	0	Reserved. Write to zero for future compatibility.	
ECLSDA 3–0	0	**Current List Descriptor Extended Address** Contains the most significant 4 bits of the 36-bit address used with RapidIO transactions only. **Note:** This field is not used for local transactions.	

15.10.42 Current List Descriptor Address Registers (DnCLSDAR*n*)

DnCLSDAR0 Current List Descriptor Address Registers 0–3 Offset 0x134
DnCLSDAR1 Offset 0x1B4
DnCLSDAR2 Offset 0x234
DnCLSDAR3 Offset 0x2B4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnCLSDAR contains the address of the current list descriptor for the specified channel. In extended chaining mode, software must initialize this register to point to the first list descriptor in memory. After finishing the last link descriptor in the current list, the DMA controller loads the contents of the DnENLSDAR and the DnNLSDAR. Then the controller evaluates the DnNLSDAR*n*[EOLSD] field. If EOLSD is cleared (0), the DMA controller reads in the new current list descriptor for processing. If EOLND is set (1) and the last link of the current list is finished, all DMA transfers are complete. **Table 15-50** describes the DnCLSDAR fields.

Table 15-50. DnCLSDAR Field Descriptions

Bits	Reset	Description	Setting
CLSDA 31–5	0	**Current List Descriptor Address** Holds the current list descriptor address of the buffer descriptor in memory. The descriptor must be 32-byte aligned. **Note:** This field is used for all transfers. For RapidIO transactions, it is the lower portion of the 36-bit address formed by combining with the ECLSDA for use with RapidIO transaction types.	
— 4–0	0	Reserved. Write to zero for future compatibility.	

15.10.43 Extended Next List Descriptor Address Registers (DnENLSDAR*n*)

DnENLSDAR0 Extended Next List Descriptor Address Registers 0–3 Offset 0x138
DnENLSDAR1 Offset 0x1B8
DnENLSDAR2 Offset 0x238
DnENLSDAR3 Offset 0x2B8

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—												ENLSDA			
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnENLSDAR contains the extended address of the next address of the list descriptor in memory. If the contents are transferred to the current list descriptor address register, they become effective for the current transfer in extended chaining mode for the specified channel.

Note: These registers are only used for RapidIO transaction types. They are not used for accesses to the internal RapidIO address space.

Table 15-51 describes the DnENLSDAR fields.

Table 15-51. DnENLSDAR Field Descriptions

Bits	Reset	Description	Setting
— 31–4	0	Reserved. Write to zero for future compatibility.	
ENLSDA 3–0	0	**Next List Descriptor Extended Address** Contains the most significant 4 bits of the 36-bit address used with RapidIO transactions only. **Note:** This field is not used for local transactions.	

15.10.44 Next List Descriptor Address Registers (DnNLSDAR*n*)

DnNLSDAR0 Next List Descriptor Address Registers 0–3 Offset 0x13C
DnNLSDAR1 Offset 0x1BC
DnNLSDAR2 Offset 0x23C
DnNLSDAR3 Offset 0x2BC

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	NLSDA											—				EOLSD
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnNLSDAR contains the address of the next address of the list descriptor in memory. If the contents are transferred to the current list descriptor address register, they become effective for the current transfer in extended chaining mode for the specified channel. **Table 15-52** describes the DnNLSDAR fields.

Table 15-52. DnNLSDAR Field Descriptions

Bits	Reset	Description	Setting
NLSDA 31–5	0	**Next List Descriptor Address** Holds the next list descriptor address of the buffer descriptor in memory. The descriptor must be 32-byte aligned. **Note:** This field is used for all transfers. For RapidIO transactions, it is the lower portion of the 36-bit address formed by combining with the ENLSDA for use with RapidIO transaction types.	
— 4–1	0	Reserved. Write to zero for future compatibility.	
EOLSD 0	0	**End-of-Lists Descriptor** Indicates whether the descriptor is the last list descriptor in memory. When the bit is set, the DMA controller halts after the last link descriptor transaction finishes. **Note:** This bit is ignored in direct mode.	0 Not the last list descriptor in memory. 1 Last list descriptor in memory.

15.10.45 Source Stride Registers (DnSSR*n*)

DnSSR0 Source Stride Registers 0–3 Offset 0x140
DnSSR1 Offset 0x1C0
DnSSR2 Offset 0x240
DnSSR3 Offset 0x2C0

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—								SSS							
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	SSS				SSD											
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The DnSSR contains the source stride size and distance. Note that the source stride information is loaded when a new list descriptor is read from memory. Therefore, the DnSSR applies for all link descriptors in the new list. Changing the source stride information for a link requires that a new list be generated. **Table 15-52** describes the DnSSR fields.

Table 15-53. DnSSR Field Descriptions

Bits	Reset	Description
— 31–24	0	Reserved. Write to zero for future compatibility.
SSS 23–12	0	**Source Stride Size** Holds the number of bytes to transfer before jumping to the next address as specified in the source stride distance field.
SSD 11–0	0	**Source Stride Distance** The source stride distance in bytes from the start byte to the end byte.

15.10.46 Destination Stride Registers (DnDSR*n*)

DnDSR0 Destination Stride Registers 0–3 Offset 0x144
DnDSR1 Offset 0x1C4
DnDSR2 Offset 0x244
DnDSR3 Offset 0x2C4

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—								DSS

The DMA general status register combines all of the status bits from each channel into one register. This register is read-only. **Table 15-55** describes the fields of the DnDGSR.

Table 15-55. DnDGSR Field Descriptions

Bits	Reset	Description	Setting
TE0 31	0	**Channel 0 Transfer Error** Indicates whether a transfer error occurred.	0 Normal operation. 1 Error condition occurred during DMA transfer.
— 30	0	Reserved. Write to zero for future compatibility.	
CH0 29	0	**Channel 0 Halted** Indicates whether the channel halted.	0 Channel not halted. 1 Channel halted.
PE0 28	0	**Channel 0 Programming Error Detected** Indicates whether a programming error was detected.	0 Normal operation. 1 Programming error detected.
EOLNI0 27	0	**Channel 0 End-of-Links Interrupt** Indicates whether an end-of-links interrupt occurred.	0 Normal operation. 1 End-of-links interrupt occurred.
CB0 26	0	**Channel 0 Busy** Indicates whether the channel is busy.	0 Channel not busy. 1 Channel busy.
EOSI0 25	0	**Channel 0 End-of-Segment Interrupt** Indicates whether an end-of-segment interrupt occurred.	0 Normal operation. 1 End-of-segment interrupt occurred.
EOLSI0 24	0	**Channel 0 End-of-Lists/Direct Interrupt** Indicates whether an end-of lists/direct interrupt occurred.	0 Normal operation. 1 End-of-list/direct interrupt occurred.
TE1 23	0	**Channel 1 Transfer Error** Indicates whether a transfer error occurred.	0 Normal operation. 1 Error condition occurred during DMA transfer.
— 22	0	Reserved. Write to zero for future compatibility.	
CH1 21	0	**Channel 1 Halted** Indicates whether the channel halted.	0 Channel not halted. 1 Channel halted.
PE1 20	0	**Channel 1 Programming Error Detected** Indicates whether a programming error was detected.	0 Normal operation. 1 Programming error detected.
EOLNI1 19	0	**Channel 1 End-of-Links Interrupt** Indicates whether an end-of-links interrupt occurred.	0 Normal operation. 1 End-of-links interrupt occurred.

Table 15-55. DnDGSR Field Descriptions (Continued)

Bits	Reset	Description	Setting
CB1 18	0	**Channel 1 Busy** Indicates whether the channel is busy.	0 Channel not busy. 1 Channel busy.
EOSI1 17	0	**Channel 1 End-of-Segment Interrupt** Indicates whether an end-of-segment interrupt occurred.	0 Normal operation. 1 End-of-segment interrupt occurred.
EOLSI1 16	0	**Channel 1 End-of-Lists/Direct Interrupt** Indicates whether an end-of lists/direct interrupt occurred.	0 Normal operation. 1 End-of-list/direct interrupt occurred.
TE2 15	0	**Channel 2 Transfer Error** Indicates whether a transfer error occurred.	0 Normal operation. 1 Error condition occurred during DMA transfer.
— 14	0	Reserved. Write to zero for future compatibility.	
CH2 13	0	**Channel 2 Halted** Indicates whether the channel halted.	0 Channel not halted. 1 Channel halted.
PE2 12	0	**Channel 2 Programming Error Detected** Indicates whether a programming error was detected.	0 Normal operation. 1 Programming error detected.
EOLNI2 11	0	**Channel 2 End-of-Links Interrupt** Indicates whether an end-of-links interrupt occurred.	0 Normal operation. 1 End-of-links interrupt occurred.
CB2 10	0	**Channel 2 Busy** Indicates whether the channel is busy.	0 Channel not busy. 1 Channel busy.
EOSI2 9	0	**Channel 2 End-of-Segment Interrupt** Indicates whether an end-of-segment interrupt occurred.	0 Normal operation. 1 End-of-segment interrupt occurred.
EOLSI2 8	0	**Channel 2 End-of-Lists/Direct Interrupt** Indicates whether an end-of lists/direct interrupt occurred.	0 Normal operation. 1 End-of-list/direct interrupt occurred.
TE3 7	0	**Channel 3 Transfer Error** Indicates whether a transfer error occurred.	0 Normal operation. 1 Error condition occurred during DMA transfer.
— 6	0	Reserved. Write to zero for future compatibility.	
CH3 5	0	**Channel 3 Halted** Indicates whether the channel halted.	0 Channel not halted. 1 Channel halted.
PE3 4	0	**Channel 3 Programming Error Detected** Indicates whether a programming error was detected.	0 Normal operation. 1 Programming error detected.
EOLNI3 3	0	**Channel 3 End-of-Links Interrupt** Indicates whether an end-of-links interrupt occurred.	0 Normal operation. 1 End-of-links interrupt occurred.
CB3 2	0	**Channel 3 Busy** Indicates whether the channel is busy.	0 Channel not busy. 1 Channel busy.
EOSI3 1	0	**Channel 3 End-of-Segment Interrupt** Indicates whether an end-of-segment interrupt occurred.	0 Normal operation. 1 End-of-segment interrupt occurred.
EOLSI3 0	0	**Channel 3 End-of-Lists/Direct Interrupt** Indicates whether an end-of lists/direct interrupt occurred.	0 Normal operation. 1 End-of-list/direct interrupt occurred.

15.10.48 Local Access Window Base Address Registers 0–9 (DnLAWBAR[0–9])

DnLAWBAR0 Local Access Window Base Address Registers 0–9 Offset 0x1C08

SRDSB1RSTCTL contains the control/status bits for the SerDes PHY and protocol converter for port 0 and SerDes PLL1.

Note: Always write to reserved bits with the value they return when read. That is, when programming the register, read the value, modify appropriate fields, and write the modified value back to the register.

Note: The SerDes Port uses a base address of 0xFFFAD000.

Table 15-60 describes the SRDSB1RSTCTL fields.

Table 15-60. SRDSB1RSTCTL Field Descriptions

Bits	Description	Settings
RSTREQ 31	**SerDes Reset Request** Resets the SerDes PLL1 lock detection and test circuitry and also resets all logic in all lanes associated with SerDes PLL1. To initiate a SerDes reset, software writes a 1. The reset state machine clears the bit before reset is completed. **Note:** Software can only set this bit but not clear it. If the bit cleared before reset is complete, the reset state machine ignores the change.	0 No reset requested. 1 SerDes reset requested.
— 30–0	Reserved. Write to zero for future compatibility.

L[A–J]TCSR3 contains functional control bits for the test control/status logic on lanes A to J.

Note: The SerDes Port uses a base address of 0xFFFAD000.

Table 15-67 describes the L[A–J]TCSR3 fields.

Table 15-68. L[A–J]TCSR3 Field Descriptions

Bits	Reset	Description	Settings
— 31–30	0	Reserved. Write to zero for future compatibility.	
LPBK_EN 29–28	Configured by Reset	**Loopback Enable** Enables loopback from the Tx serializer to the Rx amplifier to allow for on-chip system check. The recommended settings for all protocols is 00. **Note:** Loopback using PCI-Express requires Root Complex configuration for the PCI Express interface. End point loopback is not supported.	00 Application mode. 01 Digital loopback. 10 Reserved. 11 Reserved.
— 27–0	0	Reserved. Write to zero for future compatibility.	

16 Serial RapidIO Controller and Enhanced Message Complex

The RapidIO controller supports a high-performance, point-to-point, low-pin-count, packet-switched system-level interconnect that can be used in a variety of applications as an open standard. The RapidIO architecture provides a rich variety of features, including high data bandwidth, low-latency capability, and support for high-performance I/O devices. RapidIO technology provides message passing and software-managed programming models. The MSC8157E includes a serial RapidIO subsystem that supports two RapidIO ports and a shared enhanced messaging unit (eMSG) that comply with the *RapidIO Interconnect Specification, Revision 1.3* and includes some features defined by *Revision 2.1*. The RapidIO subsystem provides pass-through support, direct inbound I/O, indirect outbound I/O (using the HSSI DMA controllers), and direct messaging. Data throughput is managed using a buffer manager (BMLite) and a frame manager (FMLite).

The MSC8157E device can connect directly to a host, another MSC8157E device, or a serial RapidIO switch. Each port in the switch is point-to-point connected to the MSC8157E device through a serial RapidIO link that typically carries packets in both directions. Packets ready for processing are transported from the host to the MSC8157E, and the processed packets are transported from the MSC8157E device back to the host.

The Serial RapidIO controller directs the traffic flow between the MSC8157E and any other RapidIO device through the eMSG for messages and doorbells and through the RapidIO DMA channels for NWRITEs, NWRITE_Rs, NREADs, and SWRITEs.

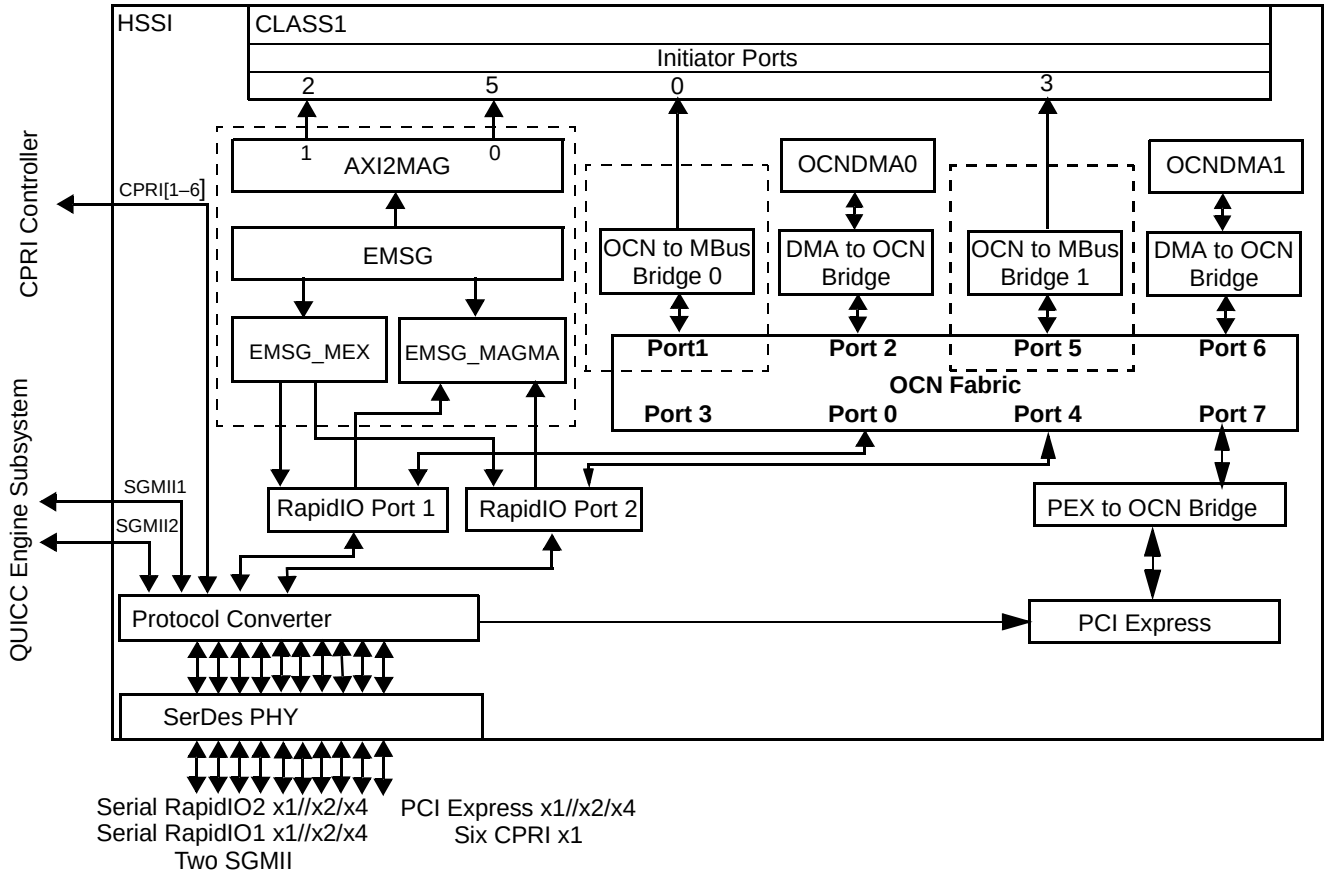
The RapidIO subsystem is supported by the HSSI (see **Chapter 15**, *High Speed Serial Interface (HSSI) Subsystem*), which includes the following:

- CLASS1 non-blocking fabric to provide a high-speed connection to the system CLASS
- Two HSSI DMA controllers for outbound I/O traffic
- OCN packet-based 64-bit interconnect fabric using 6 ports
- Protocol multiplexing unit
- Single 10-lane SerDes PHY that supports both RapidIO controllers in x4 or x2 or x1 mode at 1.25, 2.5, 3.125, or 5.0 Gbaud per lane.
- Performance monitoring

The host and the MSC8157E communicate as follows:

- The host sends messages to the destination MSC8157E device, which are sent back to the host after processing along with a short doorbell interrupt.
- Messages eliminate the latency of read accesses. The host writes to the MSC8157E and the MSC8157E writes to the host. In addition, messages can be used in applications where the host does not know the internal memory structure of the target DSP.
- The host can directly access the data in the MSC8157E memory for both reads and writes. It handshakes with the software running on a DSP core through buffer descriptors (BDs) that are messaged from the DSP core to the host.
- The host can put all the data buffers into its memory and have the MSC8157E access the data.
- Any initiator on the RapidIO system can access any internal memory space as well as the DDR SDRAM using NREAD, NWRITE, MESSAGE, and DOORBELLS. In addition, it can configure the RapidIO messaging and configuration unit using maintenance packets.
- The MSC8157E can perform NREAD, NWRITE, NWRITE_R, SWRITE, or MAINTENANCE accesses to any device directly connected to it, or to any other device that is part of the RapidIO interconnection through RapidIO switches. This capability is in addition to the MESSAGES and DOORBELL transactions already described.

Figure 16-1 shows a block diagram of the HSSI



Note: The actual signal multiplexed for each channel in the PHY is determined by the SerDes configuration field contents in the lower 32 bits of the reset configuration word, which are recorded in RCWLR[SP]. See **Chapter 5**, *Reset* for details.

Figure 16-1. HSSI Block Diagram

16.1 Serial RapidIO and eMSG Complex Overview

This section summarizes the Serial RapidIO controller and eMSG features, operating modes, and signal functionality.

16.1.1 Serial RapidIO Ports

The serial RapidIO interface provides a RapidIO port to communicate with other RapidIO devices. **Figure 16-2** shows the RapidIO port unit.

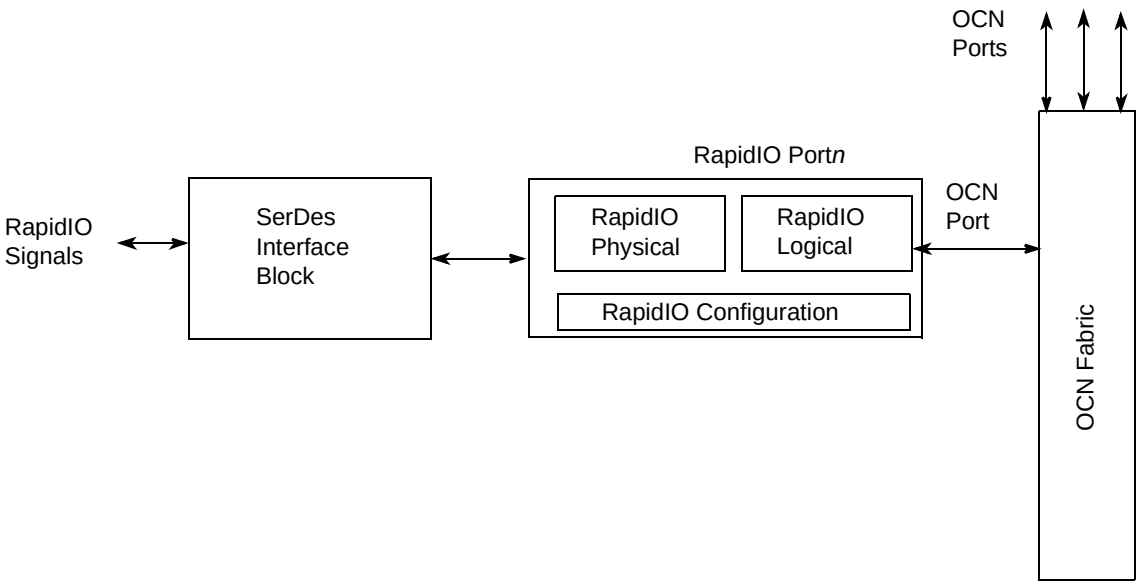


Figure 16-2. RapidIO Endpoint

The RapidIO port supports the following sections of the *RapidIO Interconnect Specification, Revision 2.1*, including all transaction flows and priorities:

- Small or large size transport information field only.
- 34-bit addressing.
- Up to 256-byte data payload.
- Up to eight outstanding unacknowledged RapidIO transactions.
- Hardware recovery only.
- All transaction flows and all priorities
- Critical request flow (CRF) as described in the *RapidIO Interconnect Specification, Revision 1.3*, Part 6: 1x/rx LP-Serial Physical Layer Specification.
- Register and register bit extensions as described in the *RapidIO Interconnect Specification, Revision 1.2, Part VIII: Error Management Extensions Specification*.
- Hot swap
- ATOMIC set/clr/inc/dec for read-modify-write operations

- IO_READ_HOME and FLUSH w/data for accessing cache-coherent data from a remote memory system
- Only supports receiver-controlled flow control
- Inbound transactions to the configuration registers are limited to 32-bit accesses only.
- Outbound maintenance transactions can be any valid size.

RapidIO endpoint supports the following user-defined features:

- Nine outbound ATMU windows with each window having up to 32 subwindows except the default window
- Five inbound ATMU windows
- Logical outbound packet time-to-live counter to prevent local processor from hanging when the RapidIO interface fails
- Accept-all mode of operation for failover support
- RapidIO random bit error injection
- Performance monitor interface

RapidIO endpoint supports the following features of RapidIO LP-Serial:

- 1x, 2x, and 4x LP-Serial link interfaces
- Transmission rates of 1.25, 2.5, 3.125, and 5 Gbaud (data rates of 1.0, 2.0, 2.5, and 4.0 Gbps) per lane
- Auto detection of 1x, 2x, and 4x mode operation during port initialization
- Error detection for packets and control symbols
- Support for link initialization, synchronization, error recovery, and time-out

The individual RapidIO endpoint does not support the following features of RapidIO LP-Serial:

- RapidIO endpoint cannot be configured as four 1x or two 2x ports

16.1.2 eMSG Unit

The eMSG supports the following:

- *RapidIO Interconnect Specification Revision 1.3*, Part 1: NWRITE and Streaming writes.
- *RapidIO Interconnect Specification Revision 1.3*, Part 2: Message Passing Logical Specification.
- *RapidIO Interconnect Specification Revision 1.3*, Part 10: Data Streaming Logical Specification.
- *RapidIO Interconnect Specification Revision 2.0*, Part 10: Stream Management Flow Control. Basic stream management flow control (XON/XOFF) using extended header message format.

- 4 Kbyte virtual memory space for partition of resources in a multi-core environment.
- 32-bit address space.
- 24 concurrent inbound reassembly operations with flow-based reservation of reassembly resources.
- One or more Type11 outbound message units with the following features:
  - byte transfers with automatic padding to double-word size.
  - supports multicast and non-multicast single segment messages to 32 RapidIO destinations and non-multicast multiple segment messages.
  - transmitting to any mailbox and extended mailbox for a single segment message.
  - segment size up to 256 bytes.
  - up to sixteen segment messages with a total payload of up to 4 Kbyte.
  - one entire message (up to 16 message segments) can be transmitted before receiving any response.
  - one entire single segment message to all multicast destination (up to 32) can be transmitted before receiving any response.
- One or more Type5 NWrite outbound units with up to 64 Kbyte total data payload.
- One or more Type6 outbound streaming write outbound units with up to 64 Kbyte total data payload.
- One or more Type11 message inbound classification units with the following features:
  - transaction steering through message header classification.
  - segment size up to 256 bytes.
  - up to sixteen segment messages with a total payload of up to 4 Kbyte.
  - all message responses are upgraded to priority 3.
- One or more Type9 data streaming inbound classifications units with the following features:
  - transaction steering through packet header classification.
  - support for concurrent interleaved Protocol Data Units (PDUs).
- One or more Type9 data streaming outbound segmentation units with up to 64 Kbyte total data payload.
- One or more Type10 doorbell inbound classification units:
  - transaction steering through doorbell header classification.
  - all doorbell responses are upgraded to priority 3.
- One or more Type10 doorbell outbound units with ordering maintained with respect to other types of traffic.
- One or more Type8 port-write inbound classification units with the following features:
  - transaction steering through port-write header classification.
  - data payloads of 4 to 64 bytes.
- One or more Type8 outbound port-write units with data payloads of 4 to 64 bytes.

- Multicast mode for Type11 in which a single segment message (256 bytes or less) is sent to multiple destinations.

RapidIO endpoint does not support or has limited support for the following features of the *RapidIO Interconnect Specification, Revision 1.3*:

- ATOMIC transaction in either direction.
- Coherent (CC-NUMA) transactions.
- Transmitter-controlled flow control.
- No support for multicast event control symbols.

The RapidIO endpoint incorporates the following features:

- Both controllers supports x4/x2/x1 modes
- Transmission rates of 1.25, 2.5, 3.125, and 5.0 Gbaud (data rates of 1.0, 2.0, 2.5, and 4 Gbps, respectively).
- Auto detection of x1/x2/x4 mode operation during port initialization.
- Error detection for packets and control symbols.
- Link initialization, synchronization, error recovery, and time-out.

RapidIO endpoint does not support the following features of RapidIO x1/x2/x4 operation:

- RapidIO endpoint cannot be configured as four x1 ports.

16.1.3 Internal Processing Support

The block includes the following support modules:

- *Queue Manager (QMLite)*. Facilitates the processing of message queues using 16-byte command descriptors (CD).
- *Buffer Manager (BMLite)*. Performs a memory reservation resource allocation function by reserving sets of buffers in memory (internal in M2/M3 and external in DDR memory) for use in message processing. By maintaining blocks of available reserved memory buffer space, the queue manager and eMSG unit can request and have access to memory without additional arbitration or the risk of the memory location being overwritten by another master device. The individual producers and consumers increment their respective indices by the number of entries they are producing/consuming. Their PI/CI registers wrap to 0x0 at twice the size of the ringer buffer. For example, the values for a 16-entry PI/CI ring wrap to 0x0 when they reach 0x1F. A 32-entry ring wraps to 0 when it reaches 0x3F, and so on. Using PI/CI values that are one bit wider than needed to address the ring entries means that the *(PI/CI) mod (index–width)* gives the correct fit of the ring buffer over the entire range where full can be distinguished from empty.

16.1.4 Operating Modes

The main operating modes of the RapidIO ports are as follows:

- x1/x2/x4 LP-Serial link interfaces (both controllers)
- Transmission rates of 1.25. 2.5, 3.125, and 5.0 Gbaud (data rates of 1.0, 2.0, 2.5, and 4.0 Gbps, respectively).

Note: Transferring high data rates at 5 Gbaud in x1 mode is not recommended and can result in excessive errors (including CCS, CRC, DE, and PE) and dropped data. For high data rates, use 5 Gbaud in x2 or x4 mode. For lower data rates, use 3.125 Gbaud, 2.5 Gbaud, or 1.25 Gbaud in x1, x2, or x4 mode.

- Small or large size transport information field.
- Accept-all mode of operation; all packets are accepted regardless of the target ID.

The main operating modes of the message unit are as follows:

- Outbound message controllers:
  - *Direct mode*. There are no descriptors, and software must initialize the required fields before starting a transfer.
  - *Chaining mode*. Software must initialize descriptors in memory and the required fields before starting a transfer.
  - *Multicast mode*. Single-segment messages can be transferred up to 32 destinations.
- Inbound message controllers:
  - *Direct mode*. There are no descriptors, and software must initialize the required fields before starting a transfer.

16.1.5 x1/x2/x4 LP-Serial Signals

Table 16-1 describes the serial RapidIO signal functionality. For details on electrical characteristics, refer to the *RapidIO Interconnect Specification, Revision 1.2*.

Table 16-1. Serial Rapid I/O Interface Signals

Port Name	Description	System Connection	I/O	Active State	Reset
SD_TX[0–3]/ SD_TX[0–3]	**Transmit Data** Serial data output for the x1 or x4 link. One differential pair output per link. This implementation supports data rates of 1.25, 2.5, 3.125, or 5 Gbaud.	Primary output pads. Asynchronous outputs.	O	—	x
SD_RX[0–3]/ SD_RX[0–3]	**Receive Data** Serial data input for x1 or x4 link. One differential pair input per link. This implementation supports data rates of 1.25, 2.5, 3.125, or 5 Gbaud.	Primary input pads. Asynchronous inputs.	I	—	x

16.1.6 RapidIO Interface Activation

There are two basic activation scenarios:

- Boot over the Serial RapidIO interface
- Non-boot operation

16.1.6.1 Initialization for Booting the MSC8157E DSP

When the RapidIO interface is use to boot the MSC8157E, the serial RapidIO master device waits for the boot program to complete the default initialization and then initializes the interface by loading code and data into the device memory. For details, see **Section 6.2.4**, *Serial RapidIO Interconnect*, on page 6-21. In this scenario, the boot operation opens the lanes before the x4 sync sequence ends and the master device can begin accessing the RapidIO interface.

16.1.6.2 Initialization for Non-Boot Operation

When used for non-boot operations, the interface is connected to a serial RapidIO transmitting device, such as an MSBA8100, MSC8144, or another MSC8157E, for example. Sync signals are received over the Rx lines, although the Tx lines remain tri-stated. The device is unable to sync in x4 mode and times out because the Tx lines are tri-stated, and the interface syncs on x1 mode. To sync on x4 mode, the device must be disabled, by writing 0x50E00001 to it, which activates the lines, removing them from tri-state, and reactivates the device in x4 mode.

16.1.7 Link Training

During port initialization, the serial RapidIO port performs lane synchronization (detecting valid symbols on a lane) and lane alignment (coordinating multiple lanes to receive valid data across lanes). Internal errors in lane synchronization and lane alignment may cause failure to achieve link initialization at the configured port width. An SRIO port configured as an x4 port may see one of three scenarios:

- One or more lanes fail to achieve lane synchronization. Depending on which lanes fail, this may result in downtraining from x4 to x2, x4 to x1 on lane 0, x4 to x1 on lane R, x2 to x1 on lane 0, or x2 to x1 on lane R. (R indicates a lane other than lane 0).
- The link may fail to achieve lane alignment as a x4, even though all four lanes achieve lane synchronization, and downtrain to x2 or x1 mode.
- If the link downtrains to x2, it may fail to complete link initialization (that is, PnCCSR[PU]=0, indicating that the port initialized, but [PO]=0, indicating that the port is not OK).

A serial RapidIO port configured as x2 may downtrain to x1 on lane 0 or lane R because of the first scenario. A serial RapidIO port configured as n x1 may fail to complete port initialization

(PnCCSR[PU] will never deassert) because of the same scenario. Once a port completes link initialization successfully, it will operate normally.

To facilitate proper training, perform the following software sequences on each serial RapidIO port prior to initiating any traffic to that port.

16.1.7.1 Initialize Link

1. Ensure that the configured port width matches the actual port width in the system.
   a. If the configured port width is wider than the width supported by the link partner or system, the SRIO port will train down to the highest common denominator, causing a false detection of a training issue.
   b. The configured port width per port is readable in SERDES SRDSPCCR0.
2. Start a counter set to ~2 ms after the SERDES reset is complete (SERDES SRDSBnRSTCTL[RST_DONE]=1 for n corresponding to the SERDES bank/PLL for the SRIO port).
3. Poll the port uninitialized status (SRIO PnESCSR[PO]) until PO=1 or the counter expires. If the counter expires, the port has failed initialization: go to Reset Link
4. Read SRIO PnCCSR
   a. For a port configured as a x4, if IPW≠b010, the port has failed initialization: go to Reset Link.
   b. For a port configured as a x2, if IPW≠b011, the port has failed initialization: go to Reset Link
5. Continue with normal SRIO initialization procedures or software retraining sequence

16.1.7.2 Reset Link

1. Set SRIO PnCCSR[PD]=1
2. Wait 50 µs.
3. Set SERDES LmGCR0BnGCRm0[RRST]=0 for each bank n and lane m used by the SRIO port
4. The lanes used by the SRIO port are readable in SERDES SRDSPCCR0.
5. Read SERDES LmGCR0BnGCRm0 for each bank n and lane m in step 3
6. Wait ≥ 100 ns.
7. Set SERDES LmGCR0BnGCRm0 [RRST]=1 for each bank n and lane m in step 3
8. Read SERDES LmGCR0BnGCRm0 for each bank n and lane m in step 3
9. Wait ≥ 300 ns.
10. Write 1s to clear all bits in SRIO PnSLCSR
11. Set SRIO PnCCSR[PD]=0.

12. Go to Initialize Link (**Section 16.1.7.1**).

16.1.7.3 Software Retraining

If the serial RapidIO port needs to retrain for any reason (for example, link partner reset), execute the following modified software retraining sequence:

1. Software on the host must ensure that all RapidIO transactions have completed and link activity has stopped.
2. Set SRIO PnCCSR[PD]=1
3. Set SRIO PnPCR[OBDEN] on the host to enable the discarding of any pending packets. (There should be none if proper steps were taken to ensure there was no link activity.)
4. Clear SRIO PnPCR[OBDEN] on the host.
5. Configure new operating width (via PnCCSR[PWO]) or any other new configurations.
6. Go to Reset Link

Note: Step 1 of the Reset Link procedure is redundant with step 2 of Software Retraining sequence, but is not harmful to repeat.

Note: The retraining sequence resumes at step 7 after completing the Initialize Link sequence.

7. Poll PnESCSR[PO] on the host until it is set, which indicates the link has attained port and link initialization.
8. Poll PnESCSR[PO] on the agent until it is set, which indicates the link has attained port and link initialization.
9. Poll PnESCSR[OES] on the agent until it is clear, which indicates the link has completed the error recovery sequence initiated from the port disable.
10. Poll PnESCSR[OES] on the host until it is clear, which indicates the link has completed the error recovery sequence initiated from the port disable.
11. Clear the agent error and status registers.
12. Clear the host error and status registers.
13. Begin normal packet transfer.

16.1.8 Special Case of x2/x1 Modes

RapidIO devices that support x2 mode as well as x1 mode transmit data on both lane 0 and lane 1 even when operating as a x1 port. The Serial RapidIO specification requires a x1/x2 Mode Detect State Machine per port to distinguish between a x2 port (transmitting striped data) and a x1 port (transmitting identical data on lanes 0 and 1). The Freescale RapidIO controller may fail to

complete training if it tries to connect to a RapidIO device that supports x2 mode and x1 mode if the devices transmits the same data on lanes 0 and 1 when in x1 mode.

Note: Freescale Serial RapidIO controllers transmit only on lane 0 if initialized as x1 on lane 0 and only transmit on lane 1 when initialized as x1 on lane 1.

Always ensure that the serial RapidIO controller is configured to match the configured width of the link partner. The preferred mechanism is through the RCW configuration. To recover after detecting a training failure due to mismatched width configuration and before restarting traffic, execute the Software Retraining sequence documented in **Section 16.1.7.3** and disable x2 operation by configuring PnCCSR[PWO] equal to 0b010, 0b011, or 0b110.

16.2 RapidIO Interface Basics

This section summarizes the RapidIO transactions, packet format, and control symbols. It also discusses how the configuration registers are accessed via the RapidIO packets and the operation of the ATMU translation windows for translating RapidIO addresses to local physical addresses and vice versa.

16.2.1 RapidIO Transactions

The RapidIO endpoint supports the RapidIO I/O transactions listed in **Table 16-2**.

Table 16-2. RapidIO I/O Transactions

IO Transaction	FTYPE	TTYPE	Status	Description
NREAD	0010	0100	NA	Read
ATOMIC inc		1100		Read and post-increment with response
ATOMIC dec		1101		Read and post-decrement with response
ATOMIC set		1110		Read and set to all-1s with response
ATOMIC clr		1111		Read and set to all-0s with response
NWRITE	0101	0100		Write with no response
NWRITE_R		0101		Write with response
SWRITE	0110	N/A		Streaming-Write
MAINT read	1000	0000		Maintenance read
MAINT write		0001		Maintenance write
MAINT read response		0010	0000	Done maintenance read response
			0111	Error response
MAINT write response		0011	0000	Done maintenance write response
			0111	Error response
MAINT port-write		0100	NA	Maintenance port-write (

Table 16-2. RapidIO I/O Transactions (Continued)

IO Transaction	FTYPE	TTYPE	Status	Description
RESPONSE without data	1101	0000	0000	I/O done response
			0111	I/O error response
RESPONSE with data		1000	0000	I/O done response with data

16.2.2 Message Passing

The serial RapidIO interprocessor communication can use explicit messages instead of going through shared memory. A message can consist of up to 16 packets of up to 256 Byte (4 Kbyte maximum) or streaming up to 64 Kbyte. The receiver defines the memory location for the messages to be buffered. **Figure 16-3** shows how messages are passed.

Figure 16-3. Message Passing

Table 16-3 summarizes the RapidIO message passing transactions that are supported by this RapidIO endpoint.

Table 16-3. RapidIO Message Passing Transactions

MSG Transaction	FTYPE	TTYPE	Status	Description
DOORBELL	1010	NA	NA	Doorbell
MESSAGE	1011			Message
RESPONSE without data	1101	0000	0000	Doorbell done response
			0011	Doorbell retry response
			0111	Doorbell error response
		0001	0000	Message done response
			0011	Message retry response
			0111	Message error response

16.2.3 RapidIO Data Streaming (Type9) Transactions

Table 16-4 summarizes the RapidIO data streaming (type 9) transactions that are supported by this RapidIO endpoint.

Table 16-4. RapidIO Data Streaming Transactions

Data Streaming Header Type	FTYPE	Start	End	XH	Description
START	1001	1	0	0	Start segment packet.
SINGLE	1001	1	1	0	Single segment packet.
CONTINUATION	1001	0	0	0	Continuation segment packet.
END	1001	0	1	0	End segment packet.
FLOW CONTROL	1001	-	-	1	Flow Control packet.

16.2.4 RapidIO GSM Transactions

Table 16-5 summarizes the RapidIO GSM transactions that are supported by this RapidIO endpoint.

Table 16-5. RapidIO GSM Transactions

GSM Transaction	FTYPE	TTYPE	Status	Description
IO_READ_HOME	0010	0010	NA	I/O Read Home (limited to RapidIO packet generation only)
FLUSH w/data	0101	0001		GSM Flush with data (limited to RapidIO packet generation only)
RESPONSE without data	1101	0000	0000	GSM done response
			0011	GSM retry response
			0101	GSM done intervention response
			0111	GSM error response
RESPONSE with data		1000	0000	GSM done response
			0001	GSM data only response

16.2.5 RapidIO Packet Format

Table 16-6 summarizes the small transport field packet formats of RapidIO transaction types for LP-Serial operation. Details on packet fields are located in the *RapidIO Interconnect Specification, Revision 2.0.1*.

Note: RapidIO endpoint limits configuration read and write requests to 32-bit data accesses. The large transport field packet format extends the destination and source IDs to 16-bits each. The MSC8157E supports small and large transport fields (large at default), so, for large transport, the destination and source IDs are 16-bits wide according to the direction of the transaction.RapidIO Control Symbol Summary

Table 16-6. RapidIO Small Transport Field Packet Format

Transaction	Bits																
	32								32					16			64
	5	2	1	2	2	4	8	8	4	4	8	8	8	13	1	2	
NREAD, ATOMIC (inc/dec/inc/dec), IO_READ_HOME	ack ID	rsv =0	crf	prio	tt	ftype	dest ID	src ID	ttype	rdsize	src TID	addr			wd ptr	xam bs	NA
NWRITE_R, FLUSH w/data	ack ID	rsv =0	crf	prio	tt	ftype	dest ID	src ID	ttype	wrsize	src TID	addr			wd ptr	xam bs	dword 0 -> dword n

1. src TID[3] of [0:7] bus must be set to ‘1’ for doorbell accesses.

16.2.6 RapidIO Control Symbol Summary

Table 16-7 summarizes the x1/x2/x4 LP-Serial control symbols and their format. Refer to the *RapidIO Interconnect Specification, Revision 1.3* Part VI: Physical Layer x1/x2/x4 LP-Serial Specifications, Chapter 4 PCS and PMA Layers for 8B/10B data and special (/PD/, /SC/, idle, sync, skip, align) characters. The 32-bit LP-Serial control symbol is composed of the 8-bit special character and the 24-bit control symbol format.

Table 16-7. x1/x2/x4 LP-Serial Control Symbol Format

Bits						Description

16.2.7 Accessing Configuration Registers via RapidIO Packets

The RapidIO endpoint limits requests to configuration register space to 32-bit data accesses. If the order of completion is important, inbound configuration accesses should be assumed incomplete until an appropriate response is received. There should be only one outstanding configuration request at a time to ensure that requests complete in the intended order.

16.2.7.1 Inbound Maintenance Accesses

There are two recommended methods by which RapidIO transactions can target RapidIO configuration register space in local memory.

The first method is based on RapidIO NREAD and NWRITE_R requests hitting a RapidIO address window defined by the Local Configuration Space Base Address Command and Status Register (LCSxBA1CSR), which is described on **page 16-190**. If external configuration accesses are disabled (LLCR[ECRAB] = 1; see **page 16-218**), any configuration access through the LCSxBA1CSR window is denied. A 32-bit data payload of all zeros is returned for a non-maintenance configuration read.

Note: Only NWRITE_R requests can access the entire internal CCSR address space. Any other write transaction is denied and does not alter the registers.

The second method is based on RapidIO MAINT requests. This method allows an external device limited access to local RapidIO configuration register space. Any maintenance access beyond the first 64 KB of RapidIO configuration register space is denied (lower 64 KB contains RapidIO architecture registers; upper 64 KB contains RapidIO implementation registers). A 32-bit data payload of all zeros is returned for a read response.

A third method that uses an inbound ATMU window to translate RapidIO NREAD and NWRITE_R requests to configuration accesses is not recommended because it does not support the configuration access protection features offered by the LCSBA1CSR window and RapidIO MAINT requests.

16.2.7.2 Guidelines

The RapidIO endpoint limits configuration register space requests to 32-bit data accesses. If the order of completion is important, assume that inbound configuration accesses are incomplete until an appropriate response is received. It is suggested that only one outstanding configuration request be active at a time to ensure that requests are completed in the intended order. For inbound configuration write results that are immediately used by another transaction, perform an inbound configuration read immediately after the configuration write to ensure that the transaction uses the updated value of the accessed configuration register.

16.2.7.3 Outbound Maintenance Accesses

Outbound NREAD_R or NWRITE requests can be translated to a RapidIO maintenance request if the internal generated address falls within the bounds of an outbound ATMU window that is setup for generating a maintenance request. The ATMU window specifies the configuration offset, hop count, source and destination ID, and priority for the outbound RapidIO packet.

16.2.8 Interaction with the Message Unit

The RapidIO controller is designed to interact with a message unit, which provides it with a message passing architecture. Please see **Section 16.1.2**, *eMSG Unit*, on page 16-5 for details on the message passing architecture. There are both inbound (Rx) and outbound (Tx) interfaces with the message unit, in addition to the Rx and Tx interfaces with the system and link.

Figure 16-4 shows RapidIO controller interaction with the message unit.

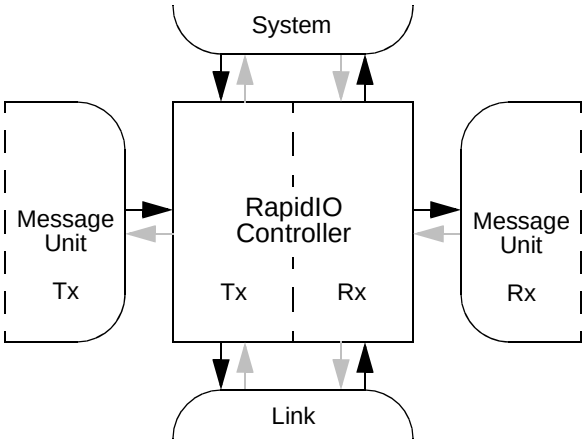

Figure 16-4. Interaction with the Message Unit

16.2.8.1 Inbound (Rx)

The inbound (Rx) interaction with the message unit is used receive message unit packets from the RapidIO link. The RapidIO link can receive message requests, responses, or flow control packets. The inbound interaction directs incoming packets to either the message unit or the controller based upon various RapidIO fields. Inbound message packets will be buffered into either a request or response queue before being sent out on the magenta interface. A round robin arbitration scheme is used to select the next transaction out to the message unit on the magenta bus.

16.2.8.2 Outbound (Tx)

The outbound (Tx) interaction with the message unit is used to transmit message unit packets to the RapidIO link. The message unit can transmit requests, responses, or flow control packets. Tx message unit packets are buffered within the RapidIO controller until they have been accepted on the link (received ack accepted). In addition, Tx message unit packets arbitrate with Tx system packets within the RapidIO controller before being transmitted to the link.

16.2.8.3 Buffer Allocation

The RapidIO controller contains buffers for Tx message unit packets. The buffers are separated into two categories...

- Tx message unit request packets
- Tx message unit response / flow control packets

Note: **Figure 16-5** shows the buffers for Tx message unit packets within the RapidIO controller.

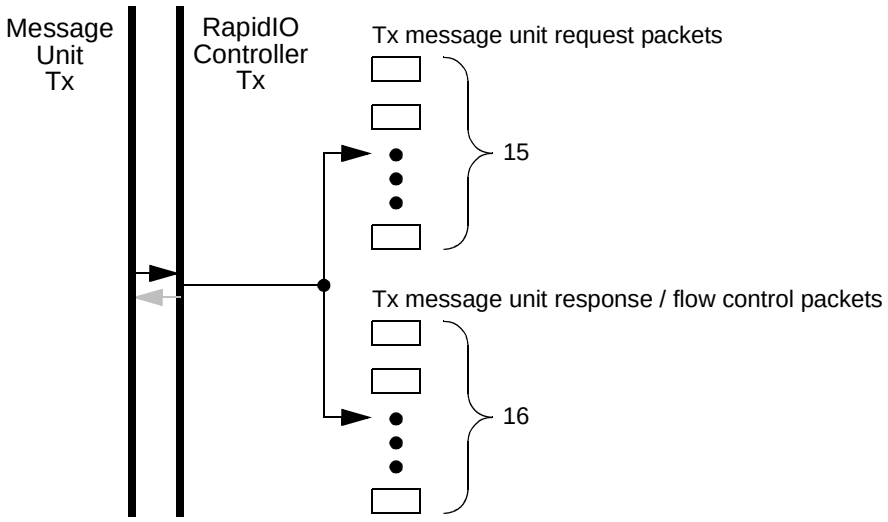

Figure 16-5. Tx Message Unit Packet Buffers

Within each category, there is dedicated and generic buffer allocation. Dedicated buffer allocation holds a specific type of message unit packet (within that category). Generic buffer allocation holds any type of message unit packet (within that category). Each buffer, regardless of its allocation (dedicated or generic), can only hold 1 message unit packet.

16.2.8.3.1 Tx Message Unit Request Packets

Tx message unit request packets have 8 types...

- Tx message unit request packet of arbitration group 0
- Tx message unit request packet of arbitration group 1
- Tx message unit request packet of arbitration group 2
- Tx message unit request packet of arbitration group 3
- Tx message unit request packet of arbitration group 4
- Tx message unit request packet of arbitration group 5
- Tx message unit request packet of arbitration group 6
- Tx message unit request packet of arbitration group 7

Each type mentioned above may have its own dedicated buffer allocation. In addition, there is also a generic buffer allocation (holds any of the types mentioned above). The number of dedicated and generic buffers for Tx message unit request packets is configurable with the following registers...

- **Section 16.4.1.53**, *Port n Message Request Tx Buffer Allocation Configuration Register 0 (PnMReqTxBACR0)*, on page 16-232
- **Section 16.4.1.54**, *Port n Message Request Tx Buffer Allocation Configuration Register 1 (PnMReqTxBACR1)*, on page 16-233

- **Section 16.4.1.55**, *Port n Message Request Tx Buffer Allocation Configuration Register 2 (PnMReqTxBACR2)*, on page 16-235

Note: There are only 15 buffers that hold message unit request packets. If the total value of the fields within the registers mentioned above exceeds 15 undefined behavior will result.

These registers are overwritten when the maximum arbitration group changes, which occurs with a write to a QMLite (OBMQDSCR1[AGQ7]) register. The new values support 1 dedicated buffer for each arbitration group, up to the maximum, and the remaining buffers are generic. The maximum total of all buffers (both dedicated and generic) is 15.

For example, when the maximum arbitration group is set to 7, then DedAG0[3:0] - DedAG7[3:0] is set to 0x1 (1 dedicated buffer for each arbitration group) and GenAG[3–0] is set to 0x7 (the remaining buffers are generic).

Another example, when the maximum arbitration group is set to 5, then DedAG0[3:0] - DedAG5[3:0] is set to 0x1, DedAG6[3:0]–DedAG7[3:0] are set to 0x0, and GenAG[3:0] is set to 0x9.

A user can change these registers after the maximum arbitration group changes. The new user values are used. A subsequent change of the maximum arbitration group overwrites the values of these registers again.

16.2.8.3.2 Tx Message Unit Response/Flow Control Packets

Tx message unit response/flow control packets have 2 types...

- Tx message unit response packet
- Tx message unit flow control packet

Each type may have its own dedicated buffer allocation. In addition, there is also generic buffer allocation (holds any of these types).

The number of dedicated and generic buffers for Tx message unit response/flow control packets is configurable using the following register...

- **Section 16.4.1.56**, *Port n Message Response/Flow Control Tx Buffer Allocation Configuration Register (PnMRspFcTxBACR)*, on page 16-236

Note: There are only 16 buffers that hold message unit response and flow control packets. The total value of the fields within the register mentioned above, must not exceed 16 (undefined behavior will result).

16.2.8.3.3 Arbitration

The RapidIO controller arbitrates amongst its Tx message unit packet buffers and an arbitration winner from the system packet buffers. Two main types of arbitration are used throughout: strict priority and weighted round robin. Strict priority arbitration, with starvation avoidance selects a winner based on priority. Starvation avoidance, which may be disabled, elevates lower priority requestors to the highest priority. This can only occur when a starvation avoidance counter has expired. This counter only counts when a requestor has lost. A counter threshold of 0s will disable this feature.

Note: Disabling starvation avoidance can cause deadlocks.

Weighted round robin arbitration selects a winner based on round robin, but with weights. The weights delay moving to the next requestor until a number, equal to the corresponding weight, of winners has been chosen. **Figure 16-6** shows the details of Tx message unit packet arbitration.

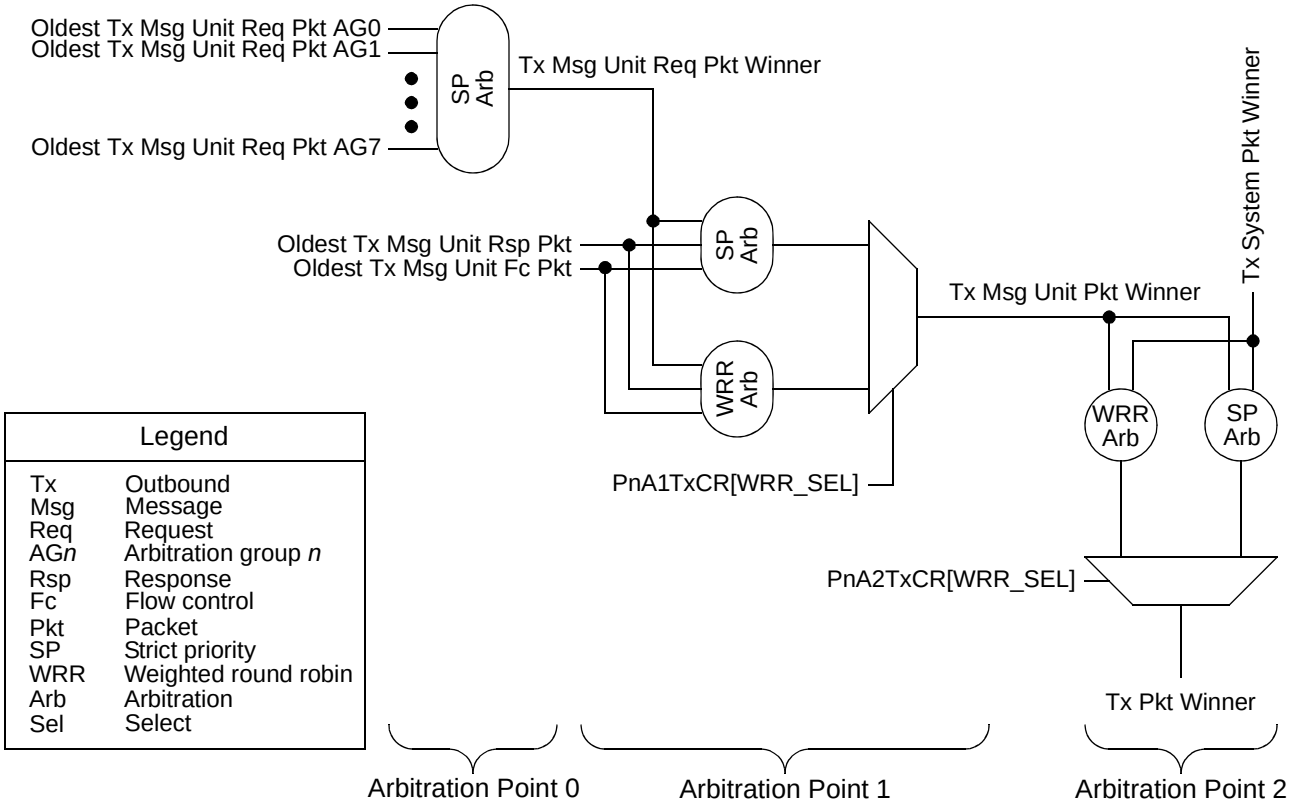

Figure 16-6. Tx Message Unit Packet Arbitration

16.2.8.3.3.1 Arbitration Point 0

Arbitration point 0 chooses a Tx message unit request packet winner. Only the oldest Tx message unit request packet of each arbitration group is eligible. Strict priority arbitration is used to select the winner. Tx message unit request packets of arbitration group 0 are the highest priority, and Tx message unit request packets of arbitration group 7 are the lowest.

Note: Arbitration point 0 is configurable with the following register...

- **Section 16.4.1.50**, *Port n Arbitration 0 Tx Configuration Register (PnA0TxCR)*

16.2.8.3.3.2 Arbitration Point 1

Arbitration point 1 chooses a Tx message packet winner. Only the Tx message unit request packet winner (chosen from arbitration point 0), the oldest Tx message unit response packet, and the oldest Tx message unit flow control packet are eligible. Two types of arbitration are available: strict priority and weighted round robin. If strict priority arbitration is selected, then the weighted round robin arbitration result is ignored. The RapidIO priorities (CRF and 2-bit priority field in the packet's header) of the 3 requestors (mentioned above) are compared. The packet with the highest RapidIO priority is chosen as the winner. In the case of a tie, round robin arbitration, based on past history, is used to select the winner.

If weighted round robin arbitration is selected, then the strict priority arbitration result is ignored. Each of the 3 requestors is considered, based on its corresponding weight, and a winner is chosen.

Arbitration point 1 is configurable with the following register...

- **Section 16.4.1.51**, *Port n Arbitration 1 Tx Configuration Register (PnA1TxCR)*

16.2.8.3.3.3 Arbitration Point 2

Arbitration point 2 chooses a Tx packet winner. Only the Tx message unit packet winner (chosen from arbitration point 1) and the system packet winner are eligible. Two types of arbitration are available: strict priority and weighted round robin. If strict priority arbitration is selected, then the weighted round robin arbitration result is ignored. The RapidIO priorities (CRF and 2-bit priority field in the packet's header) of the 2 requestors (mentioned above) are compared. The packet with the highest RapidIO priority is chosen as the winner. In the case of a tie, round robin arbitration, based on past history, is used to select the winner.

If weighted round robin arbitration is selected, then the strict priority arbitration result is ignored. Each of the 2 requestors is considered, based on its corresponding weight, and a winner is chosen.

Arbitration point 2 is configurable with the following register...

- **Section 16.4.1.52**, *Port n Arbitration 2 Tx Configuration Register (PnA2TxCR)*

16.2.9 RapidIO ATMU Implementation

The ATMU uses a set of registers to translate RapidIO packets to internal packets on inbound and to translate internal packets to RapidIO packets on outbound. ATMU window misses use the window 0 register set by default, and overlapping window hits result in the use of the lowest number window register set hit. For both inbound and outbound translation, the smallest window size is 4 K and the largest window size is 16 G for inbound translation and 64 G for outbound translation.

The default window register set causes no translation of the transaction address for inbound transactions because the RapidIO address space has 34 bits and the internal interconnect address space has 36 bits. For outbound transactions, the default window maps each of the four 16 G windows to the RapidIO 16 G address space.

The inbound and outbound translation windows must be aligned based on the granularity selected by the size fields. The packet device ID fields are not used in the inbound translation process, only the address field. The RapidIO endpoint implementation allows up to a 34-bit (0–33) RapidIO address and a 36-bit (0–35) internal interconnection address. The MSC8157E is confined to 32-bit internal addresses, therefore the top 4 bits (0–3) of the Inbound translation address and the outbound base address should be set to all 0; setting any of these bits results in undefined behavior.

As with all registers, an external processor writing the ATMU registers should never assume that the write is completed until a response is received.

Note: Booting from a serial RapidIO must always use outbound ATMU window 0.

16.2.9.1 RapidIO Outbound ATMU

All outbound windows have the capability to have 2 or 4 segments, all of which are equal in size, numbered 0–1, or 0–3, respectively. Each segment assigns attributes and the target deviceID for an outbound transaction. All segments of a window translate to the same translation address in the target. Additionally, each segment can be set up with 2, 4, or 8 subsegments, all of which are equal in size. These subsegments allow a single segment to target a number of numerically adjacent target device IDs, and, again, they all translate to the same translation address in the targets. For example, a segment with 8 subsegments can be configured to generate a transaction with the same set of attributes to target deviceIDs 0, 1, 2, 3, 4, 5, 6, or 7, depending on which subsegment is addressed.

Note: Subsegments are only supported when multiple segments are chosen.

This allows a window to be configured so that aliases can be created to the same offset within the target device so that a single window can be used to generate different transaction types. Without segmented windows, achieving the equivalent behavior would require multiple windows. **Figure 16-7** shows an example of this capability. A window is defined to be 4 Kbyte in size, and is defined to have 4 segments and no subsegments. Each segment is assigned to target deviceID 0x05, and each segment is given a different write transaction type attribute - segment 0 is assigned NWRITE, segment 1 is assigned SWRITE, segment 2 is assigned NWRITE_R, and segment 3 is assigned FLUSH. Since all of the segments are assigned to target the same device, by writing to the same offset in each segment, a different write transaction can be generated to the target to the same offset in the target.

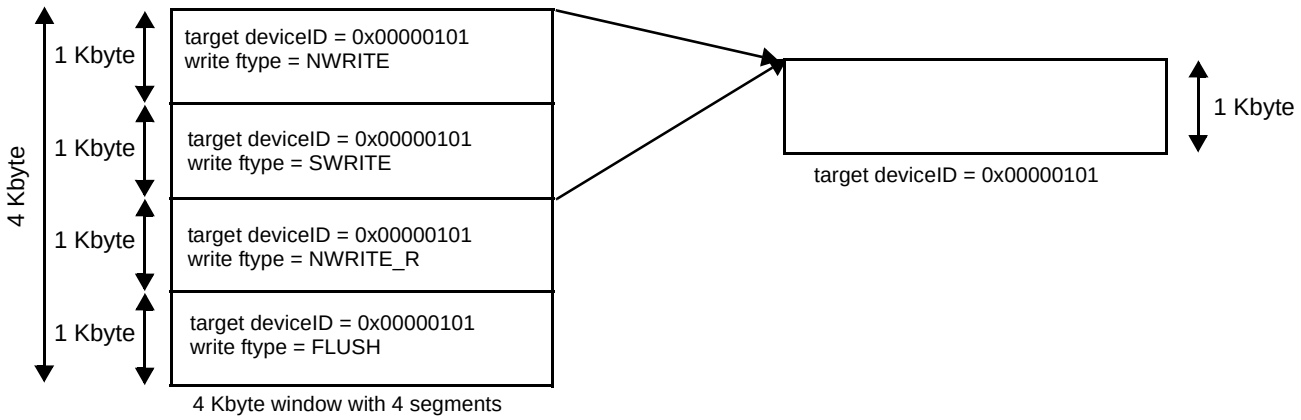

Figure 16-7. Single Target Example

So, writing to offset 0x0 in segment 0 is translated (as defined in the translation address registers) and generates a NWRITE transaction to offset 0x0 in a 1KB window in the target with deviceID = 0x05. A write to offset 0x0 in segment 2 is also translated, to the same offset in the target device as the write to segment 0, but this time a NWRITE_R transaction is generated. Another use is that the same window can be used to target multiple devices with the same translation offset. Without segmented (and subsegmented) windows, achieving the equivalent behavior would require multiple windows. **Figure 16-8** shows an example of this multi-targeting. For example, a 4kB window is set up with 2 segments of 2 subsegments. Each segment is assigned a write type of NWRITE, but each segment and subsegment has a different target deviceID. Segments 0 and 1 are assigned target deviceIDs 4 and 5, and 8 and 9, respectively.

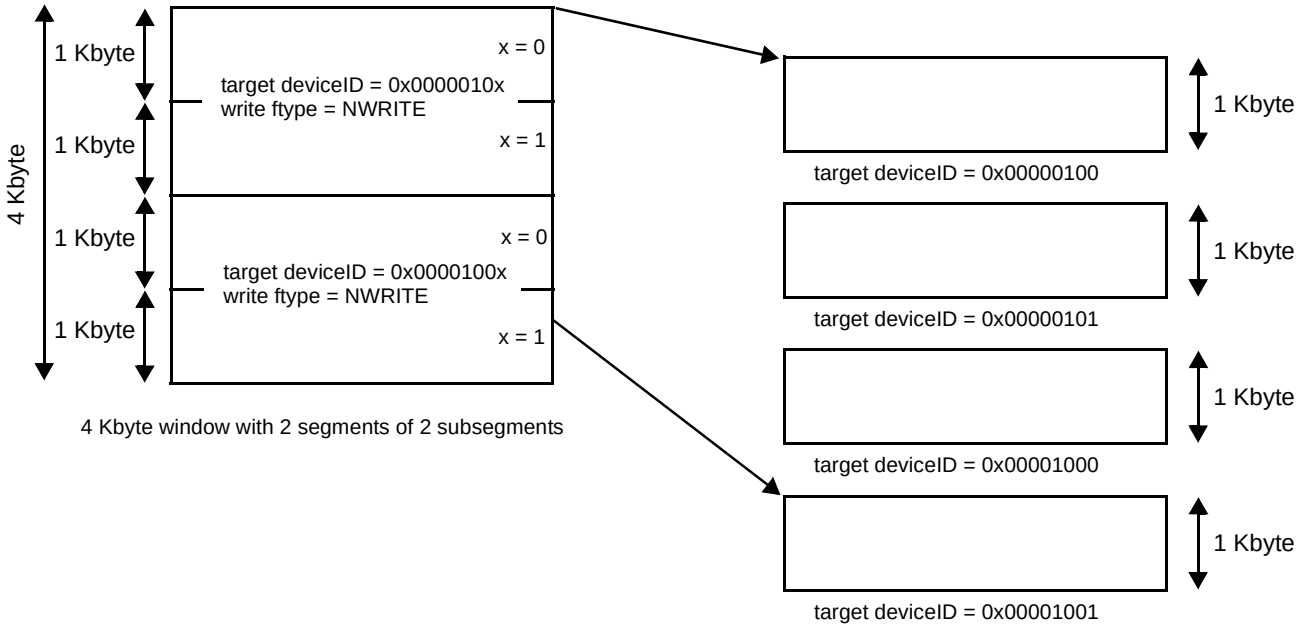

Figure 16-8. Multi-Targeting Example

In this example, a write to offset 0x0 in segment 0 is translated as defined, and a NWRITE transaction is generated targeted to deviceID 4. A corresponding write to segment 1 to offset 0x400 is also translated but also using the assigned deviceID instead of the translation address bits [22–29]. The generated NWRITE transaction has the same target device offset as the write to segment 0, but is instead targeted to deviceID 9. Combinations of aliasing and multi-targeting are also possible for a window.

16.2.9.2 Outbound Windows

RapidIO Endpoint implements nine outbound ATMU translation windows for translating local physical address to RapidIO address.

- Port n RapidIO Outbound Window Translation Address Registers 0–8 define the starting point for the RapidIO address translation and specify the RapidIO destination ID for the transaction.
- Port n RapidIO Outbound Window Attributes Registers 0–8 define the translation window size and specify the RapidIO transaction type and priority for the transaction.
- Port n RapidIO Outbound Window Segment 1–3 Registers 1–8 are used if the ATMU is segmented.

There are eight comparison windows.

- Port n RapidIO Outbound Window Base Address Register 1–8 represents the base address for each of the eight ATMU windows. The base address for each window must be aligned based on the translation window size specified in the Port n RapidIO Outbound Window Attributes Register 1–8.
- Port n RapidIO Outbound Window Translation Address Register 0 and Port n RapidIO Outbound Window Attributes Register 0 are the translation registers for the default ATMU window. It is used only if an NREAD, NWRITE, or NWRITE_R request misses all eight ATMU comparison windows.

16.2.9.3 Window Size and Segmented Windows

For the following discussion, RapidIO address[0–30] consists of xambs[0–1] and address[0–28] fields as defined in the RapidIO request packet format. RapidIO address is a 31-bit double-word physical address (or 34-bit byte address). Internal address[0–32] is a 33-bit double-word physical address (or 36-bit byte address).

The ATMU window hit definition and RapidIO address translation are as follows:

1. 4K window size (smallest window size)
   - A window hit is defined as {BEXADD[0–3], BADD[0–19]} matching internal address [0–23]
   - RapidIO addr[0–30] = {TREXAD[8–9], TRAD[0–19], internal address[24–32]}

2. 8K window size
   - A window hit is defined as {BEXADD[0–3], BADD[0–18]} matching internal address [0–22]
   - RapidIO addr[0–30] = {TREXAD[8–9], TRAD[0–18], internal address[23–32]}
3. 16K window size
   - A window hit is defined as {BEXADD[0–3], BADD[0–17]} matching internal address [0–21]
   - RapidIO addr[0–30] = {TREXAD[8–9], TRAD[0–17], internal address[22–32]}
4. Window sizes 32 K, 64 K, 128 K, 256 K, 512 K, 1 M, 2 M, 4 M, 8 M, 16 M, 32 M, 64 M, 128 M, 256 M, 512 M, 1 G, and 2 G are not shown
5. 4G window size
   - A window hit is defined as {BEXADD[0–3]} matching internal address [0–3]
   - RapidIO addr[0–30] = {TREXAD[8–9], internal address[4–32]}
6. 8G window size
   - A window hit is defined as {BEXADD[0–2]} matching internal address [0–2]
   - RapidIO addr[0–30] = {TREXAD[8], internal address[3–32]}
7. 16 G window size
   - A window hit is defined as {BEXADD[0–1]} matching internal address [0–1]
   - RapidIO addr[0–30] = {internal address[2–32]}

A window can be defined to be non-segmented or segmented depending on the NSEG field definition in the Port n RapidIO Outbound Window Attributes Register.

- A non-segmented window uses the specified RapidIO transaction type (RDTYP, WRTYP) and designated target ID (TGTID) without additional internal address comparison.
- A segmented window divides the specified window size into smaller sub-windows. A segmented window can be further divided into sub-segments as defined by the NSSEG field definition. The use of segmented and sub-segmented windows requires additional internal address comparison. There are two reasons for using a segmented ATMU window: allow a single ATMU window to generate different transactions types; allow a single ATMU window to generate multiple RapidIO target IDs.

Table 16-8 lists the various combination options.

Table 16-8. Outbound ATMU Window Segments

Desired Configuration		Registers That Need Configuration		Target ID		Transaction Type

			7	[7–3] = PnROWS3R1 [SGTGTDID], 0 = 0b110	[15–10] = PnROWTEAR0 [LTGTID], [9–8] = PnROWTAR0 [LTGTID], [7–3] = PnROWS3R1 [SGTGTDID], 0 = 0b110	
			8	[7–3] = PnROWS3R1 [SGTGTDID], 0 = 0b111	[15–10] = PnROWTEAR0 [LTGTID], [9–8] = PnROWTAR0 [LTGTID], [7–3] = PnROWS3R1 [SGTGTDID], 0 = 0b111	

The use of segmented windows impacts only the RapidIO transaction type or the destination ID. The internal address translation is a function of the Port n Outbound Window Translation Address Register and the translation window size.

16.2.9.3.1 Valid Hits to Multiple ATMU Windows

If a request hits multiple ATMU windows, window 1 has the highest priority of the nine outbound ATMU windows (windows 1–8, default). Window 2 is given the next highest priority and is followed by windows 3 through 8. The default window has the lowest priority. If a request hits (base address match) multiple ATMU windows and the transaction end address is contained within the boundary of each hit window and does not extend into another ATMU window, the translation window is the highest priority window that is hit.

If a lower priority window is programmed to lie entirely within a higher priority window, then it is possible for a transaction to cross window boundaries. Although not a practical programming application, the RapidIO endpoint handles this as follows:

1. If a request hits (base address match) an ATMU window (1–8) and the transaction end address extends into another ATMU window with lower priority but is still contained within the boundary of the hit window, the translation window is the hit window.

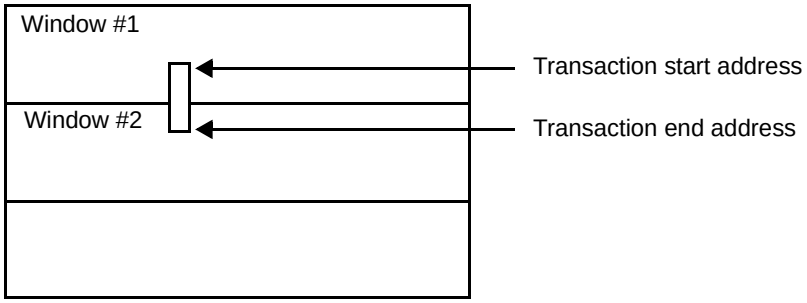

Figure 16-9. Valid Hit that Extends Into a Lower Priority Window

2. If a request hits (base address match) multiple ATMU windows (1–8) and the transaction end address extends beyond the boundary of a lower priority hit window but is still contained within the boundary of a higher priority hit window, the translation window is the highest priority window that is hit.

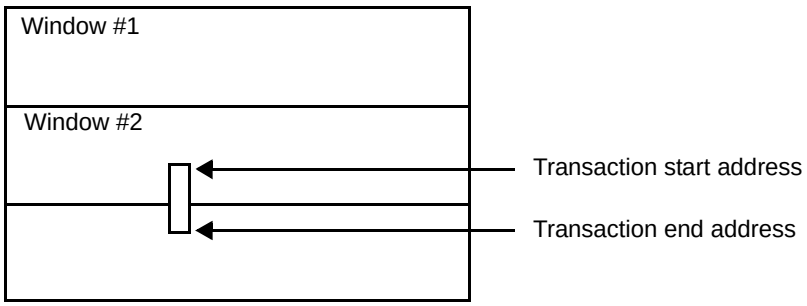

Figure 16-10. Valid Hit that Extends Beyond the Window Boundary

16.2.9.3.2 Window Boundary Crossing Errors

If a higher priority window is programmed to lie entirely within a lower priority window, then it is possible for a transaction to cross window boundaries. The RapidIO endpoint handles this as follows:

1. If a request hits (base address match) an ATMU window (1–8, default) and the transaction end address extends into another ATMU window with higher priority, an ATMU crossed boundary error is generated and logged. The outbound request is discarded.

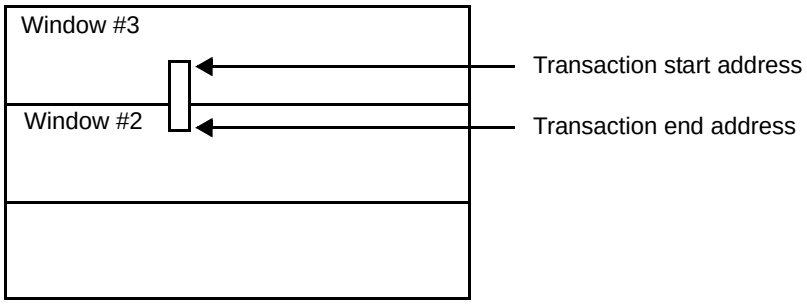

Figure 16-11. Boundary Crossing Error Due to Extension Into a Higher Priority Window

2. If a request hits multiple ATMU windows (1–8, default) and transaction end address extends beyond the boundary of a higher priority hit window, an outbound ATMU crossed boundary error is generated and logged. The outbound request is discarded.

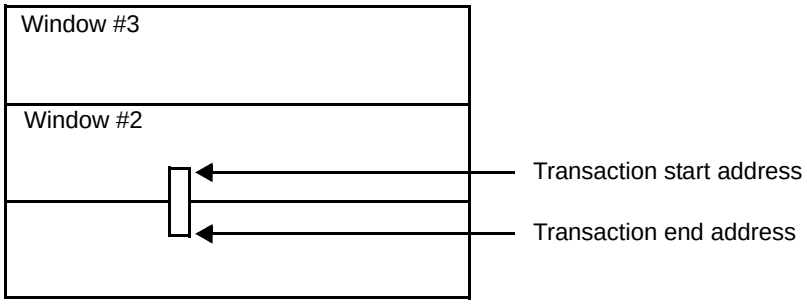

Figure 16-12. Boundary Crossing Error Due to Extension Beyond the Higher Priority Window Boundary

3. If a request hits (base address match) an ATMU window (1–8) and the transaction end address exceeds the size of the window, an outbound ATMU crossed boundary error is generated and logged. The outbound request is discarded.

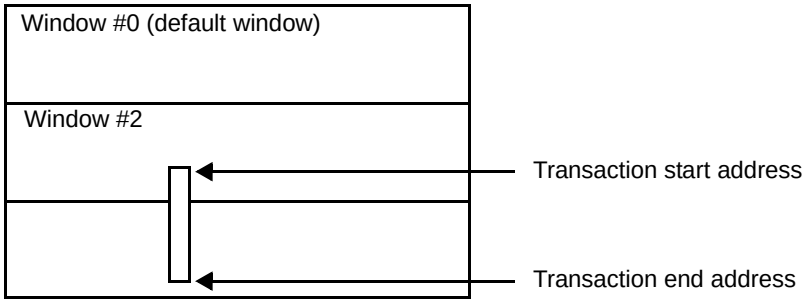

Figure 16-13. Boundary Crossing Error Due to Transaction Size Exceeding the Window Size

An internal error response is generated for internal requests that require a response. Boundary crossing errors (outbound ATMU boundary crossing, segment boundary crossing, and sub-segment boundary crossing) are logged in the LTLEDCSR[OACB] configuration register field. If a request misses all ATMU windows (1–8) and the transaction's end address exceeds the maximum size of the default window, an outbound ATMU crossed boundary error is not generated. The outbound request is forwarded to the RapidIO target device.

16.2.9.4 RapidIO Inbound ATMU

The RapidIO endpoint has five inbound ATMU translation windows for translating RapidIO addresses to local physical addresses. ATMU registers are used for inbound transactions. Their purpose is to translate RapidIO packets to on-device interconnect packets. ATMU window misses use the window 0 register set by default, and overlapping window matches result in the use of the lowest-number window register set in the match. For inbound translation, the smallest window size is 4 KB and the largest window size is 16G. The default window register set causes no translation of the transaction address for inbound transactions. The inbound translation windows must be aligned on the basis of the granularity selected by the size fields. The packet device ID fields are not used in the inbound translation process, only the address field.

The RapidIO endpoint implementation allows up to a 34-bit (0–33) RapidIO address and a 36-bit (0–35) internal addressing. The MSC8102 device is confined to 32-bit addresses, so the top 4 bits (0–3) of the inbound translation address should be set to all 0s. Other settings result in undefined behavior. An external processor should not assume that a write to any ATMU register is complete until a response is received. **Table 16-9** describes the registers for configuring the window parameters, along with the number of the page where each register is described in detail.

Table 16-9. ATMU Registers for Configuring Window Parameters

ATMU Registers	Acronym	Description	Page
Port 1–2 RapidIO Inbound Window Translation Address Registers 1–4	PnRIWTAR[1–4]	Define the starting-point for the RapidIO address translation.	**page 16-244**
Port 1–2 RapidIO Inbound Window Attributes Registers 1–4	PnRIWAR[1–4]	Define the translation window size and specify the internal priority, attributes, and the internal target port for the transaction.	**page 16-245**
Configuring the Four Comparison Windows			
The Port 1–2 RapidIO Inbound Window Base Address Registers 1–4	PnRIWBAR [1–4]	Represent the base address for each ATMU window. The base address must be aligned based on the translation window size specified in PnRIWAR 1–4	**page 16-245**
Port 1–2 RapidIO Inbound Window Translation Address Registers 0	PnRIWTAR0	Translation registers for ATMU window 0 (default window). Used for the following conditions: • NREAD, NWRITE_R request misses all four ATMU comparison windows and the LCSBA1CSR window. • NWRITE, SWRITE request misses all four comparison windows.	**page 16-244**
Port 1–2 RapidIO Inbound Window Attributes Register 0	PnRIWAR0		**page 16-245**

For the following discussion, RapidIO address[0–30] consists of xambs[0–1] and the address[0–28] fields as defined in the RapidIO request packet format. The RapidIO address is a 31-bit double-word physical address (or a 34-bit byte address). The ATMU translated address[0–32] is a 33-bit double-word physical address (or 36-bit byte address).

The ATMU window hit definition and RapidIO address translation are as follows:

- 4 KB window size (smallest window size):
  - A window hit is defined as {BEXADD[0–1], BADD[0–19]} matching RapidIO address [0–21].
  - Internal interconnection addr[0–32] = {TREXAD[0–3], TRAD[0–19], RapidIO address[22–30]}.
- 8 KB window size:
  - A window hit is defined as {BEXADD[0–1], BADD[0–18]} matching RapidIO address [0–20].
  - Internal interconnection addr[0–32] = {TREXAD[0–3], TRAD[0–18], RapidIO address[21–30]}.
- 16 KB window size:
  - A window hit is defined as {BEXADD[0–1], BADD[0–17]} matching RapidIO address [0–19].
  - Internal interconnection addr[0–32] = {TREXAD[0–3], TRAD[0–17], RapidIO address[20–30]}.

- Window sizes 32 KB, 64 KB, 128 KB, 256 KB, 512 KB, 1 MB, 2 MB, 4 MB, 8 MB, 16 MB, 32 MB, 64 MB, 128 MB, 256 MB, 512 MB, 1GB, 2 GB are not shown.
- 4 GB window size:
  - A window hit is defined as {BEXADD[0–1]} matching RapidIO address [0–1].
  - Internal interconnection addr[0–32] = {TREXAD[0–3], RapidIO address[2–30]}.
- 8 GB window size:
  - A window hit is defined as {BEXADD[0]} matching RapidIO address0.
  - Internal interconnection addr[0–32] = {TREXAD[0–2], RapidIO address[1–30]}.
- 16 GB window size (largest size):
  - A window hit is defined as any RapidIO address.
  - Internal interconnection addr[0–32] = {TREXAD[0–1], RapidIO address[0–30]}.

16.2.9.4.1 Hits to Multiple ATMU Windows

If a request hits multiple ATMU windows, window 1 has the highest priority of the five inbound ATMU windows (windows 1–4, default). Window 2 has the next highest priority, followed by windows 3 and 4. The default window has the lowest priority.

If a request hits (base address match) multiple ATMU windows and the transaction end address is contained within the boundary of each hit window and does not extend into another ATMU window, the translation window is the highest-priority window.

If a lower-priority window is programmed to lie entirely within a higher-priority window, then it is possible for a transaction to cross window boundaries. Although this is not a practical programming application, RapidIO Endpoint handles it as follows:

- If a request hits (base address match) an ATMU window (1–4) and the transaction end address extends into another ATMU window with a lower priority but contained within the boundary of the hit window, the translation window is the hit window.
- If a request hits (base address match) multiple ATMU windows (1–4) and the transaction end address extends beyond the boundary of a lower-priority hit window but is still contained within the boundary of a higher-priority hit window, the translation window is the highest priority window.

16.2.9.4.2 Window Boundary Crossing Errors

If a higher-priority window is programmed to lie entirely within a lower-priority window, then it is possible for a transaction to cross window boundaries. The RapidIO endpoint handles this situation as follows:

- If a request hits (base address match) an ATMU window (1–4, default) and the transaction end address extends into another ATMU window with a higher priority, an ATMU crossed boundary error is generated and logged.

- If a request hits multiple ATMU windows (1–4, default) and the transaction end address extends beyond the boundary of a higher priority hit window, an inbound ATMU crossed boundary error is generated and logged.

Other window boundary crossing errors are as follows:

- If a request hits (base address match) an ATMU window (1–4) and the transaction end address exceeds the size of the window, an inbound ATMU crossed boundary error is generated and logged.
- If a NREAD/NWRITE_R/NWRITE/SWRITE request hits (base address match) an ATMU window (1–4, default) and the transaction end address extends into the region defined as the local configuration space window, an inbound ATMU crossed boundary error is generated and logged.

A RapidIO error response is generated for RapidIO requests that require a response. RapidIO requests that do not require a response are dropped. Inbound ATMU boundary crossing errors are logged in the LTLEDCSR[IACB] configuration register. If a request misses all ATMU windows (1–4) and the transaction end address exceeds the maximum size of the default window, an inbound ATMU crossed boundary error is not generated.

16.2.10 Generating Link-Request/Reset-Device

In LP-Serial mode, the link partner cannot be reliably reset using the link-request/reset-device control symbols because the input port receiver cannot be disabled independently of the output port driver. The input port driver must be disabled to prevent non-idle control symbols from being transmitted between the four link-request/reset-device control symbols. For example, if a packet is received on the inbound side after one of the four link-request/reset-device control symbols is sent outbound, the required sequence of four link-request/reset-device symbols is interrupted with the packet acknowledgement (packet accept, packet retry, or packet not accept).

One method to reset the link partner is as follows.

1. Disable packet reception and transmission by setting the Port Lockout bit (PL bit = 1 in the Port n Control Command and Status Register).
2. Wait the appropriate amount of time for all outstanding packets transmitted on the link to be either retried, accepted or timed-out
3. Discard all outbound packets (OBDEN = 1 in Port n Physical Configuration Register) and clear all errors
4. Disable the input port receiver (IPD bit = 1 in the Port n Control Command and Status Register). This will allow the four consecutive link-request/reset-device control symbols to be generated with only idle control symbols between the link-request/reset-device control symbols.

5. Generate four link-request/reset-device control symbol using the Port n Link Maintenance Request register. Note that the link partner does not generate a link-response control symbol for a link-request/reset-device control symbol.
6. The link partner will expects the inbound and outbound Ack IDs to be 0 after being reset. Set the inbound and outbound Ack IDs to 0 (IA and OBA) by writing 0s to these fields in the Port n Local AckID Status Command and Status Register (PnLASCSR).
7. After the link partner has completed initialization indicated by the PO bit of Port n Error and Status Command and Status Register (PnESCSR), enable packets to be received and transmitted by clearing the Port Lockout bit (PL) in the Port n Control Command and Status Register (PnCCSR).

16.2.11 Outbound Drain Mode

The RapidIO port is placed into Drain mode when one of the following occurs:

- PnPCR[OBDEN] is set.
- he Failed Threshold has been encountered and the PnCCSR[SPF] and PnCCSR[DPE] are both set
- The packet time-to-live counter expires causing PnPCR[OBDEN] to be set

When the RapidIO port is placed into Drain mode, the RapidIO port discards all packets in the outgoing data stream. Since the data stream is invalid, the RapidIO port also puts its outbound port back to normal state. Any received acknowledgements and link-responses are considered invalid during this period (because the RapidIO port has cleared out all acknowledgement history).

The RapidIO port's outbound and outstanding ackID shows that all outstanding packets at the time Drain mode was entered were accepted, whether they were accepted or not. If the outbound ackID is not acceptable, then software should change it prior to taking the RapidIO port out of Drain mode. Also, if the link-partner needs to be returned to the inbound OK state, software should send a link-request/input-status. The recommended sequence for recovering from Drain mode is given in **Section 16.2.13**, *Software Assisted Error Recovery Register Support*, on page 16-59.

Setting PnPCR[OBDEN] also causes any queued packet acknowledgements to be discarded if the port is uninitialized; the RapidIO port allows them be transferred if the port is initialized. Drain mode due to Failed Threshold does not cause any packet acknowledgements to be dropped.

If a discarded packet in the outgoing data stream requires a logical response, a packet response time-out will occur if the packet response timer is enabled (PRTOCCSR is non 0).

16.2.12 Input Port Disable Mode

When PnCCSR[PD] is set, the RapidIO port is placed into Input Port Disable mode. This mode causes the following to occur:

- The RapidIO port discards all incoming data streams.
- Because the incoming stream is invalid, the RapidIO port returns it inbound port to the normal state. If an incoming packet is in progress when the RapidIO port is placed into Input Port Disable mode, the RapidIO port physical layer aborts the packet to the logical layer.
- The RapidIO port ends any packet capture that is in progress when the mode is invoked.
- The RapidIO port clears the link-request/reset-device count.
- The RapidIO port inbound ackID shows that all packets successfully received by the port before it entered Input Port Disable mode were accepted. If the outbound port entered Output Port Disable mode at the same time, however, some packet acknowledgements may be discarded by the RapidIO port. If the inbound ackID is not accepted, software should change it before taking the RapidIO port out of Input Port Disable mode.

16.2.13 Software Assisted Error Recovery Register Support

PnLMREQCSR is only supported for recovery from Drain mode. Therefore, software should only write to this register when the port is in Drain mode. The proper sequence for recovering from Drain mode is as follows:

1. Software ensures that link activity is stopped. This should include:

a. Software polls for Port OK bit to be set

b. Software waits longer than the link time-out value

2. Software generates a link-request/input-status to obtain the link-partner's inbound ackID value.
3. Software changes the RapidIO port's outbound ackID to this value (if necessary).
4. If the link-partner was hot-inserted, software changes the RapidIO port's inbound ackID to zero.

Note: If software can guarantee that the link-partner will not attempt to forward any packets to this RapidIO port, then software can write the outbound ackID of the link-partner to match the inbound ackID of this RapidIO port. However, if the link-partner attempts to forward another packet while this write is still outstanding, and the ackIDs is already lined up, then the write actually causes the ackIDs not to match, and the link is not recovered.

5. Software should cause the link-partner to send a link-request/input-status to ensure that the RapidIO inbound port is operating normally.
6. Software clears the Failed Encountered bit or the Output Buffer Drain Enable bit; whichever one caused the Drain mode (thus clearing Drain mode).

Software is responsible for timing software generated link-requests. If the response valid bit is not set in some reasonable period of time, the software should write another request in the register.

When software writes PnLMREQCSR, software should make sure that PnLMRESPCSR successfully reads as set; otherwise, software may read a stale ackID status/link status later.

Note: When the RapidIO port's outbound ackID is written by software using PnLASCSR, the inbound ackID is also written. Care must be taken to ensure that the inbound ackID is not written to an incorrect value. For example, PnCCSR[PL] could be set to prevent the inbound ackID from changing before PnLASCSR is written.

16.2.14 Errors and Error Handling

This section describes how the logical and physical layers detect RapidIO errors and respond to them. For details on the action of the SC3850 core when it is notified of any of these errors, see the *RapidIO Interconnect Specification, Revision 1.3,* part VII (Error Management Extensions Specifications).

16.2.14.1 RapidIO Error Description

RapidIO errors are classified under three categories: recoverable errors, notification errors, and fatal errors.

- *Recoverable errors*. Non-fatal transmission errors, such as a corrupt packet or corrupt control symbols and general protocol errors, for which there is hardware detection and recovery as described in the *RapidIO Interconnect Specification, Revision 1.3*. In these cases, the appropriate bit is set in the Port 1–2 Error Detect CSR. Only the packet containing the first detected recoverable error that is enabled for error capture (by the Port 1–2 Error Enable CSR) is captured in the Port 1–2 Error Capture CSRs. No interrupt is generated or actions required for a recoverable error. Recoverable errors are detected only in the physical layer.

- *Notification errors*. Non-recoverable non-fatal errors detected by RapidIO, such as degraded threshold, port-write received, and all logical/transport layer (LTL) errors captured. Because they are non-recoverable and in some cases have caused a packet to be dropped, notification by interrupt is available. However, because they are non-fatal, a response to the interrupt is not crucial to port performance. The port is still functional. When a notification error is detected, the appropriate bit is set in the error-specific register, an interrupt is generated, and in some cases, the error is captured. In all cases, the RapidIO port continues operating. Notification errors are detected in both the physical and logical layers.
- *Fatal errors*. There are two types of fatal errors:
  - *Exceeded failed threshold*. The port fails because its recoverable error rate has exceeded a predefined failed threshold. RapidIO sets the Output Failed-encountered bit in the Portn Error and Status CSR; the RapidIO output hardware may or may not stop (based on Stop-on-Port-Failed-Encounter-Enable and Drop-Packet-Enable bits).
  - *Exceeded consecutive retry*. The port fails because it has received too many packet retries in a row. The RapidIO controller sets the Retry Counter Threshold Trigger Exceeded bit in the Port 1–2 Implementation Error CSR; the RapidIO hardware continues to operate.

  In both cases, an interrupt is generated, and while the port continues operating at least partially, a system-level fix (such as reset) is recommended to clean up the RapidIO controller internal queues and resume normal operation. Fatal errors are detected only in the physical layer.

16.2.14.2 Physical Layer RapidIO Errors

Table 16-10 lists all the RapidIO link errors detected by the RapidIO endpoint physical layer and the actions taken by the RapidIO endpoint. The Error Enable column lists the control bits that can disable the error checking associated with a particular error. If this column is blank, error checking cannot be disabled. The Cause Field column indicates which cause field is used with the associated packet-not-accept control symbol for input error recovery. The EME Error Enable/Detect column indicates which bit of the PnERECSR (see **page 16-211**) allows the error to increment the error rate counter and lock the Port 1–2 Error Capture registers—and also which PnEDCSR bit is set when the error is detected (see **page 16-210**).

Table 16-11 shows the RapidIO endpoint behavior after certain preset limits are exceeded (degraded threshold, failed threshold, retry threshold). **Table 16-12** shows the threshold response.

Table 16-10. Physical RapidIO Errors Detected

Level	Error	Error Enable	RapidIO Endpoint Action	Cause Field	EME Error Type	EME Error Enable/ Detect
Recoverable Errors						
1a	Received character has a disparity error.		Enter input error stopped. Enter output error stopped.	5: Received invalid/illegal character	Delineation Error	DE
1a	Received an invalid character or valid but illegal character.		Enter input error stopped. Enter output error stopped.	5: Received invalid/illegal character		
1b	The four control character bits associated with the received symbol do not make sense (not 0000, 1000, 1111).		Enter input error stopped. Enter output error stopped.	5: Received invalid/illegal character		
1b	Control symbol does not begin with an /SC/ or /PD/ control character.		Enter input error stopped. Enter output error stopped.	5: Received invalid/illegal character		
1c	Received a packet with embedded idles.		Enter input error stopped.	5: Received invalid/illegal character		
1d	Received a control symbol with a bad CRC.	PnPCR[CCC] enables detect.	Enter input error stopped. Enter output error stopped.	2: Received a control symbol with bad CRC	Received corrupt control symbol	CCS
1d	Missing start: Packet data received without previous SOP control symbol.		Enter input error stopped.	7/31: General error	Protocol Error (unexpected packet/control symbol received)	PE
1e	Received packet that is < 64 bits.		Enter input error stopped.	7/31: General error		
1e	Received an EOP control symbol when no packet is received.		Enter input error stopped.	7/31: General error		
1e	Received a stomp control symbol when no packet is received.		Enter input error stopped.	7/31: General error		
2a	Received a restart-from-retry control symbol when in the OK state.		Enter input error stopped	7/31: General error	Protocol Error (unexpected packet/control symbol received)	PE
2a	Received packet with a bad CRC value.	PnPCR[CCP] enables detect.	Enter input error stopped.	4: bad CRC on packet.	Received packet with bad CRC	CRC
2a	Received packet which exceeds the maximum allowed size by the RapidIO spec.		Enter input error stopped.	7/31: General error	Received packet exceeds 276 Bytes	EM

Table 16-10. Physical RapidIO Errors Detected (Continued)

Level	Error	Error Enable	RapidIO Endpoint Action	Cause Field	EME Error Type	EME Error Enable/ Detect
2b	Received packet with unexpected ackID value (out-of-sequence ACKID)		Enter input error stopped.	1: Received unexpected ACKID on packet	Received packet with unexpected ackID	UA
2c	Received a non-maintenance packet when non-maintenance packet reception is stopped	Non-maint. packet reception stops when Input Port Enable = 0.	Enter input error stopped.	3: Non-maintenance packet reception stops	Not Captured	
2d	Any packet received while Port Lockout bit is set	All packet reception stops when Port Lockout bit is set.	Enter input error stopped.	3: Non-maintenance packet reception stops	Not Captured	
—	Received a Link request control symbol before servicing previous link request.	Not detected.				
2a	Received packet-not-accepted ACK control symbol.		Enter output error stopped.		Received packet-not-accepted symbol	PNA
2b	Received an ACK (accepted, or retry) control symbol when there are no outstanding packets		Enter output error stopped.		Unsolicited ACK symbol	UCS
2b	Received packet ACK (accepted) for a packet whose transmission has not finished		Enter output error stopped.			
2b	Received a Link response control symbol when no outstanding request.		Enter output error stopped.			
2c	Received an ACK (accepted or retry) control symbol with an unexpected ACKID.		Enter output error stopped.		Received ack. control symbol with unexpected ackID	AUA
2c	Link_response received with an ackID that is not outstanding		Re-enter Output Error Stopped.		Non-outstanding ackID	NOA
2d	An ACK control symbol is not received within the specified time-out interval.	PLTOCCSR [TV] > 0 enables detect.	Enter output error stopped.		Link time-out	LTO
2d	A Link response is not received within the specified time-out interval	PLTOCCSR [TV] > 0 enables detect.	(re-) Enter output error stopped.			

Table 16-11. Physical RapidIO Threshold Response

Error	Error Enable	RapidIO Endpoint Action	EME Error Type	Error Detect	Interrupt Clear*
Notification Errors					
Error rate counter exceeded the degraded threshold.	PnERTCSR[ERDTT] > 0 and any bit in PnERCSR enables detect and interrupt generation.	Generate interrupt. Continue to operate normally.	Degraded threshold	PnESCSR[ODE]	Write 1 to PnESCSR [ODE]
Fatal Errors					
Consecutive retry counter exceeded the retry counter threshold trigger	PRETCR[RET] > 0 enables detect and interrupt generation	Generate interrupt. Port is in priority order.	Consecutive retry threshold	PnIECSR[RETE]	Write 1 to PnIECSR [RETE]
Error rate counter exceeded the failed threshold.	PnERTCSR[ERFTT] > 0 and any bit in PnERCSR enables detect and interrupt generation.	Generate Interrupt. Port behavior depends on PnCCSR[SPF] and PnCCSR[DPE]. Port can continue transmitting packets or stop sending output packets, keeping or dropping them.	Failed threshold	PnESCSR[OFE]	Write 1 to PnESCSR [OFE]

Note: Information given here is minimal for clearing the interrupt. More detailed steps should be taken to find the cause of the interrupt, as described in the interrupt generation reference of the *RapidIO Interconnect Specification, Revision 1.2* Part VII (Error Management Extensions Specifications).

16.2.14.3 Logical Layer RapidIO Errors

This section describes how the logical layer detects and responds to RapidIO errors. The action of the core processor when it is notified of these errors is minimally described. For details, see the interrupt generation reference in the *RapidIO Interconnect Specification, Revision 1.3*, part VII (Error Management Extensions Specifications).

Table 16-12 through **Table 16-26** list all the errors detected by the RapidIO endpoint logical layer and the actions taken. Error responses are sent as follows:

- When the RapidIO endpoint action includes sending an error response to the system or the RapidIO interconnect, an error response is sent only if the original transaction is a request requiring a response. Otherwise, no error response is sent.
- For multiple errors, a discard of a packet has a higher priority than an error response.
- For misaligned transactions, the error management extension registers are updated with each child.

Table 16-12. Hardware Errors For NREAD Transaction

Error	Interrupt	Status Bit Set	Error Response	Comments
Priority Priority of read transaction is 3.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	RapidIO packet is dropped.
TransportType Received reserved TT	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
Received TT that is not enabled. Error valid is when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
DestID DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (pass_through | accept_all) is false.	Yes if LTLEECSR[ITTE] is set	LTLEDCSR[ITTE]	Yes	
SourceID Not Checked for error.				
TransactionType Received RapidIO packet with reserved TType for this ftype.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	
RdSize Not checked for error.				
SrcTID Not checked for error.				
Address:WdPtr:Xambs Read request hits overlapping ATMU windows Refer to **Section 16.2.9.4.2**, *Window Boundary Crossing Errors,* on page 16-56.	Yes if LTLEECSR[IACB] is set	LTLEDCSR[IACB]	Yes	
Address:WdPtr:Xambs Request hits a protected ATMU window or the local configuration space window.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	
Address:WdPtr:Xambs Beginning address matches LCSBA1CSR with no 32-bit read request. Performed only when ttype == 4'b0100.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	
Header Size Header size is not 12 bytes for small transport packet or not 16 bytes for large transport packet. Large transport packet has 14 valid bytes and two bytes of padding of 0s. Padding of 0s is not checked.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	Yes	
PayloadSize Not Applicable.				

Table 16-12. Hardware Errors For NREAD Transaction (Continued)

Error	Interrupt	Status Bit Set	Error Response	Comments
The Logical/Transport Layer Address Capture Command and Status Register described on **page 16-207** uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets packet bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bits 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-13. Hardware Errors For Maintenance READ/WRITE Request Transaction

Error	Interrupt	Status Bit Set	Error Response	Comments
Priority Priority of maintenance read or write request transaction is 3.	Yes if LTLEECSR[ITD] is set	LTLEDCSR[ITD]	No	RapidIO packet is dropped.
TransportType Received reserved TT.	Yes	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
Received TT that is not enabled. Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
DestID DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set	LTLEDCSR[ITTE]	Yes	
SourceID Not Checked for error.				
TransactionType Reserved transaction type for this ftype	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes	RapidIO packet is dropped.
RdSize Read/Write request size is not for 4 bytes.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes	
SrcTID Not checked for error.				

Table 16-13. Hardware Errors For Maintenance READ/WRITE Request Transaction

Error	Interrupt	Status Bit Set	Error Response	Comments
HopCount Not checked for error.				
Config Offset Not checked for error.				
Header Size Maintenance Read request Header size is not 12 bytes for a small transport packet or not 16 bytes for large transport packet. Maintenance Write request Total header size is not 12 bytes for a small transport packet or not 16 bytes for a large transport packet. Padding of 0s in last two bytes of large transport packet is not checked.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes	
PayloadSize Write request with payload not equal to 8 bytes. Read request with payload not 0 bytes	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes	
The Logical/Transport Layer Address Capture Command and Status Register described on **page 16-207** uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets packet bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bits 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-14. Hardware Errors For NWRITE, NWRITE_R

Error	Interrupt	Status Bit Set	Error Response	Comments
Priority Not UT	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped.
TransportType Received reserved TT.	Yes.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
Received TT that is not enabled. Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
DestID DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error is valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	Yes for NWRITE_R. No for NWRITE.	RapidIO packet is dropped for NWRITE.
SourceID Not applicable.				
TransactionType	Yes if LTLEECSR[UT] is set.	LTLEDCSR[UT]	Yes	
TransactionType Received RapidIO packet with reserved TType for this ftype. Packet is treated as Nwrite Transaction.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes for NWRITE_R. No for NWRITE	RapidIO packet is dropped.
WrSize Not unsupported transaction WrSize request is for one of reserved sizes.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes for NWRITE_R. No for NWRITE.	RapidIO packet is dropped for NWRITE.
Address:WdPtr:Xambs Not unsupported transaction NWRITE request hits LCSBA1CSR.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No for NWRITE.	RapidIO packet is dropped for NWRITE.
Address:WdPtr:Xambs Not unsupported transaction Request hits a protected ATMU window or the local configuration space window.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes for NWRITE_R. No for NWRITE.	RapidIO packet is dropped for NWRITE.
Address:WdPtr:Xambs Write request hits overlapping ATMU windows. Refer to **Section 16.2.9.4.2**, *Window Boundary Crossing Errors,* on page 16-56.	Yes if LTLEECSR[IACB] is set.	LTLEDCSR[IACB]	Yes for NWRITE_R. No for NWRITE.	RapidIO packet is dropped for NWRITE.
SrcTID Not Checked for error.				
Address:WdPtr:Xambs NWRITE_R address matches LCSBA1CSR with a request that is not a 32-bit read. Performed only for NWRITE_R packet.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes for NWRITE_R.	

Table 16-14. Hardware Errors For NWRITE, NWRITE_R (Continued)

Error	Interrupt	Status Bit Set	Error Response	Comments
Header Size Not unsupported transaction. Header size is less than 12 bytes for small transport packet or less than 16 bytes for large transport packet; that is, no payload is present. Large transport packet has 14 valid bytes and two bytes of padding of 0s. Padding of 0s is not checked.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes for NWRITE_R. No for NWRITE.	RapidIO packet is dropped for NWRITE.
PayloadSize Not unsupported transaction. Payload is greater than that indicated by the {wdptr:wrsize} field. Payload is not double word aligned or does not have any payload.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	Yes for NWRITE_R. No for NWRITE.	RapidIO packet is dropped for NWRITE.
The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets packet bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bits 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets packet bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-15. Hardware Errors For SWRITE Transactions

Error	Interrupt	Status Bit Set	Error Response	Comments
Priority Swrite transaction priority is 3.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped.
TransportType Received reserved TT.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
Received TT that is not enabled. Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
DestID DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error is valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	No	RapidIO packet is dropped.
SourceID Not checked for error.				
Address:WdPtr:Xambs SWRITE request hits overlapping ATMU windows. See **Section 16.2.9.4.2**, *Window Boundary Crossing Errors,* on page 16-56.	Yes if LTLEECSR[IACB] is set.	LTLEDCSR[IACB]	No	RapidIO packet is dropped.
Address:WdPtr:Xambs Request hits a protected ATMU window or the local configuration space window.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped.

Table 16-15. Hardware Errors For SWRITE Transactions (Continued)

Error	Interrupt	Status Bit Set	Error Response	Comments
PayloadSize Payload size is not in DWs, has exceeded 256 bytes, or has no payload.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped.
The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 62–63. • LTLACCSR[A] gets packet bits 32–60. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets packet bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 46–76. • LTLDIDCCSR[DIDMSB] gets packet bits 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets packet bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-16. Hardware Errors For Maintenance Response Transactions

Error	Interrupt	Status Bit Set	Error Response	Comments
Priority Not unsupported response. Response priority is not higher than the RapidIO maintenance priority.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.
TransportType Received reserved TT.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped and ignored.
Received TT that is not enabled. Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped and ignored.
DestID DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error is valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	No	RapidIO packet is dropped and ignored.
SourceID Does not match the request DestID.	Yes if LTLEECSR[UR] is set.	LTLEDCSR[UR]	No	RapidIO packet is dropped and ignored.
Transaction Type. Not unsupported transaction. Received RapidIO packet with reserved TType for the FType.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.
Not unsupported response. Maintenance read/write response does not correspond to an outstanding valid message read/write request.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.
HopCount Not checked for error.	—	—	—	—
Status Not unsupported response. Is not “Done” or “Error” Not “Done” status for “read_response” transaction type with payload “Error” status with payload.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.
Status Not unsupported response Error Response.	Yes if LTLEECSR[IER] is set.	LTLEDCSR[IER]	Yes	OCN error response is generated to requestor
TargetTID No outstanding transaction for this TargetTID	Yes if LTLEECSR[UR] is set.	LTLEDCSR[UR]	No	RapidIO packet is dropped and ignored.
Header Size Not unsupported response Maintenance Read response—total payload size with “Done” status is not greater than 4 bytes. Maintenance Write response—total header size is less than 12 bytes for small transport packet or is less than 16 bytes for large transport packet. Padding of 0s for small or large transport packet is not verified.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[TID]	No	RapidIO packet is dropped and ignored.

Table 16-16. Hardware Errors For Maintenance Response Transactions (Continued)

Error	Interrupt	Status Bit Set	Error Response	Comments
PayloadSize Not unsupported response Maintenance writeresponse—has payload. Maintenance read response—with “Done” status and payload not matching valid request size, request size for the response is invalid, or payload size is not 64-bit aligned.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.
Packet response time-out. Response is not received by configured time.	Yes if LTLEECSR[PRT] is set.	LTLEDCSR[PRT]	Yes	OCN response is generated to requestor.
The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets packet bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets bits 32–39. • LTLDIDCCSR[SID] gets bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-17. Hardware Errors For IO/GSM Response Transactions (Not Maintenance)

Error	Interrupt Generated	Status Bit Set	OCN Error Response Generated	Logical/Transport Layer Capture Register	Comments
Priority Not UR Response priority is not higher than RapidIO request priority	Yes if LTLEECSR [ITD] is set	LTLEDCSR [ITD]	No	Using the incoming RapidIO packet, for **Small Transport type packets,** LTLACCSR[XA] gets packet bits 78–79 (if available), LTLACCSR[A] gets packet bits 48–76 (if available), LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16–23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24–31, LTLCCCSR[FT] gets packet bits 12–15, LTLCCCSR[TT] gets packet bits 32–35, LTLCCCSR[MI] gets 0's **For Large Transport type packets**. LTLACCSR[XA] gets packet bits 94-95 (if available), LTLACCSR[A] gets packet bits 64-92 (if available), LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] gets packet bits 24–31, LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12–15, LTLCCCSR[TT] gets packet bits 48–51, LTLCCCSR[MI] gets 0's	RapidIO packet is dropped and ignored
Critical Request Flow CRF field is set when corresponding request's CRF field was clear	Yes if LTLEECSR [ITD] is set	LTLEDCSR [ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.
TransportType Received reserved TT for this ftype	Yes if LTLEECSR [TSE] is set	LTLEDCSR [TSE]	No	Same as first entry	RapidIO packet is dropped and ignored
Received TT which is not enabled. - Error valid when passthrough is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR [TSE] is set	LTLEDCSR [TSE]	No	Same as first entry	RapidIO packet is dropped and ignored
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough or accept_all) is false	Yes if LTLEECSR [ITTE] is set	LTLEDCSR [ITTE]	No	Same as first entry	RapidIO packet is dropped and ignored

Table 16-17. Hardware Errors For IO/GSM Response Transactions (Not Maintenance)

Error	Interrupt Generated	Status Bit Set	OCN Error Response Generated	Logical/Transport Layer Capture Register	Comments
SourceID Does not match the request's DestID	Yes if LTLEECSR [UR] is set	LTLEDCSR [UR]	No	Same as first entry	RapidIO packet is dropped and ignored
TransactionType Not UR Received RapidIO packet with reserved TType	Yes if LTLEECSR [ITD] is set	LTLEDCSR [ITD]	No	Same as first entry	RapidIO packet is dropped and ignored
Not UR IO read response does not correspond to an outstanding valid IO/GSM read request. IO write response does not correspond to an outstanding valid IO/GSM write request.	Yes if LTLEECSR [ITD] is set	LTLEDCSR [ITD]	No	Same as first entry	RapidIO packet is dropped and ignored
Status Not UR IO transaction - Is not "Done" or "Error" GSM transaction IO_Read_Home Is not "Done - Data-Only", "Done - Done-Intervention", "Done", "Retry" or "Error". Flush_w_Data response is not "Done", "Retry" or "Error" Transaction type of "Response_with_data" and status is not done	Yes if LTLEECSR [ITD] is set	LTLEDCSR [ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.
Status Not UR GSM Error response	Yes if LTLEECSR [GER] is set	LTLEDCSR [GER]	Yes if data is not received for this request.	Same as first entry except error capture is done from original request packet.	OCN error response is generated to requestor if data is not forwarded to it. Else the RapidIO packet is dropped.
Status Not UR IO Error Response	Yes if LTLEECSR [IER] is set	LTLEDCSR [IER]	Yes	Same as first entry except error capture is done from original request packet.	OCN error response is generated to requestor.
TargetTID No outstanding transaction for this TargetTID	Yes if LTLEECSR [UR] is set	LTLEDCSR [UR]	No	Same as first entry	RapidIO packet is dropped and ignored.

Table 16-17. Hardware Errors For IO/GSM Response Transactions (Not Maintenance)

Error	Interrupt Generated	Status Bit Set	OCN Error Response Generated	Logical/Transport Layer Capture Register	Comments
Packet Size Not UR (All non-maintenance and non-message) Write response - Header size is not 8 Bytes for Small Transport packet or not 12 Bytes for Large Transport packet GSM - “Done” response packet size to “Flush” is not 8 Bytes for Small Transport packet or not 12 Bytes for Large Transport packet. “Done-Intervention” is not 8 Bytes for Small Transport and 12 Bytes for Large Transport field. Two byte padding of 0’s in Large Transport field packet is not checked.	Yes if LTLEECSR [ITD] is set	LTLEDCSR [ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.
Payload Size Not UR IO - Read Response - total payload is not of the size requested. “Done” or “Done-Data_Only” response to IO_Read_Home with incorrect payload size. Response with transaction type “response_with_no_data” has payload	Yes if LTLEECSR [ITD] is set	LTLEDCSR [ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.
Retry Not UR GSM request has had one more than configured number of retries for non misaligned request. The misaligned GSM request has had one to four (cumulative for the corresponding child requests) more than configured number of retries.	Yes if LTLEECSR [RETE] is set	LTLEDCSR [RETE]	Yes	Same as first entry except error capture is done from original request.	OCN error response is generated to requestor.

Table 16-17. Hardware Errors For IO/GSM Response Transactions (Not Maintenance)

Error	Interrupt Generated	Status Bit Set	OCN Error Response Generated	Logical/Transport Layer Capture Register	Comments
Packet response time-out Response is not received by configured time for packets requiring RapidIO response. “GSM - IO_Read_Home” - Done_With_Data is not received in configured time when Done_Intervention is received for non misaligned request or last child of misaligned request. Done response is not received in configured time for non misaligned request or last child of misaligned request. EME capture occurs for each child packet response time-out.	Yes if LTLEECSR [PRT] is set	LTLEDCSR [PRT]	Yes	Same as first entry except error capture is done from original request.	OCN error response is generated to requestor.
Packet response time-out Response is not received by configured time for packets requiring RapidIO response. “GSM - IO_Read_Home” - Done_Intervention is not received in configured time when Done_With_Data is received. This is true for both non misaligned or misaligned requests.	Yes if LTLEECSR [PRT] is set	LTLEDCSR [PRT]	No	Same as first entry except error capture is done from original request.	An OCN done response is generated when the Done_With _Data is received for non misaligned requests or the last child of a misaligned request. Therefore, an error response cannot be sent when the packet response time-out occurs.
GSM - IO_Read_Home Not UR Done response, Retry response, or Error response is after Done_Intervention response or Data_only is received.	Yes if LTLEECSR [ITD] is set	LTLEDCSR [ITD]	No	Same as first entry	RapidIO packet is dropped and ignored.

Table 16-17. Hardware Errors For IO/GSM Response Transactions (Not Maintenance)

Error	Interrupt Generated	Status Bit Set	OCN Error Response Generated	Logical/Transport Layer Capture Register	Comments
Not UR Response for OCN packets not requiring response, but converted to “response” type packet by ATMU receives Error response. For example, NWrite converted to NWrite_r received “Error” response	Yes if LTLEECSR [IER]/[GER] /[RETE] is set	LTLEDCSR [IER]/[GER]/[RETE]	No	Same as first entry except error capture is done from original request.	RapidIO packet is dropped and ignored.
Response for OCN packets not requiring response, but converted to “response” type packet by ATMU is not received by configured time.	Yes if LTLEECSR [PRT] is set	LTLEDCSR [PRT]	No	Same as first entry except error capture is done from original request.	No error response is generated.

Table 16-18. Hardware Errors For Message Request Transactions

Error	Interrupt	Status Bit Set	Error Response	Comments
Priority Not applicable.				
TransportType Received reserved TT.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
Received TT that is not enabled. Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
DestID DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	Yes if priority is not 3. Else packet is dropped.	If priority is 3, packet is dropped.
SourceID Not checked for error.				
MsgLen,Ssize,Ltr,Mbox,MsgSeg Not checked for error.				
PayloadSize Message payload size is larger than the specified ssize or is of size 0 when seg_len == msg_len, or message payload size is not equal to specified ssize when seg_len≠ msg_len.	Yes if LTLEECSR[MFE] is set.	LTLEDCSR[MFE]	Yes if priority is not 3. Else packet is dropped.	If priority is 3, packet is dropped.
Reserved ssize field.	Yes if LTLEECSR[MFE] is set.	LTLEDCSR[MFE]	Yes if priority is not 3. Else packet is dropped.	If priority is 3, packet is dropped.

Table 16-18. Hardware Errors For Message Request Transactions (Continued)

Error	Interrupt	Status Bit Set	Error Response	Comments
Other Received message request with SOCAR[M] disabled.	Yes if LTLEECSR[UT] is set.	LTLEDCSR[UT]	Yes if priority is not 3. Else packet is dropped.	If priority is 3, packet is dropped.
The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bits 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets packet bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets packet bits 56–63.				

Table 16-19. Hardware Errors For Message Response Transactions

Error	Interrupt	Status Bit Set	OCN Error Response	Comments
Priority Not checked for error.				
TransportType Receive reserved TT.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped and ignored.
Received TT that is not enabled. Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped and ignored.
DestID (All non-maintenance) DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	No	RapidIO packet is dropped and ignored.
SourceID Not Checked for error.				
Status Not checked for error.				
Other Received message response with SOCAR[M] disabled.	Yes if LTLEECSR[UR] is set.	LTLEDCSR[UR]	No	RapidIO packet is dropped and ignored.

The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows:

- LTLACCSR[XA] gets packet bits 78–79.
- LTLACCSR[A] gets packet bits 48–76.
- LTLDIDCCSR[DIDMSB] gets 0s.
- LTLDIDCCSR[DID] gets packet bits 16–23.
- LTLDIDCCSR[SIDMSB] gets 0s.
- LTLDIDCCSR[SID] gets bits 24–31.
- LTLCCCSR[FT] gets packet bits 12–15.
- LTLCCCSR[TT] gets packet bits 32–35.
- LTLCCCSR[MI] gets 0s.

The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows:

- LTLACCSR[XA] gets packet bits 94–95.
- LTLACCSR[A] gets packet bits 64–92.
- LTLDIDCCSR[DIDMSB] gets packet bits 16–23.
- LTLDIDCCSR[DID] gets packet bits 24–31.
- LTLDIDCCSR[SIDMSB] gets packet bits 32–39.
- LTLDIDCCSR[SID] gets packet bits 40–47.
- LTLCCCSR[FT] gets packet bits 12–15.
- LTLCCCSR[TT] gets packet bits 48–51.
- LTLCCCSR[MI] gets packet bits 56–63.

For all entries except the first, the capture registers are loaded from the response RapidIO packet.

Table 16-20. Hardware Errors For Doorbell Request Transaction

Error	Interrupt	Status Bit Set	Error Response	Comments
Priority Not applicable.				
TransportType Received reserved TT.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No.	RapidIO packet is dropped.
Received TT that is not enabled. Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No.	RapidIO packet is dropped.
DestID DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error is valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	Yes if priority is not 3. Else packet is dropped.	
SourceID Not checked for error.				
SrcTID Not checked for error.				
Other Received doorbell request with DOCAR[D] disabled.	Yes if LTLEECSR[UT] is set.	LTLEDCSR[UT]	Yes if priority is not 3. Else packet is dropped.	

The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows:

- LTLACCSR[XA] gets packet bits 78–79.
- LTLACCSR[A] gets packet bits 48–76.
- LTLDIDCCSR[DIDMSB] gets 0s.
- LTLDIDCCSR[DID] gets packet bits 16–23.
- LTLDIDCCSR[SIDMSB] gets 0s.
- LTLDIDCCSR[SID] gets bits 24–31.
- LTLCCCSR[FT] gets packet bits 12–15.
- LTLCCCSR[TT] gets packet bits 32–35.
- LTLCCCSR[MI] gets 0s.

The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows for all entries but the blank ones:

- LTLACCSR[XA] gets packet bits 94–95.
- LTLACCSR[A] gets packet bits 64–92.
- LTLDIDCCSR[DIDMSB] gets packet bits 16–23.
- LTLDIDCCSR[DID] gets packet bits 24–31.
- LTLDIDCCSR[SIDMSB] gets packet bits 32–39.
- LTLDIDCCSR[SID] gets packet bits 40–47.
- LTLCCCSR[FT] gets packet bits 12–15.
- LTLCCCSR[TT] gets packet bits 48–51.
- LTLCCCSR[MI] gets 0s.

Table 16-21. Hardware Errors For Doorbell Response Transactions

Error	Interrupt	Status Bit Set	OCN Error Response	Comments
Priority Not UR or UT Response priority is not higher than RapidIO request priority.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.
TransportType Received reserved TT.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped and ignored.
Received TT Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped and ignored.
DestID DestID does not match this port DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error is valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	No	RapidIO packet is dropped and ignored.
SourceID Does not match the request's DestID.	Yes if LTLEECSR[UR] is set.	LTLEDCSR[UR]	No	RapidIO packet is dropped and ignored.
Status Not UR or UT Not one of Done/Error/Retry.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.
TransactionType Not UR or UT Anything other than Done_No_Data.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.
TargetTID No outstanding transaction for this TargetTID.	Yes if LTLEECSR[UR] is set.	LTLEDCSR[UR]	No	RapidIO packet is dropped and ignored.
Packet Size Not UR or UT DMA response. Header size is not 8 bytes for small transport packet or not 12 bytes for large transport packet. Two byte padding of 0s in a large transport field packet is not checked.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped and ignored.

Table 16-21. Hardware Errors For Doorbell Response Transactions

Error	Interrupt	Status Bit Set	OCN Error Response	Comments
Packet response time-out Response is not received by configured time.	Yes if LTLEECSR[PRT] is set.	LTLEDCSR[PRT]	Yes	
The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows for all entries but the last one, in which the capture registers are loaded from original request RapidIO packet: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bit 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets packet bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-22. Hardware Errors for Port-Write Transaction

Error	Interrupt	Status Bit Set	Error Response	Comments
Priority Not applicable.				
TransportType Received reserved TT.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
Received TT which is not enabled. - Error valid when passthrough is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	No	RapidIO packet is dropped.
SourceID Not checked for error.				
TransactionType Not checked for error.				
WrSize Not UT Is one of reserved sizes or less than 4 bytes.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped.
SrcTID Not checked for error.				
HopCount Not checked for error.				
ConfigOffset Not checked for error.				
PayloadSize Not UT An incorrect port-write wr_size encoding (not 4, 8, 16, 24, 32, 40, 48, 56, or 64 bytes). Payload size is greater than the value defined by wr_size. Payload size is not 64-bit aligned when the wr_size is not 4 bytes.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped.

Table 16-22. Hardware Errors for Port-Write Transaction (Continued)

Error	Interrupt	Status Bit Set	Error Response	Comments
Other Received PortWrite transaction with DOCAR[PW] disabled.	Yes if LTLEECSR[UT] is set.	LTLEDCSR[UT]	No	RapidIO packet is dropped.
In **Table 16-22**, the Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. In **Table 16-22**, the Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows for all entries but the blank ones: • LTLACCSR[XA] gets packet bits 94-95 • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bit 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets packet bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-23. Hardware Errors For Type9 Transactions

Error	Interrupt Generated	Status Bit Set	OCN Error Response Generated	Logical/Transport Layer Capture Register	Comments
TransportType Received reserved TT	Yes if LTLEECSR [TSE] is set	LTLEDCSR [TSE]	No	Using the incoming RapidIO packet, **for Small Transport Type**, LTLACCSR[XA] gets packet bits 78–79, LTLACCSR[A] gets packet bits 48–76, LTLDIDCCSR[DIDMSB] gets 0's, LTLDIDCCSR[DID] gets packet bits 16-23, LTLDIDCCSR[SIDMSB] gets 0's, LTLDIDCCSR[SID] gets packet bits 24–31, LTLCCCSR[FT] gets packet bits 12–15, LTLCCCSR[TT] gets packet bits 32–35, LTLCCCSR[MI] gets 0's **For Large Transport type packets**. LTLACCSR[XA] gets packet bits 94-95, LTLACCSR[A] gets packet bits 64-92, LTLTLTLDIDCCSR[DIDMSB] gets 16-23, LTLDIDCCSR[DID] LTL gets packet bits 24–31,LTLDIDCCSR[SIDMSB] gets bits 32-39, LTLDIDCCSR[SID] gets bits 40-47, LTLCCCSR[FT] gets packet bits 12-15, LTLCCCSR[TT] gets packet bits 48-51, LTLCCCSR[MI] gets 0's	RapidIO packet is dropped and ignored
Received TT Error valid when passthrough is disabled and accept_all is disabled Or when accept_all is enabled.	Yes if LTLEECSR [TSE] is set	LTLEDCSR [TSE]	No	Same as first entry	RapidIO packet is dropped and ignored
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough or accept_all) is false	Yes if LTLEECSR [ITTE] is set	LTLEDCSR [ITTE]	No	Same as first entry	RapidIO packet is dropped and ignored

Table 16-24. Hardware Errors for Outbound Transaction Crossed ATMU Boundary

Error	Interrupt	Status Bit Set	OCN Error Response Generated	Comments
OCN Address and payload size OCN address range for Outbound RapidIO transaction hits multiple ATMU windows.	Yes if LTLEECSR[IACB] is set and/or LTLEDCSR[PRT] is set	LTLEDCSR[OACB] LTLEDCSR[PRT]	Yes if original request requires a response.	OCN error response is generated if the request requires a response. Otherwise, the OCN packet is dropped.
The Logical/Transport Layer Address Capture Command and Status Register uses the original RapidIO packet sent out by outbound. For a small transport packet, it uses the following: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. For a large transport packet, it uses the following: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bits 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets packet bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-25. Hardware Errors for Outbound Packet Time-to-Live Errors

Error	Interrupt	Status Bit Set	OCN Error Response Generated	Comments
Packet time-to-live error.	Yes if LTLEECSR[PTTL] is set	LTLEDCSR[PTTL]	Yes if original request requires a response.	OCN error response is generated if the request requires a response. Otherwise, the OCN packet is dropped.
The Logical/Transport Layer Address Capture Command and Status Register uses the RapidIO packet attempted to send outbound. For a small transport packet, it uses the following: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. For a large transport packet, it uses the following: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bits 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets packet bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s.				

Table 16-26. Hardware Errors for Reserved Ftype

Error	Interrupt Generated	Status Bit Set if Corresponding Bit is Enabled	Error Response	Comments
Ftype Ftype is not IO Read, IO Write, SWrite, Maintenance request, Maintenance Response, Response (Ftype 13), Doorbell or Message class and it is not a passthrough transaction. (passthrough is not enabled | accept_all is enabled | transaction is addressed to this port).	Yes if LTLEECSR[UT] is set.	LTLEDCSR[UT]	No	RapidIO packet is dropped.
TransportType Received reserved TT.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
Received TT that is not enabled. Error is valid when passthrough is disabled and accept_all is disabled or when accept_all is enabled.	Yes if LTLEECSR[TSE] is set.	LTLEDCSR[TSE]	No	RapidIO packet is dropped.
DestID DestID does not match this port's DeviceID if Alternate DeviceID is disabled or DestId does not match either Alternate DeviceID or DeviceId if Alternate DeviceID is enabled. Error valid when (passthrough | accept_all) is false.	Yes if LTLEECSR[ITTE] is set.	LTLEDCSR[ITTE]	No	RapidIO packet is dropped.
Address:WdPtr:Xambs Swrite request hits overlapping ATMU windows. Refer to **Section 16.2.9.4.2**, *Window Boundary Crossing Errors,* on page 16-56. Packet is checked as a non-SWRITE packet.	Yes if LTLEECSR[IACB] is set.	LTLEDCSR[IACB]	No	RapidIO packet is dropped.
Address:WdPtr:Xambs Not UT Request hits a protected ATMU window or the local configuration space window. Packet is checked as non-Swrite packet.	Yes if LTLEECSR[ITD] is set.	LTLEDCSR[ITD]	No	RapidIO packet is dropped.
The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a small transport packet as follows: • LTLACCSR[XA] gets packet bits 78–79. • LTLACCSR[A] gets packet bits 48–76. • LTLDIDCCSR[DIDMSB] gets 0s. • LTLDIDCCSR[DID] gets packet bits 16–23. • LTLDIDCCSR[SIDMSB] gets 0s. • LTLDIDCCSR[SID] gets bits 24–31. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 32–35. • LTLCCCSR[MI] gets 0s. The Logical/Transport Layer Address Capture Command and Status Register uses the incoming RapidIO packet for a large transport packet as follows for all entries: • LTLACCSR[XA] gets packet bits 94–95. • LTLACCSR[A] gets packet bits 64–92. • LTLDIDCCSR[DIDMSB] gets packet bits 16–23. • LTLDIDCCSR[DID] gets packet bits 24–31. • LTLDIDCCSR[SIDMSB] gets packet bits 32–39. • LTLDIDCCSR[SID] gets packet bits 40–47. • LTLCCCSR[FT] gets packet bits 12–15. • LTLCCCSR[TT] gets packet bits 48–51. • LTLCCCSR[MI] gets 0s. • LTLCCCSR[MI] gets 0s.				

16.3 RapidIO Enhanced Message Unit (eMSG) Communication

The RapidIO message manager (eMSG) supports a message passing programming model for inter-processor and inter-device communication. The most common use of the message passing model is in systems where a processing element is only allowed to access memory local to itself, and communication between processing elements is achieved through message passing and is address-independent. A data streaming protocol is also supported, which defines a mechanism for transporting an arbitrary protocol over a standard RapidIO interface between two end points. The eMSG is compliant with the Type9 *RapidIO Interconnect Specification Part 2: Message Passing Logical Specification Rev. 1.3*, and Type11 *RapidIO Interconnect Specification Part 10: Data Streaming Logical Specification Rev. 1.3a.*

16.3.1 Overview

The eMSG has a total of 64 inbound classification units supporting RapidIO Type8–11. The classification units are separated into eight units per block, where the units are numbered 0–7 and the blocks 0–7. The units are managed through a set of run-time registers. Segments of a properly classified transaction are reassembled and put onto a queue for processing by software. There are 6 outbound segmentation units supporting RapidIO Type5–6 and Type8–11. These segmentation units are fed by outbound transaction queues managed by software, as follows:

- A Type5 outbound NWrite unit enables a producer to send up to 64 Kbyte of addressable data across the interconnect fabric to a consumer. eMSG does not support receiving of Type5 packets. NWrite allows for sub double-word data transfers.
- A Type6 outbound streaming write unit enables a producer to send up to 64 Kbyte of addressable data across the interconnect fabric to a consumer. eMSG does not support receiving of Type6 streaming writes. Streaming writes must be a multiple of double-words and does not include transfer size information.
- A Type8 port-write is intended as an error reporting mechanism from an end point-less device to a control processor or other system host. The eMSG also supports generation of outbound port-writes for testability and debug. Inbound port-writes have dedicated hardware for guaranteed delivery.
- A Type9 outbound segmentation unit enables a producer to send a packetized data unit (PDU) across the interconnect fabric to a consumer’s reassembly hardware. The receiving reassembly hardware places the PDU descriptor onto an inbound message queue. A PDU may consist of multiple segments supporting a total size of 64 Kbyte. PDUs can be queued for transmission in the producer’s memory and the segmentation hardware then processes them sequentially. PDUs can also be queued in the consumer’s memory while software processes them sequentially. The depths of the queues at the producer and consumer are configurable by software. Basic stream management flow control is also supported in Type9.

Note: No more than one PDU from a given RapidIO flow should be segmented at a time.

- A Type10 outbound doorbell unit enables a producer to send a small amount of software-defined information across the interconnect fabric to a consumer's doorbell unit. It is the responsibility of the processor receiving the doorbell to determine the action to undertake. A small data payload of 2 bytes is used for doorbells.
- A Type11 outbound eMSG enables a producer to send a message across the interconnect fabric to a consumer's message hardware, called a mailbox. The receiving mailbox hardware places a message descriptor onto an inbound message queue. A message may consist of one to sixteen segments. Messages can be queued for transmission in the producer's memory and the message hardware will process them sequentially. Messages can also be queued in the consumer's memory while software processes them sequentially. The depths of the queues at the producer and consumer are configurable by software. A multicast function allows single segment messages to be sent to multiple consumers.

Figure 16-14 shows a block diagram of the eMSG unit.

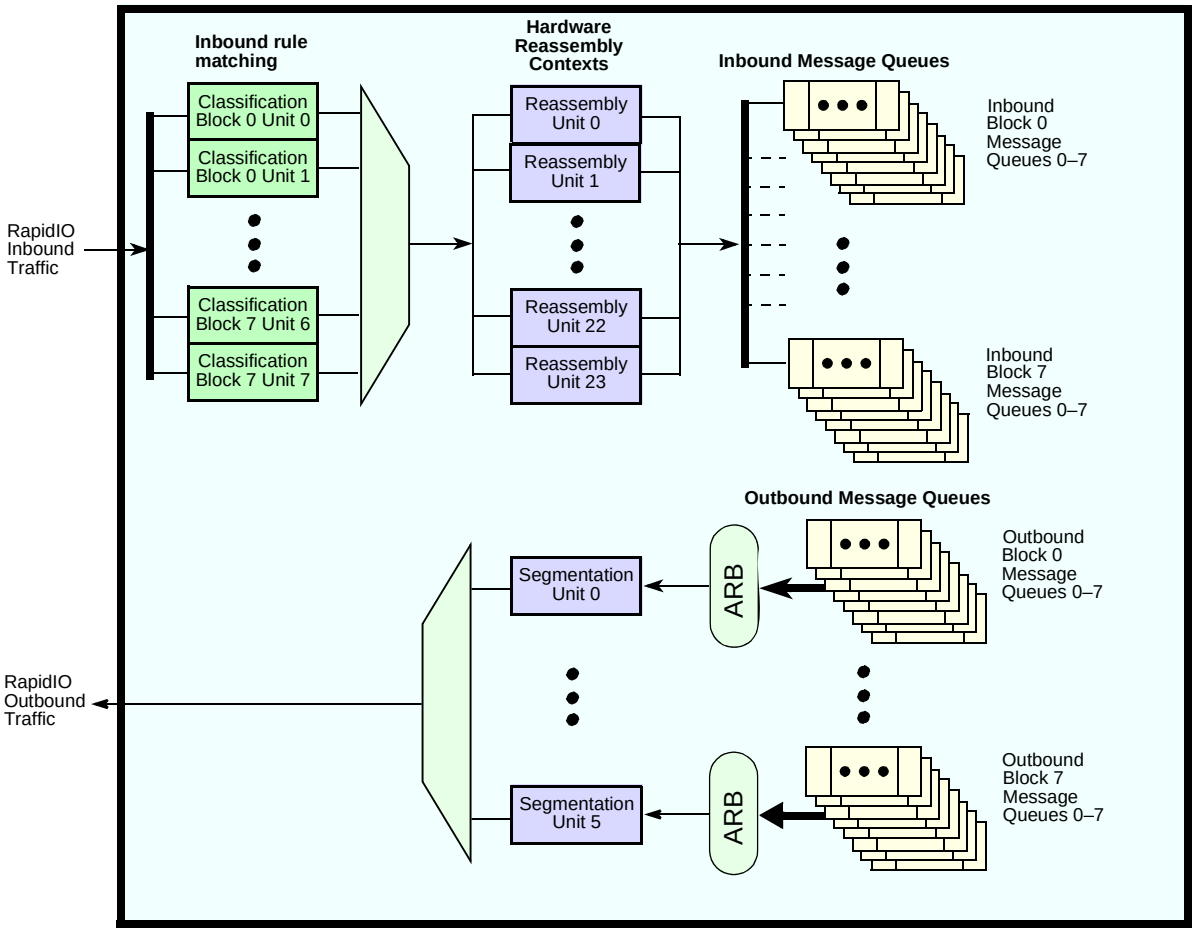

Figure 16-14. eMSG Block Diagram

16.3.2 Modes of Operation

The eMSG has two modes of operation: outbound and inbound.

16.3.2.1 Outbound Modes of Operation

The outbound units support Type5, Type6, and Type8–11 transactions. They also support Multicast Mode for Type11 in which a single segment message (256 bytes or less) is sent to multiple destinations.

16.3.2.2 Inbound Modes of Operation

The inbound classification units can be configured to handle Type8 through Type11 inbound traffic. There are a total of 64 inbound units (8 per block) that all work to classify incoming traffic based on header attributes to direct the transactions to a particular target message queue for later processing.

Classification mode is the inbound mode. In this mode, an inbound unit matches a programmable set of attributes to the inbound header, allowing steering of the transaction. A value/mask register pair is used to classify incoming packets based on header information. This process is referred to as classification and has the highest priority for inbound messages, doorbells, and packets, unless an active context is already open.

Figure 16-15 shows an example of traffic classification, where packets of Type8–11 are steered to the correct inbound unit for processing. If there is any aliasing between units, the lower numbered unit wins. A transaction that is not classified is subject to error response or is dropped.

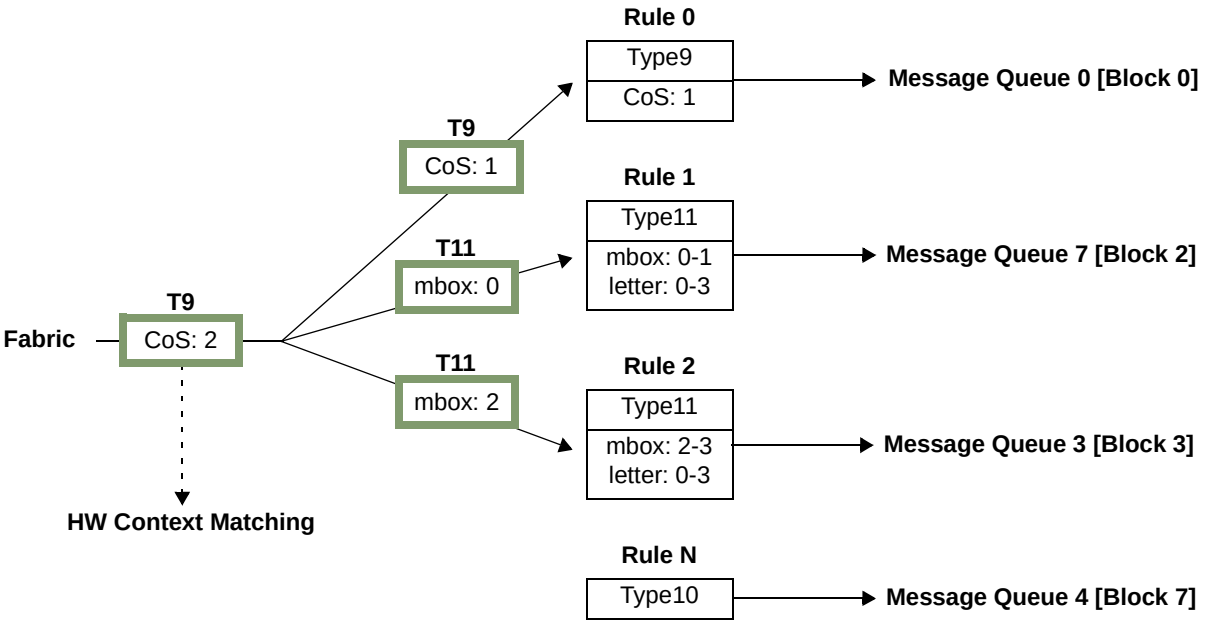

Figure 16-15. Inbound Traffic Classification

Note: The following sections describe the individual processing for each of the message types, including the outbound and inbound descriptor formats, and outbound and inbound message unit operation (where applicable).

16.3.3 Command Descriptor Format

The message unit relies on the use of the command descriptor (CD) format to enqueue/dequeue status/commands to and from the message queues.

16.3.3.1 Inbound Command Descriptor Format

The message unit enqueues Type8–11 command descriptors to the inbound message queues. Only command descriptor formats applicable to the message unit is shown in **Figure 16-16**. The status/command field (bits 31–0) is written by the message unit hardware during enqueue of inbound CD. Reserved fields must be cleared.

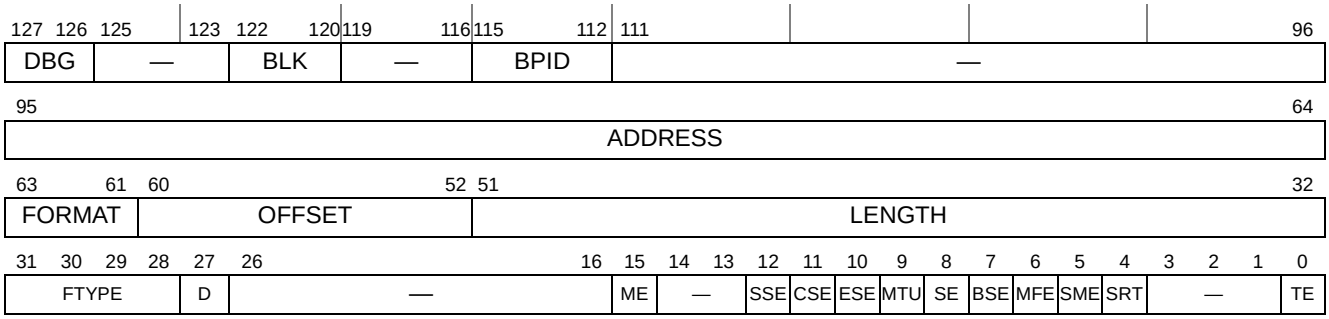

Figure 16-16. Inbound Command Descriptor Format

Table 16-27 describes the inbound command descriptor fields.

Table 16-27. Inbound Command Descriptor Field Descriptions

Bits	Name	Description
127–126	DBG	Debug
125–123	—	Reserved
122–120	BLK	Block number Added by hardware to determine the completion queue block for outbound and the enqueue block for inbound. Non-DPAA only
119–116	—	Reserved
115–112	BPID	Buffer Pool ID Specifies the buffer pool identifier used for buffer allocation associated with the data pointed to by address, offset and length fields. Non-DPAA only
111–96	—	Reserved
95–64	ADDRESS	32-bit address. See **Section 16.3.13**, *Address Alignment Requirements*.
63–61	FORMAT	Format (bits 60–32) 000 Single buffer frame, 9-bit offset, 20-bit length 100 Scatter/Gather table, 9-bit offset, 20-bit length. Valid for RapidIO Type9 only. All other values reserved or unused.

Table 16-27. Inbound Command Descriptor Field Descriptions (Continued)

Bits	Name	Description
60–52	OFFSET	Byte offset from starting address where information is stored. See **Section 16.3.13**, *Address Alignment Requirements*.
51–32	LENGTH	Total length of the data payload, excluding any scatter/gather table overhead. A buffer length of zero signifies that no data is valid and the address should not be accessed. For inbound transactions, the length indicates the total byte count written to memory, which may be less than expected if an error was encountered during reassembly.
Status and Command Fields This field is provided to allow the message unit to communicate “out of band” information to the consumer of those command descriptors.		
31–28	FTYPE	RapidIO type 1000 Type8 1001 Type9 1010 Type10 1011 Type11 All other values reserved.
27	D	Direction 0 Outbound 1 Inbound
26–16	—	Reserved
15	ME	Multiple errors Multiple errors of the same kind are reported. • Continuation segment error (CSE) • MTU size error (MTU) • Message format error (MFE)
14–13	—	Reserved
12	SSE	Single/Start segment error A start or single segment was received for an already opened context. A new PDU context is opened and the old PDU context is considered defective. Inbound Type9 only
11	CSE	Continuation segment error A continuation segment was received without a previously opened context. PDU context is considered defective. Inbound Type9 only
10	ESE	End segment error An end segment was received without a previously opened context. PDU context is considered defective. Inbound Type9 only
9	MTU	MTU violation PDU is considered defective.Inbound Type9 only
8	SE	Source error PDU was aborted by source. Inbound Type9 only
7	BSE	Buffer size error Message unit was unable to store the transaction due to insufficient buffer pool size. Inbound Type8/10/11 only
6	MFE	Message format error Duplicate, out of range, inconsistent segment number or illegal RapidIO priority or segment size received. Inbound Type10/11 only
5	SME	Size mismatch error Inbound length or byte count mismatch. Inbound Type9 only

Table 16-27. Inbound Command Descriptor Field Descriptions (Continued)

Bits	Name	Description
4	SRT	Segment request time-out error Time between end of segment reassembly to receipt of next segment. The time-out threshold value used is the same as the RapidIO PRTOCCSR (see **Section 16.4.1.16**, *Port Link Time-Out Control Command and Status Register (PLTOCCSR)*).
3–1	—	Reserved
0	TE	Internal transaction error Write access to local memory failed and the BMan resources are depleted.

16.3.3.2 Outbound Command Descriptor Format

The message unit dequeues command descriptors (CDs) of Type5, Type6, and Type8–11 from the outbound message queues. Command descriptors are also used for conveying completion status for outbound transactions when they are enqueued. Only command descriptor formats applicable to the message unit are shown **Figure 16-17**. Part of the status/command field (bits 100–127) is written by the message unit hardware during completion enqueue of CD. Reserved fields must be cleared.

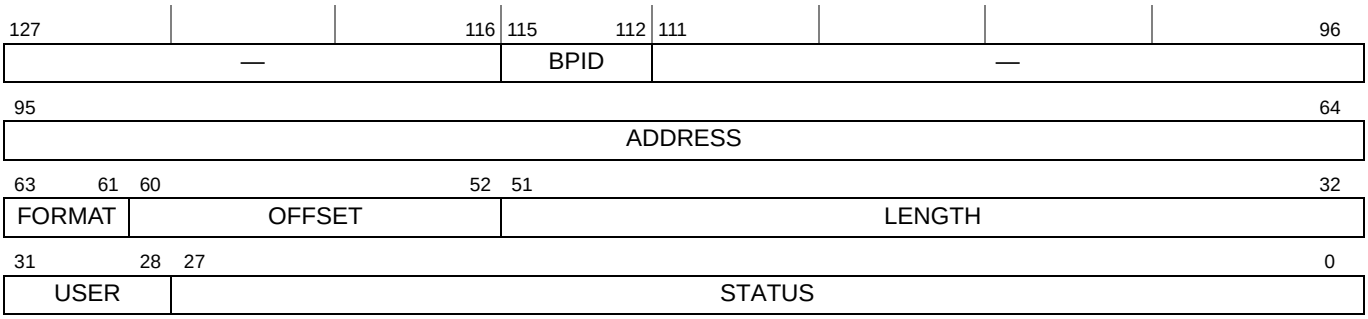

Figure 16-17. Outbound Command Descriptor Format

Table 16-28 describes the outbound command descriptor fields.

Table 16-28. Abound Command Descriptor Field Descriptions

Bits	Name	Description
127–116	—	Reserved
115–112	BPID	Buffer pool ID Specifies the buffer pool identifier used for buffer allocation associated with the data pointed to by address, offset and length fields.
111–96	—	Reserved
95–64	ADDRESS	32-bit address. See **Section 16.3.13**, *Address Alignment Requirements*.
63–61	FORMAT	Format (bits 60–32) 000 Single buffer frame, 9-bit offset, 20-bit length 100 Scatter/Gather table, 9-bit offset, 20-bit length. Valid for RapidIO Type5, Type6 and Type9 only All other values reserved or unused.

Table 16-28. Abound Command Descriptor Field Descriptions (Continued)

Bits	Name	Description
60–52	OFFSET	Byte offset from starting address where information is stored. See **Section 16.3.13**, *Address Alignment Requirements*.
51–32	LENGTH	Total length of the data payload, excluding any scatter/gather table overhead. A buffer length of zero signifies that no data is valid and the address should not be accessed.
31–28	USER	User defined field. This field is optional by the producer and is returned as-is during completion
Status Fields These field are provided to allow the message unit to communicate “out of band” information to the consumer during completion command descriptors.		
27	D	Direction 0 Outbound 1 Inbound
26–16	—	Reserved
15	ME	Multiple errors. Multiple errors of the same kind reported. • Error response received (ERR) • Multicast error response received (MCE)
14	—	Reserved
13	DE	Descriptor error A programming error was encountered when reading the scatter/gather table or message descriptor. Outbound only
12–5	—	Reserved
4	SRT	Segment response time-out error Time from segment transmitted by SRIO to logical response received by segmentation unit. The time-out threshold value used is the same as the RapidIO PRTOCCSR (see **Section 16.4.1.17**, *Port Response Time-Out Control Command and Status Register (PRTOCCSR)*)
3	MCE	Multicast error Failed to deliver message to one or more devices. The cause of error is indicated by one or more of the bits ERR/SRT/RTE/TE set. Outbound Type11 only
2	ERR	Error response received. Outbound Type10/11 only
1	RTE	Retry threshold exceeded. Outbound Type10/11 only
0	TE	Internal transaction error Data payload or scatter/gather table read access to local memory failed. **Note**: If a transaction error is encountered while reading the message descriptor, only global the transaction error is reported (MUMEDR[OTE]).

16.3.3.3 Outbound Completion Queues

Completion status information for outbound Type5, Type6, and Type8–11 transactions can be reported back to an outbound completion queue if the CS/ES bit is set in the message descriptor, unless a transaction error occurred while fetching the message descriptor. The status field, bits 100–127, carried within the command descriptor, is updated after segmentation completes. If buffer release (BR = 1) is performed successfully, the effective length field indicates zero. It is the responsibility of the outbound completion queue consumer to deallocate buffers as needed when the command descriptor length field is non-zero. If transaction or descriptor error status has

been reported, buffer pointers may have been partially released. There is one completion queue for each set of eight outbound queues.

Note: Completion order is preserved within the outbound completion queue, although transactions from the same outbound message queue may execute out of order, as dictated by the outbound ordering rules.

16.3.4 Scatter/Gather Tables

RapidIO Type5–6 and Type9 transactions may use the 16-byte scatter/gather table format for data management. The command descriptor has a format field indicating if the address/offset fields are pointing to a direct data memory location or another scatter/gather table. The scatter/gather table must be aligned to a 16-byte boundary. The definition of a scatter/gather table entry is described in **Figure 16-18**. Each scatter/gather table contains one or more entries, and may be extended to include additional tables. Each scatter/gather entry points to a data buffer or chains to another scatter/gather table as required.

Note: Do not use the scatter/gather table format for Type5, Type6, or Type9 messages during outbound segmentation. Using this format can result in segmentation unit counters being corrupted by a descriptor error (DE).

Note: Each scatter/gather entry has a 32-bit address field and a 30-bit buffer length field. The E (extension) bit determines if the address is pointing to a data buffer (E = 0) or to a new scatter/gather table (E = 1). The F (final) bit determines when the last entry of the table has been reached. Reserved fields must be cleared.

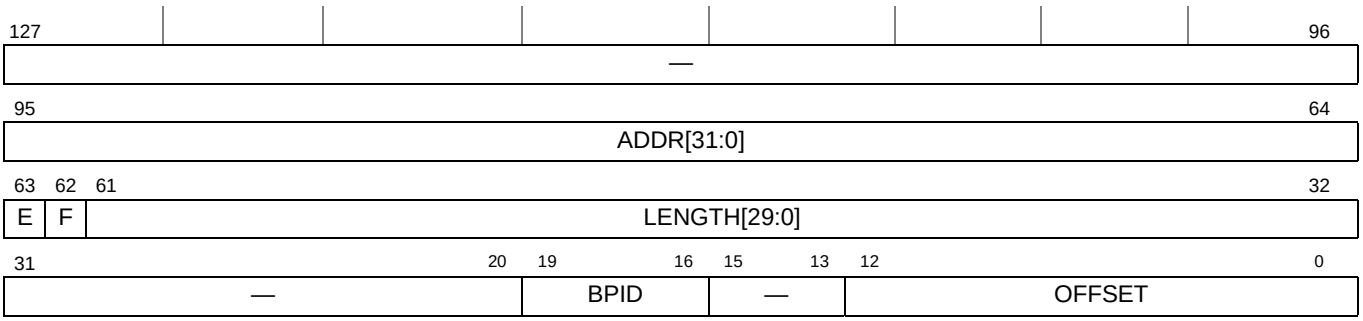

Figure 16-18. Scatter/Gather Table Entry Format

Table 16-29 describes the scatter/gather table entry fields.

Table 16-29. Scatter/Gather Table Entry Field Descriptions

Bits	Name	Description
127–96	—	Reserved
95–64	ADDRESS	32-bit byte address to data buffer or discontinued scatter/gather table entry, depending on E bit setting.

Table 16-29. Scatter/Gather Table Entry Field Descriptions (Continued)

Bits	Name	Description
63	E	Extension. 0 Address references a data buffer. 1 Address references a scatter/gather table. The extension bit has precedence over the final bit. If both are set, the final bit is ignored.
62	F	Final entry. 0 Not last table entry 1 Indicates final table entry This bit is ignored if the extension bit is set.
61–32	LENGTH	Effective length of the data buffer when E = 0, ignored when E = 1.
31–20	—	Reserved
19–16	BPID	Buffer pool ID Specifies the buffer pool identifier used for buffer allocation associated with the data pointed to by address, offset and length fields
15–13	—	Reserved
12–0	OFFSET	Byte offset from ADDRESS where data payload or scatter/gather table resides

A buffer length of zero is not allowed when the extension bit is deasserted and results in an undefined behavior. The length is ignored if the extension bit is set. Only the last scatter/gather segment may chain by setting the extension bit it does not have to chain. The offset value may be non-zero to indicate significant data is stored there.

The overall data payload length as defined by the command descriptor is also used to determine the end of a scatter/gather table. If the length has been reached, regardless of the final bit setting, the last data segment has been reached. The following occurs when the length has been reached, but the final bit is not set, and a buffer release was requested (BR=1):

- Any subsequent data buffer pointer(s) are not released
- Current and subsequent S/G table pointer(s) are not released

If software requires all pointers to be released, the final bit must be set for the last data entry as determined by the length field.

Figure 16-19 shows the format for scatter/gather chaining. If one scatter/gather table is insufficient for storing data, tables can be chained together until the desired number of entries are achieved.

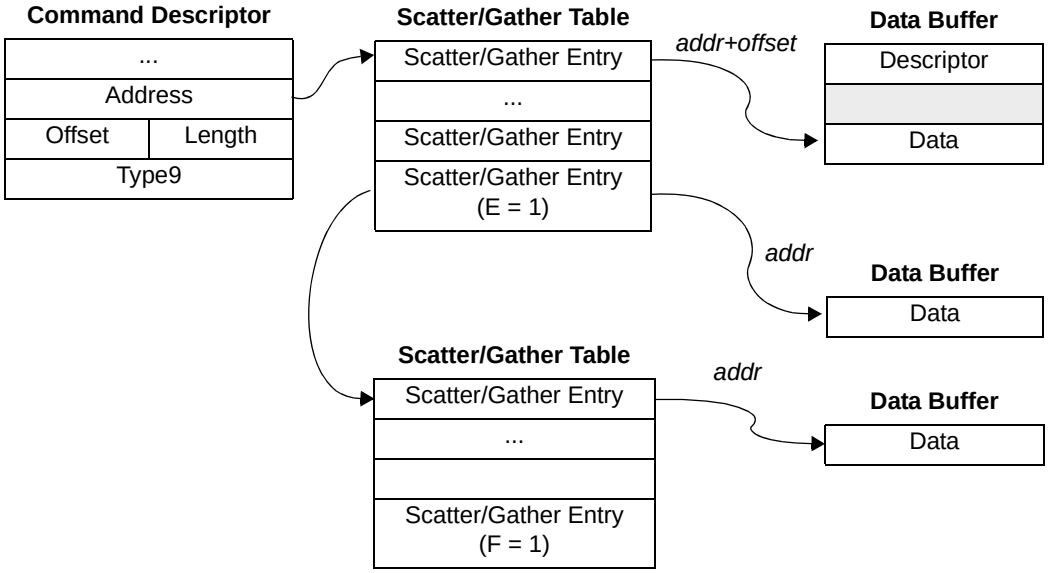

Figure 16-19. Type9 Scatter/Gather Table Chaining

16.3.5 Type5 NWrite Unit Functional Description

This section describes the Type5 NWrite descriptor formats. Type5 NWrites are only supported outbound.

16.3.5.1 Type5 Outbound NWrite Descriptor Format

The Type5 outbound descriptor contains information for the message unit to send an NWrite transaction. The message unit receives the outbound NWrite descriptor by dequeueing a command descriptor from an outbound message queue. The message descriptor points to a data buffer containing the descriptor and NWrite data payload.

Figure 16-20 shows the format of an outbound NWrite descriptor. Reserved fields must be cleared.

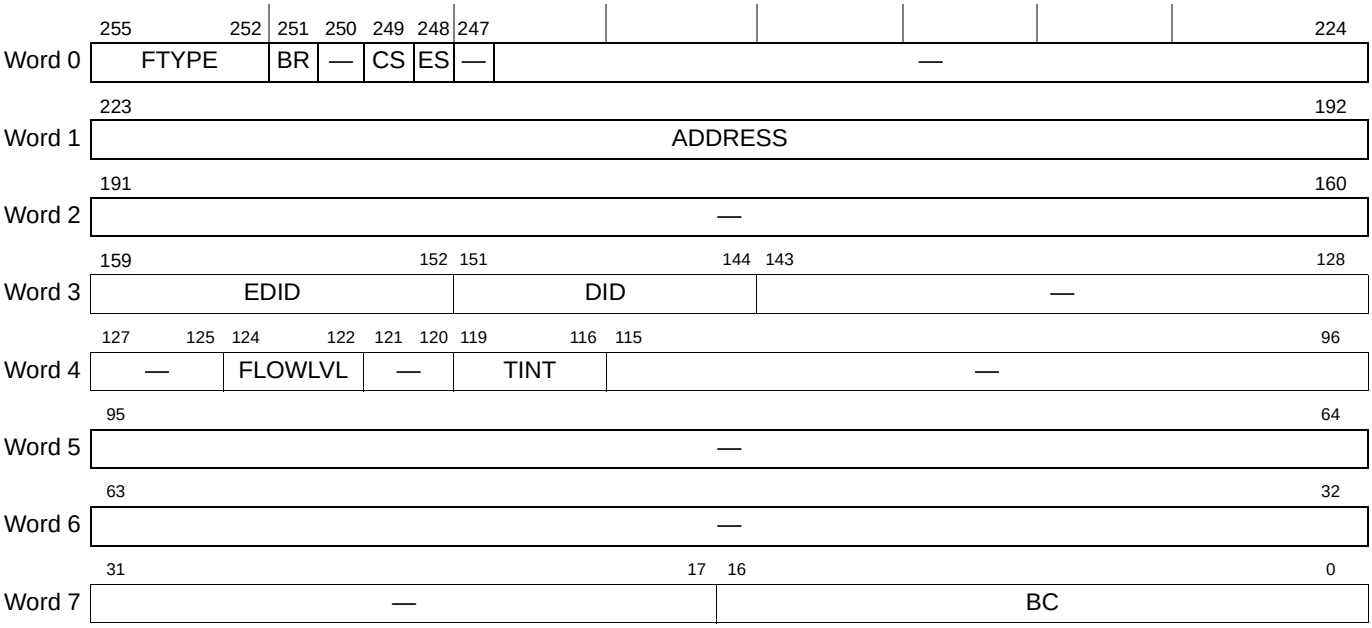

Figure 16-20. Type5 Outbound NWrite Descriptor

Table 16-30 describes the Type5 outbound NWrite descriptor fields.

Table 16-30. Type5 Outbound NWrite Descriptor Field Descriptions

Bits	Name	Description
Word 0—Header		
255–252	FTYPE	Descriptor type select 0101 Type5 All other values reserved.
251	BR	Buffer release enable 0 No hardware buffer releases performed. 1 Hardware buffer releases performed. If TE/DE error status was reported, not all buffers may have been released successfully.
250	—	Reserved
249	CS	Completion status 0 Status message queue is not updated when NWrite completes normally. 1 Status message queue is updated when NWrite completes normally.
248	ES	Error status 0 Status message queue is not updated when NWrite aborted due to error. 1 Status message queue is updated when NWrite aborted due to error.
247–224	—	Reserved
Word 1—Address		
223–192	ADDRESS	Byte aligned address of write transaction This address represents the RapidIO Type5 logical address without any address translation.
Word 2—Reserved		
191–160	—	Reserved
Word 3—Destination Port		

Table 16-30. Type5 Outbound NWrite Descriptor Field Descriptions (Continued)

Bits	Name	Description
159–152	EDID	Extended destination ID Most significant byte of a 16-bit destination ID when operating in large transport mode. Reserved when operating in small transport mode.
151–144	DID	Destination ID Contains the destination ID field of the transaction (device ID of the target).
143–128	—	Reserved
Word 4—Destination Attributes		
127–125	—	Reserved
124–122	FLOWLVL	Transaction flow level 000 Lowest priority transaction request flow 001 Next highest priority transaction request flow ... 100 Next highest priority transaction request flow 101 Highest priority transaction request flow 110 Reserved 111 Reserved
121–120	—	Reserved
119–116	TINT	Target interface 0000 RapidIO Port 1 0001 RapidIO Port 2 All other values reserved.
115–96	—	Reserved
Word 5—Reserved		
95–64	—	Reserved
Word 6—Reserved		
63–32	—	Reserved
Word 7—Byte Count		
31–17	—	Reserved
16–0	BC	Byte count Contains the number of bytes for the write operation. 0x00001 1 byte 0x00002 2 bytes 0x00003 3 bytes ... 0x0FFFF 64 Kbytes –1 0x10000 64 Kbytes All other values are reserved.

Figure 16-21 shows the format for Type5 scatter/gather tables usage. The first entry of the scatter/gather table holds the 32-byte descriptor. The data offset is specified through the

scatter/gather entry offset field. Non-scatter/gather format is also supported for Type5 if the data payload plus the descriptor offset is less than or equal to 64 Kbytes.

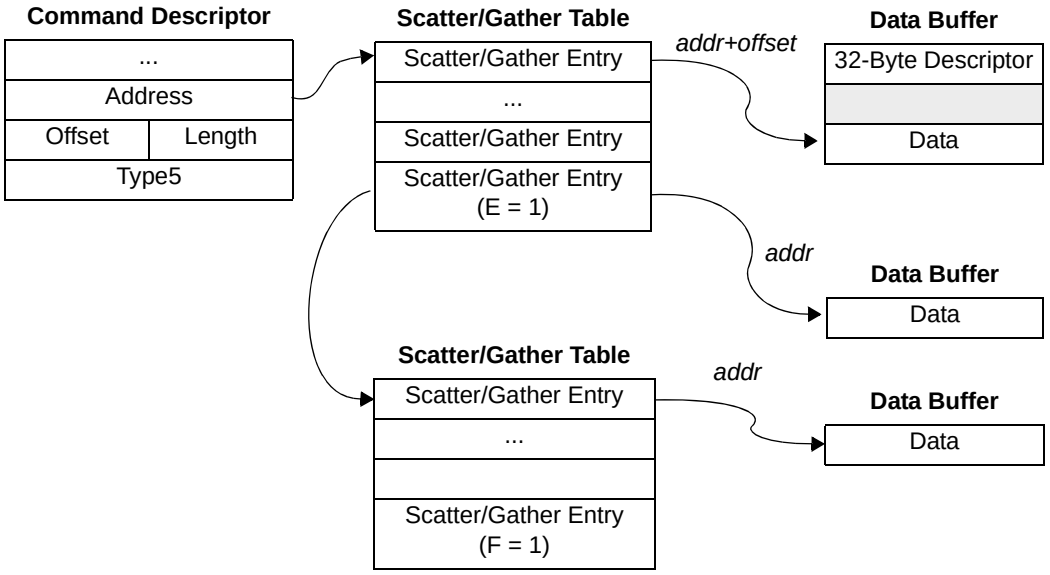

Figure 16-21. Outbound Type5 Scatter/Gather Table Format

16.3.5.2 Type5 Outbound NWrite Operation

RapidIO supports an NWrite type that contains a data payload from 1 to 64 Kbytes. The outbound message unit is responsible for sending NWrites enqueued by a producer or producers onto one of the outbound message queue owned by the message unit. Concurrent processing may occur between any number of message queues as long as the outbound ordering rules apply; see **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.5.2.1 Work Scheduling

The message unit receives all work from the outbound message queues. A producer or producers enqueueue work onto the outbound message queues owned by the message unit. To maintain any ordering between transactions, a producer must enqueue transactions with dependencies onto the same outbound message queue. The outbound ordering rules are described in **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.5.2.2 Adding NWrites to a Message Queue

A producer may add new NWrites to any message queue owned by the message unit. The producer needs to allocate buffer space for the NWrite descriptor as appropriate and enqueue the command descriptor. The message unit dequeues the command descriptor, determines the type, and proceeds to read the NWrite descriptor.

A producer should follow the following guidelines to add a new NWrite to a message queue:

- Create the 32-byte outbound NWrite descriptor as described in **Section 16.3.5.1**, *Type5 Outbound NWrite Descriptor Format*.
  - Set the descriptor type select field FTYPE = 4b0101 to indicate NWrite type.
  - Allocate buffer for the NWrite descriptor from one of the buffer pools available, preferably with the smallest buffer size (that is, 64 bytes).
  - For all other fields, see **Section 16.3.5.1**, *Type5 Outbound NWrite Descriptor Format*.
- Add the NWrite descriptor to a command descriptor and set FTYPE = 4b0101 to indicate the NWrite type.
- Enqueue the command descriptor onto the message queue.
- The message unit releases buffers used by the producer to hold the NWrite descriptor and data payload when the operation completes if the buffer release (BR) bit is set in the message descriptor.

16.3.5.2.3 NWrite Initialization

See **Section 16.3.17.6**, *Initializing Outbound Message Queues*.

16.3.5.2.4 Error Handling

The message unit can report completion status and error information after completing the command descriptor by updating the command descriptor status field.

The following steps should be performed to enable this mode.

- Software should observe the status field of the command descriptor after it has been written to the completion queue to determine success.

Table 16-31 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed.

Table 16-31. Outbound Segmentation Hardware Errors

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Message Segment Sent	Comments
NWrite Request	Command descriptor effective length less than message descriptor payload byte count	1	No	Descriptor error in command descriptor enqueued	No	No buffers released regardless of BR setting
NWrite Request	Invalid FTYPE	1	No	Descriptor error in command descriptor enqueued	No	No buffers released regardless of BR setting

Table 16-31. Outbound Segmentation Hardware Errors (Continued)

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Message Segment Sent	Comments
NWrite Request	Invalid target interface specified	1	No	Descriptor error in command descriptor enqueued	No	No buffers released regardless of BR setting
NWrite Request	End of scatter/gather table reached before message descriptor payload byte count accounted for	2	No	Descriptor error in command descriptor enqueued	Partially	—
NWrite Request	Memory transaction error	2	Message unit error if MUIER[TE] set	Transaction error in command descriptor enqueued. MUEDR[TE]. Command descriptor captured in MUECCDR0–3.	No	NWrite aborted. No additional buffers released

16.3.5.2.4.1 Descriptor Error

When a descriptor error is detected by the message unit, the following occurs.

- Completion message queue
  - The segmentation process is halted and the descriptor error bit (DE) in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status bit (ES) is set.

16.3.5.2.4.2 Transaction Errors

When a transaction error occurs during a local memory data read by the message unit, the following occurs.

- Segments that encounter a transaction error are not sent because the packet data is not available.
- Memory reads that were already generated before the transaction error occurred are also not transferred.
- Command descriptor is captured in MUMECCDR0–3.
- Global message unit error detect register MUMEDR[OTE] is set.
- Completion message queue
  - After the segmentation operation completes, the internal transaction error bit in the TE field in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status bit (ES) is set.

16.3.6 Type6 Streaming Write Functional Description

This section describes the different Typ6 SWrite descriptor formats. Type6 SWrites are only supported outbound.

16.3.6.1 Type6 Outbound SWrite Descriptor Format

The Type6 outbound descriptor contains information for the message unit to send an SWrite transaction. The message unit receives the outbound SWrite descriptor by dequeueing a command descriptor from an outbound message queue. The message descriptor points to a data buffer containing the descriptor and SWrite data payload.

Figure 16-22 shows the format of an outbound SWrite descriptor. Reserved fields must be cleared.

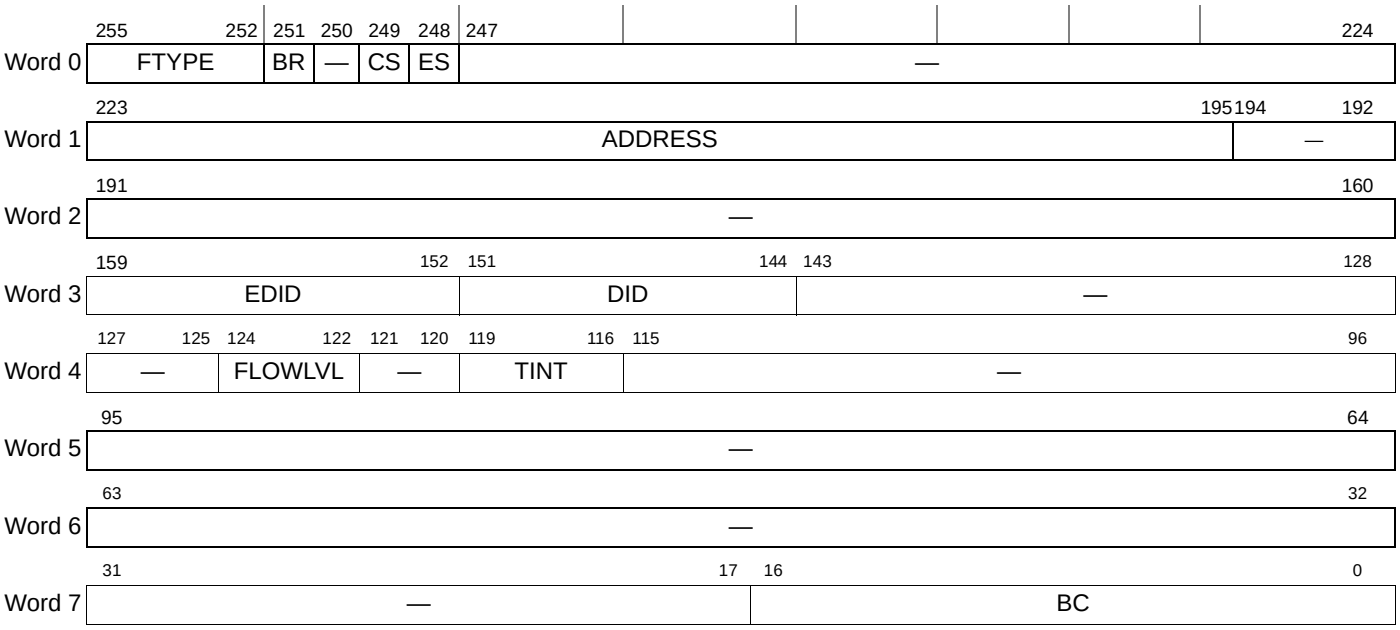

Figure 16-22. Type6 Outbound SWrite Descriptor

Table 16-32 describes the Type6 outbound SWrite descriptor fields.

Table 16-32. Type6 Outbound SWrite Descriptor Field Descriptions

Bits	Name	Description
Word 0—Header		
255–252	FTYPE	Descriptor type select 0110 Type6 All other values are reserved.
251	BR	Buffer release enable 0 No hardware buffer releases performed. 1 Hardware buffer releases performed. If TE/DE error status was reported, not all buffers may have been released successfully.

Table 16-32. Type6 Outbound SWrite Descriptor Field Descriptions (Continued)

Bits	Name	Description
250	—	Reserved
249	CS	Completion status 0 Status message queue is not updated when SWrite completes normally. 1 Status message queue is updated when SWrite completes normally.
248	ES	Error status 0 Status message queue is not updated when SWrite aborted due to error. 1 Status message queue is updated when SWrite aborted due to error.
247–224	—	Reserved
Word 1—Address

Word 5—Reserved		
95–64	—	Reserved
Word 6—Reserved		
63–32	—	Reserved

Table 16-32. Type6 Outbound SWrite Descriptor Field Descriptions (Continued)

Bits	Name	Description
Word 7—Byte Count		
31–17	—	Reserved
16–0	BC	Byte count Contains the number of bytes for the write operation. Only multiples of 8 bytes are allowed. 0x00008 8 bytes 0x00010 16 bytes 0x00018 24 bytes ... 0x0FFF8 64 Kbytes – 8 0x10000 64 Kbytes All other values reserved.

Figure 16-23 shows the format for Type6 scatter/gather tables usage. The first entry of the scatter/gather table holds the 32-byte descriptor. The data offset is specified through the scatter/gather entry offset field. Non-scatter/gather format is also supported for Type6 if the data payload plus the descriptor offset is less than or equal to 64 Kbytes.

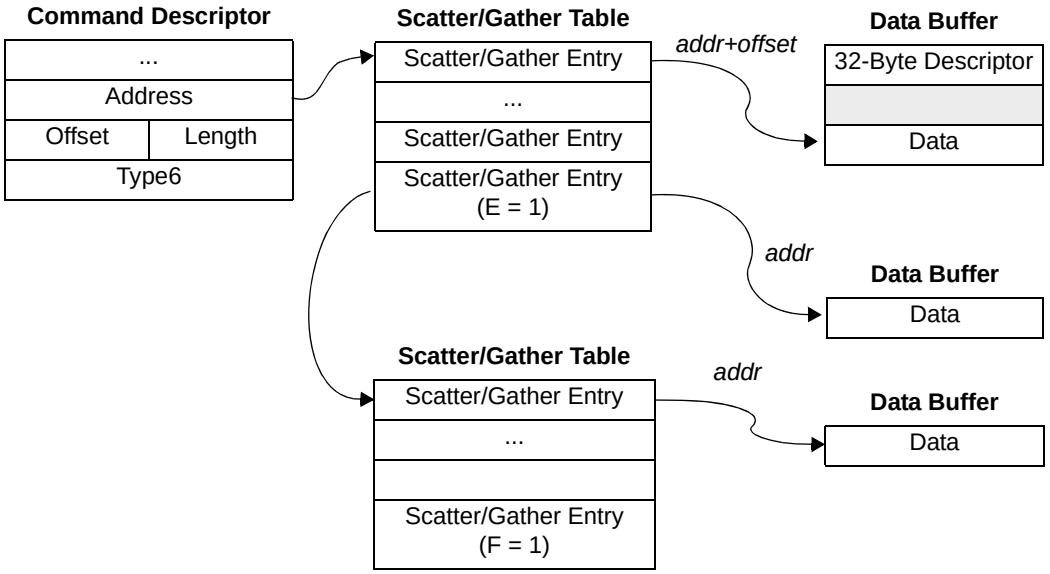

Figure 16-23. Outbound Type6 Scatter/Gather Table Format

16.3.6.2 Type6 Outbound SWrite Operation

RapidIO supports an SWrite type that contains a data payload from 1 to 64 Kbytes. The segmentation units are responsible for sending messages enqueued by a producer or producers from one of the outbound frame queues owned by the message unit. Concurrent processing may also occur between any number of message queues as long as the outbound ordering rules apply; see **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.6.2.1 Work Scheduling

The message unit receives all work from the outbound message queues. A producer or producers enqueueue work onto the outbound message queues owned by the message unit. To maintain any ordering between transactions, a producer must enqueue transactions with dependencies onto the same outbound message queue. The outbound ordering rules are described in **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.6.2.2 Adding NWrites To A Message Queue

A producer may add new SWrites to any message queue owned by the message unit. The producer needs to allocate buffer space for the SWrite descriptor as appropriate and enqueue the command descriptor. The message unit dequeues the command descriptor, determines the type, and proceeds to read the SWrite descriptor.

A producer should follow the following guidelines to add a new SWrite to a message queue:

- Create the 32-byte outbound SWrite descriptor as described in **Section 16.3.6.1**, *Type6 Outbound SWrite Descriptor Format*.
  - Set the descriptor type select field FTYPE = 4b0110 to indicate SWrite type.
  - Allocate buffer for the SWrite descriptor from one of the buffer pools available, preferably with the smallest buffer size (that is, 64 bytes).
  - For all other fields, see **Section 16.3.6.1**, *Type6 Outbound SWrite Descriptor Format*.
- Add the SWrite descriptor to a command descriptor and set FTYPE=4b0110 to indicate SWrite type.
- Enqueue the command descriptor onto the message queue.
- The message unit releases buffers used by the producer to hold the SWrite descriptor and data payload when the operation completes, if the buffer release bit (BR) is set in the message descriptor.

16.3.6.2.3 SWrite Initialization

See **Section 16.3.17.6**, *Initializing Outbound Message Queues*.

16.3.6.2.4 Error Handling

The message unit can report completion status and error information after completing the command descriptor by updating the command descriptor status field.

The following steps should be performed to enable this mode.

- Set the message descriptor completion (CS) or error (ES) status bit.
- Software should observe the status field of the command descriptor after it has been written to the completion queue to determine success.

Table 16-33 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed.

Table 16-33. Outbound Segmentation Hardware Errors

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Message Segment Sent	Comments
SWrite Request	Command descriptor effective length less than message descriptor payload byte count	1	No	Descriptor error in command descriptor enqueued	No	No buffers released regardless of BR setting
SWrite Request	Invalid FTYPE	1	No	Descriptor error in command descriptor enqueued	No	No buffers released regardless of BR setting
SWrite Request	Invalid target interface specified	1	No	Descriptor error in command descriptor enqueued	No	No buffers released regardless of BR setting
SWrite Request	End of scatter/gather table reached before message descriptor payload byte count accounted for	2	No	Descriptor error in command descriptor enqueued	Partially	—
SWrite Request	Memory transaction error	2	Message unit error if MUIER[TE] is set	Transaction error in command descriptor enqueued. MUMEDR[TE]. Command descriptor captured in MUECCDR0–3	No	SWrite aborted. No additional buffers released

16.3.6.2.4.1 Descriptor Error

When a descriptor error is detected by the message unit the following occurs:

- Completion message queue
  - The segmentation process is halted and the descriptor error bit DE in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.6.2.4.2 Transaction Errors

When an transaction error occurs during a local memory data read by the message unit the following occurs.

- Segments that encounter a transaction error are not sent because the packet data is not available.
- Memory reads that were already generated before the transaction error occurred are also not transferred.
- Command descriptor is captured in MUECCDR0–3.
- Global message unit error detect register MUEDR[OTE] is set.
- Completion message queue
  - After the segmentation operation completes, the internal transaction error bit in the TE field, in the command descriptor, is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.7 Type8 Port-Write Functional Description

Type8 port-writes are supported for both inbound and outbound, although port-writes are normally not generated by an end-point.

16.3.7.1 Type8 Outbound Port-Write Descriptor Format

The Type8 outbound descriptor contains information for the message unit to send a maintenance port-write. The message unit receives the outbound maintenance descriptor by dequeueing a command descriptor from an outbound message queue. The message descriptor points to a data buffer containing the descriptor and port-write data payload.

Figure 16-24 shows the format of an outbound port-write descriptor. Reserved fields must be cleared.

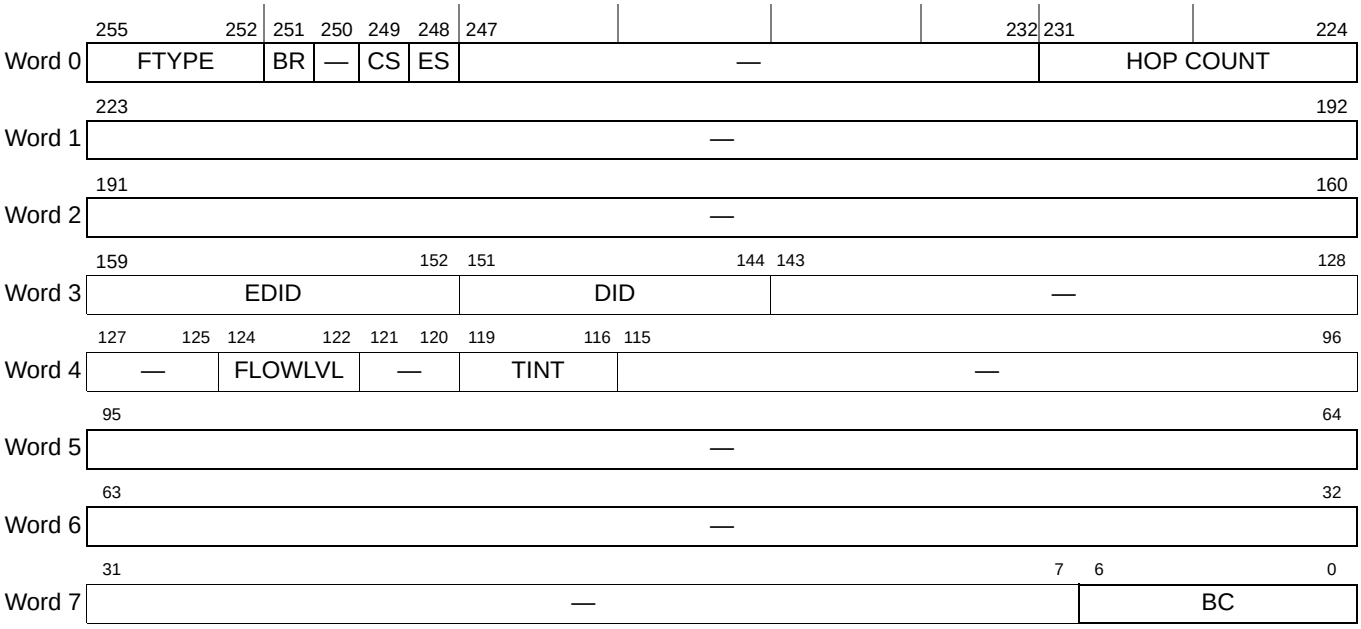

Figure 16-24. Type8 Outbound Port-Write Descriptor

Table 16-34 describes the Type8 outbound port-write descriptor fields.

Table 16-34. Type8 Outbound Port-Write Descriptor Field Descriptions

All other values reserved.

Figure 16-25 illustrates an example of a command descriptor referencing the data buffer holding the Type8 port-write descriptor and data. The starting location of the port-write data payload is calculated by adding the data offset to the command descriptor address.

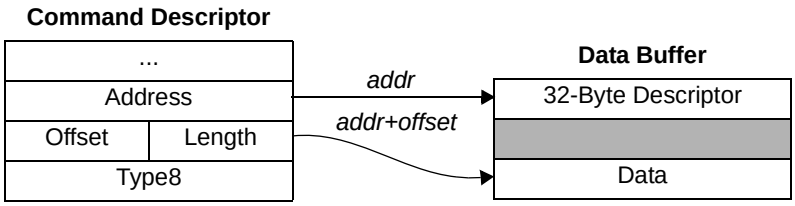

Figure 16-25. Command Descriptor Referencing Outbound Type8 Port-Write Descriptor

16.3.7.2 Type8 Inbound Port-Write Descriptor Format

This section defines the format of the inbound port-write command descriptor. No port-write message descriptor is written, because the payload contains all the necessary information. The command descriptor is then enqueued onto an inbound message queue processed by the consumer.

Figure 16-26 illustrates an example of a command descriptor referencing the data buffer holding the Type8 port-write data payload. The starting location of the port-write data payload is calculated by adding the data offset to the command descriptor address. The data offset is programmable through IB*m*T8C*n*DOR.

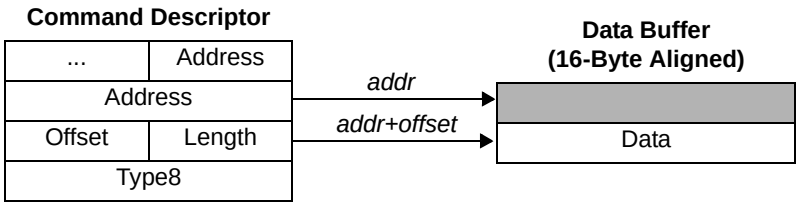

Figure 16-26. Command Descriptor Referencing Inbound Type8 Port-Write Data Payload

16.3.7.3 Type8 Outbound Port-Write Operation

RapidIO supports a maintenance port-write type that contains a data payload from 4 to 64 bytes. The segmentation units are responsible for sending messages enqueued by a producer or producers from one of the outbound frame queues owned by the message unit. Concurrent processing may also occur between any number of message queues as long as the outbound ordering rules apply, see **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.7.3.1 Work Scheduling

The message unit receives all work from the outbound message frame queues. A producer or producers enqeueue work onto the outbound message queues owned by the message unit. To maintain any ordering between transactions, a producer must enqueue transactions with dependencies onto the same outbound message queue. The outbound ordering rules are described in **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.7.3.2 Adding Port-Writes To A Message Queue

A producer may add new port-writes to any message queue owned by the message unit. The producer needs to allocate buffer space for the port-write descriptor as appropriate and enqueue the command descriptor. The message unit dequeues the command descriptor, determine the type, and proceeds to read the port-write descriptor.

A producer should follow the guidelines below to add a new port-write to a message queue:

- Create the 32-byte outbound port-write descriptor as described in **Section 16.3.7.1**, *Type8 Outbound Port-Write Descriptor Format*.
  - Set the descriptor type select field FTYPE=4b1000 to indicate port-write type.
  - Allocate buffer for the port-write descriptor from one of the buffer pools available, preferably with the smallest buffer size (that is, 64 bytes).
  - For all other fields, see **Section 16.3.7.1**, *Type8 Outbound Port-Write Descriptor Format*.
- Add the Portwrite descriptor to a command descriptor and set FTYPE=0b1000 to indicate port-write type.
- Enqueue the command descriptor onto the message queue.

- The message unit releases buffers used by the producer to hold the port-write descriptor and data payload when the operation completes if the buffer release bit (BR) bit was set in the message descriptor.

16.3.7.3.3 Port-Write Initialization

See **Section 16.3.17.6**, *Initializing Outbound Message Queues*.

16.3.7.3.4 Error Handling

The message unit can report completion status and error information after completing the command descriptor by updating the command descriptor status field.

The following steps should be performed to enable this mode.

- Set the message descriptor completion (CS) or error (ES) status bit.
- Software should observe the status field of the command descriptor after it has been written to the completion queue to determine success.

Table 16-35 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed.

Table 16-35. Outbound Port-Write Hardware Errors

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Port-Write Sent	Comments
Port-Write Request	Command descriptor effective length less than message descriptor payload byte count.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Port-Write Request	Unsupported byte count. Only 4, 8, 16, 32 and 64 bytes allowed.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Port-Write Request	Invalid FTYPE.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.

Table 16-35. Outbound Port-Write Hardware Errors (Continued)

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Port-Write Sent	Comments
Port-Write Request	Invalid target interface specified.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Port-Write Request	Memory transaction error.	2	Message unit error if MUIER[OTE] set.	Transaction error in command descriptor enqueued. MUEDR[OTE]. Command descriptor captured in MUECCDR0–3	No	Port-write aborted. No additional buffers released.

16.3.7.3.4.1 Descriptor Error

When a descriptor error is detected by the message unit the following occurs.

- Completion Message queue
  - The segmentation process is halted and the descriptor error bit DE in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.7.3.4.2 Transaction Errors

When an transaction error is detected during a local memory data read by the message unit the following occurs.

- Port-writes that encounter a transaction error are not sent because the port-write data is not available.
- Memory reads that were already generated before the transaction error occurred are also not transferred.
- Command descriptor is captured in MUECCDR0–3.
- MUEDR[OTE] is set.
- Completion message queue
  - After the port-write operation completes the transaction error bit, TE, in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.
- Buffer release (BR = 1)
  - No further buffers are released once a TE error is detected.

16.3.7.4 Type8 Inbound Port-Write Operation

The port-write is intended as an error reporting mechanism from an end point-less device to a control processor or other system host. The message unit is responsible for receiving RapidIO Type8 port-writes and placing then onto an inbound message queue. Software can specify the destination message queue for the port-write operation utilizing port-write classification, see **Section 16.3.17.2**, *Classification Initialization*. Utilizing the buffer pools, the message unit requests a single buffer to hold the port-write information. Software must provide the required sized buffer pool in IBmT8CnBPR for the message unit to store the entire port-write. The data offset is defined in IB*m*T8C*n*DOR. The message unit generates a frame size error if the inbound port-write cannot be stored in a single buffer due to insufficient buffer sizes available.

16.3.7.4.1 Inbound Port-Write Initialization

To configure the message unit for port-write operations, see **Section 16.3.17.5**, *Initializing Inbound Message Queues*.

16.3.7.4.2 Error Handling

The message unit reports errors, utilizing the inbound message queue, by setting the status field in the command descriptor before enqueueing the descriptor onto the designated inbound message queue. The consumer should read the status bits before processing the port-write to determine the appropriate action.

Table 16-36 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed.

Table 16-36. Inbound Port-Write Hardware Errors

Error	Error Checking Level	Interrupt Generated	Status Bit Set	Local Memory Updated	Comments
Buffer size too small.	1	No	Bit BSE in command descriptor enqueued.	Yes	Port-write is invalid.
Memory transaction error.	3	Message unit error if MUIER[ITEIE] set.	Transaction error in command descriptor enqueued and message unit error detect register MUEDR[ITE]. Address captured in MUECAR.	Possibly	Port-write is invalid.

Table 16-36. Inbound Port-Write Hardware Errors (Continued)

Error	Error Checking Level	Interrupt Generated	Status Bit Set	Local Memory Updated	Comments
Buffer pool exhausted.	3	Message unit error if MUIER[BAEIE] set.	Transaction error in command descriptor enqueued and Message Unit Error Detect Register MUEDR[BAE].	No	Port-write is invalid.
Failure to enqueue the command descriptor onto the inbound message queue.	4	Message unit error if MUIER[IMERIE] set.	MUMEDR[IMER]. Message queue captured in MUECMQR.	Yes	—

16.3.7.4.2.1 Buffer Size Errors

When a buffer size error is detected by the message unit, the following occurs.

- Port-write is discarded.
- The message unit sets the buffer size error bit, BSE in the command descriptor.
- After the port-write operation completes, the command descriptor is enqueued onto the message queue.

16.3.7.4.2.2 Transaction Errors

When an transaction error occurs, due to insufficient buffer resources or local memory write error, by the message unit the following occurs.

- Port-write is defective.
- The message unit sets the transaction error bit, TE, in the command descriptor.
- After the doorbell operation completes, the command descriptor is enqueued onto the message queue.
- MUEDR[ITE] is set for memory access error.
- Address is captured in MUECAR for memory access error.
- MUEDR[BAE] is set if buffer resources depleted.

16.3.8 Type9 Data Streaming Functional Description

Type9 data streaming is supported both inbound and outbound.

16.3.8.1 Type9 Segmentation Descriptor Format

The Type9 outbound descriptor contains information for the message unit to send a PDU. The message unit receives the outbound packet descriptor by dequeueing a command descriptor from

the outbound message queue. The command descriptor points to a scatter/gather table where the first entry points to the outbound descriptor.

Figure 16-27 shows the format of an outbound PDU descriptor. Reserved fields must be cleared.

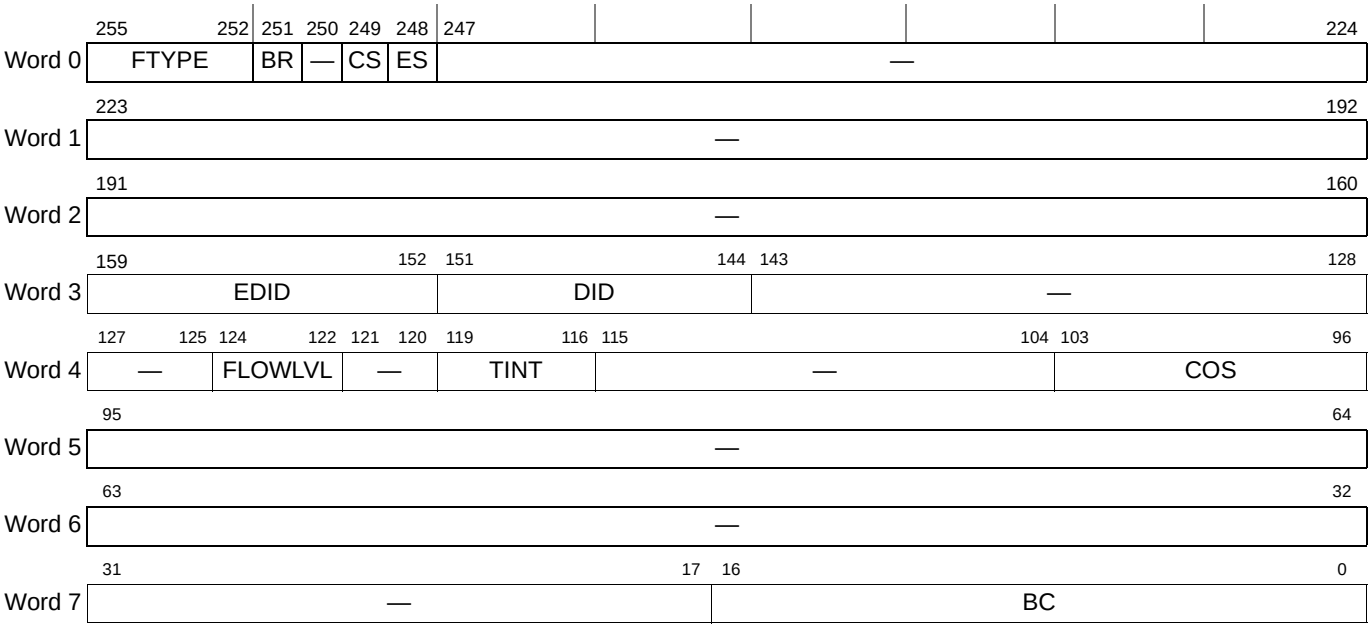

Figure 16-27. Type9 Outbound PDU Descriptor

Table 16-37 describes the Type9 outbound PDU descriptor fields.

Table 16-37. Type9 Outbound PDU Descriptor Field Descriptions

Bits	Name	Description
Word 0—Header		
255–252	FTYPE	Descriptor type select. 1001 Type9 All other values reserved.
251	BR	Buffer release enable. 0 No hardware buffer releases performed. 1 Hardware buffer releases performed. If TE/DE error status was reported, not all buffers may have been released successfully.
250	—	Reserved
249	CS	Completion status. 0 Status message queue is not updated when PDU completes normally. 1 Status message queue is updated when PDU completes normally.
248	ES	Error status. 0 Status message queue is not updated when PDU aborted due to error. 1 Status message queue is updated when PDU aborted due to error.
247–224	—	Reserved
Word 1—Reserved		
223–192	—	Reserved

Table 16-37. Type9 Outbound PDU Descriptor Field Descriptions (Continued)

Bits	Name	Description
Word 2—Reserved		
191–160	—	Reserved
Word 3—Destination Port		
159–152	EDID	Extended destination ID**.** Most significant byte of a 16-bit destination ID when operating in large transport mode. Reserved when operating in small transport mode.
151–144	DID	Destination ID. Contains the destination ID field of the transaction (device ID of the target).
143–128	STREAMID	Value for the “streamID” field in the DATA STREAMING packet.
Word 4—Destination Attributes		
127–125	—	Reserved
124–122	FLOWLVL	Transaction flow level. 000 Lowest priority transaction request flow 001 Next highest priority transaction request flow ... 100 Next highest priority transaction request flow 101 Highest priority transaction request flow 110 Reserved 111 Reserved
121–120	—	Reserved
119–116	TINT	Target interface. 0000 RapidIO Port 1 0001 RapidIO Port 2 All other values reserved.
115–104	—	Reserved
103–96	COS	Value for the “COS” field in the DATA STREAMING packet.
Word 5–6		
95–32	—	Reserved
Word 7—Byte Count		
31–17	—	Reserved
16–0	BC	Byte count. Contains the number of bytes for this segmentation operation. The maximum segmentation operation size is 64 Kbytes and the minimum is 1 byte. 0x00001 1 byte 0x00002 2 bytes 0x00003 3 bytes ... 0x0FFFF 64 Kbytes-1 0x10000 64 Kbytes All other values reserved.

Figure 16-28 shows the format for Type9 scatter/gather tables usage. The first entry of the scatter/gather table holds the 32-byte descriptor. The data offset is specified through the

scatter/gather entry offset field. Non-scatter/gather format is also supported for Type9 if the data payload plus the descriptor offset is less than or equal to 64 Kbytes.

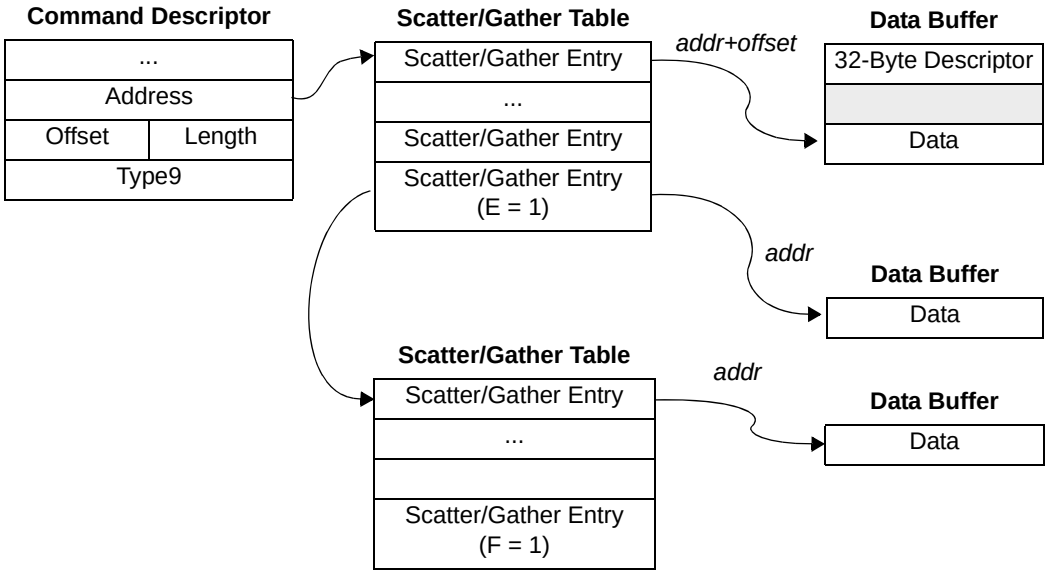

Figure 16-28. Outbound Type9 Scatter/Gather Table Format

16.3.8.2 Type9 Reassembly Descriptor Format

The Type9 inbound descriptor contains information received by the message unit. The message unit fills out the descriptor with the received control parameters before embedding a link to it in a command descriptor. The command descriptor is then enqueued onto an inbound message queue processed by the consumer.

Note: A non-Freescale RapidIO Type9 destination endpoint may be unsuccessful in correctly reassembling two or more PDUs from the same source with the same RapidIO flow when interleaving is done based on CoS. The eMSG segmentation engine includes the RapidIO field CoS (Class-of-Service) field when determining segmentation interleaving dependencies, thus PDUs of the same flow but different CoS may be interleaved. Use one of the following two methods to avoid this problem.

1. Assign outbound Type9 PDUs of the same flow with the same CoS to force a dependency between the PDUs, thus avoiding segmentation interleaving.
2. Set register bit MUMR[OSID] = 1 to disable segmentation interleaving on a destination ID basis. However, this affect all supported types and may affect performance.

Figure 16-29 shows the format of an inbound PDU descriptor. Reserved fields must be cleared.

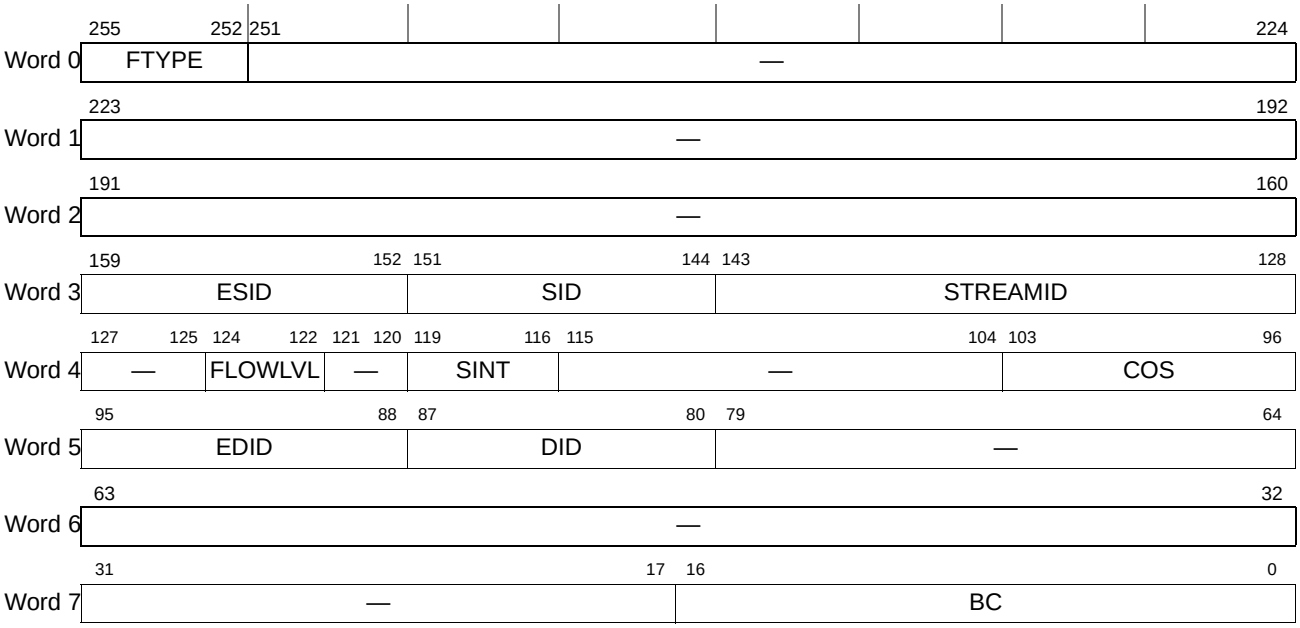

Figure 16-29. Type9 Inbound PDU Descriptor

Table 16-38 describes the Type9 inbound PDU descriptor fields.

Table 16-38. Type9 Inbound PDU Descriptor Field Descriptions

Bits	Name	Description
Word 0—Header

Word 6—Reserved		
63–32	—	Reserved
Word 7—Byte Count		
31–217	—	Reserved
16–0	BC	Byte count. Contains the number of bytes written to memory for the reassembly operation, which may be less than expected if an error was encountered during reassembly. 0x000011 byte 0x000022 bytes 0x000033 bytes ... 0x0FFFF64 Kbytes-1 0x1000064 Kbytes

Figure 16-30 shows the format for Type9 scatter/gather tables usage. The first entry of the scatter/gather table also holds the 32-byte descriptor. The first data offset is programmable

through the scatter/gather Data Offset Register MUSGDOR, but must be greater than or equal to the descriptor size. The data offset is specified through the scatter/gather entry offset field.

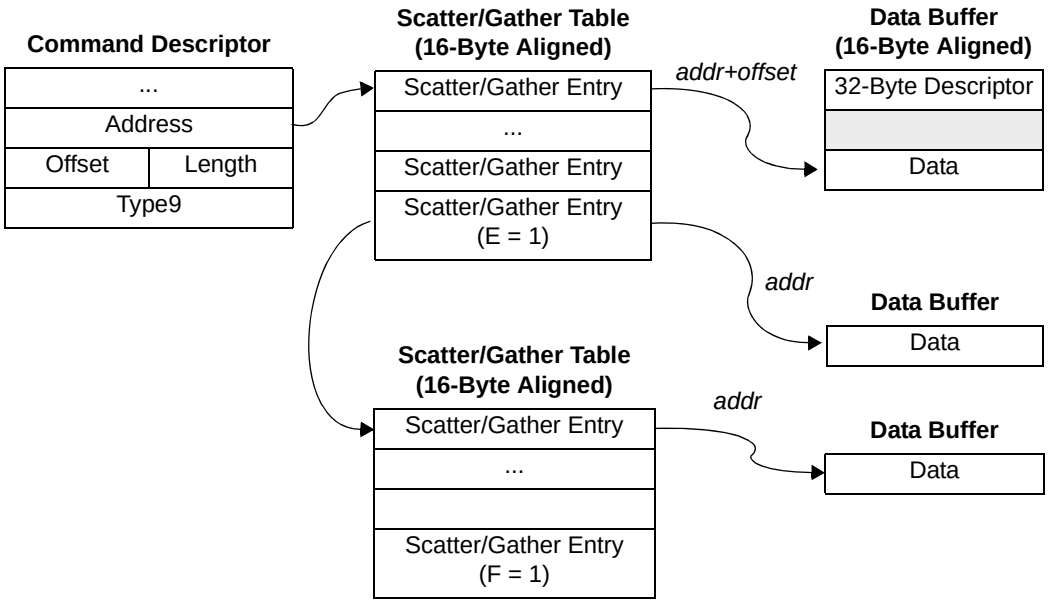

Figure 16-30. Inbound Type9 Scatter/Gather Table Format

16.3.8.3 Type9 Outbound Segmentation Operation

The segmentation units are responsible for sending PDUs enqueued by a producer or producers from one of the outbound frame queues owned by the message unit. Concurrent processing may also occur between any number of message queues as long as the outbound ordering rules apply, see **Section 16.3.14.2**, *Outbound Ordering Rules*.

Note: Do not use the scatter/gather table format for Type9 messages during outbound segmentation. Using this format can result in segmentation unit counters being corrupted by a descriptor error (DE).

16.3.8.3.1 Work Scheduling

The message unit receives all work from the outbound message queues. A producer or producers enqueueue work onto the outbound message queues owned by the message unit. To maintain any ordering between transactions, a producer must enqueue transactions with dependencies onto the same outbound message queue. The outbound ordering rules are described in **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.8.3.2 Adding PDUs To A Message Queue

A producer may add new PDUs to any message queue owned by the message unit. The producer needs to allocate buffer space for the PDU descriptor, scatter/gather table(s) and data as appropriate and enqueue the command descriptor. The message unit dequeues the command

descriptor, determines the type, and proceeds to read the first scatter/gather table, message descriptor and data.

A producer should follow the guidelines below to add a new PDU to an outbound message queue:

- Allocate a data buffer to hold the PDU descriptor and all or part of the PDU payload. If buffer pools are used, the smallest buffer size may be preferred to reduce overhead.
- Write the 32-byte outbound PDU descriptor as described in **Section 16.3.8.1**, *Type9 Segmentation Descriptor Format*, at the beginning of the first data buffer.
  - Set the descriptor type select field FTYPE=4b1001 to indicate packet type.
  - For all other fields, see **Section 16.3.8.1**, *Type9 Segmentation Descriptor Format*.
- If multiple data buffers are required to hold the data payload, allocate buffer to hold the scatter/gather table to stitch smaller data buffers together. For best performance, use a small amount of data buffers and avoid linking scatter/gather tables.
- Write the scatter/gather table where the first entry holds a pointer to the first data buffer and the following entries points to additional data buffers or additional scatter/gather tables as needed, see **Section 16.3.4**, *Scatter/Gather Tables*. The first scatter/gather table entry must have an offset to where the data payload starts (greater than the PDU descriptor size).
- Add the first scatter/gather table to a command descriptor and set FTYPE=4b1001 to indicate packet type.
- Enqueue the command descriptor onto the outbound message queue.
- The message unit releases buffers used by the producer to hold the PDU descriptor and data payload when the operation completes if the buffer release bit (BR) is set in the message descriptor.

16.3.8.3.3 Segmentation Initialization

To configure the message unit for data streaming operations, See **Section 16.3.17.6**, *Initializing Outbound Message Queues*.

16.3.8.3.4 Error Handling

The message unit can report completion status and error information after completing the command descriptor by updating the command descriptor status field.

The following steps should be performed to enable this mode.

- Set the message descriptor completion (CS) or error (ES) status bit.
- Software should observe the status field of the command descriptor after it has been written to the completion queue to determine success.

Table 16-39 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed.

Table 16-39. Outbound Segmentation Hardware Errors

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Message Segment Sent	Comments
Data Streaming Request	Command descriptor effective length less than message descriptor payload byte count.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Data Streaming Request	Invalid FTYPE.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Data Streaming Request	Invalid target interface specified.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Data Streaming Request	End of scatter/gather table reached before message descriptor payload byte count accounted for.	2	No	Descriptor error in command descriptor enqueued.	Partially	—
Data Streaming Request	Memory transaction error.	2	Message unit error if MUIER[TE] set	Transaction error in command descriptor enqueued. Message unit error detect register MUEDR[TE]. Command descriptor captured in MUECCDR0–3.	No	Message aborted. No additional buffers released.

16.3.8.3.4.1 Descriptor Error

When a descriptor error is detected by the message unit the following occurs.

- Completion message queue
  - The segmentation process is halted and the descriptor error bit DE in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.8.3.4.2 Transaction Errors

When an transaction error occurs during a local memory data read by the message unit the following occurs.

- Segments that encounter a transaction error are not sent because the packet data is not available.
- Memory reads that were already generated before the transaction error occurred are also not transferred.
- Command descriptor captured in MUECCDR0–3.
- Global message unit error detect register MUEDR[OTE] set.
- Completion message queue
  - After the segmentation operation completes, the internal transaction error bit in the TE field, in the command descriptor, is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.8.4 Type9 Reassembly Operation

The message unit is responsible for receiving packets and placing then onto an inbound message queue. Software can specify the destination message queue for a reassembly operation utilizing packet classification, see **Section 16.3.17.2**, *Classification Initialization*. Utilizing the buffer pools initialized by software, the message unit requests buffers for creating scatter/gather tables, descriptor and data buffers to hold the PDU.

16.3.8.4.1 Reassembly Initialization

To configure the message unit for data streaming operations, see **Section 16.3.17.5**, *Initializing Inbound Message Queues*.

16.3.8.4.2 Packet Steering

Packets are forwarded to a message queue based on the first inbound Type9 classification unit (numbered 1 through 64) to successfully classify the PDU based on virtual stream ID. Message queue specified by IB*m*T9C*n*MQR.

16.3.8.4.3 Packet Drop Condition

The following conditions may result in dropped packets:

- Message unit has detected a resource conflict, that is, a new PDU context was received and hardware context resources were depleted.

16.3.8.4.4 Error Handling

The message unit reports errors, utilizing the inbound message queue, by setting the status field in the command descriptor before enqueueing the descriptor onto the designated inbound message queue. The consumer should read the status bits before processing the packet to determine the appropriate action.

Table 16-40 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed. In general, when an error has been detected the reassembly continues until the end of the PDU is reached.

Table 16-40. Inbound Reassembly Hardware Errors

Error	Error Checking Level	Interrupt Generated	Status Bit Set	Data Segment Written	Message Descriptor Written	Comments
Start segment received for open context.	1	No	Bit SSE in command descriptor enqueued.	Yes. Partial defective PDU received.	Yes	New context is opened for starting segment. Old context is defective.
Segment request timeout.	1	No	Bit SRT in command descriptor enqueued.	No	Yes	PDU is defective.
Continuation segment received for new context.	2	No	Bit CSE in command descriptor enqueued.	No	Yes	PDU is defective. Message descriptor stream ID is invalid.
End segment received for new context.	2	No	Bit ESE in command descriptor enqueued.	No	Yes	PDU is defective. Message descriptor stream ID is invalid.
Source error. PDU was aborted by source.	2	No	Bit SE in command descriptor enqueued.	No	Yes	PDU is defective.
Maximum transmission unit.	2	No	Bit MTU in command descriptor enqueued.	No	Yes	PDU is defective.
Length field for end segment does not match actual byte count received.	2	No	Bit SME in command descriptor enqueued.	No	Yes	PDU is defective.
Transaction error.	3	Message unit error if MUIER[ITE] set.	Transaction error in command descriptor enqueued and Message unit error detect register MUEDR[ITE]. Address captured in MUECAR.	No	No	PDU is defective. Buffer may have been lost if scatter/gather table could not be updated.

Table 16-40. Inbound Reassembly Hardware Errors (Continued)

Error	Error Checking Level	Interrupt Generated	Status Bit Set	Data Segment Written	Message Descriptor Written	Comments
Buffer pool exhausted	3	Message unit error if MUIER[BAEIE] set.	Transaction error in command descriptor enqueued and message unit error detect register MUEDR[BAE].	No	No	PDU is defective.
Failure to enqueue the command descriptor onto the inbound message queue.	4	Message unit error if MUMIER[IMERIE] set.	Message unit error detect register MUMEDR[IMER]. Message queue captured in MUECMQR.	Yes	Yes	—

16.3.8.4.4.1 Single/Start Segment Error

When the single/start segment error is detected by the message unit the following occurs.

- The current open context is considered closed and the PDU is incomplete.
- The received single/start segment represents the first packet in a newly opened PDU context.
- The message unit sets the single/start segment error bit, SSE in the command descriptor.
- The command descriptor is enqueued onto the message queue.

16.3.8.4.4.2 Continuation Segment Error

When the continuation segment error is detected by the message unit the following occurs.

- Segment is discarded.
- The message unit sets the continuation segment error bit, CSE in the command descriptor.
- After the reassembly operation completes, the command descriptor is enqueued onto the message queue.

16.3.8.4.4.3 End Segment Error

When the end segment error is detected by the message unit the following occurs.

- Segment is discarded.
- The message unit sets the end segment error bit, ESE in the command descriptor.

After the reassembly operation completes, the command descriptor is enqueued onto the message queue.

16.3.8.4.4.4 Segment Request Timeout Errors

The segment request time-out counter starts after the first segment of a multi-segment PDU is received and the time-out counter is enabled. When a segment request time-out is detected, as defined by the RapidIO Port Response Time-out Control CSR, the following occurs.

- The current open context is considered closed and the PDU is incomplete.
- All reassembly packets that have not yet been received are considered complete.
- The message unit sets the segment request time-out error bit, SRT in the command descriptor.
- The command descriptor is enqueued onto the message queue.

16.3.8.4.4.5 MTU Violation Errors

When an MTU violation error is detected by the message unit, the following occurs.

- Packet is discarded.
- The message unit sets the MTU violation error bit, MTU in the command descriptor.
- After the reassembly operation completes, the command descriptor is enqueued to the message queue.

16.3.8.4.4.6 Source Errors

When a source error is detected by the message unit, the following occurs.

- The current open context is considered closed and the PDU is incomplete.
- All reassembly segments that have not yet been received are considered complete.
- The message unit sets the source error bit, SE in the command descriptor.
- After the reassembly operation completes, the command descriptor is enqueued to the message queue.

16.3.8.4.4.7 Size Mismatch Errors

When a size mismatch error is detected by the message unit, the following occurs.

- The current open context is considered closed and the PDU is incomplete.
- All reassembly packets that may not yet been received are considered complete.
- The message unit sets the size mismatch error bit, SME in the command descriptor.
- After the reassembly operation completes, the command descriptor is enqueued onto the message queue.

16.3.8.4.4.8 Transaction Errors

When an internal transaction error occurs, due to insufficient buffer resources or local memory write error, by the message unit the following occurs.

- Segment is discarded.
- The message unit sets the transaction error bit, TE, in the command descriptor.
- After the reassembly operation completes, the command descriptor is enqueued onto the message queue.
- Global message unit error detect register MUEDR[ITE] set for memory access error.
- Address captured in MUECAR for memory access error.
- Global message unit error detect register MUEDR[BAE] set if buffer resources depleted.

16.3.8.5 Flow Control Management

The message unit supports only basic stream management flow control (XON/XOFF) using Type9 extended header format. Any other flow control format received is accepted as basic flow control. Flow control messages are received as well as sent by the message unit. Flow control is enabled and controlled through register DSLLCCSR, hosted by the serial RapidIO controller. In addition, inbound queues are flow controlled automatically when reaching a critical level to avoid overflow of a queue.

16.3.8.5.1 Receiving Flow Control Messages

The message unit may receive stream management flow control messages. If flow control is disabled, these messages are ignored. For receiving flow control to work properly one or more classification rules must be configured for Type9 extended flow control targeting the outbound queue as specified in register IB*m*T9C*n*MQR. The block number is determined by the first rule matched. All targets for outbound queue N receiving the flow control should be considered.

Flow control messages must match inbound classification based on the following rules:

- RapidIO type9 extended.
- RapidIO port.
- RapidIO port source ID.
- If message contains wildcarded destination ID, a match always occurs, else message applies to a specific destination and the classification destination mask must be zero.
- If message contains wildcarded class-of-service, a match always occurs, else message applies to a specific set of classes which requires classification class mask to be a sub-set of the message class mask with a match on the remaining unmasked class bits.
- If traffic management stream ID is wildcarded a match always occurs, if not wildcarded an exact rule value match is required and the classification stream ID mask must be zero.

When stream management flow control is enabled, only certain combinations of class-of-service and stream ID rule mask fields are permitted for inbound classification.

- Specific stream in a specific class for specific destination:
  <DestID><CoS><StreamID>

- All streams in a specific class for a specific destination:
  <DestID><CoS>< xx >
- All streams in a group of classes for a specific destination:
  <DestID><CoS>< xx >
  where class mask if not 0x00
- All streams and classes for a specific destination:
  <DestID>< xx >< xx >
  where CoS and stream ID are wildcarded
- All streams and classes for all destinations:
  < xx >< xx >< xx >
  where destination, CoS and stream ID are wildcarded

An accepted flow control message exits (XOFF) or enters (XON) congestion management for the outbound message queue associated with the classification rule.

16.3.8.5.2 Sending Flow Control Messages

The message unit receives a congestion state change notification (CSCN) from an inbound message queue when the queue size has reached a low/high watermark, indicating the need for flow control of the source(s) of traffic. To enable the acceptance of Congestion State Change Notifications (CSCNs) from the inbound message queues perform the following:

1. Enable flow control through DSLLCCSR[TME].
2. Initialize the congestion enter/exit watermarks using IB*m*MQ*n*CMR.
3. Initialize the inbound Type9 classification flow control destination register using IB*m*T9C*n*FCDR.

For each enabled Type9 inbound classification rule targeting the inbound message queue, which is requesting flow control, an XON/XOFF stream management flow control message is generated to the programmed per port flow control destination ID register specified in the rule. An SRIO port which is in a powerdown state must not be included in the classification rule. If the inbound classification rule indicates a wildcarded source ID, the flow control destination ID register should represent a multicast target to reach all possible sources. An XON message is generated only if the queue is already in XOFF state, while an XOFF message is generated each time the enter congestion threshold is crossed.

All flow control requests are issued with the highest RapidIO flow.The traffic management operation is defined by the following fields (no other combination supported):

<DestID><CoS><StreamID> + <wild cards> + <Mask>

The following operands are generated by the message unit:

- Specific stream (classification rule with no stream wildcard):
  <DestID><CoS><StreamID> + <wc=000> + <Mask=0x00>

- All streams in a specific class (classification rule with stream wildcarded):
  <DestID><CoS>< xx > + <wc=001> + <Mask=0x00>
  where StreamID is a don't care.
- All streams in a group of classes (classification rule with class-of-service wildcarded):
  <DestID><CoS>< xx > + <wc=001> + <Mask=0xnn>
  where mask is one of the non-zero values except 0xff defined in **Table 16-132**.
- All streams and classes (classification rule with class-of-service wildcarded):
  <DestID>< xx >< xx > + <wc=011> + <Mask= xx >
  where CoS, StreamID and mask are don't cares.

Figure 16-31 shows an example of four classification rules generating traffic to a single message queue. Based on the value/mask setting of the Type9 rules, a set of flow control messages are generated.

Classification Rule 0	Value	Mask
CoS Stream ID Port	0xAA 0xBBBB —	0x00 0x0000 1
FC Destination ID (Port 1/2)	A/B	

Classification Rule 1	Value	Mask
CoS Stream ID Port	0xCC — 0	0x00 0xFFFF 0
FC Destination ID (port 1/2)	C/D	

Classification Rule 2	Value	Mask
CoS Stream ID Port	0xDD — 1	0x1F 0xFFFF 0
FC Destination ID (port 1/2)	E/F	

Classification Rule 3	Value	Mask
CoS Stream ID Port	— — —	0xFF 0xFFFF 1
FC Destination ID (port 1/2)	G/H	

Outbound Type9 Flow Control Messages

DestID	CoS	StreamID	WC	Mask	Port
A	0xAA	0xBBBB	b000	0x00	0
B	0xAA	0xBBBB	b000	0x00	1
C	0xCC	—	b001	0x00	0
F	0xDD	—	b001	0x1F	1
G	—	—	b011	—	0
H	—	—	b011	—	1

Figure 16-31. Example of Outbound Type9 Flow Control Generation

16.3.9 Type10 Doorbell Functional Description

16.3.9.1 Type10 Outbound Doorbell Descriptor Format

The Type10 outbound descriptor contains information for the message unit to send a doorbell. The message unit receives the outbound doorbell descriptor by dequeueing a command descriptor from the outbound message queue. The command descriptor points to a data buffer containing the descriptor and doorbell data.

Figure 16-32 shows the format of an outbound doorbell descriptor. Reserved fields must be cleared.

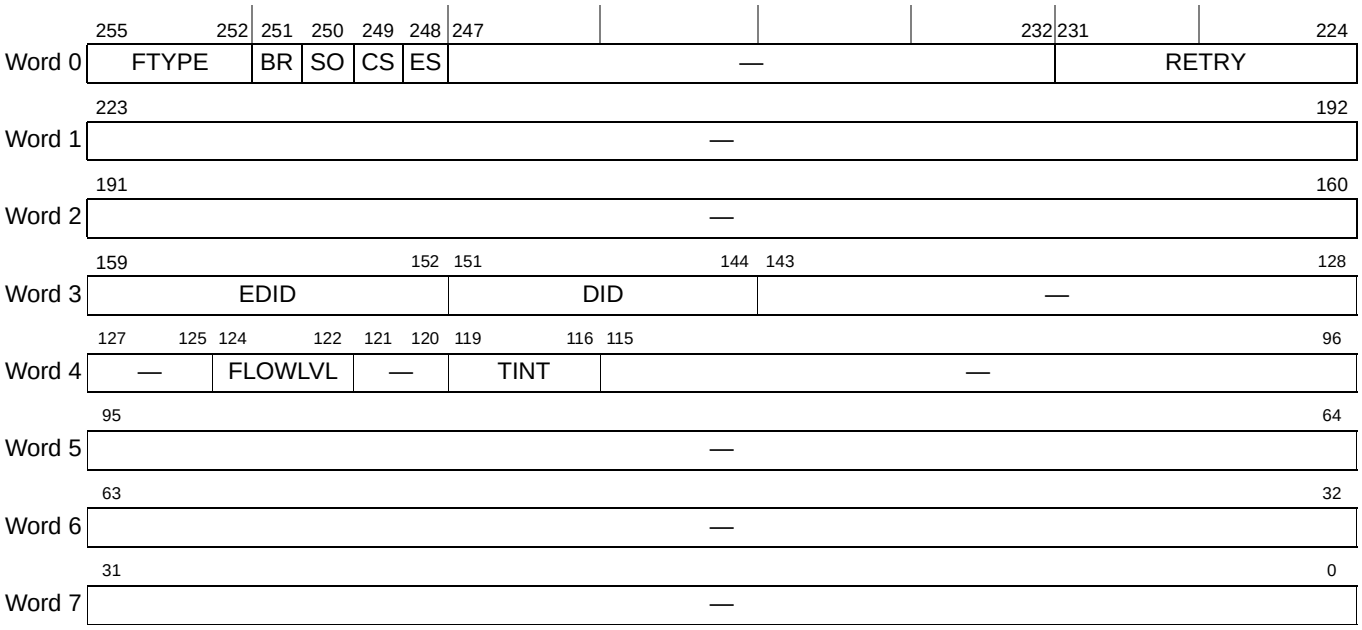

Figure 16-32. Type10 Outbound Doorbell Descriptor

Table 16-41 describes the Type10 outbound doorbell descriptor fields.

Table 16-41. Type10 Outbound Doorbell Descriptor Field Descriptions

Bits	Name	Description
Word 0—Header		
255–252	FTYPE	Descriptor type select. 1010 Type10 All other values reserved.
251	BR	Buffer release enable. 0 No hardware buffer releases performed. 1 Hardware buffer releases performed. If TE/DE error status was reported, not all buffers may have been released successfully.
250	SO	Strict ordering. A Type10 doorbell of same or lower priority than any other transaction is strictly ordered when the destination target ID and Rapid IO port interface is the same. 0 Disabled 1 Enabled
249	CS	Completion status. 0 Status message queue is not updated when doorbell completes normally. 1 Status message queue is updated when doorbell completes normally.
248	ES	Error status 0 Status message queue is not updated when doorbell aborted due to error. 1 Status message queue is updated when doorbell aborted due to error.
247–232	—	Reserved

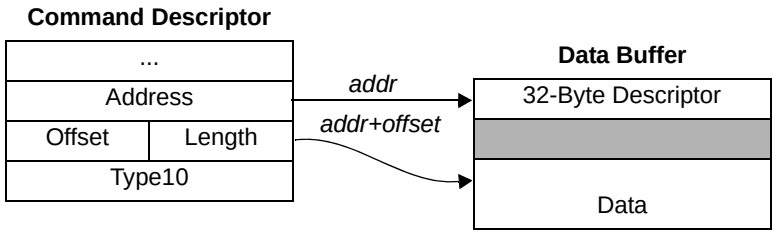

Figure 16-33. CD Using Single Buffer Referencing Type10 Outbound Message

16.3.9.2 Type10 Inbound Doorbell Descriptor Format

This section defines the format of the doorbell descriptor written to memory by the message unit. The message unit fills out the descriptor with the received control parameters before embedding a link to it in a command descriptor. The command descriptor is then enqueued onto an inbound message queue processed by the consumer.

Figure 16-34 shows the format of an inbound doorbell descriptor. Reserved fields must be cleared.

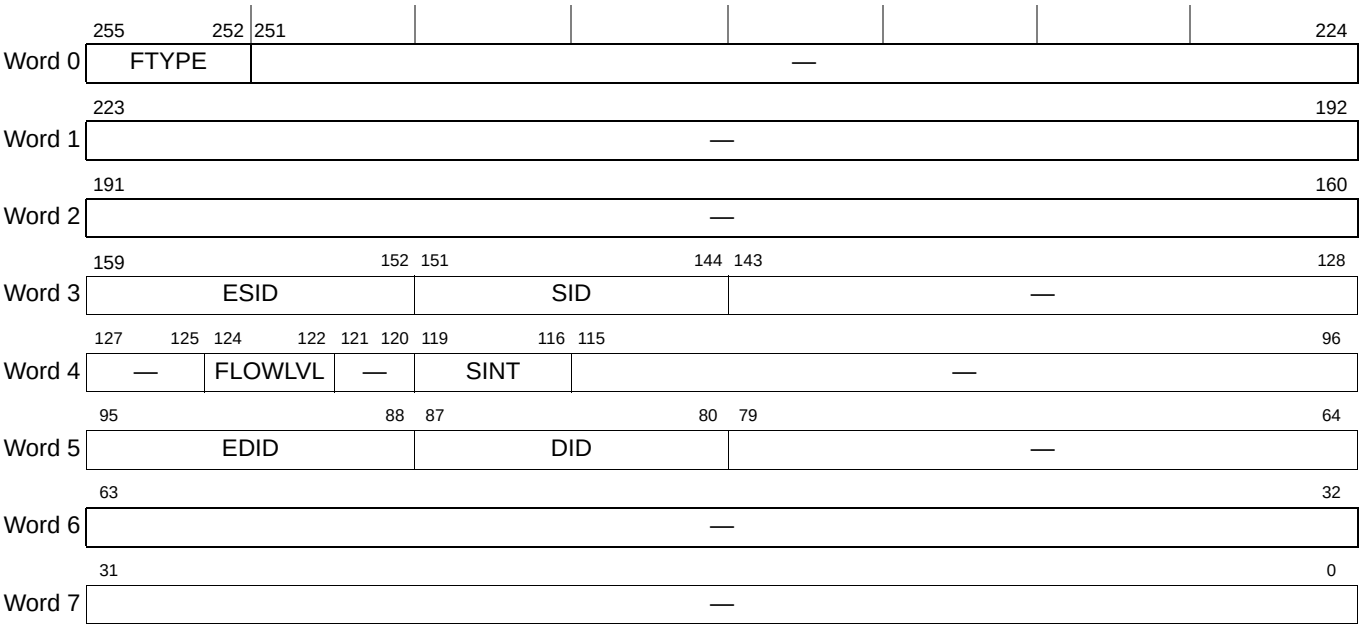

Figure 16-34. Type10 Inbound Doorbell Descriptor

Table 16-42 describes the Type10 inbound doorbell descriptor fields.

Table 16-42. Type10 Inbound Doorbell Descriptor Field Descriptions

Figure 16-39 shows the supported inbound format for Type10 data management. The command descriptor address points directly to the start of the message descriptor. The data offset is specified through the command descriptor offset field. The data offset is programmable through IT10C*n*DOR, but must be greater than or equal to the descriptor size.

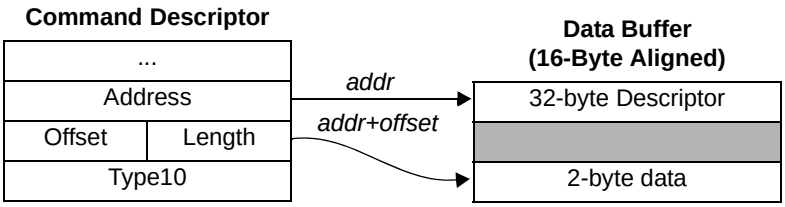

Figure 16-35. Command Descriptor Referencing a Type10 Inbound Doorbell

16.3.9.3 Type10 Outbound Doorbell Operation

RapidIO supports a doorbell type that contains a fixed 2-byte data payload. The segmentation units are responsible for sending messages enqueued by a producer or producers from one of the outbound frame queues owned by the message unit. Concurrent processing may also occur between any number of message queues as long as the outbound ordering rules apply, see **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.9.3.1 Work Scheduling

The message unit receives all work from the outbound message queues. A producer or producers enqueueue work onto the outbound message queues owned by the message unit. To maintain any ordering between transactions, a producer must enqueue transactions with dependencies onto the same outbound message queue. The outbound ordering rules are described in **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.9.3.2 Adding Doorbells To A Message Queue

A producer may add new doorbells to any message queue owned by the message unit. The producer needs to allocate buffer space for the doorbell descriptor as appropriate and enqueue the command descriptor. The message unit dequeues the command descriptor, determines the type, and proceeds to read the doorbell descriptor.

A producer should follow the guidelines below to add a new doorbell to a message queue:

- Create the 32-byte outbound doorbell descriptor as described in **Section 16.3.9.1**, *Type10 Outbound Doorbell Descriptor Format*.
  - Set the descriptor type select field FTYPE=0b1010 to indicate doorbell type.
  - Set the retry field to indicate number or times the message unit should attempt to retry the doorbell before stopping.
  - Allocate buffer for the doorbell descriptor from one of the buffer pools available, preferable with the smallest buffer size (that is, 64-bytes).
  - For all other fields, see **Section 16.3.9.1**, *Type10 Outbound Doorbell Descriptor Format*.
- Add the doorbell descriptor to a command descriptor and set FTYPE=0b1010 to indicate doorbell type.
- Enqueue the command descriptor onto the message queue.
- The message unit releases buffers used by the producer to hold the doorbell descriptor and data payload when the operation completes; if the buffer release bit (BR) is set in the message descriptor.

16.3.9.3.3 Doorbell Initialization

See **Section 16.3.17.6**, *Initializing Outbound Message Queues*.

16.3.9.3.4 Error Handling

The message unit can report completion status and error information after completing the command descriptor by updating the command descriptor status field.

The following steps should be performed to enable this mode.

- Set the message descriptor completion (CS) or error (ES) status bit.
- Software should observe the status field of the command descriptor after it has been written to the completion queue to determine success.

Table 16-43 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed.

Table 16-43. Outbound Doorbell Hardware Errors

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Doorbell Sent	Comments
Doorbell Request	Command descriptor effective length less than message descriptor payload byte count.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Doorbell Request	Invalid FTYPE.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Doorbell Request	Data format (scatter/gather) not supported.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Doorbell Request	Invalid flow level specified.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Doorbell Request	Invalid target interface specified.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Doorbell Request	Memory transaction error.	2	Message unit error if MUIER[OTE] set	Transaction error in command descriptor enqueued. Message unit error detect register MUEDR[OTE]. Command descriptor captured in MUECCDR0–3.	No	Doorbell aborted. No additional buffers released.
Doorbell Response	Number of retries exceeded.	3	No	Retry threshold exceeded in command descriptor enqueued.	Yes	Doorbell aborted.
Doorbell Response	Doorbell response timeout.	3	No	Segment response timeout in command descriptor enqueued.	Yes	Doorbell aborted.

16.3.9.3.4.1 Descriptor Error

When a descriptor error is detected by the message unit the following occurs.

- Completion message queue
  - The segmentation process is halted and the descriptor error bit DE in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.9.3.4.2 Doorbell Error Response Errors

When a doorbell error response is received by the message unit the following occurs.

- Completion message queue
  - After the doorbell operation completes, the error response received bit, ERR, in the command descriptor, is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.9.3.4.3 Doorbell Response Time-out Errors

When a doorbell response time-out is detected, as defined by the RapidIO Port Response Time-out Control CSR, the following occurs.

- Completion message queue
  - After the doorbell operation completes the doorbell response time-out error bit, SRT, in the command descriptor, is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.9.3.4.4 Retry Threshold Exceeded Errors

When a retry threshold exceeded error occurs for a doorbell the following occurs.

- Completion message queue
  - After the doorbell operation completes the retry threshold exceeded bit in the RTE field, in the command descriptor, is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.9.3.4.5 Transaction Errors

When an transaction error is detected during a local memory data read by the message unit the following occurs.

- Doorbells that encounter a transaction error are not sent because the doorbell data is not available.
- Memory reads that were already generated before the transaction error occurred are also not transferred. This includes retried message segments.
- Command descriptor captured in MUECCDR0–3.
- Global message unit error detect register MUEDR[OTE] set.
- Completion message Queue
  - After the doorbell operation completes the internal transaction error bit, TE, in the command descriptor is set.

— The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

- Buffer Release (BR=1)
  — No further buffers are released once a TE error is detected.

16.3.9.4 Type10 Inbound Doorbell Operation

The message unit is responsible for receiving RapidIO Type10 doorbells and placing then onto an inbound message queue. Software can specify the destination message queue for the doorbell operation utilizing doorbell classification, see **Section 16.3.17.2**, *Classification Initialization*. Utilizing the buffer pools initialized by software, the message unit requests buffers for creating the descriptors, which also holds the doorbell data.

Utilizing the buffer pools, the message unit requests a single buffer to hold the message descriptor and data. Software must provide the required sized buffer pool in IB*m*T10C*n*BPR for the message unit to store the entire message plus descriptor. The data offset is defined in IB*m*T10C*n*DOR. The message unit generated a frame size error if the inbound doorbell cannot be stored due to insufficient buffer sizes available.

16.3.9.4.1 Doorbell Initialization

To configure the message unit for doorbell operations, see **Section 16.3.17.5**, *Initializing Inbound Message Queues*.

16.3.9.4.2 Doorbell Steering

Doorbells are forwarded to a message queue based on the first classification unit (numbered 1 through 64) to successfully classify the doorbell based on source ID, and flow attributes. Message queue specified by IB*m*T10C*n*MQR.

16.3.9.4.3 Retry Response Condition

The conditions to generate a logical layer retry response are:

- Message unit has detected a resource conflict, that is, a doorbell was received and hardware context resources were depleted.

All responses are upgraded to priority 3.

16.3.9.4.4 Error Response Condition

The conditions to generate a logical layer error response are:

- Message unit did not have a matching classification rule.
- Message unit has detected a buffer size error.
- Message unit has detected a transaction error when allocating buffer resources or performing a local memory write.

All responses are upgraded to priority 3.

16.3.9.4.5 Error Handling

The message unit reports errors, utilizing the inbound message queue, by setting the status field in the command descriptor before enqueueing the descriptor onto the designated inbound message queue. The consumer should read the status bits before processing the doorbell to determine the appropriate action.

Table 16-44 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed.

Table 16-44. Inbound Doorbell Hardware Errors

Error	Error Checking Level	Interrupt Generated	Status Bit Set	Data Segment Written	Message Descriptor Written	Response	Comments
Illegal RapidIO request priority 3.	1	Message unit error if MUIER[MFE] set.	Message unit error detect register MUEDR[MFE].	N/A	N/A	None	Transaction dropped.
Buffer size too small (buffer size error).	2	No	Buffer size error in command descriptor enqueued.	No	Yes	Error	Doorbell is defective.
Memory transaction error.	3	Message unit error if MUMIER[ITE] set.	Transaction error in command descriptor enqueued and message unit error detect register MUEDR[ITE]. Address captured in MUECAR.	Possibly	No	Error	Doorbell is defective.
Buffer pool exhausted.	3	Message unit error if MUIER[BAEIE] set.	Transaction error in command descriptor enqueued and Message Unit Error Detect Register MUEDR[BAE].	No	No	Error	Doorbell is defective.
Failure to enqueue the command descriptor onto the inbound message queue.	4	Message unit error if MUIER[IMERIE] set.	MUEDR[IMER]. Message queue captured in MUECMQR.	Yes	Yes	None	—

16.3.9.4.5.1 Buffer Size Errors

When a buffer size error is detected by the message unit, the following occurs.

- Doorbell is discarded and an error response is returned for the segment.

- The message unit sets the buffer size error bit, BSE in the command descriptor.
- After the doorbell operation completes, the command descriptor is enqueued onto the message queue.

16.3.9.4.5.2 Transaction Errors

When an transaction error occurs, due to insufficient buffer resources or local memory write error, by the message unit the following occurs.

- Doorbell payload and message descriptor are defective and an error response is returned.
- The message unit sets the transaction error bit, TE, in the command descriptor.
- After the doorbell operation completes, the command descriptor is enqueued onto the message queue.
- Global message unit error detect register MUEDR[ITE] set for memory access error.
- Address captured in MUECAR for memory access error.
- Global message unit error detect register MUEDR[BAE] set if buffer resources depleted.

16.3.10 Type11 Message Functional Description

16.3.10.1 Type11 Outbound Message Descriptor Format

The Type11 outbound descriptor contains information for the message unit to send a messages. The message unit receives the outbound message descriptor by dequeueing a command descriptor from the outbound message queue. The command descriptor points to a data buffer containing the descriptor and message data.

Figure 16-36 shows the format of an outbound message descriptor. Reserved fields must be cleared.

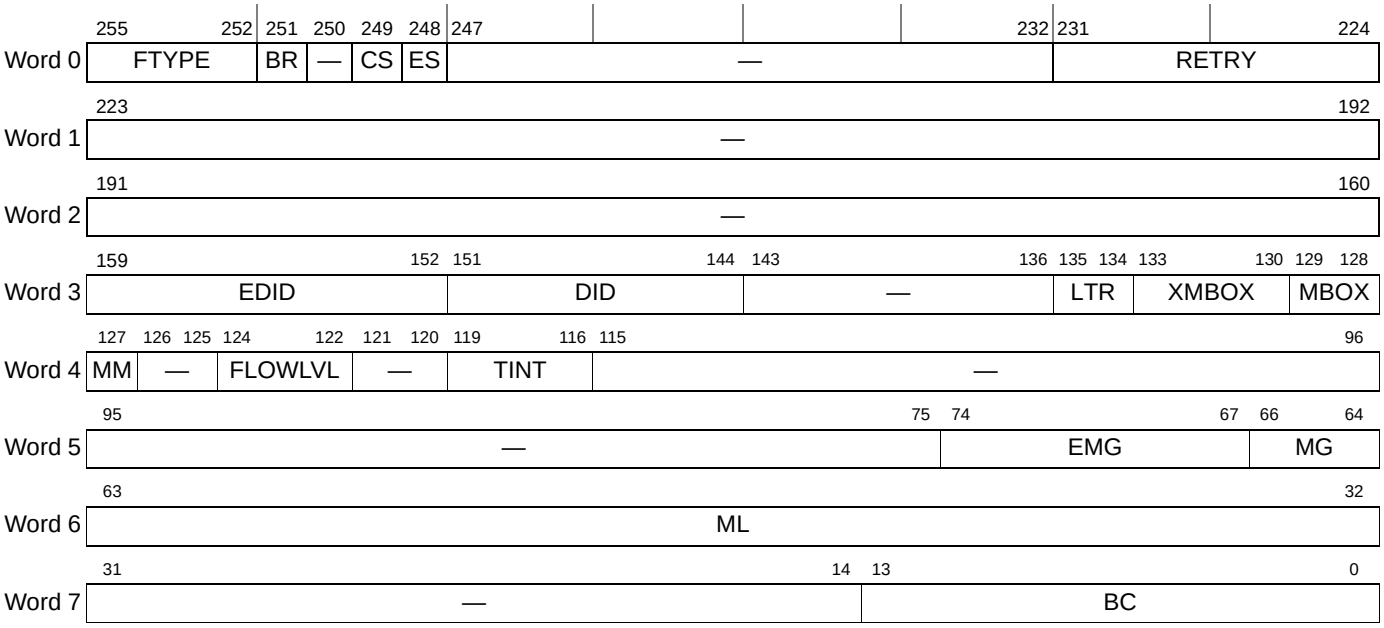

Figure 16-36. Type11 Outbound Message Descriptor

Table 16-45 describes the Type11 outbound message descriptor fields.

Table 16-45. Type11 Outbound Message Descriptor Field Descriptions

Bits	Name	Description
Word 0—Header		
255–252	FTYPE	Descriptor type select. 1011 Type11 All other values reserved.
251	BR	Buffer release enable. 0 No hardware buffer releases performed. 1 Hardware buffer releases performed. If TE/DE error status was reported, not all buffers may have been released successfully.
250	—	Reserved
249	CS	Completion status. 0 Status message queue is not updated when message completes normally. 1 Status message queue is updated when message completes normally.
248	ES	Error status 0 Status message queue is not updated when message aborted due to error. 1 Status message queue is updated when message aborted due to error.
247–232	—	Reserved
231–224	RETRY	Retry error threshold. This value is the number of times that the message unit attempts to retransmit a message segment to a particular target before reporting an error. A message segment is retransmitted if a RETRY response is received from the target. 0x00 Disabled 0x01 Message segment retransmitted only 1 time 0x02 Message segment retransmitted up to 2 times ... 0xFF Message segment retransmitted up to 255 times

Word 2—Reserved		
191–160	—	Reserved
Word 3—Destination Port		
159–152	EDID	Extended destination ID. Most significant byte of a 16-bit destination ID when operating in large transport mode. Reserved when operating in small transport mode.
151–144	DID	Destination ID. Contains the destination ID field of the transaction (Device ID of the target). This value is overridden by the multicast group and list if multicast mode is enabled. On error, if multicast mode is enabled, this field is loaded with the destination of the failed operation.
143–136	—	Reserved
135–134	LTR	Value for “letter” field in MESSAGE packet.
133–130	XMBOX	Value for “xmbox” field in MESSAGE packet. Valid only for single segment messages. Software must set this field to zero for a multi-segment message, that is, larger than 256 bytes.
129–128	MBOX	Value for “mbox” field in MESSAGE packet.
Word 4—Destination Attributes		
127	MM	Multicast mode. 0 Disabled. 1 Message operation is sent to all of the targets indicated by the multicast group and list. Messages are limited to one segment and 256 bytes or less when this mode is enabled.
126–125	—	Reserved
124–122	FLOWLVL	Transaction flow level. 000 Lowest priority transaction request flow 001 Next highest priority transaction request flow ... 100 Next highest priority transaction request flow 101 Highest priority transaction request flow 110 Reserved 111 Reserved
121–120	—	Reserved
119–116	TINT	Target interface. 0000 RapidIO Port 1 0000 RapidIO Port 2 All other values reserved.
115–96	—	Reserved
Word 5—Multicast Group		

Table 16-45. Type11 Outbound Message Descriptor Field Descriptions (Continued)

Bits	Name	Description
The multicast group (MG) value and extended multicast group number (EMG) which, in combination with the multicast list (ML) and the multicast enable (MM), indicates which device IDs are targets of a multicast operation. The multicast group represents the most significant three bits (bits[0–2]) of the RapidIO deviceIDs that are destinations of the message operation, whereas the multicast list indicates a list of targets within that group. Each individual set bit, when encoded, determines the least significant five bits of the RapidIO device IDs (bits[3–7]) that are targets of the message operation. Therefore, multicast group 0 (MG=0) contains target deviceIDs (0,1,...,31), multicast group 1 (MG=1) contains target deviceIDs (32,33,...63), etc. If in large transport mode, the extended multicast group represents the eight most significant bits (bits[0–7]), the multicast group represents the next three bits (bits[8–10]) and the multicast list indicates a list of targets within that group. If multicast is enabled, this information in the multicast group and mask register is used to determine the target of the message operation instead of the DID and EDID fields.		
95–75	—	Reserved
74–67	EMG	Extended multicast group. This is the most significant eight bits of the target device IDs for the multicast operation when operating in large transport mode.
66–64	MG	Multicast group. This is the most significant three bits of the target device IDs for the multicast operation.
Word 6—Multicast List		
63–32	ML	Multicast list. This is the group target list 0–31 for the message operation. Depending upon the value of the multicast group value, target 0 corresponds to device ID 0, 32, 64, 96, e.t.c., target 1 corresponds to deviceID 1, 33, 65, 97, e.t.c. and so on. If none of the bits are set, target 0 is assumed to be set.
Word 7—Byte Count		
31–14	—	Reserved
13–0	BC	Byte count. Contains the number of bytes for the message operation. 0x0001 1 byte 0x0002 2 bytes 0x0003 3 bytes ... 0x0FFF 4095 bytes 0X1000 4096 bytes (4 Kbytes) Byte counts greater than 256 are valid for multi-segment mode only. The maximum message operation size is 4 Kbytes and the minimum is 1 byte. Hardware performs automatic padding to double-word size. Number of segments is determined by the byte count divided by the segment size (256 bytes).

Figure 16-37 shows the command descriptor referencing a single buffer directly. The data payload offset is specified using the command descriptor offset field.

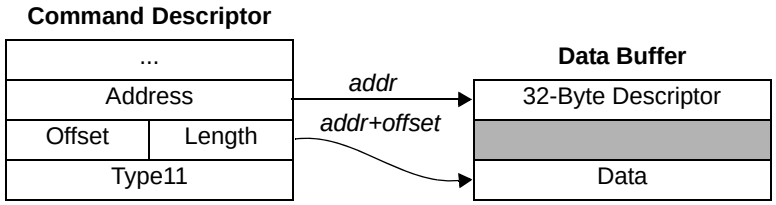

Figure 16-37. Command Descriptor Using Single Buffer Referencing Type11 Outbound Message

16.3.10.2 Type11 Inbound Message Descriptor Format

The Type11 inbound descriptor contains information received by the message unit. The message unit fills out the descriptor with the received control parameters before embedding a link to it using the predefined command descriptor format. The command descriptor is then enqueued onto an inbound message queue.

Figure 16-38 shows the format of an inbound message descriptor. Reserved fields must be cleared.

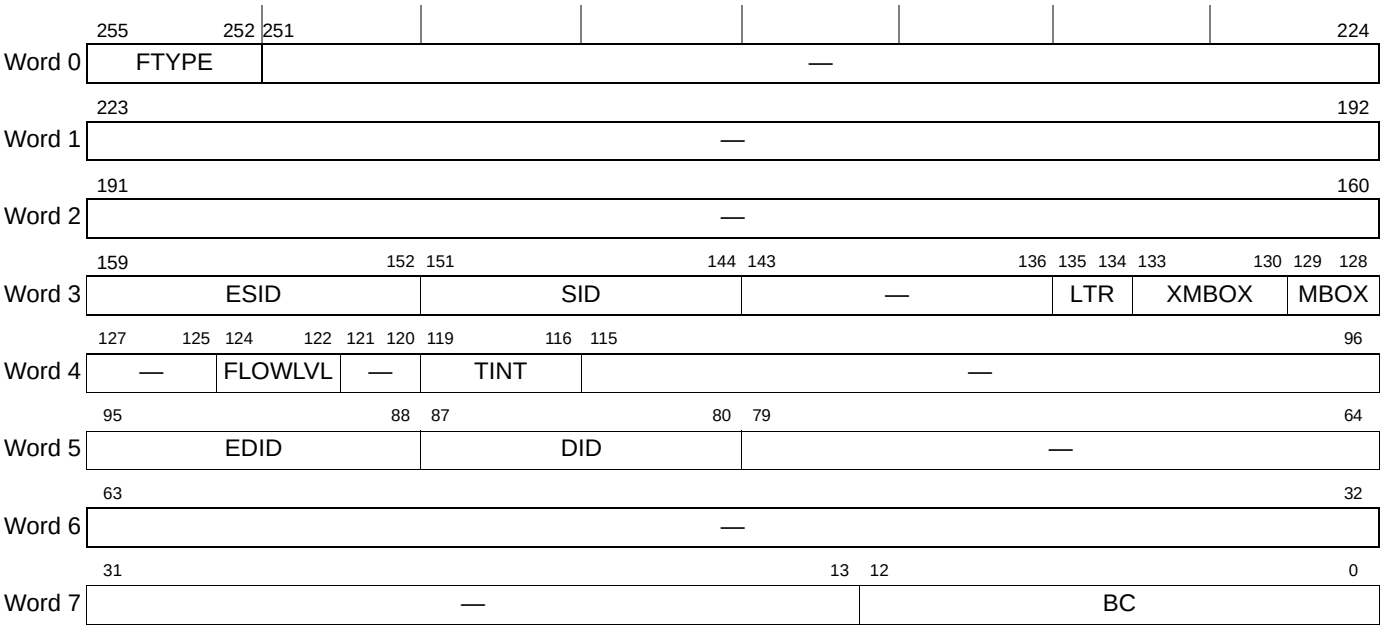

Figure 16-38. Type11 Inbound Message Descriptor

Word 5—Destination Port		
95–88	EDID	Extended destination ID. Most significant byte of a 16-bit destination ID when operating in large transport mode. Reserved when operating in small transport mode.
87–80	DID	Destination ID. Contains the destination ID field of the transaction (Device ID of the destination).
79–64	—	Reserved
Word 6—Reserved		
63–32	—	Reserved
Word 7—Byte Count		

Table 16-46. Type11 Inbound Message Descriptor Field Descriptions (Continued)

Bits	Name	Description
31–13	—	Reserved
12–0	BC	Byte count. Contains the number of bytes written to memory for the message operation, which may be less than expected if an error was encountered during reassembly. Only multiples of 8 bytes are valid. 0x0008 8 bytes ... 0x0010 16 bytes ... 0x0018 24 bytes ... 0x0FF8 4088 bytes 0x1000 4096 bytes Byte counts greater than 256 are valid for multi-segment mode only. Number of segments is determined by the byte count divided by the segment size.

Figure 16-39 shows the supported inbound format for Type11 data management. The command descriptor address points directly to the start of the message descriptor. The data offset is specified through the command descriptor offset field. The data offset is programmable through the Type11 data offset register, IT11C*n*DOR, but must be greater than or equal to the descriptor size.

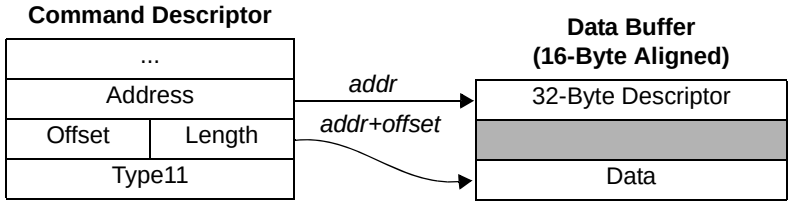

Figure 16-39. Command Descriptor Referencing a Type11 Inbound Message

16.3.10.3 Type11 Outbound Message Operation

The segmentation units are responsible for sending messages enqueued by a producer or producers from one of the outbound message queues owned by the message unit. Concurrent processing may also occur between any number of message queues as long as the outbound ordering rules apply, see **Section 16.3.14.2**, *Outbound Ordering Rules*.

An outbound segmentation unit can operate in multicast mode. In multicast mode, a single segment can be sent to multiple destinations.

16.3.10.3.1 Work Scheduling

The message unit receives all work from the outbound message queues. A producer or producers enqueue work onto the outbound message queues owned by the message unit. To maintain any

ordering between transactions, a producer must enqueue transactions with dependencies onto the same outbound message queue. The outbound ordering rules are described in **Section 16.3.14.2**, *Outbound Ordering Rules*.

16.3.10.3.2 Adding Messages to a Message Queue

A producer may add new messages to any message queue owned by the message unit. The producer needs to allocate buffer space for the message descriptor and data as appropriate and enqueue the command descriptor. The message unit dequeues the command descriptor, determines the type, and proceeds to read the message descriptor and data.

A producer should follow the guidelines below to add a new message to a message queue:

- Create the 32-byte outbound message descriptor as described in **Section 16.3.10.1**, *Type11 Outbound Message Descriptor Format*.
  - Set the descriptor type select field FTYPE=4b1011 to indicate message type.
  - Set the retry field to indicate number or times the message unit should attempt to retry the message segments before stopping.
  - For all other fields, see **Section 16.3.10.1**, *Type11 Outbound Message Descriptor Format*.
- Allocate a single buffer to hold the message descriptor and data.
- Add the buffer to a command descriptor and set FTYPE=4b1011 to indicate message type.
- Enqueue the command descriptor onto the message queue.
- The message unit releases buffers used by the producer to hold the message descriptor and data payload when the operation completes if the buffer release bit (BR) is set in the message descriptor.

16.3.10.3.3 Message Unit Initialization

To configure the message unit for message operations, see **Section 16.3.17.6**, *Initializing Outbound Message Queues*.

16.3.10.3.4 Error Handling

The message unit can report completion status and error information after completing the command descriptor by updating the command descriptor status field.

The following steps should be performed to enable this mode.

- Set the message descriptor completion (CS) or error (ES) status bit.
- Software should observe the status field of the command descriptor after it has been written to the completion queue to determine success.

Table 16-47 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at

an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed.

Table 16-47. Outbound Message Hardware Errors

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Message Segment Sent	Comments
Message Request	Command descriptor effective length less than message descriptor payload byte count.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Message Request	Message descriptor byte count exceeds 256B when multicast mode specified (MM=1).	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Message Request	Invalid FTYPE.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Message Request	Data format (scatter/gather) not supported.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Message Request	Invalid flow level specified.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Message Request	Invalid target interface specified.	1	No	Descriptor error in command descriptor enqueued.	No	No buffers released regardless of BR setting.
Message Request	Memory transaction error.	1/2	Message unit error if MUIER[OTE] set	Transaction error in command descriptor enqueued. Message unit error detect register MUEDR[OTE]. Command descriptor captured in MUECCDR0–3.	No	Message aborted. No buffers released regardless of BR setting.
Message Response	Message error response.	2	No	Message response error in command descriptor enqueued. If MM=1, multicast error also set.	Yes	Message incomplete.

Table 16-47. Outbound Message Hardware Errors (Continued)

Transaction	Error	Error Checking Level	Interrupt Generated	Status Bit Set	Message Segment Sent	Comments
Message Response	Number of segment retries exceeded.	2	No	Retry threshold exceeded in command descriptor enqueued. If MM=1, multicast error also set.	Yes	Message incomplete.
Message Response	Segment response timeout.	3	No	Segment response timeout in command descriptor enqueued. If MM=1, multicast error also set.	Yes	Message aborted.

16.3.10.3.4.1 Descriptor Error

When a descriptor error is detected by the message unit the following occurs.

- Completion message queue
  - The segmentation process is halted and the descriptor error bit DE in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.10.3.4.2 Message Error Response Errors

When a message error response is received by the message unit the following occurs:

- Completion message queue
  - After the message operation completes, the error response received bit, ERR, in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.10.3.4.3 Segment Response Time-Out Errors

When a segment response time-out is detected, as defined by the RapidIO port response time-out control CSR, for a message segment the following occurs.

- Completion message queue
  - After the message operation completes the segment response time-out error bit, SRT, in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.10.3.4.4 Retry Threshold Exceeded Errors

When a retry threshold exceeded error is detected for a message segment the following occurs.

- Completion message queue
  - After the message operation completes the retry threshold exceeded bit, RTE, in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

All segments, or targets for multicast, are transmitted even if the error is detected. Segments receiving retry are not retransmitted when the threshold is exceeded.

16.3.10.3.4.5 Multicast Errors

A multicast error is reported when operating in multicast mode, by setting bit MM=1 in the Destination Attribute descriptor field, and one of the following errors is reported by one or more destinations:

- Message Error Response (ERR)—one or more multicast destinations responded with error.
- Segment response time-out error (SRT)—one or more multicast destinations did not respond.
- Retry Threshold Exceeded (RTE)—one or more multicast destinations responded with retry.

When a multicast error is detected the following occurs.

- Completion message queue
  - After the message operation completes the multicast error bit, MCE, in the command descriptor is set.
  - The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

16.3.10.3.4.6 Transaction Errors

When an transaction error is detected during a local memory data read by the message unit the following occurs.

- Message segments that encounter a transaction error are not sent because the message data is not available.
- Memory reads that were already generated before the transaction error occurred are also not transferred. This includes retried message segments.
- Command descriptor captured in MUECCDR0–3.
- Global message unit error detect register MUEDR[OTE] set.
- Completion message queue
  - After the message operation completes the internal transaction error bit, TE, in the command descriptor is set.

— The message descriptor is enqueued onto the completion message queue if the message descriptor error status (ES) bit is set.

- Buffer release (BR=1)
  — No further buffers are released once a TE error is detected.

16.3.10.4 Type11 Inbound Message Operation

The inbound message unit is responsible for receiving messages and placing then onto an inbound message queue. Software can specify the destination message queue for an inbound message utilizing inbound message classification, see **Section 16.3.17.2**, *Classification Initialization*. The inbound message unit can receive segments of a message in any order.

Utilizing the buffer pools, the message unit requests a single buffer to hold the message descriptor and data. Software must provide the required sized buffer pool in IB*m*T11C*n*BPR for the message unit to store the entire message plus descriptor. The data offset is defined in IB*m*T11C*n*DOR. The message unit generates a frame size error if the inbound message can not be stored due to insufficient buffer sizes available.

16.3.10.4.1 Inbound Message Initialization

To configure an inbound classification unit for inbound message transactions, see **Section 16.3.17.5**, *Initializing Inbound Message Queues*.

16.3.10.4.2 Message Steering

Messages are forwarded to an inbound message queue based on the first message unit (numbered 1 through 64) to successfully classify the message based on source, mailbox, letter and extended mailbox fields. Message queue is specified by IB*m*T11C*n*MQR.

16.3.10.4.3 Retry Response Condition

The conditions to generate a logical layer retry response are:

- Message unit has detected a resource conflict, that is, a new message context was received and hardware context resources were depleted.

All responses are upgraded to priority 3.

16.3.10.4.4 Error Response Condition

The conditions to generate a logical layer error response are:

- Message unit did not have a matching classification rule.
- Message unit has detected a buffer size error.
- Message unit has detected a message format error.

- Message unit has detected a transaction error when allocating buffer resources or performing a local memory write.

All responses are upgraded to priority 3.

16.3.10.4.5 Error Handling

The message unit reports errors utilizing the inbound message queue, by setting the status field in the command descriptor before enqueueing the descriptor onto the designated inbound message queue. The consumer should read the status bits before processing the message to determine the appropriate action.

Table 16-48 indicates the possible error conditions and the outcome when detected. The error checking level indicates the order in which errors are checked. Multiple errors can be checked at an error checking level. Once an error is detected, no additional error checking beyond the current error level is performed. In general, when an error has been detected the reassembly continues until the end of the message is reached.

Table 16-48. Inbound Message Hardware Errors

Error	Error Checking Level	Interrupt Generated	Status Bit Set	Data Segment Written	Message Descriptor Written	Response	Comments
Illegal RapidIO request priority 3.	1	Message unit error if MUIER[MFE] set.	Message unit error detect register MUEDR[MFE].	N/A	N/A	None	Transaction dropped.
Segment request timeout.	1	No	Segment Response Time-out in command descriptor enqueued.	No	Yes	None	Message is defective.
The RapidIO priority is not consistent for all message segments of a message.	1	No	Message format error in command descriptor enqueued.	No	Yes	Error	Message is defective.
Insufficient buffer pool size.	2	No	Buffer size error in command descriptor enqueued.	No	Yes	Error	Message is defective.
Duplicate segment received.	2	No	Message format error in command descriptor enqueued.	No	Yes	Error	Message is defective. Segment counted.

Table 16-48. Inbound Message Hardware Errors (Continued)

Error	Error Checking Level	Interrupt Generated	Status Bit Set	Data Segment Written	Message Descriptor Written	Response	Comments
Illegal segment size.	2	No	Message format error in command descriptor enqueued.	No	Yes	Error	Message is defective.
Segment size not consistent for all message segments of a message.	2	No	Message format error in command descriptor enqueued.	No	Yes	Error	Message is defective.
Memory transaction error.	3	Message unit error if MUIER[ITE] set.	Transaction error in command descriptor enqueued and message unit error detect register MUEDR[ITE]. Address captured in MUECAR.	No	No	Error	Message is defective.
Buffer pool exhausted.	3	Message unit error if MUIER[BAEIE] set.	Transaction error in command descriptor enqueued and message unit error detect register MUEDR[BAE].	No	No	Error	Message is defective.
Failure to enqueue the command descriptor onto the inbound message queue.	4	Message unit error if MUIER[IMERIE] set.	Message unit error detect register MUEDR[IMER]. Message queue captured in MUECMQR.	Yes	Yes	None	—

16.3.10.4.5.1 Segment Request Time-Out Errors

The segment request time-out counter starts after the first valid segment of a multi-segment message is received and the time-out counter is enabled. When a segment request time-out is detected, as defined by the RapidIO Port Response Time-out Control CSR, the following occurs.

- The message unit sets the segment request time-out error bit, SRT in the command descriptor.
- All message segments that have not yet been received are considered complete.
- The command descriptor is enqueued onto the message queue.

16.3.10.4.5.2 Buffer Size Errors

When a buffer size error is detected by the message unit, due to insufficient buffer pool size, the following occurs.

- Segment is discarded and an error response is returned for the segment.
- The message unit sets the buffer size error bit, BSE in the command descriptor.
- After the message operation completes, the command descriptor is enqueued onto the message queue.

The required buffer size for a message is based on the maximum byte count allowed for the given segment size, plus the descriptor size.

16.3.10.4.5.3 Message Format Errors

When a message format error is detected by the message unit the following occurs.

- Segment is discarded and an error response is returned for the segment.
- The message unit sets the message format error bit, MFE in the command descriptor.
- After the message operation completes, the command descriptor is enqueued to the message queue.

A duplicate segment counts towards the total segments for the message transaction. This results in the context closing when the total number of segments are received.

16.3.10.4.5.4 Transaction Errors

When an transaction error occurs, due to insufficient buffer resources or local memory write error, by the message unit the following occurs.

- Segment is discarded and an error response is returned for the segment.
- The message unit sets the transaction error bit, TE, in the command descriptor.
- After the message operation completes, the command descriptor is enqueued onto the message queue.
- Global message unit error detect register MUEDR[ITE] is set for memory access error.
- Address captured in MUECAR for memory access error.
- Global message unit error detect register MUEDR[BAE] is set if buffer resources depleted.

16.3.11 Session Management

The RapidIO Session Management Protocol Specification permits a session manager to establish, manage and remove connections between two end points. **Section 16.3.11.1**, *Classification*, describes how a session manager can establish connections with other end-points.

16.3.11.1 Classification

Classification is the process of filtering inbound traffic to a programmable message queue target. Each inbound classification unit can be configured to handle a specific type. The classification value/mask register pairs are used as rule filters for accepting or rejecting incoming traffic of the programmed RapidIO type. Flow specific reassembly context resources can be allocated for session management to avoid retries in a loaded system due to exhausted hardware resources.

The Session Management Protocol may use the classification feature to establish communication with other selected end-points and to manage communication channels. The protocol allows an end-point to advertise the conveyance used for establishing a connection through the Session Management Advertising CSR. The classification rule filters should then be initialized to match the CSR conveyance type and attributes.

Figure 16-15 shows an example of traffic classification, where packets of Type8–11 are steered to the correct inbound unit for processing. If there are any aliasing between units, the lower numbered unit wins. A transaction not classified is subject to error response or dropped.

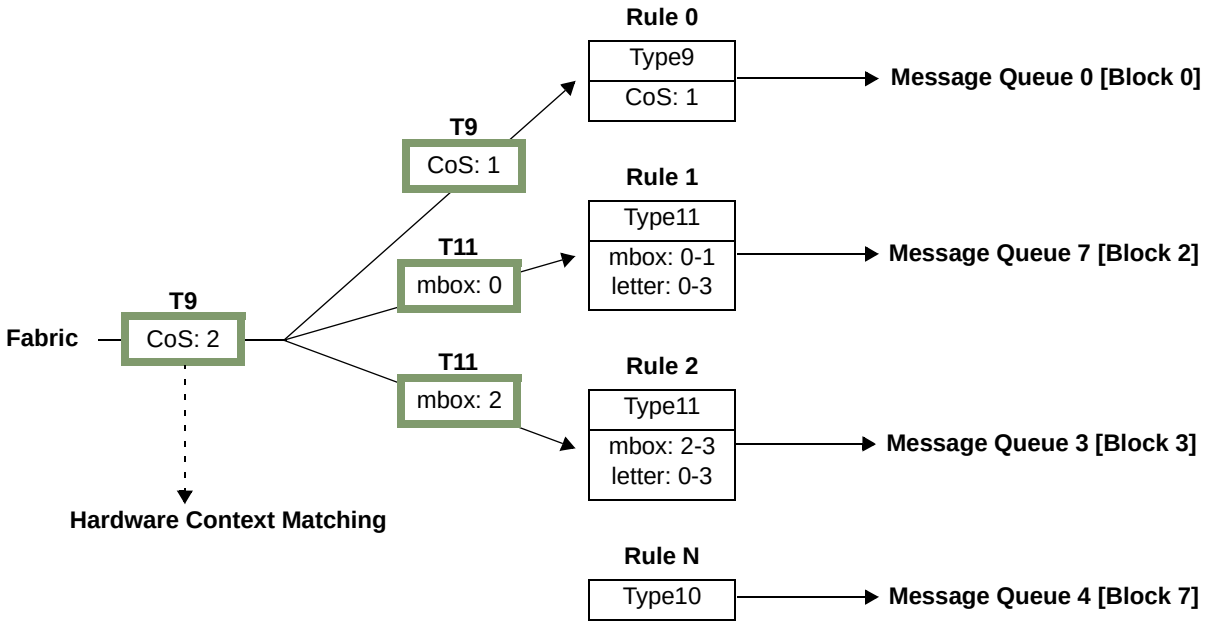

Figure 16-40. Inbound Traffic Classification

16.3.12 Hardware Context Management

The RapidIO specification defines three types of messages: Type9 data streaming, Type10 doorbells and Type11 data messages. A Type10 doorbell carries a 16-bit info field but no data and is always a single RapidIO packet. When a packet carries a data payload, the maximum size of this payload is 256 bytes.

Type9 and Type11 RapidIO transaction types define a user PDU larger than 256 bytes. They support messages with maximum PDUs of 64 Kbytes and 4 Kbytes respectively. To carry larger payloads, the protocol supports hardware segmentation and reassembly of the message payload. The RapidIO specification requires that Type10 doorbell messages and each Type11 message segment be logically acknowledged (ACK) by the receiver. When the receiver cannot temporarily accept the packet, the endpoint may send a retry ACK to the sender causing the segment to be resent again. If an error occurs, an error ACK may be sent. This logical ACK is distinct from the link-level acknowledge that occurs as the transaction crosses each link in the network.

16.3.12.1 Segmentation and Reassembly

Segmenting outbound messages is relatively straightforward in hardware. However, inbound reassembly is significantly more complex. As each segment arrives, it must be identified as either the first segment of a new message or a segment from an existing one. When the first segment of a new message arrives, hardware resources must be allocated to track and reassemble the message. Because Type11 message segments can arrive out of order, the hardware must also be capable of reordering the segments in memory back to their original order.

To maximize system performance, inbound messaging hardware should allow multiple messages from one or more sources to be received at the same time. This implies that individual segments from multiple messages are interleaved in arbitrary ways. RapidIO packet headers allow hardware to distinguish one message segment from another and reassemble similar segments into their respective messages. When the first segment of a new message arrives, a new reassembly context begins that is different from all other messages being reassembled.

As a message is transmitted segment by segment, a corresponding hardware reassembly resource (or context) is used at the destination. Due to the complexity of this hardware, the number of contexts that can be implemented is usually limited. This limitation defines the maximum number of simultaneous outstanding messages that may be in-flight to a given destination endpoint. Software can determine the number of contexts supported by any endpoint by accessing the data streaming information CAR register.

eMSG implements 24 reassembly contexts (or hardware contexts). These contexts are used by Type9–11 transaction types under various circumstances. The message unit also allows reassembly contexts to be allocated to specific flows using appropriate threshold registers. Messages assigned to flows without an allocation, draw from a generic pool set by the generic threshold register.

If the first segment of a new message arrives and is properly classified (that is, a classification rule matches) but all allocated hardware contexts are busy reassembling other messages, the behavior of the inbound hardware depends on the transaction type. Type11 transactions cause hardware to issue a logical retry, with the expectation that resources will become available soon.

Type9 transactions do not require logical ACKs and hence there is no mechanism for communicating an error or retry back to the receiver. As a result, Type9 packets are dropped.

Hardware contexts within eMSG are shared by Type9, 10 and 11 messages and allocation can not be made by transaction type. To avoid Type9 packet loss, system designers must ensure that for each endpoint the maximum number of simultaneous inbound interleaved messages of all types never exceed the pre-allocated hardware contexts.In the eMSG, each hardware context entry has the following states:

- Invalid
  - Empty entry
- Open
  - Multi-segment Type9 or 11 message
  - Not all message segments have been received
- Closed
  - Single-segment Type9–11 message
  - Multi-segment Type9 or 11 message after all segments of the message have been received
  - Message is now guaranteed to complete
  - Associated command descriptor update has not yet been issued to memory

When a single-segment Type9–11 message arrives and is classified, an invalid hardware context is allocated and its state is moved from Invalid to Closed. When hardware issues the command descriptor to memory, the hardware context state moves from Closed to Invalid.

When a new Type9 or 11 multi-segment message first arrives, an invalid hardware context is allocated and its state is moved from Invalid to Open. The entry is moved from Open to Closed when all segments of a message have been classified. Because single-segment messages move directly from Invalid to Closed, the number of hardware contexts in the Open state equals the total number of outstanding multi-segment messages.

Open hardware contexts may be allocated to specific RapidIO flow levels. A flow with no hardware contexts allocated shares the generic pool. hardware contexts remaining after per flow and generic pool are in the unassigned pool. Hardware maintains a counter per flow as well as a generic counter to track the number of Open and unassigned contexts. Counters are incremented when the first segment of a multi-segment Type9 or 11 message is classified and decremented when the last segment of a message is classified. If a counter reaches a configurable watermark threshold, no further new single- or multi-segment messages at that flow level are accepted, and subsequent Type11 messages are logically retried and Type9 messages are dropped. In all situations, Type9 packets are dropped only if the number of interleaved messages exceeds the allocation budgeted by the system.

Should the eMSG encounter unusual system congestion that significantly increases the latency of memory, inbound message segments begin to accumulate in internal buffers and eventually result in link-level retries as back-pressure is applied. Middle segments are buffered until space is no longer available after which link-level retries occur. End segments are also buffered and eventually cause Open hardware contexts to transition to Closed. First segments of messages are accepted while there are Invalid hardware contexts and their associated flow/generic counter has not reached the programmed threshold.

Under normal operating conditions, the eMSG hardware operates such that when the final segment of a message is followed by the first segment of a new one, the hardware context used by the first message is reused for the second. This is because the last (or only) segment causes the hardware context to transition quickly to Invalid as memory writes are issued. As a result of this reuse, one or more streams of single or multi-segment messages whose message segments are never interleaved require one reassembly context to be allocated.

For example, an inbound sequence of multiple single segment Type9 or 11 message streams must be allocated only a single reassembly context. However, each single-segment message still constitutes a new hardware context in terms of context interleaving and per-flow thresholds. As a result, hardware still checks the flow level of the message against the associated open thresholds. If that threshold was reached before it arrives, the single-segment message represents a new interleaved context beyond the designated allocation. As a result, a Type11 packet is retried and a Type9 packet is dropped.

An accepted single segment message never increments Open counters and hence cannot push Open counters to a threshold. Therefore, single-segment messages which are not part of flows that have already reached threshold are accepted until Invalid hardware contexts are exhausted or internal buffers fill. Once filled, link-level retry is invoked as back-pressure to avoid Type9 packet loss.

The unassigned pool makes available hardware contexts even when all allocated ones are in use. When single segment Type9 messages arrive while memory congestion prevents release of previously Closed contexts, hardware contexts from the unassigned pool are used instead. In this manner, the unassigned pool serves to manage congestion by delaying the invocation of link-level retry during short memory congestion events.

To ensure maximum performance when using Type9 traffic, it is recommended that eight hardware contexts be allocated to the congestion management (unassigned) pool to cover rare worst-case short-term congestion events. This leaves 16 entries for general system use. Failure to allocate eight for this purpose does not result in Type9 packet loss, but may cause more frequent link-level retries. Note that these retries can cause brief performance loss for higher priority streams carried by the link.

16.3.12.2 Examples

The following are some examples of system configurations and the resulting behavior. A stream as used below is defined as a sequence of messages sharing the same tuple, as follows:

- Type9: <SrcID, Destid, CoS, StreamID>
- Type11: <SrcID, DestID, MBox/XMBox, Letter>

Example 16-1.

- Inbound Traffic Types
  - 23 segment interleaved multi-segment Type11 streams over Flow A
- Context allocation
  - 23 for Flow A
  - 1 for congestion management
- Thresholds
  - Flow A = 23
  - Generic = 0
- Endpoint behavior
  - All segments of Type11 message streams 1–23 always accepted
  - Even though only 1 context is allocated for congestion management, configuration is tolerant of memory congestion because Type11 multi-segment streams are more tolerant of congestion
  - Memory congestion beyond tolerance could eventually result in Type11 logical retries, link-level retries or both depending on sequence of events and timing

Example 16-2.

- Inbound Traffic Types
  - 30 segment interleaved multi-segment Type11 streams over Flow A
- Context allocation
  - 23 for Flow A
  - 1 for congestion management
- Thresholds
  - Flow A = 23
  - Generic = 0
- Endpoint behavior
  - Messages from streams 1–30 may be accepted depending on the order of the message and segments
  - Segments of only 23 messages are accepted at any given moment.
  - All others are logically retried.
  - No control at the receive endpoint over which streams are accepted and which are retried is possible.

- Even though only 1 context is allocated for congestion management, configuration is tolerant of memory congestion because Type11 multi-segment streams are more tolerant of congestion
- Memory congestion beyond tolerance eventually results in Type11 logical retries, link-level retries or both.

Example 16-3.

- Inbound Traffic Types
  - 23 segment interleaved multi-segment Type9 streams over Flow A
- Context allocation
  - 23 for Flow A
  - 1 for congestion management
- Thresholds
  - Flow A = 23
  - Generic = 0
- Endpoint behavior
  - All segments of Type9 message streams 1–23 are always accepted.
  - Even though only 1 context is allocated for congestion management, configuration is tolerant of memory congestion because multi-segment streams are more tolerant of congestion.
  - Memory congestion beyond tolerance eventually results in link-level retries.

Example 16-4.

- Inbound Traffic Types
  - 30 segment interleaved multi-segment Type9 streams over Flow A
- Context allocation
  - 23 for Flow A
  - 1 for congestion management
- Thresholds
  - Flow A = 23
  - Generic = 0
- Endpoint behavior
  - Various messages from Type9 streams 1–30 may be accepted depending on the order of the message and segments
  - No more than 23 messages are reassembled at one time.
  - All others messages are dropped.
  - No control at the receive endpoint over which streams are accepted and which are dropped is possible.

Example 16-5.

- Inbound Traffic Types
  - 16 segment interleaved multi-segment Type11 streams over Flow A
  - 1 single-segment Type9 stream over Flow A
- Context allocation
  - 16 for Flow A
  - 8 for congestion management
- Thresholds
  - Flow A = 16
  - Generic = 0
- Endpoint behavior
  - All segments of Type11 message streams 1–16 always accepted
  - Type9 segments are dropped if they arrive when all 16 Type11 streams have outstanding segments (that is, all 16 contexts are in Open state thus causing the threshold for flow A to be reached)

Example 16-6.

- Inbound Traffic Types
  - 8 interleaved single-segment Type9 streams over Flow A
  - 8 interleaved single-segment Type9 streams over Flow B
- Context allocation
  - 8 for Flow A
  - 8 for Flow B
  - 8 for congestion management
- Thresholds
  - Flow A = 8
  - Flow B = 8
  - Generic = 0
- Endpoint behavior
  - All segments of Type9 message streams 1–8 always accepted over Flow A
  - All segments of Type9 message streams 1–8 always accepted over Flow B
  - Tolerant of memory congestion because recommended 8 entries are allocated for congestion management
  - Memory congestion beyond tolerance eventually results in link-level retries.

Example 16-7.

- Inbound Traffic Types
  - 15 segment interleaved multi-segment Type11 streams over Flow A
  - 16 single segment Type9 streams over Flow B

- Context allocation
  - 15 for Flow A
  - 1 for Flow B
  - 8 for congestion management
- Thresholds
  - Flow A = 15
  - Flow B = 1
  - Generic = 0
- Endpoint behavior
  - All segments of Type11 message streams 1–15 always accepted
  - All segments of Type9 message streams 1–16 always accepted
  - Only a single context is required for one or more streams of single segment messages
  - Tolerant of memory congestion because recommended 8 entries are allocated for congestion management
  - Memory congestion beyond tolerance eventually results in Type11 logical retries, link-level retries or both.

Example 16-8.

- Inbound Traffic Types
  - 11 segment interleaved Type11 streams over Flow A where each stream is a mix of single and multi-segment messages
  - 5 segment interleaved Type9 streams over Flow B where each stream is a mix of single and multi-segment messages
- Context allocation
  - 11 for Flow A
  - 5 for Flow B
  - 8 for congestion management
- Thresholds
  - Flow A = 11
  - Flow B = 5
  - Generic = 0
- Endpoint behavior
  - All segments of Type11 message streams 1–11 always accepted
- All segments of Type9 message streams 1–5 always accepted
  - Tolerant of memory congestion because recommended 8 entries are allocated for congestion management
  - Memory congestion beyond tolerance eventually results in Type11 logical retries, link-level retries or both.

16.3.13 Address Alignment Requirements

The inbound and outbound address alignment requirements are as follows:

- Inbound—Software must align scatter/gather tables and message descriptors to a 16 byte address boundary. This requirement forces all buffer pools programmed for inbound reassembly to supply 16 byte aligned buffer addresses.
- Outbound—No address alignment restrictions exist for scatter/gather table, message descriptor or data payload.

16.3.14 Ordering Rules

The RapidIO fabric implies no ordering rules between different types of transactions such as doorbells and messages. The transaction source must use priorities to ensure in-order delivery in these cases. The following sections describe the ordering rules applied by the message unit.

16.3.14.1 Inbound Ordering Rules

- Inbound Type9 Packets
  - Type9 packets (PDUs) with the same Virtual Stream ID (Port + Source ID + Destination ID + Class-of-Service + Flow) are enqueued to the assigned message queue in order of delivery.
  - Type9 packets (PDUs) with different Virtual Stream IDs may be enqueue out of order if assigned to the same message queue.
  - There are no ordering rules between PDUs assigned to different message queues.
- Inbound Type10 Doorbells
  - There are no implied ordering rules between doorbells.
- Inbound Type11 Messages
  - There are no implied ordering rules between messages.
- Inbound mixed
  - A Type10 doorbell following a Type9 PDU or Type11 message from the same source ID, same destination ID, same or lower priority and assigned to the same message queue, is guaranteed to be enqueued in order.
  - There are no implied ordering rules between messages and PDUs.

16.3.14.2 Outbound Ordering Rules

- Outbound Type5 writes without response
  - NWrites with the same Source ID + Destination ID + Flow are transmitted in order, if from the same message queue.
- Outbound Type6 streaming writes
  - SWrites with the same Source ID + Destination ID + Flow are transmitted in order, if from the same message queue.

- Outbound Type8 port-writes
  - There are no implied ordering rules between port-writes.
- Outbound Type9 PDUs
  - Type9 packets (PDUs) with the same Virtual Stream ID (Source ID + Destination ID + Class-of-Service + Flow) are transmitted in order if from the same message queue. PDUs of the same VSID should not be occupying two different transmit queues to avoid reassembly errors at the destination.
  - Type9 packets (PDUs) with different Virtual Stream IDs may be transmitted out of order regardless of the message queue from which it was dequeued.
- Outbound Type10 doorbells
  - Doorbells with the same Source ID + Destination ID + Flow are transmitted in order, regardless of the message queue.
- Outbound Type11 messages
  - Type11 messages with the same Source ID + Destination ID + Mailbox + Letter are transmitted in order, regardless of the message queue.
  - For multicast messages, all possible destination IDs are considered for dependency.
  - A single segment message have no ordering requirements on another single segment message when the extended mailbox number is unique.
- Outbound mixed
  - A Type10 doorbell following a Type9–11 transaction with same or lower priority and same destination ID, are transmitted in order if the doorbell descriptor SO (strict ordering) bit is set.
  - There are no implied ordering rules between messages and PDUs.
  - NWrites and SWrites of the same Source ID + Destination ID + Flow are transmitted in order, if from the same message queue.

16.3.14.3 Outbound Segmentation Interleaving

Assigning the same RapidIO flow level to transactions in different arbitration groups is not allowed. All transactions in a particular arbitration group should use the same RapidIO flow level and each arbitration group should use a unique flow level. Failure to follow these rules may result in illegal interleaving of Type9 messages whose VSID differs only in streamID and result in undefined reassembly at the destination.

To achieve a higher transmit rate, the outbound segmentation units may interleave segments when no order dependencies exists, as defined by the outbound ordering rules, between two or more transactions. While this may increase the performance on the transmit side, additional hardware reassembly resources may be needed on the receive side. Outbound segmentation interleaving can be controlled per destination by setting the register bit MUMR[OSI].

16.3.14.4 Transaction Priorities

The message unit uses the following transaction priorities for read and write transactions to and from the memory sub-system, see **Table 16-49**.

Table 16-49. Memory Read/Write Priorities

Memory Transaction	Priority
Memory write of data payload	RapidIO priority
Memory write of message descriptor	RapidIO priority
Memory read of scatter/gather table	2
Memory read of message descriptor	2
Memory read of data payload	Arbitration group bits [0:1]

16.3.15 Congestion Management

Congestion can occur within the message unit for several reason, this includes:

- Congestion due to slow memory subsystem resulting in the inbound dispatch queue to fill.
  - Physical retry is performed
- Congestion due to context availability, or lack thereof.
  - Transactions are accepted speculatively, meaning without a hardware context, up to a certain threshold after which logical retry occurs for Type10/11 and Type9 is dropped.
- Congestion due to buffer availability
  - Reassembly terminated with error, subsequent segments dropped.
- Congestion due to target message queue full.
  - Critical watermark stops further delivery of traffic to the queue.

16.3.15.1 Critical Flow Control

The message unit supports a built-in critical flow control mechanism that guarantees no inbound queue overflows. Operating at a near full queue (30 entries remaining) triggers critical flow control, disabling the receipt of new transactions. This flow control mechanism results in physical retry for subsequent transactions when the enter watermark has been reached as indicated by the classification unit status bit IBmTtCnSR[XOFF] = 1. To exit the critical flow level condition, software should process transactions in the inbound queue to bring the level below the exit watermark as specified by IB*m*MQ*n*CMR[EXIT_WM]. The classification rule could also be disabled to clear the condition, but it is not recommended unless the queue level is also dealt with.

16.3.16 Interrupts

The message unit only generates one global error interrupt. The interrupt error detect from register MUEDR is qualified with its corresponding interrupt enable from register MUIER. The result of each is combined to form one global error interrupt. **Figure 16-41** shows the interrupt structure.

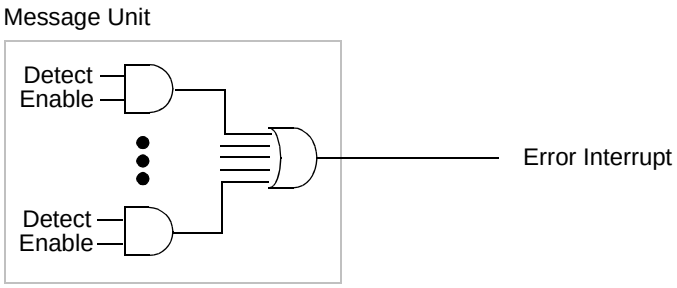

Figure 16-41. Interrupt Structure

16.3.17 Initialization Information

The message unit needs to be initialized properly to be able start processing transactions. The following sections describe the setup for:

- Global register setup—error detection, interrupts and flow control
- Inbound classification rules and inbound queues
- Outbound queues

16.3.17.1 Initializing the Global Registers

The following steps are recommended for correct device initialization:

1. Clear the error detect register, see **Section 16.4.2.96**, *Message Unit Error Detect Registers (MUEDR).*, by writing a 1 to the fields. If not cleared, incorrect error status information is indicated.
2. Initialize stream management flow control through register DSLLCCSR for Type9 data streaming.

16.3.17.2 Classification Initialization

There are many ways in which software can interact with the inbound classification units. One method to initialize the message unit to use one or more inbound units for classification is as follows:

- Disable the unit, if enabled. Any pending transactions are completed. Poll the status register busy bit to make sure the unit is not busy with any previously initiated transactions.
- Initialize the inbound Buffer Pool ID and data offset registers, for all types, used to build the scatter/gather tables and data structures in memory for inbound transactions.

- Type8—Port-Write
  - Set the classification value/mask registers IB*m*T8C*n*RVR0 and IB*m*T8C*n*RMR0 to accept the selected inbound port-write.
  - Set the message queue target register, IB*m*T8C*n*MQR.
  - Set the inbound unit type, IB*m*T9C*n*MR[FTYPE]=4b1000.
  - Enable the classification rule, IB*m*T8C*n*MR[CUE]=1 after the target queue has been initialized.
- Type9—Data Streaming Reassembly
  - Set the classification value/mask registers IB*m*T9C*n*RVR0/1 and IB*m*T9C*n*RMR0/1 to accept the selected inbound PDUs.
  - Set the message queue target register, IB*m*T9C*n*MQR.
  - Set the inbound unit type, IB*m*T9C*n*MR[FTYPE]=4b1001 and IB*m*T9C*n*MR[EXT]=0.
  - Set the inbound flow control destination register, IB*m*T9C*n*FCDR, if flow control is enabled DSLLCCSR[TME]=1
  - Enable the classification rule, IB*m*T9C*n*MR[CUE]=1 after the target queue has been initialized.
- Type9 Extended—Outbound Traffic Management
  - Set the classification value/mask registers IB*m*T9C*n*RVR0/1 and IB*m*T9C*n*RMR0/1 to accept the required data streaming flow control messages.
  - Set the message queue target register, IB*m*T9C*n*MQR.
  - Set the inbound unit type, IB*m*T9C*n*MR[FTYPE]=4b1001 and IB*m*T9C*n*MR[EXT]=1.
  - Enable the classification rule, IB*m*T9C*n*MR[CUE]=1.
- Type10—Doorbell
  - Set the classification value/mask registers IB*m*T10C*n*RVR0/1 and IB*m*T10C*n*RMR0/1 to accept the selected inbound doorbells.
  - Set the message queue target register IB*m*T10C*n*MQR.
  - Set the inbound unit type, IB*m*T10C*n*MR[FTYPE]=4b1010.
  - Enable the classification rule, IB*m*T10C*n*MR[CUE]=1 after the target queue has been initialized.
- Type11—Message
  - Set the classification value/mask registers IB*m*T11C*n*RVR0/1 and IB*m*T11C*n*RMR0/1 to accept the selected inbound messages
  - Set the message queue target register IB*m*T11C*n*MQR.
  - Set the inbound unit type, IB*m*T11C*n*MR[FTYPE]=4b1011.
  - Enable the classification rule, IB*m*T11C*n*MR[CUE]=1 after the target queue has been initialized.

16.3.17.3 Dynamically Changing Rules

Software may wish to dynamically reassign a classification rule to a previously initialized inbound target queue. If the rule is currently not in use, it may be enabled without further action.

To modify an active inbound rule, software should perform the following actions:

1. Stop all sources of traffic before disabling the classification rule to avoid loss of transactions. Software must also ensure that any pending transaction associated with the rule has completed. This should be handled by the session management protocol and is beyond the scope of this discussion.
2. Disable the rule. For Type9 rules with congestion management enabled, software should make sure that both the source and destination reflect the same consistent flow control setting. It is recommended that the inbound target queue be in an XON state before disabling the rule.
3. Modify and then enable the rule for an existing active inbound queue.
4. Software communicates to the source that traffic can start for the new rule using the session management protocol.

16.3.17.4 Mixing Classification Rule Types

Multiple classification rules of a different RapidIO type may target the same inbound queue. It should be noted that only classification rules of Type9 extended can generate flow control. The source must be able to respond to a single Type9 flow control for congestion management to work properly, or the inbound queue may fill with non-Type9 transactions. The source endpoint could have a single mixed mode outbound queue generating all traffic.

16.3.17.5 Initializing Inbound Message Queues

There are many ways in which software can interact with the inbound message queues. One method to initialize the message queues is as follows:

- Disable all classification rules targeting the inbound queue, IB*m*T[8–11]C*n*MR[CUE], if enabled. See **Section 16.3.17.3**, *Dynamically Changing Rules*.
- Disable the inbound message queue, IB*m*MQ*n*MR[EN]=0.
- Clear the error detect registers, IB*m*MQ*n*EDR and IB*m*MQ*n*MEDR.
- Set the inbound message queue size, IB*m*MQ*n*MR[CQ_SIZE], field.
- Initialize the inbound message queue pointers, IB*m*MQ*n*(E)DPAR and IB*m*MQ*n*(E)EPAR to match.
- Initialize the flow control watermark levels, IB*m*MQ*n*CMR. For data streaming, flow control must be enabled (DSLLCCSR[TME] = 1) to generate outbound flow control messages.

- Enable the inbound message queue, IB*m*MQ*n*MR[EN] = 1.
- Follow the classification initialization sequence, see **Section 16.3.17.2**, *Classification Initialization*.

16.3.17.6 Initializing Outbound Message Queues

There are many ways in which software can interact with an outbound message queue. One method to initialize an outbound message queue is as follows:

- Disable the outbound message queue, OB*m*MQ*n*MR[EN]=0. Poll the status register busy bit, OB*m*MQ*n*SR[MQB] to make sure all completion results have been received.
- Clear the error detect registers OB*m*MQ*n*(M)EDR.
- Configure the arbitration group number of message queues using configuration register OMQDSCR1. Queue arbitration weight per AG is configured using OMQDSCR2.
- Set the message queue size, OB*m*MQ*n*MR[CQ_SIZE], field.
- Initialize the outbound message queue pointers, OB*m*MQ*n*(E)DPAR and OB*m*MQ*n*(E)EPAR to match.
  - The outbound message queue detects address pointer wrap conditions only when enabled. If the pointers are unequal when the queue is enabled, no wrap condition must exist.
- Enable the outbound message queue, OB*m*MQ*n*MR[EN] = 1.
- Enable the message unit, OB*m*MU*n*MR[MUE] = 1. This enables the unit to start dequeueing from the outbound message queue as soon as work is available (message queue pointers not equal).

16.4 RapidIO/eMSG Programming Model

The RapidIO registers include:

- Architectural Registers:
  - Device Identity Capability Register (DIDCAR), **page 16-181**
  - Device Information Capability Register (DICAR), **page 16-182**
  - Assembly Identity Capability Register (AIDCAR), **page 16-182**
  - Assembly Information Capability Register (AICAR), **page 16-183**
  - Processing Element Features Capability Register (PEFCAR), **page 16-184**
  - Source Operations Capability Register (SOCAR), **page 16-185**
  - Destination Operations Capability Register (DOCAR), **page 16-186**
  - Data Streaming Information Capability Register (DSICAR), **page 16-188**
  - Data Streaming Logical Layer Control Command and Status Register (DSLLCCSR), **page 16-189**
  - Processing Element Logical Layer Control Command and Status Register (PELLCCSR), **page 16-190**

- Local Configuration Space Base Address 1 Command and Status Register (LCSBA1CSR), **page 16-190**
- Base Device ID Command and Status Register (BDIDCSR), **page 16-191**
- Host Base Device ID Lock Command and Status Register (HBDIDLCSR), **page 16-192**
- Component Tag Command and Status Register (CTCSR), **page 16-192**

- Extended Features Space: x1/x2/x4 LP-Serial
  - Port Maintenance Block Header 0 (PMBH0), **page 16-193**
  - Port Link Time-Out Control Command and Status Register (PLTOCCSR), **page 16-194**
  - Port Response Time-out Control Command and Status Register (PRTOCCSR), **page 16-194**
  - Port General Control Command and Status Register (PGCCSR), **page 16-195**
  - Port 1–2 Link Maintenance Request Command and Status Register (PnLMREQCSR), **page 16-196**
  - Port 1–2 Link Maintenance Response Command and Status Register (PnLMRESPCSR), **page 16-197**
  - Port 1–2 Local ackID Status Command and Status Register (PnLASCR), **page 16-198**
  - Port 1–2 Error and Status Command and Status Register (PnESCSR), **page 16-199**
  - Port 1–2 Control Command and Status Register (PnCCSR), **page 16-200**
- Extended Features Space: Error Reporting, Logical
  - Error Reporting Block Header (ERBH), **page 16-203**
  - Logical/Transport Layer Error Detect Command and Status Register (LTLEDCSR), **page 16-203**
  - Logical/Transport Layer Error Enable Command and Status Register (LTLEECSR), **page 16-205**
  - Logical/Transport Layer Address Capture Command and Status Register (LTLACCSR), **page 16-207**
  - Logical/Transport Layer Device ID Capture Command and Status Register (LTLDIDCCSR), **page 16-208**
  - Logical/Transport Layer Control Capture Command and Status Register (LTLCCCSR), **page 16-209**
- Extended Features Space: Error Reporting, Physical
  - Port 1–2 Error Detect Command and Status Register (PnEDCSR), **page 16-210**
  - Port 1–2 Error Rate Enable Command and Status Register (PnERECSR), **page 16-211**
  - Port 1–2 Error Capture Attributes Command and Status Register (PnECACSR), **page 16-212**
  - Port 1–2 Packet/Control Symbol Error Capture Command and Status Register (PnPCSECCSR0), **page 16-213**

- ATMU
  - Port 1–2 RapidIO Outbound Window Translation Address Register (PnROWTARx), **page 16-238**
  - Port 1–2 RapidIO Outbound Window Translation Extended Address Register (PnROWTEARx), **page 16-239**
  - Port 1–2 RapidIO Outbound Window Base Address Register (PnROWBARx), **page 16-240**
  - Port 1–2 RapidIO Outbound Window Attributes Register (PnROWARx), **page 16-241**
  - Port 1–2 RapidIO Outbound Window Segment 1–3 Registers (PnROWSxRy), **page 16-243**
  - Port 1–2 RapidIO Inbound Window Translation Address Registers (PnRIWTARx); **page 16-244**
  - Port 1–2 RapidIO Inbound Window Base Address Registers (PnRIWBARx), **page 16-244**
  - Port 1–2 RapidIO Inbound Window Attributes Registers (PnRIWARx), **page 16-245**

The eMSG registers (including the BMLite and QMLite registers) include the following:

- Inbound Classification Unit Registers (for Block m [0–7] Unit n [0–7])
  - Type8 Registers (IB*m*T8C*n*MR[FTYPE]=0b1000)
    - Inbound Block m Type8 Classification Unit n Mode Register (IBmT8CnMR), **page 16-247**
    - Inbound Block m Type8 Classification Unit n Status Register (IBmT8CnSR), **page 16-248**
    - Inbound Block m Type8 Classification Unit n Message Queue Register (IBmT8CnMQR), **page 16-248**
    - Inbound Block m Type8 Classification Unit n Rule Value Register 0 (IBmT8CnRVR0), **page 16-249**
    - Inbound Block m Type8 Classification Unit n Rule Value Register 1 (IBmT8CnRVR1), **page 16-249**
    - Inbound Block m Type8 Classification Unit n Rule Mask Register 0 (IBmT8CnRMR0), **page 16-251**
    - Inbound Block m Type8 Classification Unit n Rule Mask Register 1 (IBmT8CnRMR1), **page 16-251**
    - Inbound Block m Type8 Classification Unit n Data Buffer Pool Register (IBmT8CnDBPR), **page 16-253**
    - Inbound Block m Type8 Classification Unit n Data Offset Register (IBmT8CnDOR), **page 16-255**
  - Type9 Registers (IB*m*T9C*n*MR[FTYPE]=0b1001

- Inbound Block m Type9 Classification Unit n Mode Register (IBmT9CnMR), **page 16-255**
- Inbound Block m Type9 Classification Unit n Status Register (IBmT9CnSR), **page 16-256**
- Inbound Block m Type9 Classification Unit n Message Queue Register (IBmT9CnMQR, **page 16-257**
- Inbound Block m Type9 Classification Unit n Rule Value Register 0 (IBmT9CnRVR0), **page 16-258**
- Inbound Block m Type9 Classification Unit n Rule Value Register 1 (IBmT9CnRVR1), **page 16-258**
- Inbound Block m Type9 Classification Unit n Rule Mask Register 0 (IBmT9CnRMR0), **page 16-259**
- Inbound Block m Type9 Classification Unit n Rule Mask Register 1 (IBmT9CnRMR1), **page 16-259**
- Inbound Block m Type9 Classification Unit n Flow Control Destination Register (IBmT9CnFCDR), **page 16-261**
- Inbound Block m Type9 Classification Unit n Data Buffer Pool Register (IBmT9CnDBPR), **page 16-262**
- Inbound Block m Type9 Classification Unit n Data Offset Register (IBmT9CnDOR), **page 16-263**
- Inbound Block m Type9 Classification Unit n Scatter/Gather Buffer Pool Register (IBmT9CnGBPR), **page 16-264**

— Type10 Registers (IB*m*T10C*n*MR[FTYPE]=0b1010)

- Inbound Block m Type10 Classification Unit n Mode Register (IBmT10CnMR), **page 16-265**
- Inbound Block m Type10 Classification Unit n Status Register (IBmT10CnSR), **page 16-266**
- Inbound Block m Type10 Classification Unit n Message Queue Register (IBmT10CnMQR, **page 16-267**
- Inbound Block m Type10 Classification Unit n Rule Value Register 0 (IBmT10CnRVR0), **page 16-267**
- Inbound Block m Type10 Classification Unit n Rule Value Register 1 (IBmT10CnRVR1), **page 16-267**
- Inbound Block m Type10 Classification Unit n Rule Mask Register 0 (IBmT10CnRMR0), **page 16-269**
- Inbound Block m Type10 Classification Unit n Rule Mask Register 1 (IBmT10CnRMR1), **page 16-269**

- Inbound Block m Type10 Classification Unit n Data Buffer Pool Register (IBmT10CnDBPR), **page 16-271**
- Inbound Block m Type10 Classification Unit n Data Offset Register (IBmT10CnDOR), **page 16-272**

— Type11 Registers (IB*m*T11C*n*MR[FTYPE]=0b1011)

- Inbound Block m Type11 Classification Unit n Mode Register (IBmT11CnMR), **page 16-273**
- Inbound Block m Type11 Classification Unit n Status Register (IBmT11CnSR), **page 16-275**
- Inbound Block m Type11 Classification Unit n Message Queue Register (IBmT11CnMQR, **page 16-275**
- Inbound Block m Type11 Classification Unit n Rule Value Register 0 (IBmT11CnRVR0), **page 16-276**
- Inbound Block m Type11 Classification Unit n Rule Value Register 1 (IBmT11CnRVR1), **page 16-276**
- Inbound Block m Type11 Classification Unit n Rule Mask Register 0 (IBmT11CnRMR0), **page 16-278**
- Inbound Block m Type11 Classification Unit n Rule Mask Register 1 (IBmT11CnRMR1), **page 16-278**
- Inbound Block m Type11 Classification Unit n Data Buffer Pool Register (IBmT11CnDBPR), **page 16-280**
- Inbound Block m Type11 Classification Unit n Data Offset Register (IBmT11CnDOR), **page 16-281**

■ Queue Manager Inbound Block Message Queue Registers (for Block m [0–7] Queue n [0–7])

— Inbound Block m Message Queue n Mode Register (IBmMQnMR), **page 16-281**
— Inbound Block m Message Queue n Status Register (IBmMQnSR), **page 16-282**
— Inbound Block m Message Queue n Dequeue Pointer Address Register (IBmMQnDPAR), **page 16-283**
— Inbound Block m Message Queue n Enqueue Pointer Address Register (IBmMQnEPAR), **page 16-284**
— Inbound Block m Message Queue n Congestion Management Register (IBmMQnCMR), **page 16-285**
— Inbound Block m Message Queue n Interrupt Enable Register (IBmMQnIER), **page 16-286**
— Inbound Block m Message Queue n Interrupt Detect Register (IBmMQnIDR), **page 16-288**
— Inbound Block m Message Queue n Interrupt Coalescing Register (IBmMQnICR), **page 16-289**

- Queue Manager Outbound Block Message Queue Registers (for Block m [0–7] Queue n [0–7])
  - Outbound Block m Message Queue n Mode Register (OBmMQnMR), **page 16-290**
  - Outbound Block m Message Queue n Status Register (OBmMQnSR), **page 16-292**
  - Outbound Block m Message Queue n Dequeue Pointer Address Register (OBmMQnDPAR), **page 16-292**
  - Outbound Block m Message Queue n Enqueue Pointer Address Register (OBmMQnEPAR), **page 16-293**
  - Outbound Block m Message Queue n Interrupt Enable Register (OBmMQnIER), **page 16-294**
  - Outbound Block m Message Queue n Interrupt Detect Register (OBmMQnIDR), **page 16-296**
- Queue Manager Outbound Block m Completion Queue Registers (for Block m [0–7])
  - Outbound Block m Completion Queue Mode Register (OBmCQMR), **page 16-297**
  - Outbound Block m Completion Queue Status Register (OBmCQSR), **page 16-298**
  - Outbound Block m Completion Queue Dequeue Pointer Address Register (OBmCQDPAR), **page 16-298**
  - Outbound Block m Completion Queue Enqueue Pointer Address Register (OBmCQEPAR), **page 16-299**
  - Outbound Block m Completion Queue Interrupt Coalescing Register (OBmCQICR), **page 16-300**
- Buffer Manager Software Portal n Registers (for Portal n [0–7]; index k [A–H])
  - Software Portal n Interrupt Status Register (SWPn_ISR), **page 16-301**
  - Software Portal n Interrupt Enable Register (SWPn_IER), **page 16-302**

RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

DIDCAR is a read-only register. The device vendor identity field (DVI) identifies the vendor that manufactured the device containing the processing element. A value for DVI is uniquely assigned to a device vendor by the registration authority of the RapidIO Trade Association. The device identity field (DI) is intended to uniquely identify the type of device from the vendor specified by DVI. The values for DI are assigned and managed by the respective vendor.

Table 16-50. DIDCAR Field Descriptions

Bits	Reset	Description
DI 31–16	0x1828	**Device Identity** Uniquely identifies the type of device from the vendor specified by DVI. The values for DI are assigned and managed by the respective vendor. The value for the MSC8157E = 0x1828.
DVI 15–0	0x0002	**Device Vendor Identity** Identifies the vendor that manufactures the device containing the processing element. A value for DVI is uniquely assigned to a device vendor by the registration authority of the RapidIO Trade Association. The value for Freescale Semiconductor, Inc. is 0x0002.

16.4.1.2 Device Information Capability Register (DICAR)

DICAR Device Information Capability Register Offset 0x00004

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DR															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	DR															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DICAR is a read-only register. The device revision field (DR) identifies the revision level of the Serial RapidIO controller. The value for DR is assigned and managed by the vendor specified by DIDCAR[DVI]. DICAR represents a copy of the device system version register (SVR).

Table 16-51. DICAR Field Descriptions

Bit	Reset	Description
DR 31–0	0x00000000	**Device Revision** Identifies the revision level of the device. The value for DR is assigned and managed by the vendor specified by DIDCAR[DVI].

16.4.1.3 Assembly Identity Capability Register (AIDCAR)

AIDCAR Assembly Identity Capability Register Offset 0x00008

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	AI

	AVI															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

AIDCAR is a read-only register. The assembly vendor identity field (AVI) identifies the vendor that manufactured the assembly or subsystem containing the device. A value for AVI is uniquely assigned to an assembly vendor by the registration authority of the RapidIO Trade Association.

The assembly identity field (AI) is intended to uniquely identify the type of assembly from the vendor specified by AVI. The values for AI are assigned and managed by the respective vendor.

Table 16-52. AIDCAR Field Descriptions

Bit	Name	Description
AI 31–16	0x0000	**Assembly Identity** Uniquely identifies the type of assembly from the vendor specified by AVI. The values for AI are assigned and managed by the respective vendor.
AVI 15–0	0x0000	**Assembly Vendor Identity** Identifies the vendor that manufactures the assembly or subsystem containing the device. A value for AVI is uniquely assigned to an assembly vendor by the registration authority of the RapidIO Trade Association.

16.4.1.4 Assembly Information Capability Register (AICAR)

AICAR Assembly Information Capability Register Offset 0x0000C

	—										CRF	CTLS	EF	EAS		
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	1	1	1	0	0	1

PEFCAR identifies the major functionality provided by the processing element.

Table 16-54. PEFCAR Field Descriptions

Bit	Reset	Description	Settings	
BR 31	1	**Bridge** Specifies whether the MSC8157E can bridge to another interface.		
MEM 30	1	**Memory** Specifies whether the MSC8157E has physically addressable local address space and can be accessed as an endpoint through non-maintenance operations.		
PROC 29	1	**Processor** Specifies whether the MSC8157E contains a local processor that executes code.		
SW 28	0	**Switch** The MSC8157E does not bridge to another external RapidIO interface. (SW=0)		
— 27–6	0	Reserved. Write to zero for future compatibility.		
CRF 5	1	**Critical Request Flow** Specifies whether the RapidIO Controller supports the critical request flow.	0 1	Critical request flow not supported. Critical request flow supported.
CTLS 4	1	**Common Transport Large Systems** Specifies whether the RapidIO Controller supports large systems. This is configured at power-up through the reset configuration word.	0 1	Only common transport small systems (up to 256 devices). Large systems up to 65,536 devices.
EF 3	1	**Extended Features** Specifies whether the extended features pointer is valid.		
EAS 2–0	0b001	**Extended Address Support** Indicates the number of address bits supported by the RapidIO controller both as a source and target of an operation.	000 010 001	Reserved. Reserved. 34-bit addresses.

16.4.1.6 Source Operations Capability Register (SOCAR)

SOCAR Source Operations Capability Register 0x00018

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TYPE	R															
RESET	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0

SOCAR defines the set of RapidIO logical operations that can be issued by the MSC8157E.

Table 16-55. SOCAR Field Descriptions

Bit	Reset	Description
R 31	0	**Read Operation** MSC8157E does not support.
IR 30	0	**IRead Operation** MSC8157E does not support.
RO 29	0	**Read-to-Own Operation** MSC8157E does not support.
DCI 28	0	**Data Cache Invalidate Operation** MSC8157E does not support.
C 27	0	**Castout Operation** MSC8157E does not support.
F 26	0	**Flush Operation** MSC8157E does not support a flush operation.
IOR 25	0	**I/O-Read Operation** MSC8157E does not support an I/O read operation.
ICI 24	0	**Instruction Cache Invalidate Operation** MSC8157E does not support.
TIE 23	0	**TLBIE Operation** MSC8157E does not support.
TIES 22	0	**TLBSYNC Operation** MSC8157E does not support.
— 21–20	0	Reserved. Write to zero for future compatibility.
DSTM 19	1	**Data Streaming Traffic Management Operation** MSC8157E supports operation.
DS 18	1	**Data Streaming Operation** MSC8157E supports operation.
— 17–16	0	Reserved. Write to zero for future compatibility.
NR 15	1	**NREAD Operation** MSC8157E supports operation.
NW 14	1	**NWRITE Operation** MSC8157E supports operation.
SW 13	1	**SWRITE Operation** MSC8157E supports operation.

Table 16-55. SOCAR Field Descriptions (Continued)

Bit	Reset	Description
NWR 12	1	**NWRITE_R Operation** MSC8157E supports operation.
M 11	1	**Message Operation** MSC8157E supports message operation.
D 10	1	**Doorbell Operation** MSC8157E supports doorbell operation.
— 9	—	Reserved. Write to zero for future compatibility.
ATS 8	0	**Atomic-Test-and-Swap Operation** MSC8157E does not support.
AI 7	0	**Atomic-Inc Operation** MSC8157E does not support.
AD 6	0	**Atomic-Dec Operation** MSC8157E does not support.
AS 5	0	**Atomic-Set Operation** MSC8157E does not support.
AC 4	0	**Atomic-Clr Operation** MSC8157E does not support.
— 3	0	Reserved. Write to zero for future compatibility.
PW 2	0	**Port-Write Operation** MSC8157E does not support.
— 1–0	0	Reserved. Write to zero for future compatibility.

16.4.1.7 Destination Operations Capability Register (DOCAR)

DOCAR Destination Operations Capability Register 0x0001C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TYPE	R															
RESET	1	1	1	1	1	1	0	0	0	0	0	0	0	1	0	0

DOCAR defines the set of RapidIO I/O operations that the MSC8157E can support as a target.

Table 16-56. DOCAR Field Descriptions

Bit	Reset	Description
R 31	0	**Read Operation** MSC8157E does not support.
IR 30	0	**IRead Operation** MSC8157E does not support.
RO 29	0	**Read-to-Own Operation** MSC8157E does not support.

Table 16-56. DOCAR Field Descriptions (Continued)

Bit	Reset	Description
DCI 28	0	**Data Cache Invalidate Operation** MSC8157E does not support.
C 27	0	**Castout Operation** MSC8157E does not support.
F 26	0	**Flush Operation** MSC8157E does not support.
IOR 25	0	**I/O-Read Operation** MSC8157E does not support.
ICI 24	0	**Instruction Cache Invalidate Operation** MSC8157E does not support.
TIE 23	0	**TLBIE Operation** MSC8157E does not support.
TIES 22	0	**TLBSYNC Operation** MSC8157E does not support.
— 21–20	0	Reserved. Write to zero for future compatibility.
DSTM 19	1	**Data Streaming Traffic Management Operation** Supported
DS 18	1	**Data Streaming Operation** Supported
— 17–16	0	Reserved. Write to zero for future compatibility.
NR 15	1	**Nread Operation** Supported.
NW 14	1	**Nwrite Operation** Supported.
SW 13	1	**Swrite Operation** Supported.
NWR 12	1	**Nwrite_R Operation** Supported.
M 11	1	**Message Operation** Supported.
D 10	1	**Doorbell Operation** Supported.
— 9	—	Reserved. Write to zero for future compatibility.
ATS 8	0	**Atomic-Test-and-Swap Operation** MSC8157E does not support.
AI 7	0	**Atomic-Inc Operation** MSC8157E does not support.
AD 6	0	**Atomic-Dec Operation** MSC8157E does not support.
AS 5	0	**Atomic-Set Operation** MSC8157E does not support.
AC 4	0	**Atomic-Clr Operation** MSC8157E does not support.
— 3	0	Reserved. Write to zero for future compatibility.

Table 16-56. DOCAR Field Descriptions (Continued)

Bit	Reset	Description
PW 2	1	**Port-Write Operation** Supported.
— 1–0	0	Reserved. Write to zero for future compatibility.

16.4.1.8 Data Streaming Information Capability Register (DSICAR)

DSICAR Data Streaming Information Capability Register 0x0003C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	MaxPDU															
TYPE	R															
RESET	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	SegSupport															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

DSICAR defines the data streaming capabilities of a processing element. It is required for destination end point devices. DSICAR is a read-only register.

Table 16-57. DSICAR Field Definitions

Bits	Reset	Description	Settings
MaxPDU 31–16	0x0000	**Maximum PDU** Specifies the maximum PDU size supported by the destination end point (MaxPDU = 0x0000)	0x0000 64 Kbytes
SegSupport 15–0	0x0018	**Segment Support** Indicates the number of segmentation contexts supported by the destination end point.	0x0018 24 segmentation contexts.

16.4.1.9 Data Streaming Logical Layer Control Command and Status Register (DSLLCCSR)

DSLLCCSR Data Streaming Logical Layer Control Command and Status Register — Offset 0x00048

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TMTypesSupport				TMModes				—

	—														EAC	
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

PELLCCSR controls the extended addressing abilities. RapidIO endpoint supports only 34-bit addressing.

Table 16-59. PELLCCSR Field Descriptions

Bit	Reset	Description
— 31–3	0	Reserved. Write to zero for future compatibility.
EAC 2–0	0b001	**Extended Addressing Control** The read-only value of 0b001 specifies 34-bit addresses.

16.4.1.11 Local Configuration Space Base Address 1 Command and Status Register (LCSBA1CSR)

LCSBA1CSR Local Configuration Space Base Address 1 Command and Status Register — Offset 0x0005C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—	LCSBA														—
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCSBA1CSR specifies the least significant bits of the local physical address double-word offset for the RapidIO configuration register space allowing the configuration register space to be physically mapped in the processing element. This register allows configuration and maintenance of an RapidIO block through regular read and write operations rather than maintenance operations. The double-word offset is right justified in the register. This window has priority over

all ATMU windows. As with all registers, an external processor writing to LCSBA1CSR should not assume that the write occurs until a response is received.

Table 16-60. LCSBA1CSR Field Descriptions

Bit	Reset	Description
— 31	0	Reserved. Write to zero for future compatibility.
LCSBA 30–17	0x1FFE	Local configuration space base address. These bits correspond to the highest 14 bits of the 34-bit RapidIO address space.
— 16–0	0	Reserved. Write to zero for future compatibility.

16.4.1.12 Base Device ID Command and Status Register (BDIDCSR)

BDIDCSR Base Device ID Command and Status Register Offset 0x00060

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—								BDID							
TYPE	R								R/W

	LBDID															
TYPE	R/W															
RESET	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

BDIDCSR contains the base device ID values for the processing element.

Table 16-61. BDIDCSR Field Descriptions

Bit	Reset	Description
— 31–24	0	Reserved. Write to zero for future compatibility.
BDID 23–16	0xFF	**Base Device ID in Small Common Transport System (RapidIO Device ID)** Valid only if PEFCAR[CTLS] is cleared. If the RapidIO controller is configured as a host, the highest 5 bits of BDID are cleared and the lowest 3 bits are equal to the lowest three bits of the RCWHR[DEVID] field (see **Section 5.3.2**, *Reset Configuration Word High Register (RCWHR)*, on page 5-20). If the RapidIO controller is configured as an agent, BDID = 0xFF.
LBDID 15–0	0xFFFF	**Large Base Device ID in Large Common Transport System** Valid only if PEFCAR[CTLS] is set. If the RapidIO controller is configured as a host, the highest 13 bits of LBDID are cleared and the lowest 3 bits are equal to the lowest three bits of the RCWHR[DEVID] field (see **Section 5.3.2**, *Reset Configuration Word High Register (RCWHR)*, on page 5-20). If the RapidIO controller is configured as an agent, LBDID = 0xFFFF.

16.4.1.13 Host Base Device ID Lock Command and Status Register (HBDIDLCSR)

HBDIDLCSR Host Base Device ID Lock Command and Status Register Offset 0x00068

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	HBDID															
TYPE	R															
RESET	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

HBDIDLCSR contains the base device ID value for the processing element in the system that initializes this device. The HBDID field is a write-once/resettable field with a lock function. When HBDID is written, all subsequent writes to the field are ignored, except when the value written matches the value in the field. Then, the register is reinitialized to 0xFFFF. After HBDID is written, the processing element must read the host base device ID lock CSR to verify that it owns the lock before it attempts to initialize the device.

Table 16-62. HBDIDLCSR Field Descriptions

Bit	Reset	Description
— 31–16	0	Reserved. Write to zero for future compatibility.
HBDID 15–0	0xFFFF	**Host Base Device ID** The host base device ID for the processing element that initializes this device. Only the first write to this field is accepted; all other writes are ignored, except when the value written matches the value contained in the field. In this case, the register is reinitialized to 0xFFFF.

16.4.1.14 Component Tag Command and Status Register (CTCSR)

CTCSR Component Tag Command and Status Register Offset 0x0006C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	CT															
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	CT															
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CTCSR contains a component tag value for the processing element that software can assign when the device is initialized. It is unused internally in RapidIO Endpoint.

Table 16-63. CTCSR Field Descriptions

Bit	Reset	Description
CT 31–0	0	**Component Tag**

16.4.1.15 Port Maintenance Block Header 0 (PMBH0)

PMBH0 Port Maintenance Block Header 0 Offset 0x00100

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EFPTR															
TYPE	R															
RESET	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	EFID															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

PMBH0 contains a pointer (EFPTR) to the next extended features space, error management block, extended features block (EFBLK), and the EFID that identifies it as the generic endpoint port maintenance block header. While registers defined by software-assisted error recovery are supported, software-assisted error recovery is not. Therefore, the RapidIO Endpoint is defined here as not supporting software-assisted error recovery.

Table 16-64. PMBH0 Field Descriptions

Bit	Reset	Description

	TV								—							
TYPE	R/W								R							
RESET	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	1

PLTOCCSR contains the link time-out value for all ports. This time-out is for link events such as sending a packet to receive the corresponding acknowledge and sending a link-request to receive the corresponding link-response. The reset value is the maximum time-out interval and represents between 3 and 5 seconds.

Table 16-65. PLTOCCSR Field Descriptions

Bit	Reset	Description
TV 31–8	0xFFFFFF	**Time-Out Value** Clearing this field to all zeros disables the link time-out timer. This value is loaded each time the link time-out timer starts.
— 7–0	0x01	Reserved. Write to 0x01 for future compatibility.

16.4.1.17 Port Response Time-Out Control Command and Status Register (PRTOCCSR)

PRTOCCSR Port Response Time-Out Control Command and Status Register — Offset 0x00124

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TV															
TYPE	R/W

	TV								—							
TYPE	R/W								R							
RESET	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0

PRTOCCSR contains the time-out timer count for all ports. This time-out is for sending a request packet to receive the corresponding response packet.The reset value is the maximum time-out

interval and represents between 3 and 5 seconds. This applies to RapidIO Endpoint and the messaging unit.

Table 16-66. PRTOCCSR Field Descriptions

Bit	Reset	Description
TV 31–8	0xFFFFFF	**Time-Out Value** Clearing this field to all zeros disables the response time-out timer. This value is loaded each time the response time-out timer starts.
— 7–0	0	Reserved. Write to zero for future compatibility.

16.4.1.18 Port General Control Command and Status Register (PGCCSR)

PGCCSR Port General Control Command and Status Register Offset 0x0013C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	H	M	D	—												
TYPE	R/W															
RESET	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PGCCSR contains control register bits for the RapidIO interface.

The user must initialize the value of M to 1. Otherwise, no outbound transactions are initiated by the MSC8157E, including messages and doorbells.

Table 16-67. PGCCSR Field Descriptions

Bit	Reset	Description	Settings
H 31	RCWHR [RHE]	**Host** Determines the host/agent configuration for the device. Notice that by default H = 0.	0 Agent device. 1 Host device.
M 30	RCWHR [RHE]	**Master** Clearing this bit (M = 0) disables all outbound transactions and prevents sending any outbound packets.	0 Device is not enabled to send requests to the system. 1 Device is enabled to send requests to the system.
D 29	RDWHR [RHE]	**Discovered** Indicates whether the device is discovered by the system host.	0 Device not discovered by system host. 1 Device is discovered by system host.
— 28–0	0	Reserved. Write to zero for future compatibility.	

16.4.1.19 Port 1–2 Link Maintenance Request Command and Status Register (PnLMREQCSR)

P1LMREQCSR Port 1–2 Link Maintenance Request Offset 0x00140
P2LMREQCSR Command and Status Register Offset 0x00160

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
TYPE	R

RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The Port 1–2 link maintenance request command and status register (PnLMREQCSR), is accessible both by the local processor and an external device. A write to this register generates a link-request control symbol on the corresponding RapidIO endpoint port interface. Make sure when writing this register that is not used for software-assisted error recovery (which is not supported). **Table 16-68** lists PnLMREQCSR fields.

Table 16-68. PnLMREQCSR Field Descriptions

Bit	Reset	Description
— 31–3	0	Reserved. Write as zero for future compatibility.
C 2–0	0	**Link Request Command** Contains the link request command to send. If read, this field returns the last written value. If written with a value other than 0x011 (reset device) or 0b100 (input status), the resulting operation is undefined. All other values are reserved in the RapidIO specification.

16.4.1.20 Port 1–2 Link Maintenance Response Command and Status Register (PnLMRESPCSR)

P1LMRESPCSR Port 1–2 Link Maintenance Response Offset 0x00144
P2LMRESPCSR Command and Status Register Offset 0x00164

The Port 1–2 link maintenance response command and status register (PnLMRESPCSR), is accessible both by the local processor and an external device. A read to this register returns the status received in a link-response control symbol. This register is read-only. **Table 16-69** lists PnLMRESPCSR fields.

Table 16-69. PnLMRESPCSR Field Descriptions

Bit	Reset	Description	Settings
RV 31	0	**Response Valid** This bit indicates one of two conditions: • If the link-request causes a link-response, a set bit indicates that the link-response was received and the status fields are valid. • If the link-request did not cause a link-response, a set bit indicates that the link-request was transmitted. **Note:** This bit clears on read.	0 Link response not received, link response not valid, or link request was not transmitted. 1 Link response received with valid status bits or link request was transmitted.
— 30–10	0	Reserved. Write as zero for future compatibility.	
AS 9–5	0	**AckID_Status** This field holds the AckID status field from the link response.	
LS 4–0	0	**Link Status** This field holds the link status field from the link response.	

16.4.1.21 Port 1–2 Local ackID Command and Status Register (PnLASCR)

P1LASCSR Port 1–2 Local ackID Command and Status Register Offset 0x00148
P2LASCSR Offset 0x00168

The Port 1–2 local ackID status command and status register (PnLASCSR) is accessible both by the core processor and an external device. A read to this register returns the local ackID status for both the output and input ports of the device. Care should be taken not to use this register for software error management. **Table 16-70** lists PnLASCSR fields.

Table 16-70. PnLASCSR Field Descriptions

Bit	Reset	Description
— 31–29	0	Reserved. Write as zero for future compatibility.
IA 28–24	0	**Input ackID** The value of the next expected Input port ackID.
23–13	0	Reserved. Write as zero for future compatibility.
OUTA 12–8	0	**Outstanding Port Unacknowledged ackID Status** Next expected acknowledge control symbol ackID field that indicates the ackID value expected in the next received acknowledge control symbol. Note that this value is read only even though RapidIO specification allows for it to be writable.
— 7–5	0	Reserved. Write as zero for future compatibility.
OBA 4–0	0	**Outbound ackID Output Port Next Transmitted ackID Value** This can be written by software but only if there are no outstanding unacknowledged packets. If there are, a newly-written value will be ignored

16.4.1.22 Port 1–2 Error and Status Command and Status Register (PnESCSR)

P1ESCSR Port n Error Command and Status Register Offset 0x00158
P2ESCSR Offset 0x00178

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—					OPD	OFE	ODE	—			ORE	OR	ORS	OEE	OES
TYPE	R					W1C	W1C	W1C				W1C	R		W1C	R
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**

TYPE	R						W1C	R						W1C	R	
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

PnESCSR is accessed when a local master or an external device needs to examine the port error and status information.

Table 16-71. PnESCSR Field Descriptions

Bit	Reset	Description
— 31–27	0	Reserved. Write to zero for future compatibility.
OPD 26	0	**Output Packet-Dropped** Output port has discarded a packet. A packet is discarded if: • It is received while OFE is set and PnCCSR[DPE] (drop packet enable) is set and PnCCSR[SPF] (stop on port failed) is set. • It is received while PnPCR[OBDEN] (output buffer drain enable) is set. • The link-partner does not accept it while the PnERTCSR[ERFTT] (error rate failed threshold trigger) is met or exceeded, PnCCSR[DPE] is set, and PnCCSR[SPF] is not set (and link-response returns the expected ID acknowledge). When OPD is set, it remains set until it is written with a logic 1 to clear it.
OFE 25	0	**Output Fail Encountered** The output port has encountered a failed condition because the error rate counter (PnEERCSR[ERC]) has met or exceeded the port failed error threshold (PnERTCSR[ERFTT]). OFE remains set until it is written with a logic 1 to clear it. When it is cleared, it does not assert again unless the error rate counter dips below the port failed error threshold and then meets or exceeds it again.
ODE 24	0	**Output Degraded Condition Encountered** The output port has encountered a degraded condition because the error rate counter (PnEERCSR[ERC]) has met or exceeded the port degraded error threshold (PnERTCSR[ERDTT]). ODE remains set until it is written with a logic 1 to clear it. When it is cleared, it does not assert again unless the error rate counter dips below the port degraded error threshold and then meets or exceeds it again.
— 23–21	0	Reserved. Write to zero for future compatibility.
ORE 20	0	**Output Retry Condition Encountered** The output port has encountered a retry condition. This bit is set when ORS is set. ORE remains set until it is written with a logic 1 to clear it.
OR 19	0	**Output Retry** The output port has received a packet retry control symbol and cannot make forward progress. OR is set when ORS is set and cleared when a packet-accepted or packet-not-accepted control symbol is received. Read only.
ORS 18	0	**Output Stop** The output port stops due to a retry. Read only.

Table 16-71. PnESCSR Field Descriptions (Continued)

Bit	Reset	Description
OEE 17	0	**Output Error Encounter** The output port encountered (and possibly recovered from) a transmission error. OEE is set when OES is set. It remains set until it is written with a logic 1 to clear it.
OES 16	0	**Output Error Stop** The output port is stopped due to a transmission error. Read only.
— 15–11	0	Reserved. Write to zero for future compatibility.
IRS 10	0	**Input Retry Stop** The input port is stopped due to a retry. Read only.
IEE 9	0	**Input Error Encounter** The input port encountered (and possibly recovered from) a transmission error. IEE is set when IES is set. It remains set until it is written with a logic 1 to clear it.
IES 8	0	**Input Error Stop** The input port is stopped due to a transmission error. Read only.
— 7–5	0	Reserved. Write to zero for future compatibility.
PWP 4	0	**Port Write** Port has encountered a condition requiring it to initiate a maintenance port-write operation. PWP is valid only if the device can issue a maintenance port-write transaction. RapidIO Endpoint cannot issue port-writes. This bit is hard-wired to 0. Read only.
— 3	0	Reserved
PE 2	0	**Port Error** The input or output port has encountered an error from which hardware could not recover. PE remains set until it is written with a logic 1 to clear it. PE indicates that OFE is set while PnCCSR[SPF] is set. That is, reaching the failed threshold has caused the output port to stop transmitting packets.
PO 1	0	**Ports Operating** The input and output ports are initialized and the port is exchanging error-free control symbols with the attached device. Read only.
PU 0	1	**Ports Uninitialized** Input and output ports are not initialized. This bit and PO are mutually exclusive. Read only.

16.4.1.23 Port 1–2 Control Command and Status Register (PnCCSR)

P1CCSR Port 1–2 Control Command and Status Register Offset 0x0015C
P2CCSR Offset 0x0017C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PW		IPW			PWO			PD	OPE	IPE	ECD	MEP	—	EB	—

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—												SPF	DPE	PL	PT
TYPE	R												R/W			R
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

PnCCSR contains control register bits for the RapidIO port. This register is for serial implementation only.

Table 16-72. PnCCSR Field Descriptions

Bit	Reset	Description	Settings
PW 31–30	0b11	**Port Width** Specifies the supported hardware port widths. Read only.	00 Single-lane port supported. 01 Single and four-lane port supported 10 Single and two-lane port supported. 11 Single-, two-, and four-lane port supported (default)
IPW 29–27	0b010	**Initialized Port Width** Specifies the width of the ports after they are initialized. Read only. If the port degrades to x1, the value changes to 0b000. In single lane mode, the RapidIO block can synchronize on lane 0 or lane 2. Programming the PWO field to 010 forces the controller to synchronize on lane 0.	000 Single-lane port, lane 0. 001 Single-lane port, lane 2. 010 Four-lane port, lanes 0–3. 011 Two-lane port, lanes 0–1. 100–111 Reserved.
PWO 26–24	0b000	**Port Width Override** Soft port configuration to control the width modes available for port initialization. The meaning of bits 25–24 is determined by the value of bit 26. When bit 26 = 0b1, bit 25 controls enabling x4 mode and bit 24 controls enabling of x2 mode. **Note:** This field should be changed only when the port is uninitialized. To achieve this, first set PnCCSR[PD] to 1 (port disabled). Then change PWO to any legal value. Finally, set PD back to 0 (enabled)	000 No override (the default). 001 Reserved. 010 Force single lane, lane reversal not forced. 011 Force single lane and lane reversal. 100 x2 and x4 mode disabled. 101 x2 mode enabled, x4 mode disabled. 110 x2 mode disabled, x4 mode enabled. 111 x2 mode enabled, x4 mode enabled.
PD 23	0	**Port Disable** When this bit is set, the port does not accept or transmit any transaction. The output will congest if packets are sent to a disabled port.	0 Port receiver/drivers are enabled. 1 Port receiver/drivers are disabled and are unable to receive or transmit.
OPE 22	1	**Output Port Transmit Enable** Specifies whether the port is enabled to issue packets. If OPE = 0, the following conditions apply: • Inbound non-maintenance requests packets can generate responses. • If the device configuration allows outbound requests to be pending in the controller, inbound maintenance requests may not generate responses. • Outbound maintenance requests are not be transmitted. Set the bit (1) to allow transmission of any request or response packet. To allow responses to inbound maintenance requests when OPE = 0, disable any LAWs with a RapidIO target to prevent outbound request packets from being sent to the RapidIO controller. The initial value of OPE is read from configuration pins.	0 Port is stopped and not enabled to issue packets. Port may generate responses to inbound maintenance and to other types of transactions. 1 Port is enabled to issue packets.

Table 16-72. PnCCSR Field Descriptions (Continued)

Bit	Reset	Description	Settings
IPE 21	1	**Input Port Receive Enable** Specifies whether the port is enabled to respond to packets. When IPE is cleared, the port can only route or respond to I/O logical maintenance packets. Other packets generate packet-not-accepted control symbols to force an error condition to be signalled by the sending device. Control symbols are not affected and are received and handled normally. The value of IPE must equal the value of OPE for the RapidIO controller to function properly. The initial value of IPE is read from configuration pins.	0 Port is stopped and not enabled to respond to packets. 1 Port is enabled to respond to packets.
ECD 20	0	**Error Checking Disable** Disables all RapidIO transmission error checking. This bit is hard-wired to 0.	0 Error checking and recovery is enabled. 1 Error checking and recovery is disabled.
MEP 19	0	**Multicast Event Participant** This bit is hard-wired to 0. The MSC8157E does not participate in multicast events.	
— 18	0	Reserved. Write to zero for future compatibility.	
EB 17	0	**Enumeration Boundary** An enumeration boundary aware system algorithm honors this flag. The algorithm, at either the ingress or the egress port, will not count past a port with this bit set.	0 No enumeration boundary checking. 1 Enumeration boundary checking enabled.
— 16–4	0	Reserved. Write to zero for future compatibility.	
SPF 3	0	**Stop on Port Failed Encounter Enable** Used with the DPE bit to force certain behavior when the error rate failed threshold is met or exceeded.	0 Stop on port failed disabled. 1 Stop on port failed enabled.
DPE 2	0	**Drop Packet Enable** Used with the SPF bit to force certain behavior when the error rate failed threshold is met or exceeded.	0 Drop packet response disabled. 1 Drop packet response enabled.
PL 1	0	**Port Lockout** Stops the port so that is cannot issue or receive packets. The input port can still follow the training procedure and can still send and respond to link requests. All received packets return packet-not-accepted control symbols to force the sending device to signal an error condition.	0 Packets that can be received and issued are controlled by the state of the OPE and IPE bits. 1 The port is stopped and not enabled to issue or receive packets.
PT 0	1	**Port Type** Hard-wired to 1.	0 Reserved. 1 Serial port.

16.4.1.24 Error Reporting Block Header (ERBH)

ERBH Error Reporting Block Header Offset 0x00600

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	EFPTR															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	EFID															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

ERBH contains the EFPTR to the next EFBLK. The next EFPTR is 0x0000 since this is the last set of registers in the extended features space. ERBH also contains EFID that identifies this as the error reporting block header.

Table 16-73. ERBH Field Descriptions

Bit	Reset	Description
EFPTR 31–16	0	**Extended Features Pointer** Points to the next EFBLK.
EFID 15–0	0x0007	**Extended Features ID** Identifies this as the error reporting block header.

16.4.1.25 Logical/Transport Layer Error Detect Command and Status Register (LTLEDCSR)

LTLEDCSR Logical/Transport Layer Error Detect Command and Status Register Offset 0x00608

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	IER	—	GER	—	ITD	ITTE	—	PRT	UR	UT	MDSC	OE DSC	LDSS	SDSS	DSP DUL	—
TYPE	R/W										R					R/W

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—								IACB	OACB	—	RETE	TSE	PTTL	—	
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LTLEDCSR indicates the error that was detected by the logical or transport logic layer. LTLEDCSR is stored in each RapidIO Endpoint port and the Message Unit, although the values in this register can differ for each port/Message Unit. A port's LTLEDCSR cannot detect any errors if the port or the Message Unit has captured an enabled Logical/Transport layer error until the detected error is cleared, and likewise, the Message Unit's LTLEDCSR cannot detect any errors if the Message Unit or any port has captured an enabled Logical/Transport layer error.

Software writes this register with all 0s to clear the detected error and unlock the capture registers. Error information that corresponds to two or more different error events is not captured on the same clock cycle. However, one error event such as a corrupted inbound packet can cause multiple bits to be set. The priority of errors is PRT and all other errors. An error that is not enabled sets the detect bit in this register as long as a capture has not yet occurred. If more than one port or Message Unit detects one or more enabled errors in the same cycle, the capture registers will be saved in the top port / Message Unit in the SBus daisy chain that detected an enabled error, and the set and enabled detect bits of the port(s)/Message Unit below will be masked from the SBus daisy chain. This means that a read of LTLEDCSR will only return the disabled set bits from any port/Message Unit and enabled set bits from the top port / Message Unit in the daisy chain with a set enabled error, and that a read of the capture registers will return the values in the top port / Message Unit in the daisy chain with a set enabled error; that is, the set enabled detect bits will correspond to the capture registers.You can program fields in this register to emulate a hardware error during software development. Undefined results occur if fields in this register are set while an actual Logical/Transport Layer error is detected. Note that this register can be written with an invalid combination of bits set, and care should be taken to avoid this.

Table 16-74. LTLEDCSR Field Descriptions

Bit	Name	Description
IER 31	0	**I/O Error Response** Indicates an error response for an I/O logical layer request.
— 30	0	Reserved. Write to zero for future compatibility.
GER 29	0	**GSM Error Response** Indicates a response of ERROR for a GSM logical layer request.
— 28	0	Reserved. Write to zero for future compatibility.
ITD 27	0	**Illegal Transaction Decode** Indicates received illegal fields in the request/response packet for a supported transaction (IO/MSG logical)
ITTE 26	0	**Illegal Transaction Target Error** Indicates a packet containing a destination ID that is not defined for this end point when accept-all is not enabled.
— 25	0	Reserved. Write to zero for future compatibility.
PRT 24	0	**Packet Response Time-Out** Indicates that a required response was not received within the specified time-out interval (IO/MSG logical)
UR 23	0	**Unsolicited Response** Indicates that an unsolicited/unexpected response packet was received (IO/MSG logical).
UT 22	0	**Unsupported Transaction** Indicates a received transaction that is not supported in the destination operations CAR.
MDSC 21	0	**Missing Data Streaming Context** A continuation or end data streaming segment was received for a closed or non-existent segmentation context.
OEDSC 20	0	**Open Existing Data Streaming Context** A start or single data streaming segment was received for an already open segmentation context.
LDSS 19	0	**Long Data Streaming Segment** Received a data streaming segment with a payload size greater than the MTU.

Table 16-74. LTLEDCSR Field Descriptions (Continued)

Bit	Name	Description
SDSS 18	0	**Short Data Streaming Segment** Received a start or continuation data streaming segment with a payload size less than the MTU.
DSPDUL 17	0	**Data Streaming PDU Length** The length of a reassembled PDU differs from the PDU length carried in the end data streaming segment. packet header
— 16–8	0	Reserved. Write to zero for future compatibility.
IACB 7	0	**Inbound ATMU Crossed Boundary** Indicates a received transaction that crosses an Inbound ATMU boundary.
OACB 6	0	**Outbound ATMU Crossed Boundary** Indicates a received transaction that crosses an outbound ATMU boundary, a segment boundary, or a subsegmented boundary.
— 5	0	Reserved. Write to zero for future compatibility.
RETE 4	0	**Retry Error Threshold Exceeded** Indicates that the allowed number of logical retries (given by LRETCR[RET]) has been exceeded. The message unit also drives RETE when the allowed number of message retries is exceeded.
TSE 3	0	**Transport Size Error** The tt field is not consistent with bit 27 of the processing element features CAR (that is, the tt value is reserved or indicates a common transport system unsupported by this device).
PTTL 2	0	**Packet Time-to-Live Error** Indicates that a packet time-to-live error occurred (that is, a packet could not be successfully transmitted before the packet time-to-live counter expired).
— 1–0	0	Reserved. Write to zero for future compatibility.

16.4.1.26 Logical/Transport Layer Error Enable Command and Status Register (LTLEECSR)

LTLEECSR Logical/Transport Layer Error Enable Command and Status Register — Offset 0x0060C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LTLEECSR contains the bits that control whether an error condition locks the logical/transport layer error detect and capture registers and is reported to the system host. LTLEECSR is stored in all ports and the message unit.

Table 16-75. LTLEECSR Field Descriptions

Bit	Name	Description
IER 31	0	**I/O Error Response Enable** Enables reporting of an I/O error response. It captures and locks the error.
— 30	0	Reserved. Write to zero for future compatibility.
GER 29	0	**GSM Error Response Enable** Enables reporting of a GSM error response. It captures and locks the error.
— 28	0	Reserved. Write to zero for future compatibility.
ITD 27	0	**Illegal Transaction Decode Error Enable** Enables reporting of an illegal transaction decode error. It captures and locks the error.
ITTE 26	0	**Illegal Transaction Target Error Enable** Enables reporting of an illegal transaction target error. It captures and locks the error.
— 25	0	Reserved. Write to zero for future compatibility.
PRT 24	0	**Packet Response Time-Out Error Enable** Enables reporting of a packet response time-out error. It captures and locks the error.
UR 23	0	**Unsolicited Response Error Enable** Enables reporting of an unsolicited response error. It captures and locks the error.
UT 22	0	**Unsupported Transaction Error Enable** Enables reporting of an unsupported transaction error. It captures and locks the error.
MDSC 21	0	**Missing Data Streaming Context** Enables reporting of an unsupported transaction error. Capture and lock the error.
OEDSC 20	0	**Open Existing Data Streaming Context** Enable reporting of an unsupported transaction error. Capture and lock the error.
LDSS 19	0	**Long Data Streaming Segment** Enable reporting of an unsupported transaction error. Capture and lock the error.
SDSS 18	0	**Short Data Streaming Segment** Enable reporting of an unsupported transaction error. Capture and lock the error.
DSPDUL 17	0	**Data Streaming PDU Length** Enable reporting of an unsupported transaction error. Capture and lock the error.
— 16–8	0	Reserved. Write to zero for future compatibility.
IACB 7	0	**Inbound ATMU Crossed Boundary Error Enable** Enables reporting of a received transaction that crosses an inbound ATMU boundary. It captures and locks the error.
OACB 6	0	**Outbound ATMU Crossed Boundary** Indicates a received transaction that crosses an outbound ATMU boundary, a segment boundary, or a subsegmented boundary.
— 5	0	Reserved. Write to zero for future compatibility.
RETE 4	0	**Retry Error Threshold Exceeded Enable** Enables reporting when the allowed number of logical retries is exceeded.
TSE 3	0	**Transport Size Error Enable** Enables error reporting when the field is not consistent with the CTLS bit of the processing element features CAR (that is, the tt value is reserved or indicates a common transport system unsupported by this device).
PTTL 2	0	**Packet Time-to-Live Error Enable** Enables reporting of a packet time-to-live error. Capture and lock the result.
— 2–0	0	Reserved. Write to zero for future compatibility.

16.4.1.27 Logical/Transport Layer Address Capture Command and Status Register (LTLACCSR)

LTLACCSR Logical/Transport Layer Address Capture Command and Status Register — Offset 0x00614

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	A															
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	A													—	XA	
TYPE	R/W													R	R/W	
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LTLACCSR contains error information. It is locked when a logical/transport error is detected and the corresponding enable bit is set. LTLACCSR is stored in the port and in the message unit, although the values in this register can differ between the port and the message unit. The message unit LTLACCSR cannot lock if the port is locked; the port LTLACCSR cannot lock if the message unit is locked.

Note: Fields in this register can be set by writing to the register. You can use this to emulate a hardware error during software development. Undefined results occur if fields in the register are changed while an actual Logical/Transport error is being detected.

Table 16-76. LTLACCSR Field Descriptions

Bit	Reset	Description
A 31–3	0	**Address** Normally, the least significant 29 bits of the address associated with the error (for requests, for responses, if available). For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors*, on page 16-64.
— 2	0	Reserved. Write to zero for future compatibility.
XA 1–0	0	**Extended Address MSBs** Normally the extended address bits of the address associated with the error (for requests, responses, if available). For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors,* on page 16-64.

16.4.1.28 Logical/Transport Layer Device ID Capture Command and Status Register (LTLDIDCCSR)

LTLDIDCCSR Logical/Transport Layer Device ID Capture Command and Status Register — Offset 0x00618

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DIDMSB								DID							
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	SIDMSB								SID							
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LTLDIDCCSR contains error information. It is locked when a logical/transport error is detected and the corresponding enable bit is set. LTLDIDCCSR is stored in the port and in the message unit, although the values in this register can differ between the port and the message unit. The message unit LTLDIDCCSR cannot lock if the port is locked; the port LTLDIDCCSR cannot lock if the message unit is locked.

Note: Fields in this register can be set by writing to the register. You can use this to emulate a hardware error during software development. Undefined results occur if fields in the register are changed while an actual Logical/Transport error is being detected.

Table 16-77. LTLDIDCCSR Field Descriptions

Bit	Reset	Description
DIDMSB 31–24	0	**Destination ID MSB** Normally, the most significant byte of the destination ID associated with the error. This field is valid only if the CTLS bit of the Processing Element Features CAR is set (large transport systems only). For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors,* on page 16-64.
DID 23–16	0	**Destination ID** Normally, the destination ID (or least significant byte of the destination ID if large transport system) associated with the error. For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors,* on page 16-64.
SIDMSB 15–8	0	**Source ID MSB** Normally, the most significant byte of the source ID associated with the error. This field is valid only if the CTLS bit of the Processing Element Features CAR is set (large transport systems only). For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors,* on page 16-64.
SID 7–0	0	**Source ID** Normally, the source ID (or least significant byte of the source ID if large transport system) associated with the error. For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors,* on page 16-64.

16.4.1.29 Logical/Transport Layer Control Capture Command and Status Register (LTLCCCSR)

LTLCCCSR Logical/Transport Layer Control Capture Command and Status Register — Offset 0x0061C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FT				TT				MI							
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	EPN				—											
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LTLCCCSR contains error information. LTLCCCSR is stored in the port and in the message unit, although the values in this register can differ between the port and the message unit. The message unit LTLCCCSR cannot lock if the port is locked; the port LTLCCCSR cannot lock if the message unit is locked.

Note: Fields in this register can be set by writing to the register. You can use this to emulate a hardware error during software development. Undefined results occur if fields in the register are changed while an actual Logical/Transport error is being detected.

Table 16-78. LTLCCCSR Field Descriptions

Bit	Reset	Description
FT 31–28	0	**Format Type** Normally, the format type associated with the error. For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors,* on page 16-64.
TT 27–24	0	**Transaction Type** Normally, the transaction type associated with the error. For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors,* on page 16-64.
MI 23–16	0	**Message Information** Normally, the message information: letter, mbox, and msgseg for the last message request received for the mailbox with an error (message errors only). For details, see **Section 16.2.14.3**, *Logical Layer RapidIO Errors,* on page 16-64.
EPN 15–12	0	**Encoded Port Number** Indicates the port from which the error information was captured.
— 11–0	0	Reserved. Write to zero for future compatibility.

16.4.1.30 Port 1–2 Error Detect Command and Status Register (PnEDCSR)

P1EDCSR Port 1–2 Error Detect Command and Status Register Offset 0x00640
P2EDCSR Offset 0x00680

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—									CCS	AUA	PNA	UA	CRC	EM	—
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—										NOA	PE	—	DE	UCS	LTO
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnEDCSR indicates transmission errors detected by the hardware. Software can write bits in this register with a value of 1 to increment the error rate counter. Undefined results occur if this register is written while actual physical layer errors are detected by the port

Table 16-79. PnEDCSR Field Descriptions

Bit	Reset	Description
— 31–23	0	Reserved. Write to zero for future compatibility.
CCS 22	0	**CRC Control Symbol** Received a control symbol with a bad CRC value.
AUA 21	0	**Acknowledge Control With Unexpected Acknowledge ID** Received an acknowledge control symbol with an unexpected acknowledge ID (packet-accepted or packet-retry).
PNA 20	0	**Packet Not Accepted** Received packet-not-accepted acknowledge control symbol.
UA 19	0	**Unexpected Acknowledge ID** Received packet with unexpected ackID value.
CRC 18	0	**Bad CRC** Received a packet with a bad CRC value.
EM 17	0	**Exceed Maximum** Received packet which exceed the maximum allowed size (276 bytes).
— 16–6	0	Reserved. Write to zero for future compatibility.
NOA 5	0	**Not Outstanding Acknowledge** Link-response received with an ackID that is not outstanding.
PE 4	0	**Protocol Error** An unexpected packet or control symbol was received.
— 3	0	Reserved. Write to zero for future compatibility.
DE 2	0	**Delineation Error** Received unaligned /SC/ or /PD/ or undefined code-group.
UCS 1	0	**Unsolicited Control Symbol** An unsolicited acknowledge control symbol was received.
LTO 0	0	**Link Time-Out** An acknowledge or link-response control symbol is not received within the specified time-out interval.

16.4.1.31 Port 1–2 Error Rate Enable Command and Status Register (PnERECSR)

P1ERECSR Port 1–2 Error Rate Enable Command and Status Register Offset 0x00644
P2ERECSR Offset 0x00684

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—									CCS	AUA	PNA	UA	CRC	EM	—
TYPE	R/W

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—										NOA	PE	—	DE	UCS	LTO
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnERECSR contains the bits that control when an error condition is allowed to increment the error rate counter in the Port 1–2 error rate threshold register and lock the Port 1–2 error capture registers.

Table 16-80. PnERECSR Field Descriptions

Bit	Reset	Description
— 31–23	0	Reserved. Write to zero for future compatibility.
CCS 22	0	**CRC Control Symbol Enable** Enable error counting of a corrupt control symbol.
AUA 21	0	**Acknowledge Control With Unexpected Acknowledge ID Enable** Enable error rate counting of an acknowledge control symbol with an unexpected acknowledge ID.
PNA 20	0	**Packet Not Accepted Enable** Enable error rate counting of packet-not-accepted acknowledge control symbols.
UA 19	0	**Unexpected Acknowledge ID Enable** Enable error rate counting of packets with an unexpected ackID value.
CRC 18	0	**Bad CRC Enable** Enable error rate counting of packets with a bad CRC value.
EM 17	0	**Exceed Maximum Enable** Enable error rate counting of packets that exceed the maximum allowed size (276 bytes).
— 16–6	0	Reserved. Write to zero for future compatibility.
NOA 5	0	**Not Outstanding Acknowledge** Enable error rate counting of ink-responses received with an acknowledge ID that is not outstanding.
PE 4	0	**Protocol Error** Enable error rate counting of protocol errors.
— 3	0	Reserved. Write to zero for future compatibility.
DE 2	0	**Delineation Errors** Enable error rate counting of delineation errors.
UCS 1	0	**Unsolicited Control Symbol** Enable error rate counting of unexpected acknowledge control symbols.
LTO 0	0	**Link Time-Out** Enable error rate counting of an acknowledge or link-response control symbol not received within the specified time-out interval.

16.4.1.32 Port 1–2 Error Capture Attributes Command and Status Register (PnECACSR)

P1ECACSR Port 1–2 Error Capture Attributes Command and Status Register Offset 0x00648
P2ECACSR Offset 0x00688

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	ECI7	ECI6	ECI5	ECI4	ECI3	ECI2	ECI1	ECI0	—							CVI
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnECACSR indicates the type of information contained in the Port 1–2 error capture registers. For multiple errors detected during the same clock cycle, one of the errors must be reflected in the error type field. Undefined results occur if this register is written while actual physical layer errors are detected by the port. Before the capture registers are read, software should verify that the PnECACSR[CVI] bit is set to ensure that the error is properly captured.

Table 16-81. PnECACSR Field Descriptions

Bit	Reset	Description	Settings
IT 31–30	0	**Information Type** Type of information logged.	00 Packet. Error capture registers hold the first 4 words of the packet or the entire packet if it is less than four words long. 01 Control symbol. Only the error capture register 0 is valid. 10 Reserved. 11 Undefined. Not clearly a control symbol or packet error. Error capture registers hold the symbol that caused the error and the next thee symbols.
— 29	0	Reserved. Write to zero for future compatibility.	
ET 28–24	0	**Error** The encoded value of the bit in the Port 1–2 error detect CSR that describes the error captured in the Port 1–2 error capture CSRs.	

Table 16-81. PnECACSR Field Descriptions

Bit	Reset	Description	Settings
ECI 23–8	0	**Extended Capture Information** ECI contains the control/data character signal corresponding to each byte of captured data.	ECI15] Associated with PnPCSECCSR0[31–24]. ECI14 Associated with PnPCSECCSR0[23–16]. ECI13 Associated with PnPCSECCSR00[15–8]. ECI12 Associated with PnPCSECCSR0[7–0]. ECI11 Associated with PnPECCSR1[31–24]. ECI10 Associated with PnPECCSR1[25–16]. ... ECI1 Associated with PnPECCSR3[15–8]. ECI0 Associated with PnPECCSR3[7–0].
— 7–1	0	Reserved. Write to zero for future compatibility.	
CVI 0		**Contain Valid Information** Hardware sets CVI to indicate that the packet/control symbol capture registers contain valid information. For control symbols, only capture register 0 contains meaningful information.	

16.4.1.33 Port 1–2 Packet/Control Symbol Error Capture Command and Status Register (PnPCSECCSR)

P1PCSECCSR Port 1–2 Packet/Control Symbol Error Capture Command and Status Register Offset 0x0064C
P2PCSECCSR Offset 0x0068C

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	C0

	C0															
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnPCSECCSR0 contains the first 4 bytes of captured packet symbol information or a control character and control symbol. Undefined results occur if this register is written while actual physical layer errors are detected by the port. Software should verify that the PnECACSR[CVI] bit is set before reading the capture registers to ensure that the error is properly captured.

Table 16-82. PnPCSECCSR0 Field Descriptions

Bit	Reset	Description
C0 31–0	0	**Capture 0** Control character and control symbol or bytes 0–3 of the packet header.

16.4.1.34 Port 1–2 Packet Error Capture Command and Status Register 1 (PnPECCSR1)

P1PECCSR1 Port 1–2 Packet Error Capture Command and Status Register 1 Offset 0x00650
P2PECCSR1 Offset 0x00690

RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnERCSR is used with the Portn Error Rate Threshold Command and Status Register (PnERTCSR) to monitor and control the reporting of transmission errors.

Table 16-86. PnERCSR Field Descriptions

Bit	Reset	Description	Setting
ERB 31–24	0b1000_0000	**Error Rate Bias** Provides the error rate bias value.	0x00 Do not decrement the error rate counter. 0x01 Decrement every 1 ms (±34%). 0x02 Decrement every 10 ms (±34%). 0x04 Decrement every 100 ms (±34%). 0x08 Decrement every 1 s (±34%). 0x10 Decrement every 10 s (±34%). 0x20 Decrement every 100 s (±34%). 0x40 Decrement every 1000 s (±34%). 0x80 Decrement every 10000 s (±34%). Other values are reserved and cause undefined operation.
— 23–18	0	Reserved. Write to zero for future compatibility.	
ERR 17–16	0	**Error Rate** Limits increments of the error rate counter above the failed threshold trigger. This counter never increments above 0xFF, even if the combined settings of ERR and the failed threshold trigger imply that it would.	0b00 Count only 2 errors above. 0b01 Count only 4 errors above. 0b10 Count only 16 error above. 0b11 Do not limit increments above the error rate count.
PER 15–8	0	**Peak Error Rate** Contains the peak value attained by the error rate counter.	

Table 16-86. PnERCSR Field Descriptions (Continued)

Bit	Reset	Description	Setting
ERC 7–0	0	**Error Rate Counter** Counts the number of transmission errors detected by the port, decremented by the error rate bias, to create an indication of the link error rate. Software should not attempt to write to ERC a value higher than the failed threshold trigger plus the number of errors specified in the ERR field (the maximum ERC value).	

16.4.1.38 Port 1–2 Error Rate Threshold Command and Status Register (PnERTCSR)

P1ERTCSR Port 1–2 Error Rate Threshold Command and Status 'Register — Offset 0x0066C
P2ERTCSR — Offset 0x006AC

	—															
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LLCR contains general port-common logical layer mode enables.

Table 16-88. LLCR Field Descriptions

Bit	Reset	Description
— 31–30	0	Reserved. Write to zero for future compatibility.
ECRAB 29	0	**External Configuration Register Access Block** Blocks all maintenance requests and accesses to LCSBA1CSR. Reads return all 0s, and writes are ignored (both return a done response). When ECRAB is cleared, any external RapidIO device can access the registers.
NPUE 28	0	**NWRITE_R Priority Update Enable** When set, all inbound NWRITE_R transactions return a response with priority set to 3. When cleared, normal functionality of returning a response with Priority + 1 is assumed.
— 27–0	0	Reserved. Write to zero for future compatibility.

16.4.1.40 Error/Port-Write Status Register (EPWISR):

EPWISR Error/Port-Write Interrupt Status Register Offset 0x10010

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	PINT0	PINT1	—													
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—															
TYPE	R															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPWISR contains status bits of the interrupts generated by the port or the message unit for physical or logical/transport layer errors or inbound port-writes. Because errors from the port are reported to the SC3850 core with one interrupt signal, this register provides the core with quick

access to where the error occurred. This register is read-only and stored in the port and the message unit as a logically equivalent copy.

Table 16-89. EPWISR Field Descriptions

Bit	Reset	Description
PINT0 31	0	**Physical or Logical/Transport Error Interrupt Port 1** Indicates a physical or logical transport error interrupt was generated by port 1.
PINT1 30	0	**Physical or Logical/Transport Error Interrupt Port 2** Indicates a physical or logical transport error interrupt was generated by port 2.
— 29–0	0	Reserved. Can be used to indicate errors on more ports if they exist.

16.4.1.41 Logical Retry Error Threshold Configuration Register (LRETCR)

LRETCR Logical Retry Error Threshold Configuration Register Offset 0x10020

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	—								RET							
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

LRETCR contains the retry error threshold for the logical layer. When the number of consecutive logical retries for a given packet is greater than this value, an error interrupt is generated. Notice that the number of retries must be greater than the threshold value, which is not the case for other registers that define a retry threshold.

Table 16-90. LRETCR Field Descriptions

Bit	Reset	Description	
— 31–8	0	Reserved. Write to zero for future compatibility.	
RET 7–0	0xFF	**Retry Error Threshold** The threshold value for the number of consecutive logical retries received for a given packet that causes the RAPIDIO ENDPOINT to report an error condition.	0x00 Disable the retry threshold. 0x01 Set the error reporting threshold to 1. ... 0xFF Set the error reporting threshold to 255.

16.4.1.42 Physical Retry Error Threshold Configuration Register (PRETCR)

PRETCR Physical Retry Error Threshold Configuration Register Offset 0x10080

	—								RET							
TYPE	R								R/W							
RESET	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

PRETCR contains the retry error threshold for the physical layer. When the number of consecutive acknowledge-retries is greater than or equal to this value, an error interrupt is generated.

Table 16-91. PRETCR Field Descriptions

Bit	Reset	Description	Settings
— 31–8	0	Reserved. Write to zero for future compatibility.	
RET 7–0	0xFF	**Retry Error Threshold** The threshold value for the number of consecutive acknowledge-retries received that cause the RAPIDIO ENDPOINT to report an error condition.	0x00 Disable the retry threshold. 0x01 Set the error reporting threshold to 1. ... 0xFF Set the error reporting threshold to 255.

16.4.1.43 Port 1–2 Alternate Device ID Command and Status Register (PnADIDCSR)

P1ADIDCSR Port 1–2 Alternate Device ID Command and Status Register Offset 0x10100
P2ADIDCSR Offset 0x10180

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	ADE	—							ADID							
TYPE	R/W	R							R/W							
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	LADID															
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnADIDCSR contains san alternate device ID. This register should be enabled before the initiator enabled bit of the PGCCSR is set (see **Table 16-67*PGCCSR Field Descriptions,*** on page 16>-195). Therefore, when the PGCCSR bit is enabled, all other devices in the RapidIO system (including switches) send and receive packets from the device ID in PnADIDCSR instead of the device ID in BDIDCSR. When the alternate deviceID is enabled, inbound RapidIO

endpoint accepts only packets sent with the device ID in PnADIDCSR or the deviceID in BDIDCSR. An exception is Accept All mode, in which the inbound RapidIO Endpoint accept packets using the same common transport system. The outbound RapidIO endpoint generates requests using only the device ID in PnADIDCSR. It generates responses with the deviceID in the original request packet (either from PnADIDCSR or BDIDCSR). The selection between a large or small transport system is done during the power-up sequence by using the CTLS bit in the RCW.

Table 16-92. PnADIDCSR Field Descriptions

Bit	Reset	Description
ADE 31	0	**Alternate Device ID Enable** Causes the port to use the device ID specified in this register instead of the device ID specified in BDIDCSR.
— 30–24	0	Reserved. Write to zero for future compatibility.
ADID 23–16	0	**Alternate Device ID** Alternate device ID in a small transport system.
LADID 15–0	0	**Large Alternate Device ID** Alternate device ID for the device in a large transport system.

16.4.1.44 Port 1–2 Pass-Through Accept-All Configuration Register (PnPTAACR)

P1PTAACR Port 1–2 Pass-Through Accept-All Configuration Register Offset 0x10120
P2PTAACR Offset 0x101A0

	TV								—							
TYPE	R/W								R							
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The Port 1–2 logical outbound packet time-to-live configuration register (PnLOPTTLCR) contains the time-to-live count for all ports on a device. This packet time-to-live counter starts when a packet is ready to be transmitted. If the packet is not successfully transmitted before the timer expires, the packet is discarded. Successfully transmitted means that a packet accept was received for the packet on the RIO interface. If the packet requires a response, an internal error response will be returned after the response time-out occurs (PRTOCCSR). The packet time-to-live counter prevents the local processor from being stalled when packets cannot be successfully transmitted (acknowledged with an accept by the link partner at the physical level). The value of this register should always be larger than the link time-out value (PLTOCCSR). The

reset value is the maximum time-out interval and represents between 3 and 5 seconds. When the packet time-to-live counter expires, PnPCR[OBDEN] is automatically set. PnPCR[OBDEN] must be cleared by software.

Table 16-94. PnLOPTTLCR Field Descriptions

Bit	Reset	Description
TV 31–8	0	**Time-out Value** Setting to all zeros disables the time-to-live time-out timer. This value is loaded each time the time-to-live time-out timer starts.
— 7–0	0	Reserved. Write to zero for future compatibility.

16.4.1.46 Port 1–2 Implementation Error Command and Status Register (PnIECSR)

P1IECSR Port 1–2 Implementation Error Command and Status Register Offset 0x10130
P2IECSR Offset 0x101B0

RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnSLEICR controls the injection of bit errors into the transmit bit stream and is used to generate pseudo-random errors into the outbound serial RapidIO data stream. If the EIC field is non-zero, error injection is enabled and, at pseudo-random intervals, an error is injected by inverting a

single bit in the outgoing data stream. The range of the pseudo-random value (delay between injected errors) is controlled by the EIR field. That is, the value of EIR, multiplied by 32, determines the maximum number of character times between injected errors.

Table 16-99. PnSLEICR Field Descriptions

Bit	Reset	Description	Settings
EIC 31–27	0	**Error Injection Control** Enables and controls serial link error injection as follows.	00000 Error injection is disabled. 10000 Error injection, lane 0 only. 01000 Error injection, lane 1 only 00100 Error injection, lane 2 only 00010 Error injection, lane 3 only 11110 Error injection, all lanes simultaneously 11111 Error injection, randomly distributed over all 4 lanes All other values reserved.
— 26–20	0	Reserved. Write to zero for future compatibility.	
EIR 19–0	0	**Error Injection Range** The value of EIR × 32 determines the maximum value of the pseudo-random delay between errors. For example, a value of 0x1 indicates a maximum delay of 32 character times. The value within this register should be right-justified.	

16.4.1.50 Port *n* Arbitration 0 Tx Configuration Register (P*n*A0TxCR)

PnROWTARx points to the starting addresses in the RapidIO address space for window hits within the outbound translation windows. The new translated address is created by concatenating the transaction offset to this translation address.

Table 16-109. PnROWTAR*x* Field Descriptions

Bit	Reset	Description
LTGTID 31–30	0	**Large Transport System Target Address** LTGTID corresponds to bits 6–7 of the targetID for a large transport system. This field is valid only if the PEFCAR[CTLS] bit is set (see **Section 16.4.1.5**, *Processing Element Features Capability Register (PEFCAR),* on page 16-184). Bits 0–5 of the target ID are specified in the PnROWTEARX (see **Section 16.4.1.60**, *Port 1–2 RapidIO Outbound Window Translation Extended Address Registers x (PnROWTEARx),* on page 16-239
TREXAD 29–20	0	**Translation Extended Address** TREXAD[0–7] corresponds to the target ID for a small transport system or the least significant byte (bits 8–15) of the target ID for a large transport system. TREXAD[8–9] correspond to bits 0–1 of a 34-bit RapidIO translation address. For maintenance transactions and default window 0, TREXAD[8–9] are reserved.
TRAD 19–0	0	**Translation Address** System address that represents the starting point of the outbound translated address. The translation address must be aligned based on the field size. This corresponds to bits 2–21 of the 34-bit RapidIO translation address. For maintenance transactions, the hop count is formed from TRAD[0–7] and the upper 12 bits of the maintenance offset is formed from TRAD[8–19]. The rest of the maintenance offset is reserved for default window 0.

16.4.1.60 Port 1–2 RapidIO Outbound Window Translation Extended Address Registers x (PnROWTEARx)

P1ROWTEAR[0–8] Port 1–2 RapidIO Outbound Window Translation Extended Address Registers 0–8 Offset 0x10C04 + x*0x20
P2ROWTEAR[0–8] Offset 0x10E04 + x*0x20

	—										LTGTID					
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnROWTEARx points to the starting addresses in the RapidIO address space for window hits within the outbound translation windows. The new translated address is created by concatenating the transaction offset to this translation address.

Table 16-110. PnROWTAR*x* Field Descriptions

Bit	Reset	Description
— 31–6	0	Reserved. Write to zero for future compatibility.
LTGTID 5–0	0	**Large Transport System Target ID** Corresponds to bits 0–5 of the target ID for a large transport system. This field is valid only if the PEFCAR[CTLS] bit is set (see **Section 16.4.1.5**, *Processing Element Features Capability Register (PEFCAR),* on page 16-184). Bits 6–7 of the target ID are specified in the corresponding PnROWTARx.

16.4.1.61 Port 1–2 RapidIO Outbound Window Base Address Registers x (PnROWBARx)

P1ROWBAR[1–8] Port 1–2 RapidIO Outbound Offset 0x10C08 + x*0x20
P2ROWBAR[1–8] Window Base Address Registers 1–8 Offset 0x10E08 + x*0x20

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	**15**	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
	BADD															
TYPE	R/W															
RESET	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PnROWBARx selects the base address for the windows that are translated to an alternate target address space. Addresses for outbound transactions are compared with the addresses of these windows. If such a transaction does not fall within one of these spaces, it is forwarded to the interior of the device using the default window. For information on transactions that cross more than one window, see **Section 16.2.9.4.2**, *Window Boundary Crossing Errors*, on page 16-56.

Table 16-111. PnROWBAR*x* Field Descriptions

Bit	Reset	Description
— 31–24	0	Reserved. Write to zero for future compatibility.
BEXAD 23–20	0	**Base Extended Address** Bits 0–3 of the 36-bit RapidIO base address. **Note:** Bit 0 is the most significant bit.
BADD 19–0	0	**Base Address** A system address that is the starting-point for the outbound translation window. The window must be aligned on the basis of the size selected in the window size bits. This corresponds to bits 4–23 of the 36-bit RapidIO base address. **Note:** Bit 0 is the most significant bit.

16.4.1.62 Port 1–2 RapidIO Outbound Window Attributes Registers x (PnROWARx)

P1ROWARx Port 1–2 RapidIO Outbound Offset 0x10C10 + x*0x20
P2ROWARx Window Attributes Registers 0–8 Offset 0x10E10 + x*0x20

	WRTYP				—						SIZE					
TYPE	R/W				R						R/W (R for default window 0)					
RESET	0	1	0	0	0	0	0	0	0	0	1	0	0	0	1	1

Note: For x = 0, the reset value for the EN field = 1. For all other registers (x = 1 to 8), the reset value of the EN field = 0.

The RapidIO outbound window attributes registers define the window sizes to translate and other attributes of the translations. The largest window size allowed is 64 GB. For a segmented window, these attributes are used for segment 0. The PCI window bit applies for all segments.

Table 16-112. PnROWAR*x* Field Descriptions

Bit	Reset	Description	Settings
EN 31	0	**Enable Address Translation** For default window 0 only, this bit is set to 1 and read-only.	0 Window disabled. 1 Window enabled.
— 30–29	0	Reserved. Write to zero for future compatibility.	
CRF 28	0	**Critical Request Flow** For packets that are destined for the same output port of a switch, this bit is used to raise the precedence of the request above requests of other packets at the same flow level that have a CRF value of 0.	0 Do not raise flow precedence. 1 Raise flow precedence.
TFLOWLV 27–26	00	**Transaction Flow Level** Selects the transaction flow priority level. This field must be cleared (00) if the PCI bit is set. Also, the RapidIO priority given by this field must always be greater than or equal to the internal priority or a deadlock can occur. Normally, the internal priority of all packets is 0.	00 Lowest priority transaction request flow. 01 Medium priority transaction request flow. 10 Highest priority transaction request flow. 11 Reserved.
PCI 25	0	**PCI Window** If set, this window follows PCI ordering rules as defined in the RapidIO Inter-operability specification. The TFLOWLV field must be 00 if this bit is set causing reads to have RapidIO priority 0 and writes to have RapidIO priority 1.	0 Non-PCI window rules. 1 PCI window rules.
— 24	0	Reserved. Write to zero for future compatibility.	
NSEG 23–22	00	**Number of Segments** Number of segments for this window. **Note:** This field is reserved for default window 0.	00 One segment (normal) 01 Two segments (half-size aliasing window) 10 Four segments (quarter-size aliasing window) 11 Reserved.

Table 16-112. PnROWAR*x* Field Descriptions (Continued)

Bit	Reset	Description	Settings
NSSEG 21–20	00	**Number of Subsegments per Segment** Defines the number of segments to use with each segment. **Notes:** **1.** This field is reserved for default window 0. **2.** This field is valid only if NSEG = 1 or 2.	00 One target deviceID per segment 01 Two target deviceIDs per segment. 10 Four target deviceIDs per segment. 11 Eight target deviceIDs per segment.
RDTYP 19–16	0100	**Read Type** Transaction type to run on the RapidIO interface if the access is a read.	0100 Read. 0111 Maintenance Read. All other values are reserved.
WRTYP 15–12	0100	**Write Type** Transaction type to run on the RapidIO interface if access is a write. A write-requiring-response sent from an internal source must generate a write-requiring-response to the RapidIO interface. Therefore, if an internal write-requiring-response request hits a window with WRTYP = SWRITE or NWRITE, the RapidIO endpoint generates an NWRITE_R instead.	0011 SWRITE. 0100 NWRITE. 0101 NWRITE_R. 0111 Maintenance Write All other values are reserved.
— 11–6	0	Reserved. Write to zero for future compatibility.	
SIZE 5–0	100011	**Window Size** Outbound translation window size N, which is the encoded 2^(N+1) byte window size. The smallest window size is 4 Kbyte. **Note:** This field is read-only for default window 0.	000000 Reserved. ... 001011 4 KB window size. 001100 8 KB window size. ... 011111 4 GB window size. 100000 8 GB window size. 100001 16 GB window size. 100010 32 GB window size. 100011 64 GB window size. 100100 Reserved ... 111111 Reserved.

The portn RapidIO inbound window attributes registers define the window sizes to translate and other attributes of the translations. The largest window size allowed is 16 GB. The RDTYP and WRTYP fields are used for attributes on the request, but they do not change the type of the transaction. In other words, PnRIWAR*x* does not modify whether the request requires a response or not. This type of attribute remains unchanged on the request as it is translated through the ATMU.

Table 16-116. PnRIWAR*x* Field Descriptions

Bit	Description	Settings
EN 31	**Enable Address Translation** Set to 1 and read-only for default window 0.	
PW 30	**Protected Window** Indicates that this window is protected. Writes requiring a response and reads to this window generate an error response. Writes not requiring a response are silently discarded.	

Table 16-116. PnRIWAR*x* Field Descriptions (Continued)

Bit	Description	Settings
— 29–24	Reserved. Write to zero for future compatibility.	
TGINT 23–20	**Target Interface** If this field is set to anything other than local address space, the attributes for the transaction must be assigned in a corresponding outbound window at the target.	*For Port 1:* 0000 OCN to MBus 0 0001 OCN to MBus 1 0010 SRIO Port 1 0011 SRIO Port 2 0100–1111 Reserved. *For Port 2:* 0000 OCN to MBus 1 0001 OCN to MBus 0 0010 SRIO Port 1 0011 SRIO Port 2 0100–1111 Reserved.
RDTYP 19–16	**Read Type** Transaction type to run on the local memory if the access is a read.	0000 Reserved. ... 0011 Reserved. 0100 Read. 0101 Reserved. ... 1111 Reserved.
WRTYP 15–12	Transaction type to run on local memory if access is a write.	0000 Reserved. ... 0011 Reserved. 0100 Write. 0101 Reserved. ... 1111 Reserved.
— 11–6	Reserved. Write to zero for future compatibility.	
SIZE 5–0	**Window Size** Inbound translation window size N, which is the encoded 2^(N+1) byte window size. The smallest window size is 4 KB. This field is read-only for default window 0.	000000 Reserved. ... 001011 4 KB window size. 001100 8 KB window size. ... 011111 4 GB window size. 100000 8 GB window size. 100001 16 GB window size. 100010 Reserved. ... 111111 Reserved.

Note: When using the same OCN-to-MBus (O2M) for Read and Write transactions, the write transactions may write incorrect data for specific access sequences. To preclude this

scenario, use one bridge for Write transactions and the other bridge for read transactions.

16.4.2 eMSG, BMLite, and QMLite Registers

16.4.2.1 Inbound Block m Type8 Classification Unit n Mode Register (IBmT8CnMR)

The doorbell mode register allows software to enable the doorbell unit to control various doorbell operation characteristics. The IB*m*T8C*n*MR is shown in **Figure 16-42**.

Bits	Name	Description
31–3	—	Reserved
2–0	MQID	Message queue ID. For proper operation, this field should only be modified when the inbound classification unit is not enabled.

16.4.2.4 Inbound Block *m* Type8 Classification *n* Rule Value Register 0 (IB*m*T8C*n*RVR0) and Inbound Block *m* Type8 Classification *n* Rule Value Register 1 (IB*m*T8C*n*RVR1)

The inbound Type8 classification rule value registers are used to configure a port-write rule directing inbound port-writes to a programmable message queue. The value registers are used in conjunction with the mask registers to create the rule. For example if the source field is set to 0x07 and the corresponding mask register field is set to 0x03, the inbound unit would accept any source route values from 0x4-0x7. If multiple inbound Type8 classification units match the same port-write rules, the lowest numbered enabled inbound classification unit wins.

Table 16-128. IB*m*T9C*n*MQR Field Descriptions

Bits	Name	Description
31–3	—	Reserved
2–0	MQID	Message queue ID. For proper operation, this field should only be modified when the inbound classification unit is not enabled.

16.4.2.11 Inbound Block *m* Type9 Classification *n* Rule Value Register 0 (IB*m*T9C*n*RVR0) and Inbound Block *m* Type9 Classification *n* Rule Value Register 1 (IB*m*T9C*n*RVR1)

The inbound Type9 classification value registers are used to configure a data streaming rule directing inbound PDUs to a programmable message queue. The value register is used in conjunction with the mask register to create the rule. For example if the class-of-service field is set to 0x20 and the corresponding mask register field is set to 0x07, the inbound Type9 classification unit would accept any class-of-service values from 0x20-0x25. If multiple classification units match the same packet attributes, the lowest numbered enabled inbound classification unit wins.

16.4.2.13 Inbound Block *m* Type9 Classification *n* Flow Control Destination Register (IB*m*T9C*n*FCDR)

This is the flow control destination register, for inbound Type9 classification. When an inbound message queue receiving a Type9 PDUs enters or exist flow control, a RapidIO stream management flow control request is sent to the source or sources generating traffic to the message queue. The destination register ID should match the possible sources for the classification rule. If multiple sources are included (non-zero mask), the destination ID should reflect a multicast destination ID for the RapidIO switch.

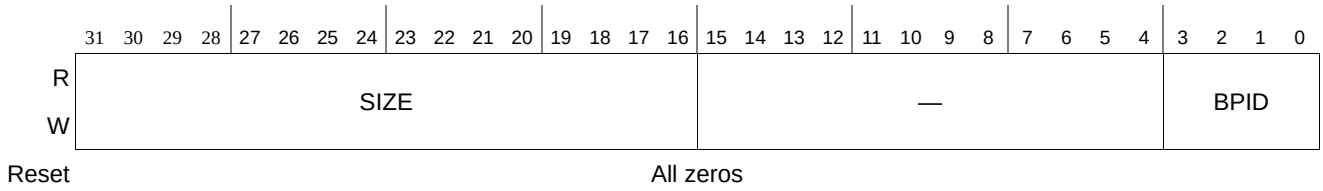

Figure 16-59. Inbound Block *m* Type9 Classification *n* Data Buffer Pool Register (IB*m*T9C*n*DBPR)

Table 16-134. IB*m*T9C*n*DBPR Field Descriptions

Bits	Name	Description
31–16	SIZE	Buffer size. Indicates the buffer size for the Buffer Pool used. 0x0000 64 K bytes 0x0040 64 bytes 0x0041 65 bytes ... 0x0080 128 bytes 0x0081 129 bytes ... 0x0100 256 bytes ... 0xFFFF 64K bytes – 1 Minimum buffer size is 64 bytes. **Note:** If 0x0000 is selected, the inbound buffer size is interpreted as 0 bytes and not 64 Kbytes. Therefore, do not select this value. If the buffer size is 64 Kbytes, the software can set IBmT9CnhDBPR[SIZE] to anything less than 64 Kbyte, but larger than the required message size to avoid a buffer size error.
15–4	—	Reserved.
3–0	BPID	Buffer Pool ID. Statically assigned buffer pool identifier for requesting free storage.

16.4.2.15 Inbound Block *m* Type9 Classification *n* Data Offset Register (IB*m*T9C*n*DOR)

This is the Type9 descriptor data offset register. Inbound transactions of Type9 writes the descriptor information into byte zero 0 of the first allocated data buffer. The offset specified here

indicates where the first byte of the data payload is located within the buffer. To allow for the descriptor, the minimum offset must be 32-bytes.

Offset: B0C0: 0034; B0C1: 0134;

Table 16-139. IB*m*T10C*n*MQR Field Descriptions

Bits	Name	Description
31–3	—	Reserved
2–0	MQID	Message queue ID. For proper operation, this field should only be modified when the inbound classification unit is not enabled.

16.4.2.20 Inbound Block *m* Type10 Classification *n* Rule Value Register 0 (IB*m*T10C*n*RVR0) and Inbound Block *m* Type10 Classification *n* Rule Value Register 1 (IB*m*T10C*n*RVR1)

The inbound Type10 classification rule value registers are used to configure a doorbell rule directing inbound doorbells to a programmable message queue. The value registers are used in conjunction with the mask registers to create the rule. For example if the source field is set to 0x07 and the corresponding mask register field is set to 0x03, the inbound unit would accept any

source route values from 0x4-0x7. If multiple inbound Type10 classification units match the same doorbell rules, the lowest numbered enabled inbound classification unit wins.

Reset: All zeros

Figure 16-78. Inbound Block *m* Type11 Classification Unit *n* Data Buffer Pool Register (IB*m*T11C*n*DBPR)

Table 16-153. IB*m*T11C*n*DBPR Field Descriptions

Bits	Name	Description
31–16	SIZE	Buffer size. Indicates the buffer size for the Buffer Pool used. 0x0000 64K bytes 0x0040 64 bytes 0x0041 65 bytes ... 0x0080 128 bytes 0x0081 129 bytes ... 0x0100 256 bytes ... 0x0000 64K bytes – 1 Minimum buffer size is 64 bytes. Although larger buffer sizes are supported, message data payload is maximum 4K bytes plus descriptor size. The minimum buffer size must account for the last segment being equal to the segment size. For example, if the message has 4 segments and the segment size is 256 bytes, the buffer size must accommodate the maximum data payload of 1 KB, regardless of the last segment size. **Note:** If 0xFFFF is selected, the inbound buffer size is interpreted as 0 bytes and not 64 Kbytes. Therefore, do not select this value. If the buffer size is 64 Kbytes the software can set IBmT11CnhDBPR[SIZE] to anything less than 64 Kbytes, but larger than the required message size to avoid a buffer size error.
15–4	—	Reserved.
3–0	BPID	Buffer Pool ID. Statically assigned buffer pool identifier for requesting free storage.

16.4.2.30 Inbound Block *m* Type11 Classification Unit *n* Data Offset Register (IB*m*T11C*n*DOR)

This is the Type11 descriptor data offset register. Inbound transactions of Type11 writes the descriptor information into byte zero (0) of the first allocated data buffer. The offset specified here indicates where the first byte of the data payload is located within the buffer. To allow for the descriptor, the minimum offset must be 32-bytes.

Table 16-156. IB*m*MQ*n*SR Field Descriptions

Bits	Name	Description
31–18	—	Reserved
17	QE	Queue empty. Read-only. 0 Queue is not empty. 1 Queue is empty.
16	QF	Queue full. Read-only. 0 Queue is not full. 1 Queue is full.
15–1	—	Reserved
0	XOFF	Message queue has entered congestion management (XOFF), and generated an outbound stream management flow control message to all possible sources of traffic. If this bit is set and the exit congestion threshold is reached, an XON outbound stream management flow control message is generated. This bit is automatically cleared if the message queue is disabled. This bit reflects received enqueue operations that may not have been committed to memory.

16.4.2.33 Inbound Block *m* Message Queue *n* Dequeue Pointer Address Registers (IB*m*MQ*n*DPAR)

The inbound message queue dequeue pointer address registers contain the address of the first command descriptor in memory to be processed by software. Software must initialize these registers to point to the first command descriptor in memory. After processing this command descriptor, software either write IB*m*MQ*n*DPAR to point to the next descriptor location in memory or sets IB*m*MQ*n*MR[DI] to cause the message unit to increment IB*m*MQ*n*DPAR to point to the next descriptor. The message queue is not empty if the inbound message queue enqueue pointers and the inbound message queue dequeue pointers are not equal. This is also reflected by the status bit IB*m*MQ*n*SR[QE] being clear. If the two pointers are equal, it could mean the queue is either full or empty and the status register IB*m*MQ*n*SR should be read to avoid

an underflow. Writing the dequeue pointer to a value outside of the queue size boundary will results in undefined behavior.

When software initializes the dequeue pointer, the queue to which it points must be aligned on a boundary equal to the number of queue entries x command descriptor size. For example, if there are 64 entries, the queue must be 1024-byte aligned.

3–0	—	Reserved

16.4.2.34 Inbound Block *m* Message Queue *n* Enqueue Pointer Address Registers (IB*m*MQ*n*EPAR)

The inbound message queue enqueue pointer address registers contain the address of the next command descriptor to be added by the message unit. Software must initialize these registers to point to the first command descriptor in memory. After adding a new command descriptor, the message unit increments the inbound message descriptor queue enqueue pointer address in IB*m*MQ*n*EPAR to point to the next descriptor. The message queue is not empty if the inbound message queue enqueue pointers and the inbound message queue dequeue pointers are not equal. This is also reflected by the status bit IB*m*MQ*n*SR[QE] being clear. If the two pointers are equal, it could mean the queue is either full or empty and the status register IB*m*MQ*n*SR should be read. If the queue becomes full when the message unit writes a new command descriptor, the queue full status condition will occur, IB*m*MQ*n*SR[QF]=1. If the queue is full when the message unit tries to write a new command descriptor, the queue overflow condition will occur. If

IB*m*MQIER[QOIE]=1 and IB*m*MQIDR[QO]=1, a queue overflow interrupt will be generated. If the write of the command descriptor causes an internal transaction error, the transaction error condition will occur and the pointer will not be updated. If MQIER[TEIE]=1 and MQEDR[TE]=1, a transaction error interrupt will be generated. When software initializes the enqueue pointer, the queue to which it points must be aligned on a boundary equal to the number of queue entries x command descriptor size. For example, if there are 64 entries, the queue must be 1024-byte aligned.

16.4.2.35 Inbound Block *m* Message Queue *n* Congestion Management Register (IB*m*MQ*n*CMR)

The inbound message queue congestion management register allows the setting of watermark levels for generating basic stream management XON/XOFF flow control messages. Stream management flow control is enabled through DSLLCCSR (see SRIO block guide for definition) and is intended for Type9 only. The exit watermark is also used to clear the critical watermark condition, IB*m*T*t*C*n*SR[XOFF], set in the classification unit if an inbound queue reaches critical congestion.

The congestion enter watermark should be greater than the exit watermark for proper operation. The watermark levels should be set to accommodate system latencies for in-flight transactions to avoid overflow of the inbound queue.

Table 16-159. IB*m*MQ*n*CMR Field Descriptions

Bits	Name	Description
31–30	—	Reserved
29–16	ENTER_WM	Congestion enter watermark level. When the number of entries in the circular queue has passed over the enter watermark, a stream management XOFF flow control message is sent to all source devices directing traffic to this queue. For proper operation, this field should be greater than the exit watermark, less than the queue size and only be modified when the inbound message queue is not enabled. A value of zero disables the watermark.
15–14	—	Reserved
13–0	EXIT_WM	Congestion exit watermark level. When the number of entries in the circular queue has passed below the exit watermark, a stream management XON flow control message is sent to all source devices directing traffic to this queue. For proper operation, this field should be less than the exit watermark and only be modified when the inbound message queue is not enabled. A value of zero disables the watermark.

16.4.2.36 Inbound Block *m* Message Queue Interrupt Enable Registers (IB*m*MQIER)

The inbound message queue interrupt enable register determines if an event should cause an interrupt. An interrupt occurs if a bit in this register is set and the corresponding bit in the status or interrupt detect register is also set.

To clear an interrupt, write a 1 to the interrupt detect register. Interrupts caused by normal status conditions are cleared by responding to the condition for which the interrupt was caused.

Inbound Block *m* Message Queue *n* Interrupt Coalescing Register (IB*m*MQ*n*ICR)

Table 16-162. IB*m*MQ*n*ICR Field Descriptions

Bits	Name	Description
31	ICEN	Interrupt coalescing enable. 0 Interrupt coalescing is disabled. 1 Interrupt coalescing is enabled. If the message queue threshold interrupt is enabled (IB*m*MQ*n*IER[MQTIE] is set), an interrupt is raised when the threshold number of messages is reached (defined by IB*m*MQ*n*ICR[ICMT]) or when the threshold timer expires (determined by IB*m*MQ*n*ICR[ICTT]).
30–20	—	Reserved

Table 16-162. IB*m*MQ*n*ICR Field Descriptions (Continued)

Bits	Name	Description
19–16	ICMT	Interrupt coalescing message threshold. While interrupt coalescing is enabled (IBmMQICR[ICEN] is set), this values determines the minimum number of transactions present in the inbound queue before raising an interrupt. Software should set the dequeue pointer after processing the event such that the number of transactions in the queue is less than the threshold to avoid further interrupts. 0000 0 (disabled) 0001 1 message 0010 2 messages 0011 4 messages 0100 8 messages 0101 16 messages 0110 32 messages 0111 64 messages 1000 128 messages 1001 256 messages 1010 512 messages 1011 1024 messages 1100 2048 messages 1101 Reserved ... 1111 Reserved For proper operation, this field should only be modified when the inbound message queue is not enabled.
15–0	ICTT	Interrupt coalescing timer threshold. While interrupt coalescing is enabled (IB*m*MQ*n*ICR[ICEN] is set), this values determines the maximum amount of time after receiving a message before raising an interrupt. If messages have been received but the message threshold has not been met, an interrupt is raised when the threshold timer reaches zero. The threshold timer is reset to this value upon receiving a new message or the queue becomes is empty as a result of software writing the dequeue pointer.

16.4.2.39 Outbound Block *m* Message Queue *n* Mode Registers (OB*m*MQ*n*MR)

The outbound message queue mode register allows software to control various message queue operation characteristics.

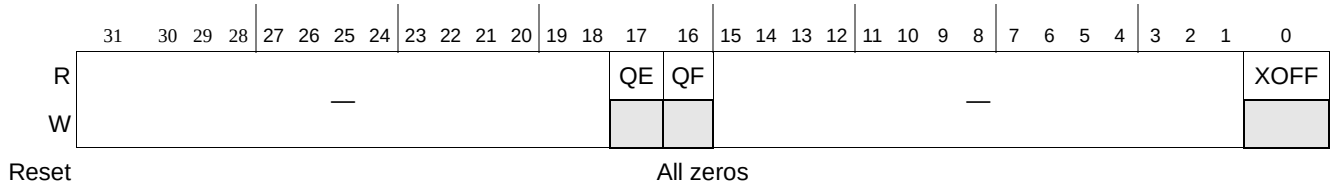

Figure 16-85. Outbound Block *m* Message Queue *n* Status Registers (OB*m*MQ*n*SR)

Table 16-164. OB*m*MQ*n*SR Field Descriptions

Bits	Name	Description
31–18	—	Reserved
17	QE	Queue empty. Read-only. 0 Queue is not empty. 1 Queue is empty. This bit is automatically cleared if the message queue is disabled.
16	QF	Queue full. Read-only. 0 Queue is not full. 1 Queue is full. This bit is automatically cleared if the message queue is disabled.
15–1	—	Reserved
0	XOFF	Message queue has entered congestion management (XOFF), temporarily halting further processing of transactions. There are two reasons for entering congestion: • Inbound XOFF flow control received from target device(s). • Outbound completion queue reached critical level. To exit congestion state, the outbound completion queue must be below critical level and all XOFF target devices must be XON. Up to 32 target devices are tracked for XOFF/XON state. This bit is automatically cleared if the message queue is disabled.

16.4.2.41 Outbound Block *m* Message Queue *n* Dequeue Pointer Address Registers (OB*m*MQ*n*DPAR)

The outbound message queue dequeue pointer address registers contain the address of the first command descriptor in memory to be processed. Software must initialize these registers to point to the first command descriptor in memory. After processing this descriptor, the message queue increments the outbound message queue dequeue pointer address in OB*m*MQ*n*DPAR to point to

the next descriptor. If the outbound message queue enqueue pointer and the outbound message queue dequeue pointer are not equal (indicating that the queue is not empty), the message queue reads the next descriptor from memory for processing. If the enqueue and dequeue pointers are equal after the dequeue pointer has been incremented by the message queue, the queue is empty and further processing halts until the enqueue pointer is incremented by the processor. Incrementing the pointer indicates that a new descriptor has been added to the queue and is ready for transmission. If the queue becomes empty, OB*m*MQ*n*SR[QE]=1 is set. If the read of the command descriptor causes an internal transaction error, the transaction error condition will occur and the pointer will not be updated. If MQIER[TEIE]=1 and MQEDR[TE]=1, a transaction error interrupt will be generated. When software initializes the dequeue pointer, the queue to which it points must be aligned on a boundary equal to the number of queue entries x command descriptor size. For example, if there are 64 entries, the queue must be 1024-byte aligned.

Bits	Name	Description
31–4	MQDPA	Message queue dequeue pointer address. Contains the address of the first command descriptor in memory to process. The descriptor must be aligned to a 16 byte boundary. For proper operation, this field should only be modified when the outbound message queue is not enabled.
3–0	—	Reserved

16.4.2.42 Outbound Block *m* Message Queue *n* Enqueue Pointer Address Registers (OB*m*MQ*n*EPAR)

The outbound message queue enqueue pointer address registers contain the address for the next command descriptor in memory to be added to the queue. Software must initialize these registers to match the outbound message queue dequeue pointer address. When a message is ready to be sent, the processor writes a command descriptor to the next location in the queue (indicated by the address in OB*m*MQ*n*EPAR), and then either writes OB*m*MQ*n*EPAR to point to the next

descriptor location in memory or sets OB*m*MQ*n*MR[EI]. The queue is full when the enqueue pointer and the dequeue pointer are equal. Writing the enqueue pointer to a value outside of the queue size boundary will results in undefined behavior. When software initializes the enqueue pointer, the queue to which it points must be aligned on a boundary equal to the number of queue entries x command descriptor size. For example, if there are 64 entries, the queue must be 1024-byte aligned.

3–0	—	Reserved

16.4.2.43 Outbound Block *m* Message Queue Interrupt Enable Registers (OB*m*MQIER)

The outbound message queue interrupt enable register determines if an event should cause an interrupt. An interrupt occurs if a bit in this register is set and the corresponding bit in the interrupt detect register is also set. To clear an interrupt, write a 1 to the interrupt detect register.

Interrupts caused by normal status conditions are cleared by responding to the condition for which the interrupt was caused.

15–-0	—	Reserved

16.4.2.47 Outbound Block *m* Completion Queue Dequeue Pointer Address Registers (OB*m*MQ*n*DPAR)

The outbound completion queue dequeue pointer address registers contain the address of the first command descriptor in memory to be processed by software. Software must initialize these registers to point to the first command descriptor in memory. After processing this command descriptor, software either write OB*m*CQDPAR to point to the next descriptor location in memory or sets OB*m*CQMR[DI] to cause the message unit to increment OB*m*CQDPAR to point to the next descriptor. The completion queue is not empty if the outbound completion queue enqueue pointers and the outbound completion queue dequeue pointers are not equal. This is also reflected by the status bit OB*m*CQSR[QE] being clear. If the two pointers are equal, it could mean the queue is either full or empty and the status register OB*m*CQSR should be read to avoid an underflow. Writing the dequeue pointer to a value outside of the queue size boundary will results in undefined behavior. When software initializes the dequeue pointer, the queue to which

it points must be aligned on a boundary equal to the number of queue entries x command descriptor size. For example, if there are 64 entries, the queue must be 1024-byte aligned.

Offset: B0: 080C; B1: 180C; B2: 280C; B3: 380C; B4: 480C; B5: 580C; B6: 680C; B7: 780C — Access: Read/Write

3–0	—	Reserved

16.4.2.48 Outbound Block *m* Completion Queue Enqueue Pointer Address Registers (OB*m*CQEPAR)

The outbound completion queue enqueue pointer address registers contain the address of the next command descriptor to be added by the message unit. Software must initialize these registers to point to the first command descriptor in memory. After adding a new command descriptor, the message unit increments the outbound completion descriptor queue enqueue pointer address in OB*m*CQEPAR to point to the next descriptor. The completion queue is not empty if the outbound completion queue enqueue pointers and the outbound completion queue dequeue pointers are not equal. This is also reflected by the status bit OB*m*CQSR[QE] being clear. If the two pointers are equal, it could mean the queue is either full or empty and the status register OB*m*CQSR should be read. If the queue becomes full when the message unit writes a new command descriptor, the queue full status condition will occur, OB*m*CQSR[QF]=1. An internal critical level watermark will stop the completion queue from reaching overflow condition. If this watermark has been reached, outbound dequeue is automatically halted for all queues associated with the completion queue. Software should enable the completion queue threshold detect in advance to avoid reaching this condition. If the write of the command descriptor causes an internal transaction error, the transaction error condition will occur. If MQIER[TEIE]=1 and MQEDR[TE]=1, a transaction error interrupt will be generated. When software initializes the enqueue pointer, the queue to which it points must be aligned on a boundary equal to the number of queue entries x

command descriptor size. For example, if there are 64 entries, the queue must be 1024-byte aligned.

Figure 16-95. Outbound Block *m* Completion Queue Interrupt Coalescing Register (OB*m*CQICR)

Table 16-173. OB*m*CQICR Field Descriptions

Bits	Name	Description
31	ICEN	Interrupt coalescing enable. 0 Interrupt coalescing is disabled. 1 Interrupt coalescing is enabled. If the completion queue threshold interrupt is enabled (OB*m*MQIER[CQTIE] is set), an interrupt is raised when the threshold number of completions is reached (defined by OB*m*CQICR[ICMT]) or when the threshold timer expires (determined by OB*m*CQICR[ICTT]).
30–20	—	Reserved
19–16	ICCT	Interrupt coalescing completion threshold. While interrupt coalescing is enabled (OB*m*CQICR[ICEN] is set), this values determines the minimum number of transactions present in the completion queue before raising an interrupt. Software should set the dequeue pointer after processing the event such that the number of transactions in the queue is less than the threshold to avoid further interrupts. 0000 0 (disabled) 0001 1 completion 0010 2 completions 0011 4 completions 0100 8 completions 0101 16 completions 0110 32 completions 0111 64 completions 1000 128 completions 1001 256 completions 1010 512 completions 1011 1024 completions 1100 2048 completions 1101 Reserved ... 1111 Reserved For proper operation, this field should only be modified when the outbound completion queue is not enabled.
15–0	ICTT	Interrupt coalescing timer threshold. While interrupt coalescing is enabled (OB*m*CQICR[ICEN] is set), this values determines the maximum amount of time after receiving a completion before raising an interrupt. If completions have been received but the completion threshold has not been met, an interrupt is raised when the threshold timer reaches zero. The threshold timer is reset to this value upon receiving a completion.

16.4.2.50 Software Portal Interrupt Status Register (SWP*n*_ISR)

BMLite contains a line per processor interrupt line for signalling functional conditions to software. This ISR register identifies the source of the interrupt within BMLite. Any asserted bit in this register can assert its interrupt line if enabled to do so in the SWP*n*_IER register. Once a bit in this register is asserted, it will remain asserted until cleared by writing a 1 into its bit location (write-1-to-clear).

16.4.2.55 Software Portal Configuration/Assign, Enable, and Base Address Registers

Software portal *n*'s ring buffers are configured via these registers. Acquire and release ring buffers are configured in pairs. SWP*n*_CONFIG and SWP*n*_ASSIGN allows configuration of the memory footprint of the acquire and release ring buffers by setting the number of ring buffers and their size. The location of the ring buffers is determined by SWP*n*_BAR1 and SWP*n*_BAR2 where SWP*n*_BAR1 determines the location of ring buffer pair A and SWP*n*_BAR2 determines the location of a ring buffer pair set by SWP*n*_CONFIG. SWPn_EN provides per-ring pair enable bits that allow software to selectively enable/disable individual ring pairs within the software portal.

A maximum sized configuration would result in 8 ring buffer pairs with room for 128 buffer pointers per ring buffer. This would consume (8 ring buffer pairs * 2 per-pair (acq&rel) * 128 entries * 4B/ptr + 64B(hardware PI/CI) = 8256Bytes). If a smaller footprint is required, the number of enabled ring buffer pairs or the size of the ring buffers can be reduced. The block of memory for acquire and release buffers can be split between BAR1 and BAR2 to allow some ring buffers to occupy a different memory region.

The amount of contiguous memory in bytes required for a software portal can be calculated as

```
BAR1_RING_MAX = (8-BAR2_RINGS) or less if the corresponding rings are not enabled
BAR2_RING_MAX = (BAR2_RINGS) or less if the corresponding rings are not enabled
BAR1_SPACE = (BAR1_RING_MAX * 2) * (2^RB_SIZE) * 4B
BAR2_SPACE = (BAR2_RING_MAX * 2) * (2^RB_SIZE) * 4B
PICI_SPACE = 64B if SWPn_CONFIG[PD] is asserted, 0B otherwise
```

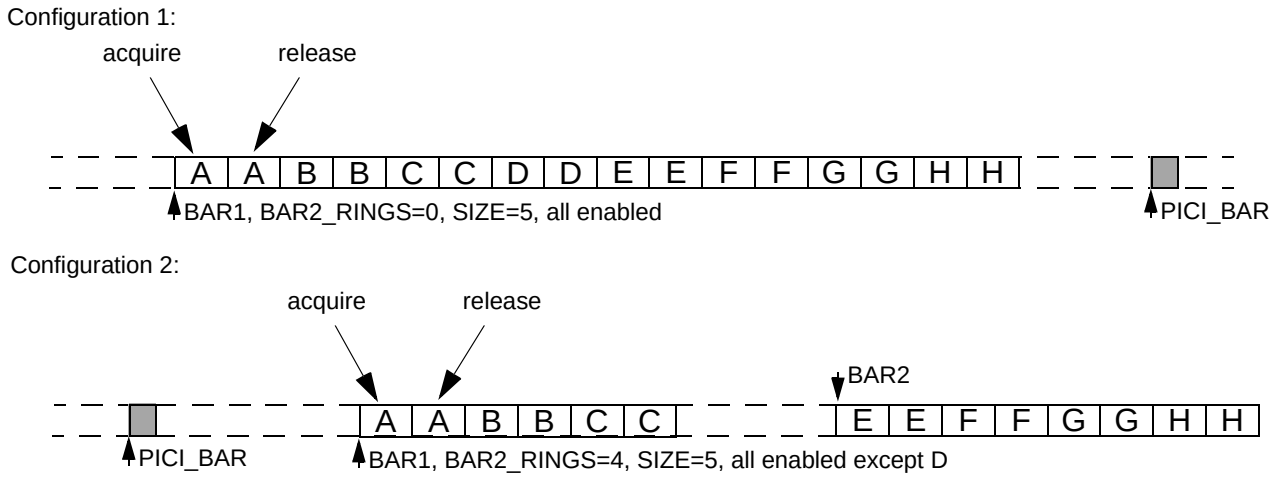

Figure 16-101. Example Ring Buffer Memory Footprints

The PI/CI region (**Figure 16-101**) is a 64 Byte region located at SWP*n*_PICI_BAR. Disabled ring buffers (SWP*n*_EN) do not contain valid values. These values are written intermittently by the hardware when the ring buffers are enabled. The hardware never reads these locations.

Figure 16-102. PI/CI Region Format (Software Portal Ring Buffers)

Note: the PI/CI region is 64B, though the individual PI/CIs could be fit into a 32B region since each PI/CI is 8 bits.The ring buffers A through H can be assigned to any pool (pools 0 through 15) and the same pool can be assigned to multiple ring buffers. If reconfiguration is required (updating SWP*n*_{CONFIG,ASSIGN,BAR1,BAR2,_PICI_BAR}) software shall not modify these registers unless it has taken care to empty the ring buffers and ensure that hardware will not be accessing them during the reconfiguration.

- For **release** ring buffers; do not produce further buffer pointers into the ring buffer, and trigger hardware consumption of the current ring buffer entries by announcing the current producer indices to hardware (write SWP*n*_REL_PI_RING*k*, initiating consumption from those ring buffers), then waiting for the ring buffer to empty (PI=CI).
- For **acquire** ring buffers; consume all buffer pointers in the ring buffer, and do not update consumer indices (write SWP*n*_ACQ_CI_RING*k*) implying that the ring buffers are full. (if SIZE=0x7 and CI=0, then PI=128, and PI-CI=128 such that the ring buffer appears full to hardware).

Note that deasserting the enable bits (SWP*n*_EN) does *not* guarantee that the hardware will not access the ring buffer memory locations since memory accesses may still be in-flight at the time of the register write. No new memory accesses will be initiated while the enable bit is deasserted.

Note that the ring buffers should not be enabled (SWP*n*_EN) until after the base address registers (SWP*n*_BAR1, SWP*n*_BAR2, SWP*n*_PICI_BAR) and configuration registers (SWP*n*_CONFIG, SWPn_ASSIGN) have been written.

16.4.2.56 Software Portal Acquire Consumer Index (SWP*n*_ACQ_CI_RING*k*)

This register allows a software client to inform/update hardware on the current state of the consumer index (CI) of ring buffer *k* within portal *n*. The consumer index is a value managed by the software client (the consumer) that explicitly indicates the next item in the ring buffer that software shall consume and implicitly indicates to the producer items that have been consumed.

Updates/changes to this value will typically permit hardware (the producer) to acquire more buffers from a corresponding pool and load them into the corresponding ring buffer.

16.4.2.58 Software Portal Acquire Producer Index (SWP*n*_ACQ_PI_RING*k*)

This register allows a software client to learn the current state of the producer index (PI) of ring buffer *k* within portal *n*. The producer index is a value managed by BMLite (the producer) that explicitly indicates the next location in the ring buffer that BMLite shall produce into and implicitly indicates to the consumer items that have been produced. Changes to this value indicate that there are new buffers available in the ring buffer for software (the consumer) to acquire.

16.4.2.60 Message Queue Mode Register (MQMR)

The mode register allows for global control of system access parameters.

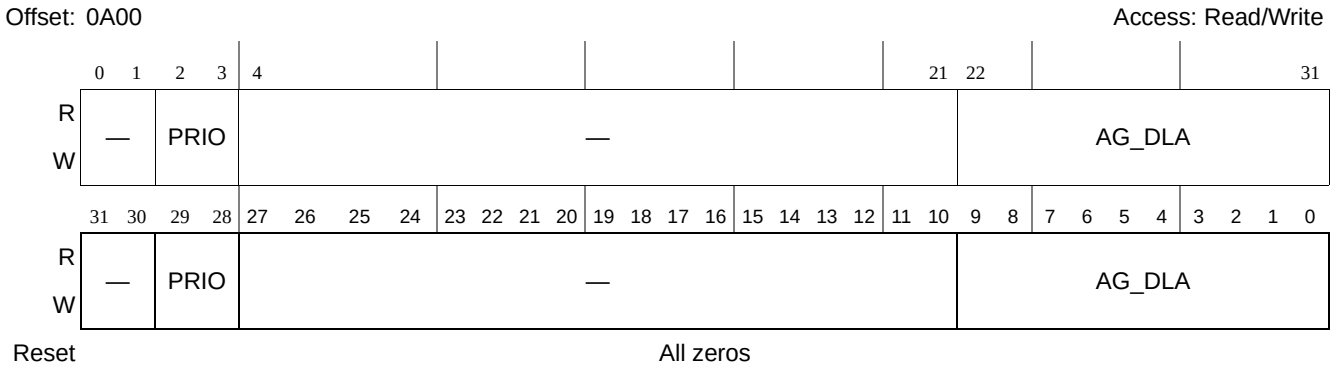

Figure 16-111. Message Queue Mode Register (MQMR)

Table 16-187. MQMR Field Descriptions

Bits	Name	Description
31–30	—	Reserved
29–28	PRIO	Priority used for memory access.
27–10	—	Reserved
9–0	AG_DLA	Arbitration group deadlock avoidance. This field controls the deadlock avoidance threshold for arbitration group selection. Deadlock avoidance is applied if a lower priority request has lost arbitration *N* number of times. A request that has reached the deadlock watermark will Round-Robin with other request in the same state and has priority over normal requests. A zero value will disable the deadlock avoidance mechanism and perform strict priority only.

16.4.2.61 Outbound Message Queue Dequeue Scheduler Configuration Register 1 (OMQDSCR1)

The dequeue scheduler configuration register 1 is used to configure the arbitration group of message queues based on the dequeue scheduling arbitration scheme. The maximum number of arbitration groups used in the system is defined by the highest assigned arbitration group number.

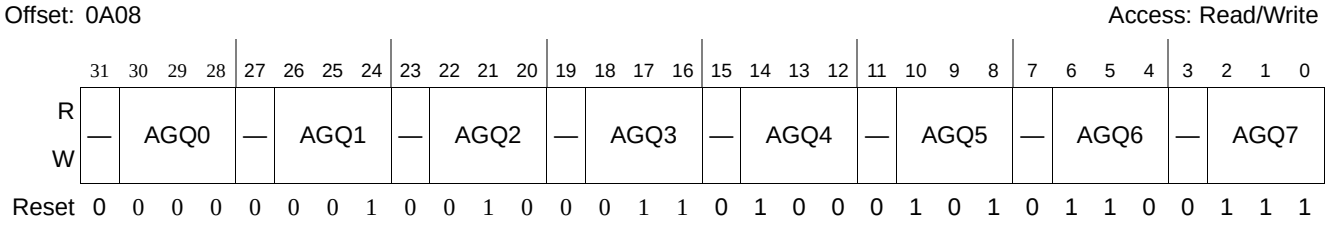

Figure 16-112. Outbound Message Queue Dequeue Scheduler Configuration Register 1 (OMQDSCR1)

16.4.2.63 Message Queue Interrupt Enable Register (MQIER)

The message queue interrupt enable register determines if a detected error condition should cause an interrupt. An interrupt occurs if a bit in this register is set and the corresponding bit in the error detect register is also set. To clear the interrupt, write a 1 to the error detect register.

Offset: 0A10 Access: Read/Write

	31	30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7 6 5 4	3 2 1	0

Bits	Name	Description
31	MEIE	Multiple error interrupt enable. 0 Disabled. 1 Multiple error interrupt enabled.
30–1	—	Reserved
0	TEIE	Transaction error interrupt enable. 0 Disabled. 1 Transaction error interrupt enabled.

16.4.2.64 Message Queue Error Detect Registers (MQEDR)

The message queue error detect register indicates if an error condition was detected. Detection of a condition can be disabled through the error capture disable register. Some errors will cause the

error capture registers to be updated with additional information. Write 1 to clear the detected condition and the interrupt, if enabled.

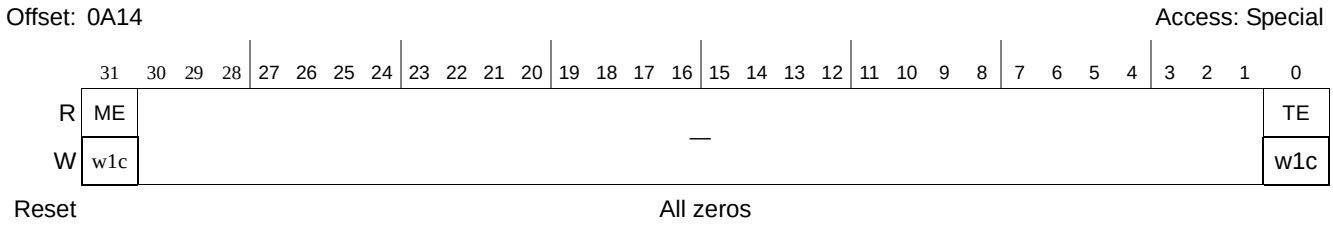

Figure 16-115. Message Queue Error Detect Register (MQEDR)

Table 16-191. MQEDR Field Descriptions

Bits	Name	Description
31	ME	**Multiple Error** Multiple errors of the same kind reported. Write 1 to clear. The following conditions will set this bit: • Transaction error encountered while previously set.
30–1	—	Reserved
0	TE	**Transaction Error** A read/write access to memory has caused an access violation. The Message Queue Error Capture Address Registers (MQECARs) has captured the memory address. Write 1 to clear.

16.4.2.65 Message Queue Error Capture Address Register (MQECAR)

This is the message queue error capture address register. When an enabled error condition occurs, additional information may be captured to indicate the source of the error. Software must clear the error condition to capture the next address. Transaction error (MQEDR[TE]) condition captures the memory address:.

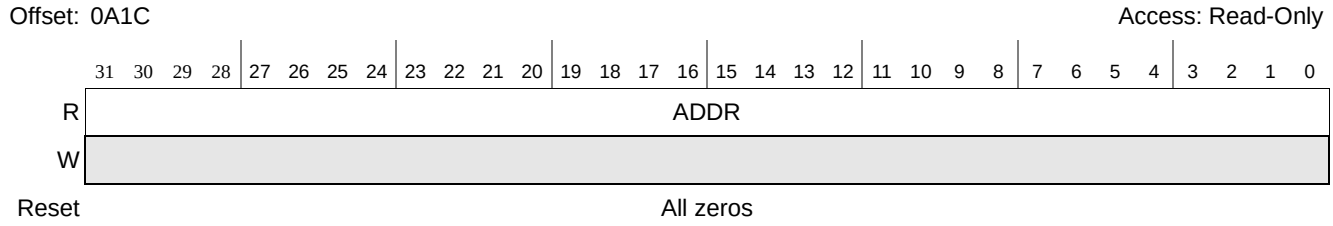

Figure 16-116. Message Queue Error Capture Address Register

Table 16-192. MQECAR Field Descriptions

Bits	Name	Description
31–0	ADDR	Address.

16.4.2.66 S/W Portal Depletion Entry Threshold Register (POOL*k*_SWDET)

The S/W portals can be notified through a BSCN functional interrupt when the number of free buffers available in pool *k* falls below the threshold set by this register. An entry threshold of zero or an entry threshold greater than the pool's exit threshold, will disable depletion reporting on pool *k* to all software portals.

1-0 BWA	Buffer pool AXI write access priority See FRA.

16.4.2.75 Buffer Pointer Range Release Registers (BPRR_{CFG,START,END})

This register specifies a range of addresses to be released in a Buffer Pointer Range Release. The BMLite will release a Buffer Pointer BPRR_START into the pool specified in BPRR_CFG.POOLID, then increment by BPRR_CFG.STRIDE and repeat until > BPRR_END.

If BPRR_START and BPRR_END are aligned with respect to the BPRR_CFG.STRIDE, the range release will be inclusive such that both BPRR_START and BPRR_END will be released to the specified buffer pool.

To initiate a range release, the registers shall be updated in the following order:

1. write BPRR_START = first Buffer Pointer to release
2. write BPRR_END = last Buffer Pointer to release, and
3. write BPRR_CFG.POOLID and BPRR_CFG.STRIDE, initiating range release on write.

When BPRR_CFG is written in the last step, the hardware will assert BPRR_CFG.BUSY and start releasing buffers into the indicated buffer pool. The writes to these registers (BPRR_START, BPRR_END, BPRR_CFG) will be ignored while BPRR_CFG.BUSY is asserted. BPRR_CFG.BUSY can be read to see when the command has completed. It will deassert upon completion.

If a range release must stop due to FBPR exhaustion, the BPRR_CFG.BUSY will deassert and BPRR_CFG.ERR will assert. In this event BPRR_START will contain the next Buffer Pointer that would have been released. Once the FBPR exhaustion issue has been resolved by software, the interrupted range release may be resumed from where it left off by re-writing the original command but using the updated BPRR_START address.

For **FBPR** Range Releases, registers shall be set to the following: BPRR_CFG.STRIDE=6 (2^6=64B), BPRR_CFG.POOLID=16 (FBPR pool), and BPRR_START shall be 64B aligned such that the lower 6 bits are zero and BPRR_START shall never be set to zero. (FBPR pointer zero is the null pointer indicating end-of-linked-list.) Contravening these requirements will result in an ERR being reported.

If a range release is requested for an invalid POOLID, an ERR will be reported.

Table 16-207. Register DPM_CFG Bits Description

Field	Description
31 EN	Dynamic Power Management Enable. When EN is asserted, perform dynamic power management, turning off the internal clocks to a portion of the block while ipg_idle is asserted. EN does not affect the operation of ipg_idle. While performing dynamic power management, the block will still appear fully functional, ready to leave the idle state and process new work. 0: DPM disabled 1: DPM enabled
30–28	Reserved, read as 0.
27 RSVSM	Reserved, read as 0.
26 RSVSD	Reserved, read as 0.
25–4	Reserved, read as 0.
3–0 DELAY	Idle Delay Configure the delay as idle (ipg_idle). Will wait 2^DELAY cycles after the block finishes processing before asserting ipg_idle. (min DELAY=0: 2^0=1 cycle, max: DELAY=15: 2^15=32k cycles = 65.6us @ 500MHz, longer delays should be implemented in software by deasserting EN, setting DELAY=0 and performing SoC level power management)

16.4.2.80 Error Interrupt Status Register (ERR_ISR)

BMLite contains one dedicated interrupt line for signalling error conditions to software. This ISR register identifies the source of the interrupt within BMLite. Any asserted bit in this register can assert its interrupt line if enabled to do so in the ERR_IER register. Once a bit in this register is asserted, it will remain latched asserted until cleared by writing a 1 into its bit location.

Figure 16-132. Error Interrupt Status Register (ERR_ISR)

Table 16-208. Register ERR_ISR Bits Description

Field	Description
31–16 BASCN	Buffer Pool Availability State change notification interrupt Pool 0: bit 15–Pool 15: bit 0
15 BDP	Bad DCP (Direct Connect Portal) Pool ID The DCP was directed to release a buffer into a pool that does not exist. (DCP pool ID signal is 6 bits but there are only 16 valid pools (0-15), if an invalid pool ID is specified this interrupt will occur.)
14 BDB	Bad DCP (Direct Connect Portal) Buffer Pointer The DCP was directed to release a buffer pointer that is too large. (DCP buffer pointer signals are 48 bits but BMLite only supports 32 bits, if the upper bits [47:32] are asserted this interrupt will occur.)
13–7	Reserved, read as 0.
6 EMCI	External memory corruption detected.
5 EMAI	External memory access exception.
4	Reserved, read as 0.
3 FPD	FBPR Low Watermark Interrupt. This interrupt is asserted if the FBPR free pool occupancy drops below a programmable threshold, see **Section 16.4.2.78**, *FBPR Free Pool Depletion Interrupt Threshold (FBPR_FP_THRES)*".
2 MBEI	Multi Bit ECC Error Interrupt. This interrupt is asserted if a multi bit ECC error is detected in one or more of the BMLite internal memories.
1 SBEI	Single Bit ECC Error Interrupt. This interrupt is asserted if the number of single bit ECC errors detected in one or more of the Man internal memories exceeds a programmable threshold. The threshold is described in **Section 16.4.2.85**, *Single Bit ECC Error Threshold Register (SBET)*.
0	Reserved, read as 0.

16.4.2.81 Error Interrupt Enable Register (ERR_IER)

The ERR_IER register provides the ability to individually enable each interrupt source to assert the error interrupt signal. If a bit location is asserted in both ERR_ISR and ERR_IER, the interrupt will be asserted. Clearing of an interrupt is achieved by first clearing the interrupt source if applicable, then clearing the associated bit in ERR_ISR.

Offset 0x0eB4 (ERR_IER) Access: R/W

Table 16-209. Register ERR_IER Bits Description

Field	Description
31–0	Interrupt Enable bit for each bit in the Interrupt Status Register (ISR). All fields in this register carry the same assignment as in the ISR register, see **Section 16.4.2.80**, *Error Interrupt Status Register (ERR_ISR)*.

16.4.2.82 Interrupt Status Disable Register (ERR_ISDR)

The ERR_ISDR register controls reporting of interrupts in the ERR_ISR register. A bit in ERR_ISR will never be asserted if the corresponding bit in the ERR_ISDR register is set (that is, interrupt status is disabled). A set ISR bit will be cleared if the corresponding bit in the ISDR register is set.

Figure 16-137. Single Bit Error Threshold Register (SBET)

Table 16-213. Register SBET Bits Description

Field	Description
31 ECD	Error Correction and Detection Disable. This field allows ECC error correction and detection to be individually disabled for each of BMLite's internal memories. The definition of each bit is as follows: 0 = ECC correction and ECC error reporting are enabled in the memory associated with this bit. 1 = ECC correction and ECC error reporting are disabled in the memory associated with this bit. The memory associated with this bit is the Stockpile memory.
30–8	Reserved, read as 0.
7–0 SBET	Single Bit Error Threshold. Threshold value for the number of single bit ECC errors in the BMLite internal memories that are detected before reporting an error. When the count in one of the SBEC registers is greater than SBET, an error is reported in ERR_ISR (unless it is disabled in ERR_ISDR).

16.4.2.86 Single Bit ECC Error Count Registers (SBEC)

This register provides a count of the number of single bit ECC errors on the internal memory. Eight bits are provided for the linear count, when it reaches a maximum of 255 it will hold until cleared on a read access.

Offset 0x0eD4 (SBEC) Access: RR

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 16-138. Single Bit Error Count Registers (SBEC)

Table 16-214. SBEC Bits Description

Field	Description
31–8	Reserved, read as 0.
7–0 N	Single Bit Error Count. Provides a count of the number of single bit ECC errors that have occurred when reading from the internal stockpile memory. This register is cleared on read. When the count reaches its max value (0xFF), it will stick at that value without rollover until this register is read.

16.4.2.87 External Memory Access Interrupt Capture Register (EMAI_ECR)

If an error occurs on a BMLite initiated read or write to external memory, an AXI exception may be returned. Since data read from external memory can be a data structure (FBPR) belonging to one of the buffer pool lists or the list of free FBPRs, then an exception that occurs on a read will cause BMLite to no longer use the affected list and possibly start a new one if there exists resources to do so. Like-wise a write would eventually result in a corresponding read exception and so is treated in exactly the same manner. BMLite can create more than one new list on the same pool in case of multiple errors, provided sufficient memory resources exist. All BMLite initiated read and write transactions are through an AXI interface to external memory. If an AXI error response is detected an interrupt will be signalled by setting EMAI in ERR_ISR. BMLite will detect the exception and use the EMAI_ECR register to report the event, the buffer pool or FBPR free list affected by the first exception, and whether or not more errors have occurred since the first one (that is, more than one list may be affected).All fields in this register, with the exception of the multiple exceptions (M) field in this register, are latched on the first exception. Upon further exceptions the M field will also latch. The content of this register will remain latched until the EMCI ERR_ISR is cleared.

Offset 0x0eE0 (EMAI_ECR) Access: R

Figure 16-139. Exception Fetch/Flush Capture Register (EMAI_ECR)

Table 16-215. Register EMAI_ECR Bits Description

Field	Description
31 M	Multiple exceptions. More than one exception has occurred since the EMAI bit of ERR_ISR was asserted.
30 RW	Read/Write This bit indicates whether a read or a write caused the first exception. 0: Read 1: Write
29–9	Reserved, read as 0.
8–7 RESP	AXI Response The AXI response for the first exception memory transaction. 2: SLVERR -- slave error (the slave has returned an exception for this access) 3: DECERR -- decode error (no slave at this address)
6	Reserved, read as 0.
5–0 ID	ID. Identifies the buffer pool FBPR list in external memory or the affected Software Portal that has been affected by the first exception. ID = 0 to 15; List for Pool 0 to Pool 15 ID = 16; List of free FBPRs ID = 32 to 39; Software Portal 0 to Software Portal 7 All other values reserved.

16.4.2.88 External Memory Access Interrupt Address Register (EMAI_EADR)

If an exception occurs on a BMLite initiated read or write to external memory as described in EMAI_ECR, the external memory address used in the transaction will be captured in this register. The content of this register will remain latched until EMAI ERR_ISR is cleared.

Offset 0x0eE4 (EMAI_EADR) Access: R

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 16-140. Exception Fetch/Flush Address Register (EMAI_EADR)

Table 16-216. Register EMAI_EADR Bits Description

Field	Description
31–4 ADDR	Address. This field identifies the external memory address used for a read or write transaction that resulted in a data error described in **Section 16.4.2.87**, *External Memory Access Interrupt Capture Register (EMAI_ECR)*
3–0	Reserved, read as 0.

16.4.2.89 External Memory Corruption Interrupt Capture Register (EMCI_ECR)

To detect memory scribbling by other devices or FBPRs that are released more than once to the BMLite, the pool ID and a rotating 3-bit field per-free-list or buffer pool are recorded within the FBPR itself. When the FBPR is read, the recorded and expected values are compared. If this check fails then the FBPR has been corrupted and the buffer pool or free list is treated as in the AXI memory access exception case (including signalling an interrupt). This case will be indicated the EMCI ERR_ISR bit. All fields in this register and the Address register (EMCI_EADR), with the exception of the multiple exceptions (M) field in this register, are latched on the first exception. Upon further exceptions the M field will also latch. The content of this register will remain latched until the EMCI ERR_ISR is cleared.

Offset 0x0eF0 (EMCI_ECR) Access: R

Figure 16-144. IP Block Revision 2 Register (IP_REV_2)

Table 16-220. Register IP_REV_2 Bits Description

Field	Description
31–24	Reserved, read as 0.
23–16 IP_INT	Integration options. This is currently set to 0x01. This field indicates the Software Portal access method is via ring buffers and register access for 8 SWP.
15–8 IP_ERR	Errata revision level. This is currently set to 0x00.
7–0 IP_CFG	Configuration options. This is currently set to 0x08. This field indicates the number of buffer pools available in this implementation.

16.4.2.93 Message Unit Mode Register (MUMR)

The mode register allows for global control of hardware.

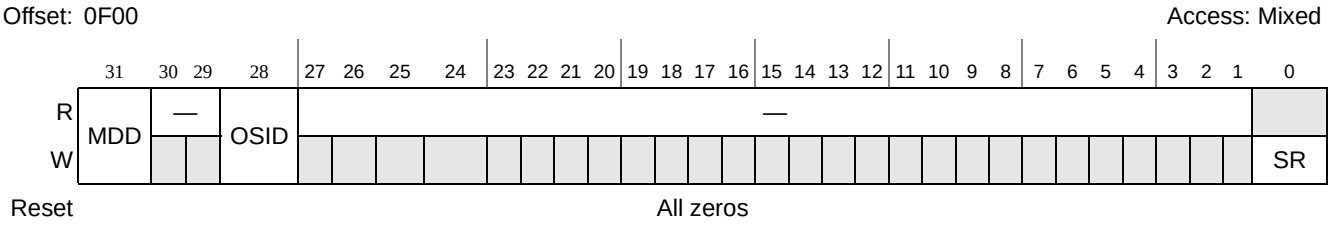

Figure 16-145. Message Unit Mode Register (MUMR)

Table 16-221. MUMR Field Descriptions

Bits	Name	Description
31	MDD	Inbound message descriptor write disable. 0 Inbound message descriptor written to memory for inbound transaction. 1 No message descriptor written. A performance improvement may be achieved by not writing the message descriptor. Note that several of the fields in the descriptor can be extracted from the classification unit(s) rules.
30–29	—	Reserved
28	OSID	Outbound segmentation interleaving disable. Segmentation interleaving allows the message unit to interleave segments from two or more transactions with the same destination device ID (regardless of type). This may increase performance for transmission but may also consume additional reassembly resources at the destination. 0 Segmentation interleaving enabled. 1 Segmentation interleaving disabled.
27–1	—	Reserved
0	SR	Soft reset. Write only. Setting this bit causes reset of all registers and state for the message unit, all state will be lost. Care should be taken when setting this bit as external interfaces must also be in an idle state for proper operation after reset. Writing zero to this bit has no effect.

16.4.2.94 Message Unit Status Register (MUSR)

The status register indicates current status of hardware resources.

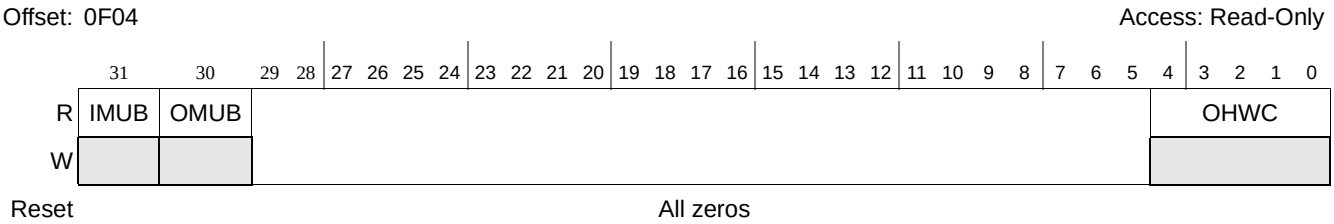

Figure 16-146. Message Unit Status Register (MUSR)

Table 16-222. MUSR Field Descriptions

Bits	Name	Description
31	IMUB	Inbound message unit busy. Read-only. 0 Inbound message unit is idle. 1 Inbound message unit operation in progress.
30	OMUB	Outbound message unit busy. Read-only. 0 Outbound message unit is idle. 1 Outbound message unit operation in progress.
29–5	—	Reserved
4–0	OHWC	Open hardware contexts. The current number of hardware context used for reassembly. A zero value indicates that all hardware contexts are available for reassembly. Based on the MURCAR[0–2] values, if the open threshold has been reached, new transactions are retried (Type10/11) or dropped (Type9).

16.4.2.95 Message Unit Interrupt Enable Registers (MUIER)

The message unit interrupt enable register determines if a detected status or error condition should cause an interrupt. An interrupt occurs if a bit in this register is set and the corresponding bit in the error detect register is also set. To clear the interrupt, write a 1 to the error detect register.

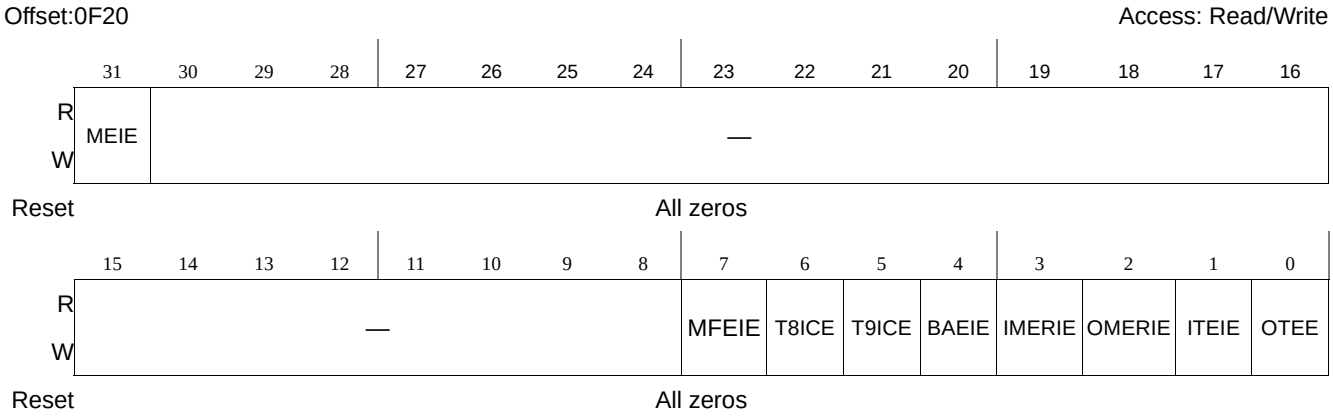

Figure 16-147. Message Unit Interrupt Enable Register (MUIER)

Table 16-223. MUIER Field Descriptions

Bits	Name	Description
31	MEIE	Multiple error interrupt enable. 0 Disabled. 1 Multipe error interrupt enable.
30–8	—	Reserved
7	MFEIE	Message format error interrupt enable. 0 Disabled. 1 Message format error interrupt enabled.
6	T8ICE	Type8 interrupt coalescing drop threshold enable. 0 Disabled. 1 Interrupt coalescing drop threshold enabled.

Table 16-223. MUIER Field Descriptions (Continued)

Bits	Name	Description
5	T9ICE	Type8 interrupt coalescing drop threshold enable. 0 Disabled. 1 Interrupt coalescing drop threshold enabled.
4	BAEIE	Buffer allocation error interrupt enable. 0 Disabled. 1 Buffer allocation error interrupt enabled.
3	IMERIE	Inbound message queue enqueue rejection interrupt enable. 0 Disabled. 1 Inbound message queue enqueue rejection interrupt enabled.
2	OMERIE	Outbound message queue enqueue rejection interrupt enable. 0 Disabled. 1 Outbound message queue enqueue rejection interrupt enabled.
1	ITEIE	Inbound transaction error interrupt enable. 0 Disabled. 1 Inbound transaction error interrupt enabled.
0	OTEIE	Outbound transaction error interrupt enable. 0 Disabled. 1 Outbound transaction error interrupt enabled.

16.4.2.96 Message Unit Error Detect Registers (MUEDR).

Offset:0F24 Access: Special

	31	30 29 28	27 26 25 24	23 22 21 20	19 18 17 16	15 14 13 12	11 10 9 8	7	6	5	4	3	2	1	0
R	ME	—						MFE	T8IC	T9IC	BAE	IMER	OMER	ITE	OTE
W	w1c							w1c	w1c	w1c	w1c	w1c	w1c	w1c	w1c
Reset	All zeros														

Figure 16-148. Message Unit Error Detect Register (MUEDR)

The message unit error detect register indicates if an error condition was detected. Detection of a condition can be disabled through the error capture disable register. Some errors will cause the error capture registers to be updated with additional information. Write 1 to clear the detected condition and the interrupt, if enabled.

Note: As noted in **Section 25.2.9.1**, *Debug Errors*, on page 25-25, all message errors are ORed with Serial RapidIO errors for reporting to the cores. If an error is reported to the core and no message errors are flagged in MUEDR, check the Serial RapidIO status registers to determine the source of the error/interrupt.

Table 16-224. MUEDR Field Descriptions

Bits	Name	Description
31	ME	Multiple error. Multiple errors of the same kind reported. Write 1 to clear.
30–8	—	Reserved
7	MFE	Message format error. One of the following conditions will cause the error: • A transaction of priority 3 was received for Type10 doorbell or Type11 message. Transaction has been dropped. • Spurious (or duplicate) response received. Response has been dropped.

Table 16-224. MUEDR Field Descriptions (Continued)

Bits	Name	Description
6	T8IC	Type8 interrupt coalescing drop threshold exceeded. The drop counter value in MUT8DCR has exceeded the interrupt coalescing interrupt threshold MUICR[T8ICDT]. Write 1 to clear.
5	T9IC	Type9 interrupt coalescing drop threshold reached. The drop counter value in MUT9DCR has exceeded the interrupt coalescing interrupt threshold MUICR[T9ICDT]. Write 1 to clear.
4	BAE	Buffer allocation error. A data buffer could not be acquired for an inbound transaction. This has caused an inbound transaction to complete with an internal error. Write 1 to clear.
3	IMER	Inbound message queue enqueue rejection. In an attempt to enqueue, the inbound message queue rejected the command descriptor. Rejection occurs due to a disabled/full queue or a memory transaction error. This error has caused an inbound transaction to be discarded. The Message Unit Error Capture CD Registers (MUECCDR0–3) will contain the command descriptor of the attempted enqueue operation. Write 1 to clear.
2	OMER	Outbound message queue enqueue rejection. In an attempt to enqueue, the completion queue rejected the command descriptor. Rejection occurs due to a disabled queue or a memory transaction error. This error has caused an outbound completion event to be discarded. Write 1 to clear.
1	ITE	Inbound transaction error. A write access to memory has caused a violation. The Message Unit Error Capture Address Register will contain the violating memory address. Write 1 to clear.
0	OTE	Outbound transaction error. A read access to memory has caused a violation. The Message Unit Error Capture CD Registers (MUECCDR[0–3]) will contain the command descriptor which caused the memory transaction error. Write 1 to clear.

16.4.2.97 Message Unit Interrupt Coalescing Registers (MUICR)

The message unit interrupt coalescing register configures the threshold parameters for interrupt coalescing associated with inbound Type8/9 transactions that may be dropped to congestion or failed classification.

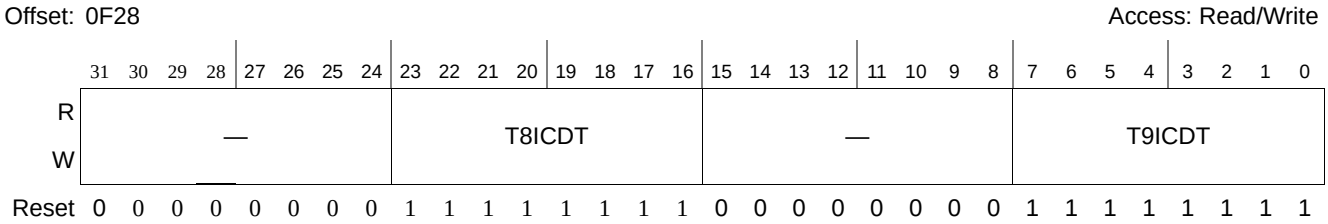

Figure 16-149. Message Unit Interrupt Coalescing Registers (MUICR)

Table 16-225. MUICR Field Descriptions

Bits	Name	Description
31–24	—	Reserved
23–16	T8ICDT	Type8 interrupt coalescing drop threshold. This values determines how many RapidIO Type8 maintenance port-writes are allowed to be dropped before setting the error detect bit MUEDR[T8IC]. MUEDR[ME] may be set if the threshold is crossed a second time before clearing the error detect bit. The total drop count is available in register MUT8DCR[DROP_CNT].

Table 16-225. MUICR Field Descriptions (Continued)

Bits	Name	Description
15–8	—	Reserved
7–0	T9ICDT	Type9 interrupt coalescing drop threshold. This values determines how many RapidIO Type9 segments are allowed to be dropped before setting the error detect bit MUEDR[T9IC]. MUEDR[ME] may be set if the threshold is crossed a second time before clearing the error detect bit. The total drop count is available in register MUT9DCR[DROP_CNT].

16.4.2.98 Message Unit T8 Drop Counter Registers (MUT8DCR)

The message unit Type8 drop counter register tracks number of inbound maintenance port-writes dropped due to pending port-writes or failed classification.

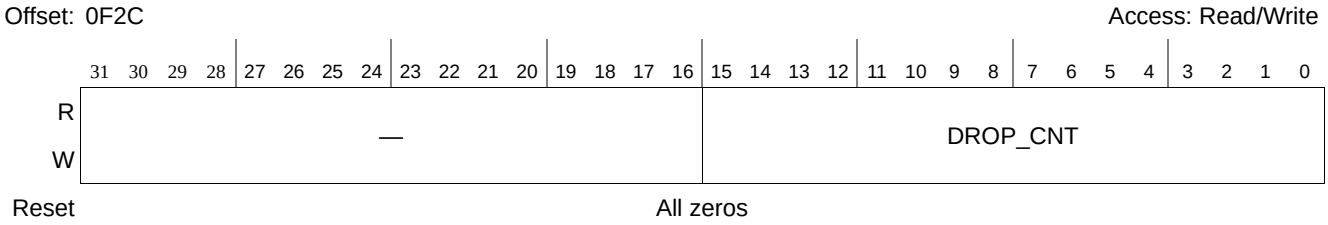

Figure 16-150. Message Unit T8 Drop Counter Registers (MUT8DCR)

Table 16-226. MUT8DCR Field Descriptions

Bits	Name	Description
31–16	—	Reserved
15–0	DROP_CNT	Drop count for RapidIO Type8 maintenance port-writes due to hardware resource restrictions (pending port-writes) or failed classification. Software should clear this register field by reading if an interrupt has occured due to the counter exceeding the interrupt coalescing threshold value MUICR[T8ICDT] to avoid additional interrupts.

16.4.2.99 Message Unit T9 Drop Counter Registers (MUT9DCR)

The message unit Type9 drop counter register tracks number of inbound PDU segments dropped due to exhausted hardware resources or failed classification.

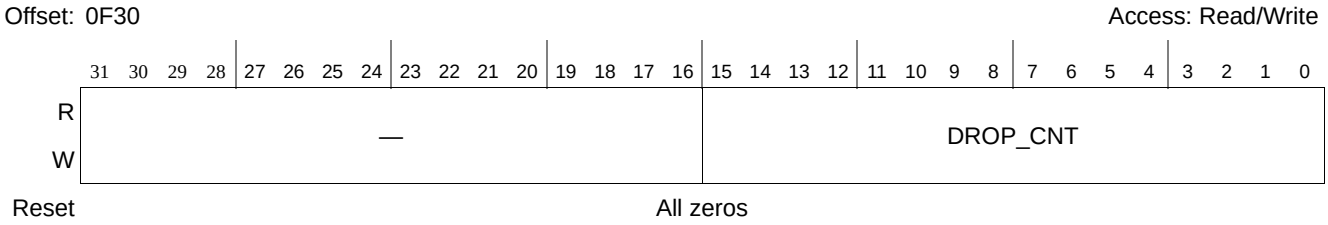

Figure 16-151. Message Unit T9 Drop Counter Registers (MUT9DCR)

Table 16-227. MUT9DCR Field Descriptions

Bits	Name	Description
31–16	—	Reserved
15–0	DROP_CNT	Drop count for RapidIO Type9 PDU segments due to exhausted hardware resources or failed classification. Software should clear this register field by reading if an interrupt has occurred due to the counter exceeding the interrupt coalescing threshold value MUICR[T9ICDT] to avoid additional interrupts.

16.4.2.100 Message Unit Error Capture MQ Register (MUECMQR)

This is the message unit error capture message queue register. When an enabled error condition occurs, additional information may be captured to indicate the source of the error. Software must clear the error condition(s) to capture the next error. The following error condition(s) will capture the message queue identifier:

- Inbound enqueue rejection (MUEDR[IMER])

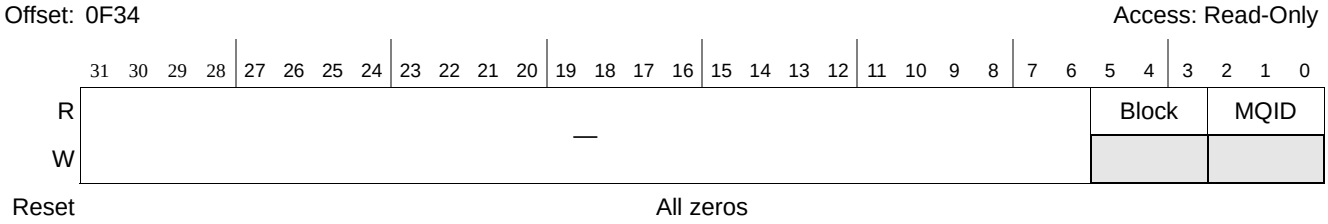

Figure 16-152. Message Unit Error Capture MQ Register (MUECMQR)

Table 16-228. MUECMQR Field Descriptions

Bits	Name	Description
31–6	—	Reserved
5–3	UNIT	Block associated with the error.
2–0	MQID	Message queue ID associated with the error.

16.4.2.101 Message Unit Error Capture CD Register 0 (MUECCDR0)

This is the message unit error capture command descriptor register 0. When an enabled error condition occurs, additional information may be captured to indicate the source of the error. Software must clear the error condition(s) to capture the next command descriptor. The following error condition(s) will capture the command descriptor:

- Outbound transaction error (MUEDR[OTE])..

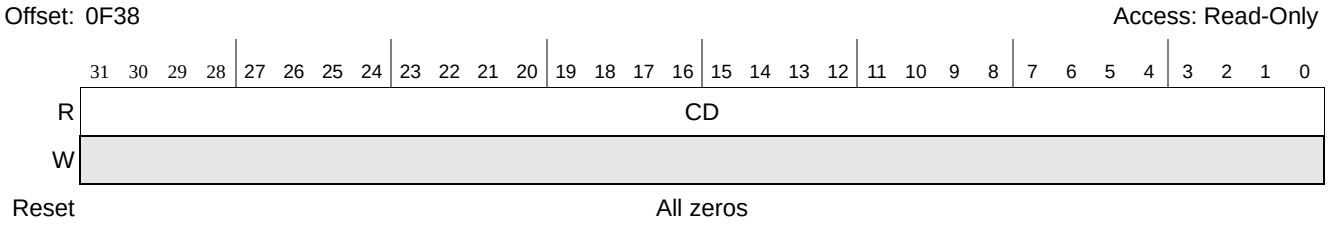

Figure 16-153. Message Unit Error Capture CD Register 0

Table 16-229. MUECCDR0 Field Descriptions

Bits	Name	Description
31–0	CD	Command descriptor associated with the error, bits 127–96.

16.4.2.102 Message Unit Error Capture CD Register 1 (MUECCDR1)

This is the message unit error capture command descriptor register 1. See **Section 16.4.2.101**, *Message Unit Error Capture CD Register 0 (MUECCDR0)* for description.

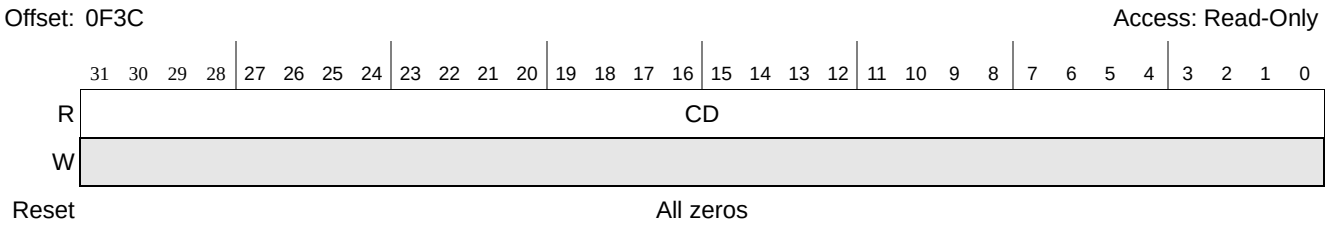

Figure 16-154. Message Unit Error Capture CD Register 1

Table 16-230. MUECCDR1 Field Descriptions

Bits	Name	Description
31–0	CD	Command descriptor associated with the error, bits 95–64.

16.4.2.103 Message Unit Error Capture CD Register 2 (MUECCDR2)

This is the message unit error capture command descriptor register 2. See **Section 16.4.2.101**, *Message Unit Error Capture CD Register 0 (MUECCDR0)* for description.

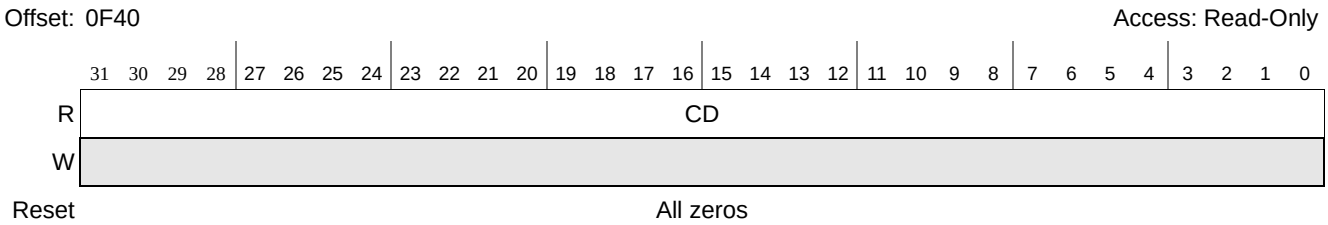

Figure 16-155. Message Unit Error Capture CD Register 2

Table 16-231. MUECCDR2 Field Descriptions

Bits	Name	Description
31–0	CD	Command descriptor associated with the error, bits 63–32.

16.4.2.104 Message Unit Error Capture CD Register 3 (MUECCDR3)

This is the message unit error capture command descriptor register 3. See **Section 16.4.2.101**, *Message Unit Error Capture CD Register 0 (MUECCDR0)* for description.

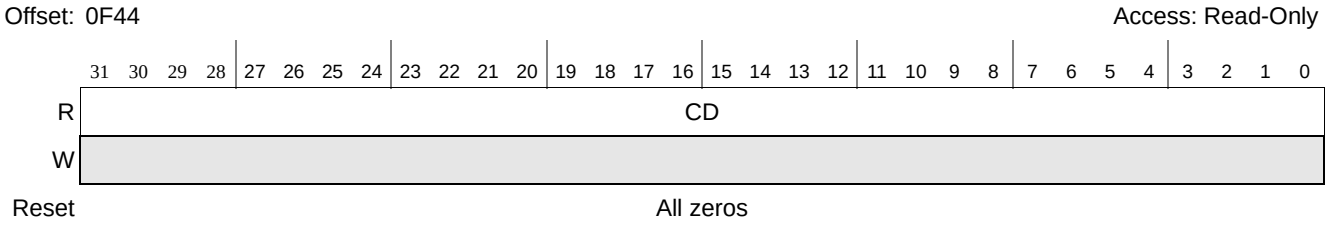

Figure 16-156. Message Unit Error Capture CD Register 3

Table 16-232. MUECCDR3 Field Descriptions

Bits	Name	Description
31–0	CD	Command descriptor associated with the error, bits 31–0.

16.4.2.105 Message Unit Error Capture Address Register (MUECAR)

This is the message unit error capture address register. When an enabled error condition occurs, additional information may be captured to indicate the source of the error. Software must clear the error condition to capture the next address. An inbound transaction error (MUEDR[ITE]) condition(s) captures the memory address:

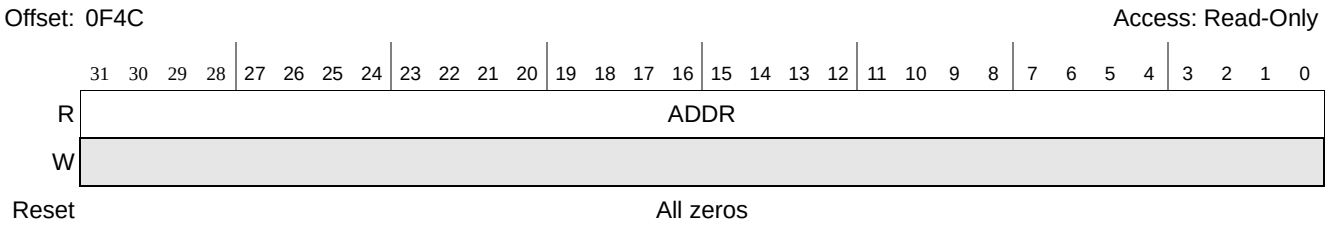

Figure 16-157. Message Unit Error Capture Address Register

When an enabled error condition occurs, additional information may be captured to indicate the source of the error. Software must clear the error condition to capture the next address.

The following error condition(s) captures the memory address:

- Inbound transaction error (MUEDR[ITE]).

Table 16-233. MUECAR Field Descriptions

Bits	Name	Description
31–0	ADDR	Memory address associated with the error. This is the lower address bits 31–0. For Type8, the address indicates the allocated buffer pointer address and may not be precise.

16.4.2.106 Message Unit Arbitration Weight Register (MUAWR)

Offset: 0F50 Access: Read//Write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	OREQW				ORSPW				OFCW				—												OSST							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	1	1

Figure 16-158. Message Unit Arbitration Weight Register (MUAWR)

The message unit arbitration weight register controls the weight of several outbound arbitration points, including segmentation unit starvation threshold and outbound RapidIO request/response/ flow control arbitration.

The weighted round-robin arbitration scheme used works as follows:

1. All selection counters start at 0.
2. A requestor is eligible for selection if its selection counter does not equal its programmed weight.
3. A work conserving round-robin selection is made among all eligible requestors. The selection counter for the selected requestor is incremented if the threshold has not been reached.
4. The counter of the selected port is reset when the counter has reached the threshold. In this instance, the round-robin arbiter is also updated.

Table 16-234. MUAWR Field Descriptions

Bits	Name	Description
31–28	OREQW	Outbound request arbitration weight. This field controls the arbitration weight in a weighted Round-Robin scheme for access to the outbound RapidIO port(s).
27–24	ORSPW	Outbound response arbitration weight. This field controls the arbitration weight in a weighted Round-Robin scheme for access to the outbound RapidIO port(s).
23–20	OFCW	Outbound flow control arbitration weight. This field controls the arbitration weight in a weighted Round-Robin scheme for access to the outbound RapidIO port(s).

Table 16-234. MUAWR Field Descriptions (Continued)

Bits	Name	Description
19–10	—	Reserved.
9–0	OSST	Outbound segmentation strict-priority threshold. This field controls the deadlock avoidance threshold for granting access to a segmentation unit for a lower priority arbitration group. Deadlock avoidance is applied if a lower priority request has lost arbitration N number of times. A request that has reached the deadlock watermark will round-robin with other requests in the same state and has priority over normal requests. Default is maximum value. A zero value will disable the deadlock avoidance mechanism and perform strict priority only.

16.4.2.107 Message Unit Outbound Interleaving Mask Register (MUOIMR)

The message unit outbound interleaving mask register provides a more coarse control of transaction interlock for the purpose of interleaving transactions based on outbound ordering rules. The setting of a mask bit excludes it for comparison when determining outbound interleaving. For example, an endpoint may be assigned a range of destination IDs, but may require strict ordering for the entire range. This could for example be used to provide additional mailbox/letter combinations by utilizing multiple destination IDs. The setting of bits in this mask register must be contiguous.

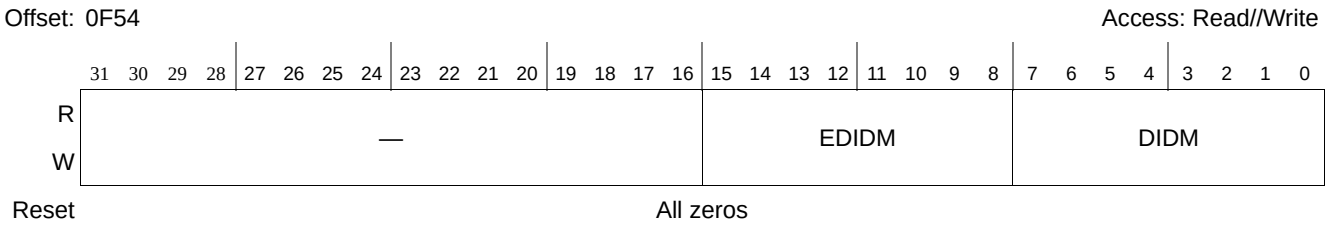

Figure 16-159. Message Unit Outbound Interleaving Mask Register (MUOIMR)

Table 16-235. MUOIMR Field Descriptions

Bits	Name	Description
31–16	—	Reserved.
15–8	EDIDM	Extended destination ID bit mask . Most significant byte of a 16-bit destination ID when operating in large transport mode. Reserved when operating in small transport mode.
7–0	DIDM	Destination ID bit mask. Contains the destination ID field of the transaction (Device ID of the destination).

16.4.2.108 Message Unit Segmentation Execution Privilege Register 0 (MUSEPR0) and Message Unit Segmentation Execution Privilege Register 1 (MUSEPR1)

The message unit segmentation execution privilege registers specify the arbitration group execution privileges for each segmentation unit present. Writing the arbitration group assignment register, OMQDSCR1, will re-initialize the execution privileges for all segmentation units to a

setting based on the maximum number of arbitration groups supported; see **Table 16-236**. Writing this register will override the default setting.

Table 16-236. SU Execution Privileges Based on Maximum AG Setting.

16.4.2.109 Message Unit Reassembly Context Assignment Registers 0–2 (MURCAR0–2)

The message unit reassembly context assignment registers controls the management of inbound hardware reassembly contexts on a per flow basis. The total number of system available reassembly contexts is 16. A flow with one or more dedicated resources does not share the generic pool. The amount of dedicated and generic contexts should not exceed the total available number of reassembly contexts or undefined results may occur. The total number of open contexts at one given time can be determined through register MUSR[OHWC].

16.5 Programming Restrictions

The MSC8157E has the following programming restrictions regarding the programming of the eMSG unit:

- The message manager performs pre-fetching of descriptors when sending outbound RapidIO Type5, Type6, or Type9 transactions. This occurs as a fetch of the first scatter/gather table entry followed by the message descriptor when the format is defined as scatter/gather. The message manager allows for out-of-order pre-fetching between transactions such that a Type9 may fetch the scatter/gather table entry, followed by a Type11 fetching the message descriptor. In this case, the Type11 transaction is ready for segmentation before Type 9. In the event a scatter/gather type transaction receives the message descriptor at the same time a newer transaction is sent to an outbound segmentation unit, there is a possibility the scatter/gather transaction is lost. The loss is due to using multiple arbitration groups and mixing data formats. Limiting to a single arbitration group, however, can affect performance. If an application must mix data formats, use a single arbitration group. If only one type of data format is used, there are no other restrictions.

- The eMSG unit can transmit a duplicate message segment when the same arbitration group (typically equals the SRIO flow level) is allowed to use more than one segmentation unit and the messages are not all multicast type. For a single segment message, the duplication does not produce an error during eMSG inbound reassembly. For multi-segment messages, eMSG inbound reassembly produce a time-out error when only a single segment is received for a multi-segment message. Use one of the following two options to avoid this situation:

1. Restrict messages to single segment and enable multicast. Messages intended for only one destination must be set to a multicast of one with the correct bit set in the multicast list.
2. Restrict a given arbitration group to use only one segmentation unit. For example, Arb group 0 uses SU 0, Arb group 1 uses SU 1, and so on. There is a varying performance impact when using fewer Arb groups than the number of segmentation units. Execution privileges can be set in MMSEPR. This option also requires the following rules:
   a. A message context cannot be reused across arbitration groups.
   b. A dummy message must be sent through all segmentation units used for messages OR you must avoid the use of mailbox 0, letter 0, or destination 0.

17 PCI Express Controller

The PCI Express controller supports communication with PCI Express devices connected to the MSC8157E device. The PCI Express interface is designed to comply with the *PCI Express Base Specification, Revision 2.0* (available from http://www.pcisig.org). This chapter describes the PCI Express controller and provides a basic description of the PCI Express protocol. Designers of systems incorporating PCI Express devices should refer to the specification for a thorough description of PCI Express structure and functionality.

17.1 Overview

The PCI Express controller connects the MSC8157E device through the High Speed Serial Interface (HSSI) to a 5-GHz serial interface configurable for up to a x4 interface. As both an initiator and a target device, the PCI Express interface is capable of high-bandwidth data transfer and is designed to support next generation I/O devices. When selected and enabled by the device configuration, the PCI Express interface performs link width negotiation and exchanges flow control credits with its link partner after it completes its reset sequence. Once link autonegotiation is successful, the controller is available to transfer data. In x4 mode only, the controller permits lanes to be reversed between the transmitting and the receiving device (that is, transmitter lanes 0-1-2-3 are swapped to 3-2-1-0 of the receiver).

Note: See **Chapter 15**, *High Speed Serial Interface (HSSI) Subsystem* for details on signal multiplexing and data communications with the MSC8157E cores, memory, and internal peripherals.

Internally, the design contains queues to keep track of inbound and outbound transactions. Control logic handles buffer management, bus protocol, transaction spawning and tag generation. In addition, memory blocks store inbound and outbound data. **Figure 17-1** is a high-level block diagram of the PCI Express controller.

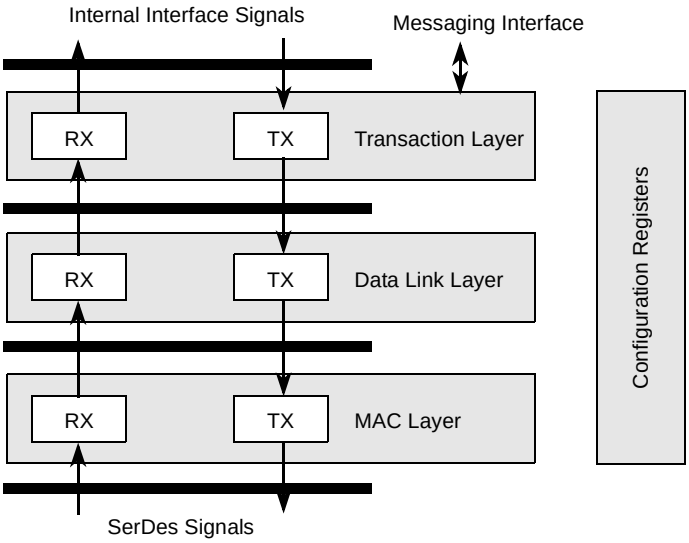

Figure 17-1. PCI Express Controller Block Diagram

The PCI Express controller can be configured to operate as either a PCI Express root complex (RC) or an endpoint (EP) device. An RC device connects the core processor/memory subsystem to I/O devices while an EP device typically denotes a peripheral or I/O device. In RC mode, a PCI Express type 1 configuration header is used; in EP mode, a PCI Express type 0 configuration header is used.

As an initiator, the PCI Express controller supports memory read and write operations with a maximum transaction size of 256 bytes. In RC mode, the controller also supports configuration and I/O transactions. As a target interface, the PCI Express controller accepts read and write operations to local memory space. When configured as an EP device, the PCI Express controller accepts configuration transactions to the internal PCI Express configuration registers. Message generation and acceptance are supported in both RC and EP modes. Locked transactions and inbound I/O transactions are not supported.

17.1.1 Outbound Transactions

Outbound internal platform transactions to PCI Express are first mapped to a translation window to determine what PCI Express transactions to issue. A transaction from the internal platform can become a PCI Express Memory, I/O, Message, or Configuration transaction depending on the window attributes.

A transaction may be broken up into smaller sized transactions depending on the original request size, transaction type, and either the PCI Express device control register [MAX_PAYLOAD_SIZE] field for write requests or the PCI Express device control register [MAX_READ_SIZE] field for read requests. The controller performs PCI Express ordering rule checking to determine which transaction is to be sent on the PCI Express link.

In general, transactions are serviced in the order that they are received. Only when there is a stalled condition does the controller apply PCI Express ordering rules to outstanding transactions. For posted write transactions, once all data has been received, the data is forwarded to the PCI Express link and the transaction is considered as done. For non-posted write transactions, the controller waits for the completion packets to return before considering the transaction finished. For non-posted read transactions, the controller waits for all completion packets to return and then forwards all data back to the internal platform before terminating the transaction.

Note: After reset or when recovering from a link down condition, external transactions should not be attempted until the link has successfully trained. Software can poll the LTSSM state status register (PEX_LTSSM_STAT) to check the status of link training before issuing external requests.

17.1.1.1 Training to 2.5 Gbaud After Reset

The RCW bit PFREQ has no effect on the speed at which the PCI Express runs after power-on reset. The PCI Express controller runs at 5 Gbaud after the system exits reset if the external PCI Express controller is a Gen2 device and the PCI Express controller cannot train to 2.5 Gbaud after exiting power-on reset if the external device supports Gen2 speed even if value of RCW Bit PFREQ = 1 (2.5 Gbaud). To run the PCI Express controller at 2.5 Gbaud, write the specified values to the following fields in PEX_LSCR (offset 0x108):

- PEX_LSCR[LSRS] = 0b0001
- PEX_LSCR[LSM] = 0b1
- PEX_LSCR[LSR] = 0b1

This allows the PCI Express controller to train to 2.5 Gbaud.

17.1.1.2 Link Width Downtraining

When PCI Express controller is downtrained as a x2 or a x1 link from a x4 or a x2 link, the PCI Express controller may flag a correctable error: CED set in the PCI Express Device Status Register and RXE (Receiver error status) set in the PCI Express Correctable Error Status Register. Therefore, after training and before initiating any transaction towards the PCI Express interface, clear the CED field in the PCI Express Device Status Register and the RXE field in the PCI Express Correctable Error Status Register, to allow real error reports in the functional mode.

17.1.2 Inbound Transactions

Inbound PCI Express transactions to internal platform are first mapped to a translation window to determine what internal platform transactions to issue. A transaction may be broken up into smaller sized transactions when sending to the internal platform depending on the original request size, byte enables and starting/ending addresses. The controller performs PCI Express ordering rule checking to determine what transaction to send next to the internal interface.

In general, transactions are serviced in the order that they are received from the PCI Express link. Only when there is a stalled condition does the controller apply PCI Express ordering to outstanding transactions. For posted write transactions, once all data has been received from the PCI Express link, the data is forwarded to the internal platform and the transaction is considered as done. For non-posted read transactions, the controller forwards internal platform data back to the PCI Express link.

Note: The controller splits transactions at the crossing of every 256-byte-aligned boundary when sending data back to the PCI Express link.

Note: Ensure that all inbound PCI Express read accesses are 4-byte aligned. Read errors may appear on unaligned accesses.

17.2 Features

The PCI Express controller includes the following features:

- Designed to comply with the *PCI Express Base Specification, Revision 2.0* with backward compatibility with Revision 1.1.
- Supports root complex (RC) and endpoint (EP) configurations.
- 32- and 64-bit address support.
- x4, x2, or x1 link support.
- Supports accesses to all PCI Express memory and I/O address spaces (requestor only).
- Supports posting of processor-to-PCI Express and PCI Express-to-memory writes.
- Supports strong and relaxed transaction ordering rules.
- PCI Express configuration registers (type 0 in EP mode, type 1 in RC mode).
- Baseline and advanced error reporting support.
- One virtual channel (VC0).
- 256-byte maximum payload size (MAX_PAYLOAD_SIZE).
- Supports three inbound general-purpose translation windows, one 64-bit message signalled interrupt (MSI) window (RC mode only), and one configuration window that can be alternately configured as a general purpose window.
- Supports 32- or 64-bit MSIs.
- Supports four outbound translation windows and one default window.
- Supports eight non-posted and four (with Serial RapidIO transactions) or six (without Serial RapidIO transactions) posted PCI Express transactions.
- Supports up to six priority 0 internal platform reads and eight priority 0 to 2 internal platform writes. The maximum number of outstanding transactions at any given time is eight.
- Credit-based flow control management.
- Supports PCI Express messages and interrupts.
- Accepts up to 256-byte transactions.
- Software-controllable, dynamic link width and speed.

17.3 Modes of Operation

The PCI Express controller can function as either a root complex (RC) or an endpoint (EP) on the PCI Express link. The mode and port width are selected by reset configuration signals (see **Chapter 5**, *Reset* for details.

17.4 Functional Description

The PCI Express protocol relies on a requestor/completer relationship where one device requests that some desired action be performed by some target device and the target device completes the task and responds. Usually the requests and responses occur through a network of links, but to the requestor and to the completer, the intermediate components are transparent.

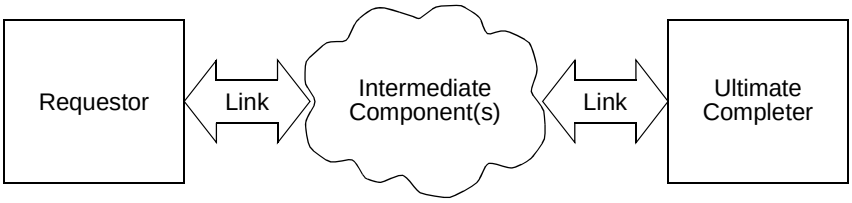

Figure 17-2. Requestor/Completer Relationship

Each PCI Express device is divided into two halves: transmit (TX) and receive (RX). Each half is further divided into three layers: transaction, data link, and physical, as shown in **Figure 17-3**.

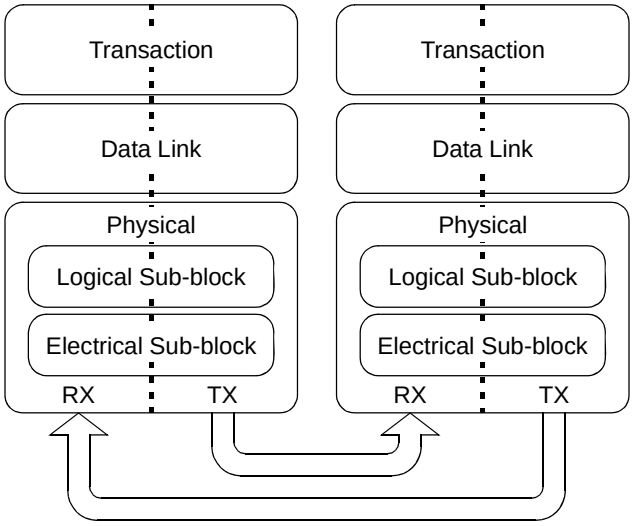

Figure 17-3. PCI Express High-Level Layering

Packets are formed in the transaction layer (TLPs) and data link layer (DLLPs). Each subsequent layer adds the necessary encodings and framing, illustrated in **Figure 17-4**. As packets are received, they are decoded and processed by the same layers, but in reverse order for processing by the layer or by the device application software.

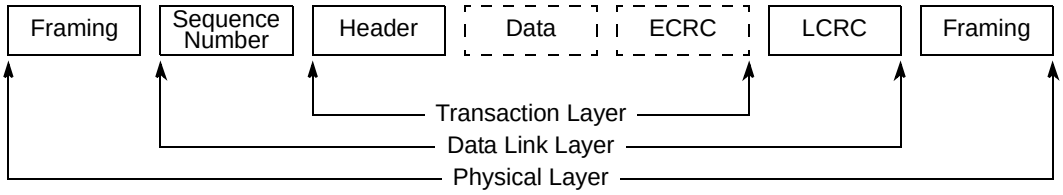

Figure 17-4. PCI Express Packet Flow

17.4.1 PCI Express Transactions

Table 17-1 lists the transactions that the PCI Express controller supports as an initiator and a target.

Table 17-1. PCI Express Transactions

PCI Express Transaction	Supported as an Initiator	Supported as a Target	Definition
Mrd	Yes	Yes	Memory Read Request
MRdLk	No	No	Memory Read Lock. As a target, CplLk with UR status is returned.
MWr	Yes	Yes	Memory Write Request to memory-mapped PCI-Express space
IORd	Yes (RC only)	No	I/O Read request. As a target, Cpl with UR status is returned
IOWr	Yes (RC only)	No	I/O Write Request. As a target, Cpl with UR status is returned
CfgRd0	Yes (RC only	Yes	Configuration Read Type 0
CfgWr0	Yes (RC only)	Yes	Configuration Write Type 0
CfgRd1	Yes (RC only)	No	Configuration Read Type 1. As a target, Cpl with UR status is returned.
CfgWr1	Yes (RC only)	No	Configuration Write Type 1. As a target, Cpl with UR status is returned.
Msg	Yes	Yes	Message Request
MsgD	Yes (RC only)	Yes (EP only)	Message Request with Data payload. Note that Set_Slot_Power_Limit is the only message with data that is supported and then only when the controller is an initiator and in RC mode or a target and in EP mode.
Cpl	Yes	Yes	Completion without Data
CplD	Yes	Yes	Completion with Data
CplLk	No	Yes	Completion for Locked Memory Read without Data. The only time that CplLk is returned with UR status is when the controller receives a MRdLk command.
CplDLk	No	No	Completion for Locked Memory Read with Data

17.4.1.1 Byte Ordering

Whenever data must cross a bridge between two buses, the byte ordering of data on the source and destination buses must be considered. The internal platform bus of this device is inherently big endian and the PCI Express bus interface is inherently little endian.

There are two methods to handle ordering of data as it crosses a bridge—address invariance and data invariance. Address invariance preserves the addressing of bytes within a scalar data element, but not the relative significance of the bytes within that scalar. Conversely, data invariance preserves the relative significance of bytes within a scalar, but not the addressing of the individual bytes that make up a scalar.

This device uses address invariance as its byte ordering policy. As stated above, address invariance preserves the byte address of each byte on an I/O interface as it is placed in memory or moved into a register. This policy can have the effect of reversing the significance order of bytes (most significant to least significant and vice versa), but it has the benefit of preserving the format of general data structures. Provided that software is aware of the endianness and format of the data structure, it can correctly interpret the data on either side of the bridge.

Figure 17-5 shows the transfer of a 4-byte scalar, 0x4142_4344, from a big endian source across an address invariant bridge to a little endian destination.

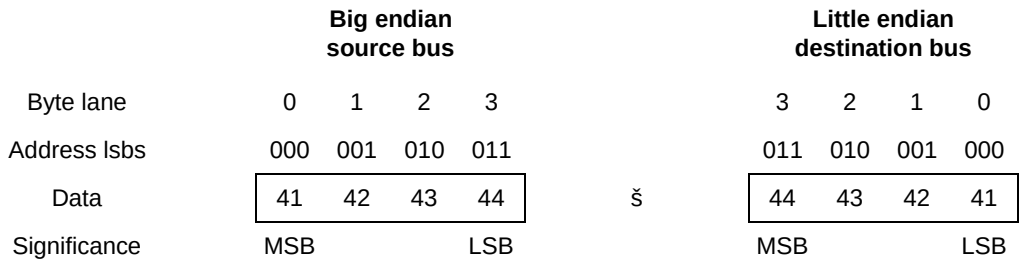

Figure 17-5. Address Invariant Byte Ordering—4 bytes Outbound

Note: Although the significance of the bytes within the scalar has changed, the address of the individual bytes that make up the scalar has not changed. As long as software is aware that the source of the data used a big endian format, the data can be interpreted correctly.

Figure 17-6 shows data flowing the other way, from a little endian source to a big endian destination.

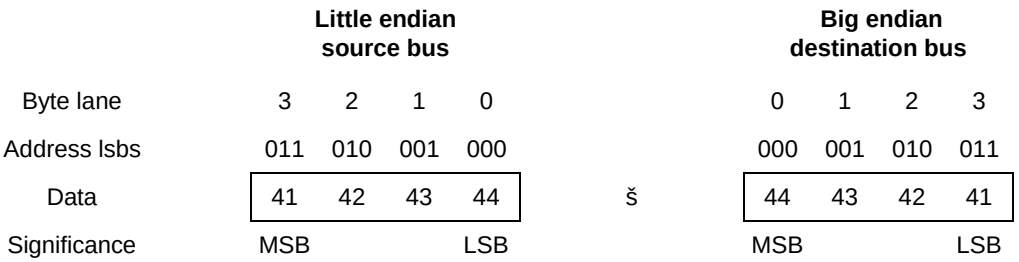

Figure 17-6. Address Invariant Byte Ordering—4 bytes Inbound

Figure 17-7 shows an outbound transfer of an 8-byte scalar, 0x5455_1617_CDCE_2728, using address invariance.

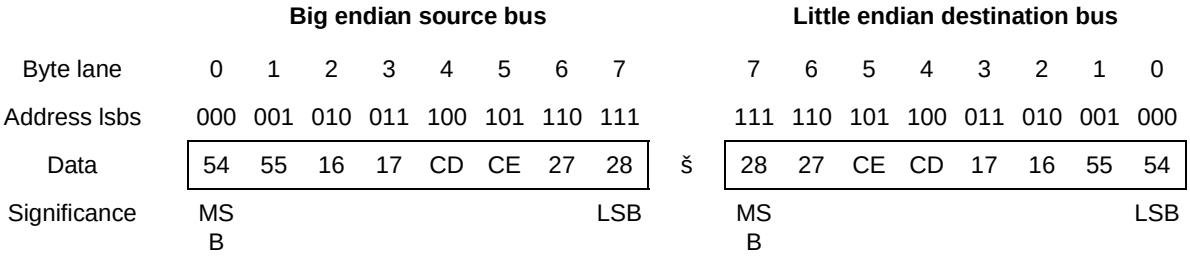

Figure 17-7. Address Invariant Byte Ordering—8 bytes Outbound

Figure 17-8 shows an inbound transfer of a 2-byte scalar, 0x5837, using address invariance.

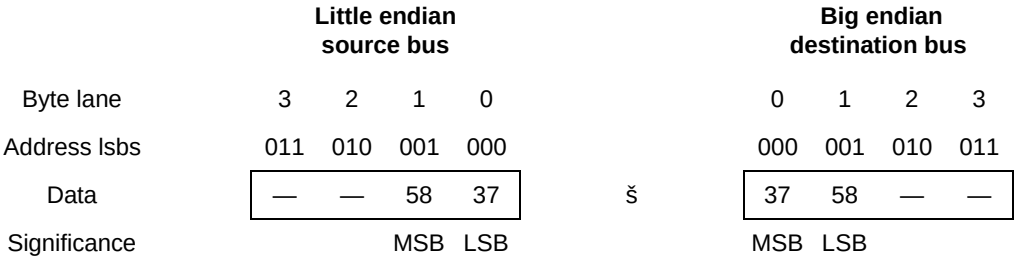

Figure 17-8. Address Invariant Byte Ordering—2 bytes Inbound

Note: In all of these examples, the original addresses of the individual bytes within the scalars (as created by the source) are preserved.

17.4.1.2 Byte Order for Configuration Transactions

All internal memory-mapped registers in the CCSR space use big endian byte ordering. However, the PCI Express specification defines PCI Express configuration registers as little endian. All accesses to the PCI Express configuration port, PEX_CONFIG_DATA, including the those targeting the internal PCI Express configuration registers, use the address invariance policy as shown in **Figure 17-9**. Therefore, software must access PEX_CONFIG_DATA with little-endian formatted data—either by using the **swapb** instruction or by manipulating the data before writing to and after reading from PEX_CONFIG_DATA.

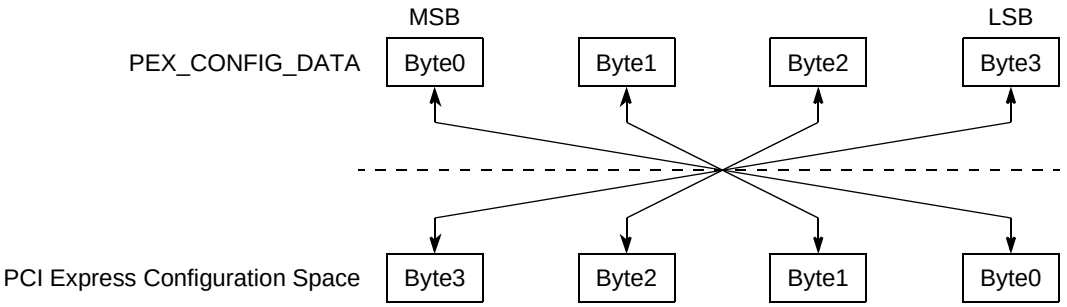

Figure 17-9. PEX_CONFIG_DATA Byte Ordering

17.4.1.3 Transaction Ordering Rules

In general, transactions are serviced in the order that they are received. However, transactions can be reordered as they are sent due to a stalled condition such as a full internal buffer. The following are the ordering rules for sending the next outstanding request:

- A posted request can and will bypass all other transactions except another posted request.
- A completion can and will only bypass non-posted requests. It can and will bypass posted requests only if the relaxed ordering (RO) bit is set.
- A non-posted request cannot bypass posted or other non-posted requests, but it can bypass a completion if the relaxed ordering (RO) bit is set.

17.4.1.4 Memory Space Addressing

A PCI Express memory transaction can address a 32- or 64-bit memory space. **Table 17-2** describes the Fmt and Type field contents in the PCI Express TLP header for memory transactions.

Table 17-2. TLP Header Type and Format Field Definitions for Memory Transactions

Request	Fmt[1–0]	Type[4–0]
Mem read (32-bit)	00	00000
Mem read (64-bit)	01	00000
Mem write (32-bit)	10	00000
Mem write (64-bit)	11	00000

As an initiator, the controller is capable of sending 32- or 64-bit memory packets. Any transaction from the internal platform that (after passing through the translation mechanism) has a translated address greater than 4G is sent as a 64-bit memory packet. Otherwise, a 32-bit memory packet is sent. As a target device, the controller is capable of decoding 32- or 64-bit memory packets. This is done through two 32-bit inbound windows and two 64-bit inbound windows. All inbound addresses are translated to 36-bit internal platform addresses.

17.4.1.5 I/O Space Addressing

The controller does not support I/O transactions as a target. As an initiator, the controller can send I/O transactions in RC mode only by programming one of the outbound translation window attributes to send I/O transactions. All I/O transactions only access 32-bit address I/O space. **Table 17-3** describes the Fmt and Type field contents in the PCI Express TLP header for I/O transactions.

Table 17-3. TLP Header Type and Format Field Definitions for I/O Transactions

Request	Fmt[1–0]	Type[4–0]
I/O read (32-bit)	00	00010
I/O write (32-bit)	10	00010

17.4.1.6 Configuration Space Addressing

As an initiator, the controller supports both type 0 and type 1 configuration cycles when configured in RC mode. There are two methods of generating a configuration transaction; refer to **Section 17.5.1.10, *PCI Express Configuration Space Access, on page 17-71***, for more information. A configuration transaction can hit into the controller internal configuration space, it can be sent out on the PCI Express link, or it can be internally terminated. **Table 17-4** describes the Fmt and Type field contents in the PCI Express TLP header for configuration transactions.

Table 17-4. TLP Header Type and Format Field Definitions for Configuration Transactions

Request	Fmt[1–0]	Type[4–0]
Config Type 0 read	00	00100
Config Type 0 write	10	00100
Config Type 1 read	00	00101
Config Type 1 write	10	00101

Note that all configuration transactions sent on PCI Express require a response regardless whether they are read or a write configuration transactions. The controller does not generate configuration transactions in EP mode. Only inbound configuration transactions are supported in EP mode.

17.4.1.7 Serialization of Configuration and I/O Writes

Configuration and I/O writes originating are serialized by the controller. The logic after issuing a configuration write or IO write will not issue any new transactions until the outstanding configuration or I/O write is finished. This means that an acknowledgement packet from the link partner in the form of a CpL TLP packet must be seen or the transaction has timed out. If the CpL packet contains a CRS status, then the logic re-issues the configuration write transaction. It keeps retrying the request until either a status other than CRS is returned or the transaction times out.

Note: It is possible for outbound configuration read request to be requeued and be placed at the end of the request queue due to CRS condition.

17.4.2 Messages

Software message generation is supported in both RC and EP modes.

17.4.2.1 Outbound ATMU Message Generation

Software can choose to send a message by programming PEXOWAR*n*[WTT] = 0x5. A message is sent by writing a 4-byte transaction in big-endian format that hits in an outbound window configured to send messages. Part of the 4-byte data is used to store information such as message code and routing information. **Table 17-5** describes the message data format.

Table 17-5. Internal Platform (OCN) Message Data Format

Bits	Name	Reset Value	Description
0–15	—	—	Reserved
16–18	Routing	x	Routing mechanism. Contains the message's routing information
19–23	—	—	Reserved
24–31	Code	x	Message code. Contains the actual message type to be sent.

In addition to the outbound ATMU, the PEX PM Command register also provides the capability to send PME_Turn_Off message or PM_PME message by setting bits 31 or 29. See **Section 17.5.1.2.4**, *PCI Express Power Management Command Register (PEX_PMCR)*, on page 17-39 for more information.

Table 17-6 provides a complete list of supported outbound messages depending on whether RC or EP is configured.

Table 17-6. PCI Express ATMU Outbound Messages

Name	Code[7–0]	Routing[2–0]	RC	EP	Description
PM_Active_State_Nak	0001 0100	100	Yes	N/A	Terminate at receiver
PM_PME	0001 1000	000	N/A	Yes	Sent Upstream by PME-requesting component
PME_Turn_Off	0001 1001	011	Yes	N/A	Broadcast Downstream
PM_TO_Ack	0001 1011	101	N/A	Yes	Sent Upstream by Endpoint
ERR_COR	0011 0000	000	N/A	Yes	Sent by component when it detects a correctable error
ERR_NONFATAL	0011 0001	000	N/A	Yes	Sent by component when it detects a Non-fatal, uncorrectable error
ERR_FATAL	0011 0011	000	N/A	Yes	Sent by component when it detects a Fatal, uncorrectable error
Unlock	0000 0000	000	No	N/A	Not supported
Set_Slot_Power_Limit	0101 0000	100	Yes	N/A	Set Slot Power Limit in Upstream Port
Vendor_Defined Type 0	0111 1110		No	No	Not supported
Vendor_Defined Type 1	0111 1111		No	No	Not supported

17.4.2.2 Inbound Messages

Table 17-7 provides a complete list of supported inbound messages in RC mode.

Table 17-7. PCI Express RC Inbound Message Handling

Name	Code[7–0]	Routing[2–0]	Action
Assert_INTA	0010 0000	100	Send to interrupt controller
Assert_INTB	0010 0001	100	Send to interrupt controller
Assert_INTC	0010 0010	100	Send to interrupt controller
Assert_INTD	0010 0011	100	Send to interrupt controller
Deassert_INTA	0010 0100	100	Send to interrupt controller
Deassert_INTB	0010 0101	100	Send to interrupt controller
Deassert_INTC	0010 0110	100	Send to interrupt controller
Deassert_INTD	0010 0111	100	Send to interrupt controller
PM_Active_State_Nak	0001 0100	100	No action taken
PM_PME	0001 1000	000	Generate interrupt to interrupt controller if enabled
PME_Turn_Off	0001 1001	011	No action taken
PME_TO_Ack	0001 1011	101	Set PEX_PME_MES_DR[ENL23] bit and generate interrupt to interrupt controller if enabled
ERR_COR	0011 0000	000	Generate interrupt to interrupt controller if enabled
ERR_NONFATAL	0011 0001	000	Generate interrupt to interrupt controller if enabled
ERR_FATAL	0011 0011	000	Generate interrupt to interrupt controller if enabled
Unlock	0000 0000	000	No action taken
Set_Slot_Power_Limit	0101 0000	100	No action taken
Vendor_Defined Type 0	0111 1110	—	No action taken
Vendor_Defined Type 1	0111 1111	—	No action taken

Table 17-8 provides a complete list of supported inbound messages in EP mode.

Table 17-8. PCI Express EP Inbound Message Handling

Name	Code[7–0]	Routing[2–0]	Action
Assert_INTA	0010 0000	100	No action taken
Assert_INTB	0010 0001	100	No action taken
Assert_INTC	0010 0010	100	No action taken
Assert_INTD	0010 0011	100	No action taken
Deassert_INTA	0010 0100	100	No action taken
Deassert_INTB	0010 0101	100	No action taken
Deassert_INTC	0010 0110	100	No action taken
Deassert_INTD	0010 0111	100	No action taken
PM_Active_State_Nak	0001 0100	100	No action taken
PM_PME	0001 1000	000	No action taken
PME_Turn_Off	0001 1001	011	Set PEX_PME_MES_DR[PTO] bit. Send interrupt if enabled.
PM_TO_Ack	0001 1011	101	No action taken
ERR_COR	0011 0000	000	No action taken
ERR_NONFATAL	0011 0001	000	No action taken
ERR_FATAL	0011 0011	000	No action taken
Unlock	0000 0000	000	No action taken
Set_Slot_Power_Limit	0101 0000	100	Update power value in PCI Express device capability register in configuration space.

Table 17-8. PCI Express EP Inbound Message Handling (Continued)

Name	Code[7–0]	Routing[2–0]	Action
Vendor_Defined Type 0	0111 1110	—	No action taken
Vendor_Defined Type 1	0111 1111	—	No action taken

17.4.3 Error Handling

The PCI Express specification classifies errors as correctable and uncorrectable. Correctable errors result in degraded performance, but uncorrectable errors generally result in functional failures. As shown in **Figure 17-10** uncorrectable errors can further be classified as fatal or non-fatal.

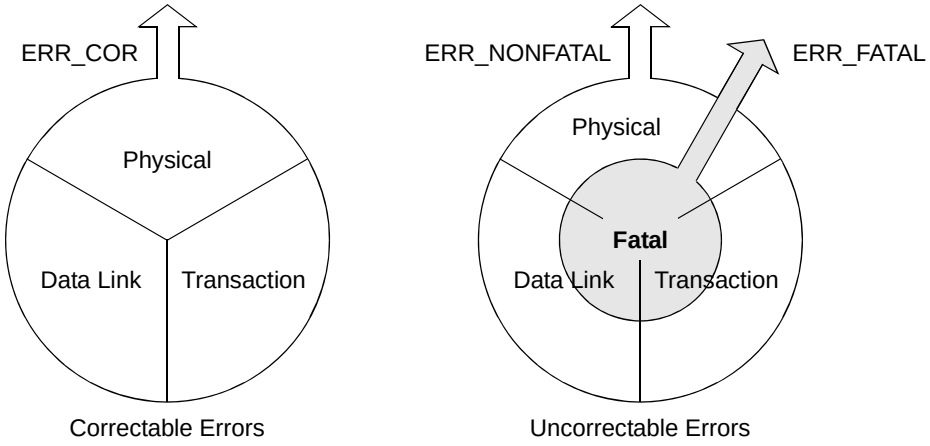

Figure 17-10. PCI Express Error Classification

17.4.3.1 PCI Express Error Logging and Signaling

Figure 17-11 shows the PCI Express-defined sequence of operations related to signalling and logging of errors detected by a device. Note that the PCI Express controller on this device supports the advanced error handling capabilities shown within the dotted lines.

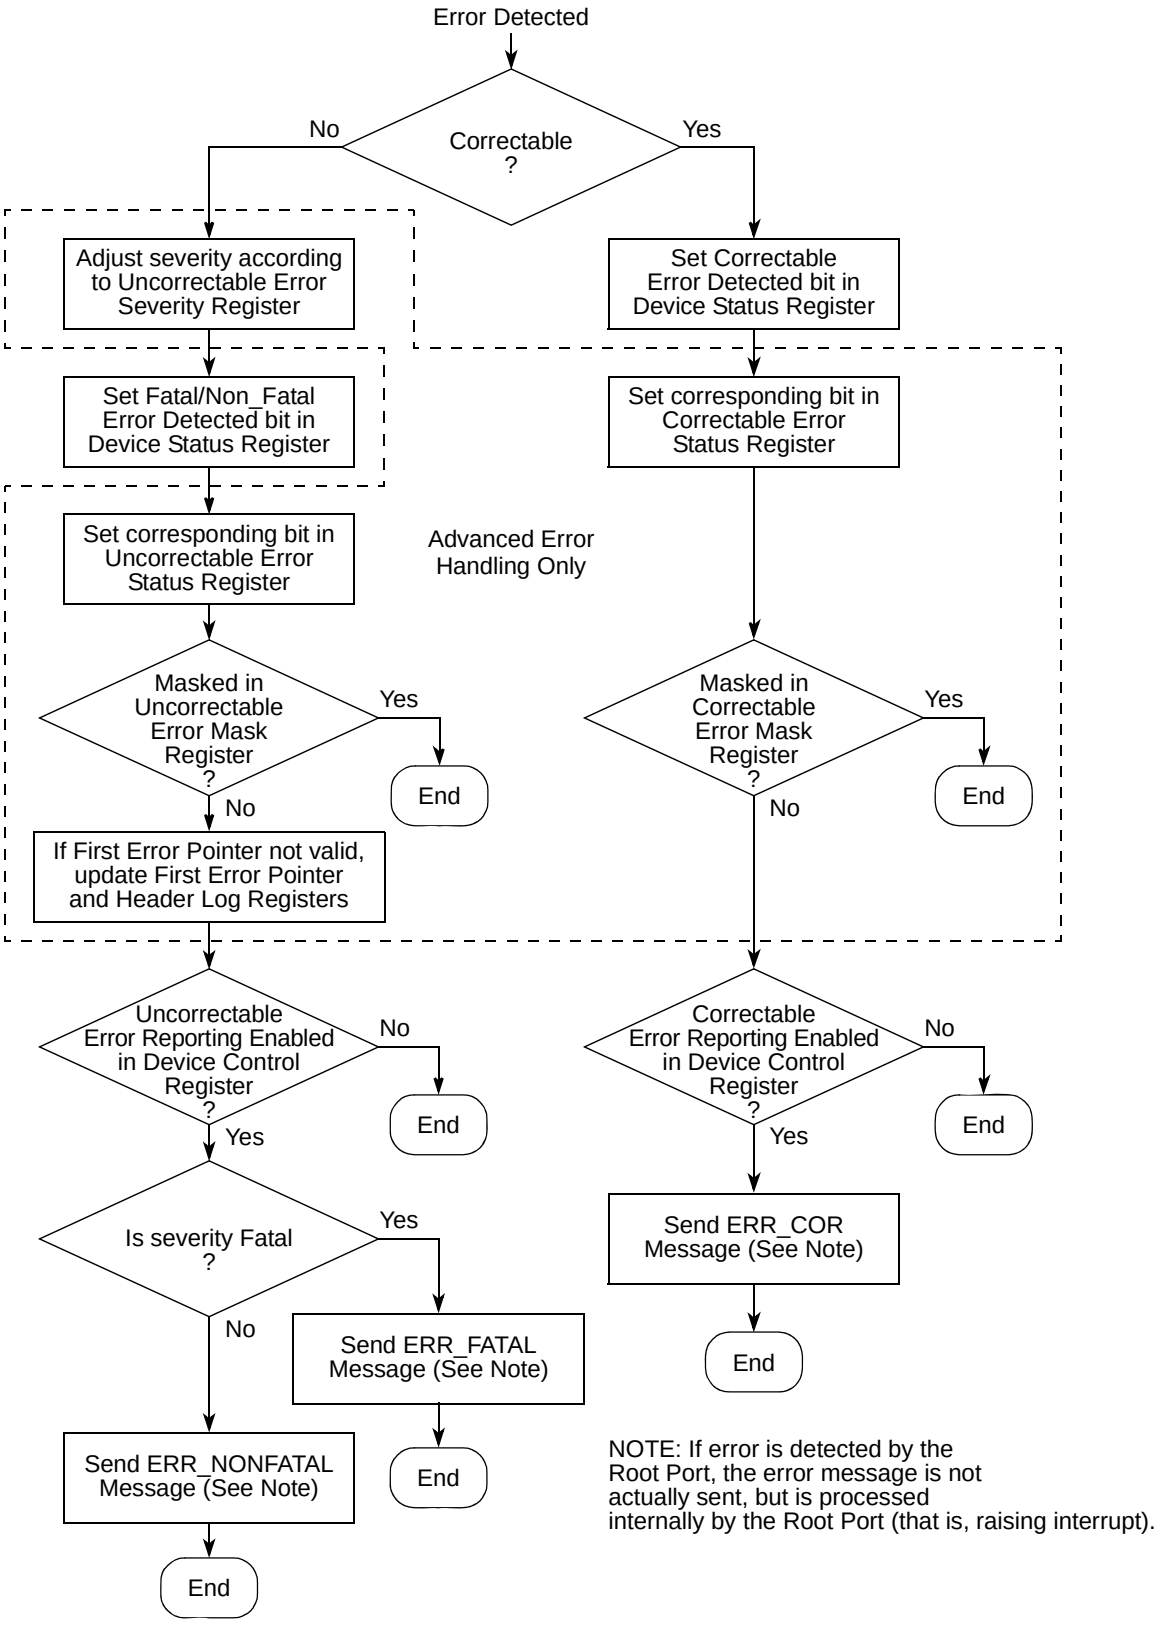

Figure 17-11. PCI Express Device Error Signaling Flowchart

17.4.3.2 PCI Express Controller Internal Interrupt Sources

Table 17-9 describes the sources of the PCI Express controller internal interrupt to the EPIC and the preconditions for signalling the interrupt.

Table 17-9. PCI Express Internal Controller Interrupt Sources

Status Register Bit	Preconditions
Any bit in PEX_PME_MES_DR set	The corresponding interrupt enable bits must be set in PEX_PME_MES_IER
Any bit in PEX_ERR_DR set	The corresponding interrupt enable bits must be set in PEX_ERR_EN.
PCI Express Root Status Register[16] (PME status) is set	PCI Express Root Control Register [3] (PME interrupt enable) is set
PCI Express Root Error Status Register[6] (fatal error messages received) is set	PCI Express Root Error Command Register [2] (fatal error reporting enable) is set or PCI Express Root Control Register [2] (system error on fatal error enable) is set
PCI Express Root Error Status Register [5] (non-fatal error messages received) is set	PCI Express Root Error Command Register [1] (non-fatal error reporting enable) is set or PCI Express Root Control Register [1] (system error on non-fatal error enable) is set
PCI Express Root Error Status Register[0] (correctable error messages received) is set	PCI Express Root Error Command Register[0] (correctable error reporting enable) is set or PCI Express Root Control Register[0] (system error on correctable error enable) is set.
Any correctable error status bit in PCI Express Correctable Error Status Register is set	The corresponding error mask bit in PCI Express Correctable Error Mask Register is clear and PCI Express Root Error Command Register[0] (correctable error reporting enable) is set
Any fatal uncorrectable error status bit in PCI Express Uncorrectable Error Status Register is set. (The corresponding error is classified as fatal based on the severity setting in PCI Express Uncorrectable Error Severity Register.)	The corresponding error mask bit in PCI Express Uncorrectable Error Mask Register is clear and either PCI Express Device Control Register[2] (fatal error reporting) is set or PCI Express Command Register[8] (SERR) is set.
Any non-fatal uncorrectable error status bit in PCI Express Uncorrectable Error Status Register is set. (The corresponding error is classified as non-fatal based on the severity setting in PCI Express Uncorrectable Error Severity Register.)	The corresponding error mask bit in PCI Express Uncorrectable Error Mask Register is clear and either PCI Express Device Control Register[1] (non-fatal error reporting) is set or PCI Express Command Register[8] (SERR) is set.
PCI Express Secondary Status Register[8] (master data parity error) is set.	PCI Express Secondary Status Interrupt Mask Register[0] (mask master data parity error) is cleared and PCI Express Command Register[6] (parity error response) is set.
PCI Express Secondary Status Register[11] (signaled target abort) is set	PCI Express Secondary Status Interrupt Mask Register[1] (mask signalled target abort) is cleared.
PCI Express Secondary Status Register[12] (received target abort) is set	PCI Express Secondary Status Interrupt Mask Register[2] (mask received target abort) is cleared.
PCI Express Secondary Status Register[13] (received master abort) is set	PCI Express Secondary Status Interrupt Mask Register[3] (mask received master abort) is cleared.
PCI Express Secondary Status Register[14] (signalled system error) is set.	PCI Express Secondary Status Interrupt Mask Register[4] (mask signalled system error) is cleared.
PCI Express Secondary Status Register[15] (detected parity error) is set	PCI Express Secondary Status Interrupt Mask Register[5] (mask detected parity error) is cleared.

Table 17-9. PCI Express Internal Controller Interrupt Sources (Continued)

Status Register Bit	Preconditions
PCI Express Slot Status Register[0] (attention button pressed) is set	PCI Express Slot Control Register[0] (attention button pressed enable) is set and PCI Express Slot Control Register[5] (hot plug interrupt enable) is set and either PCI Express PM Control Register[1–0] = 00 (the function power state is D0) or PCI Express PM Control Register[8] (PME enable) is set.
PCI Express Slot Status Register[1] (power fault detected) is set	PCI Express Slot Control Register[1] (power fault detected enable) is set and PCI Express Slot Control Register[5] (hot plug interrupt enable) is set and either PCI Express PM Control Register[1–0] = 00 (the function power state is D0) or PCI Express PM Control Register[8] (PME enable) is set.
PCI Express Slot Status Register[2] (MRL sensor changed) is set	PCI Express Slot Control Register[2] (MRL sensor changed enable) is set and PCI Express Slot Control Register[5] (hot plug interrupt enable) is set and either PCI Express PM Control Register[1–0] = 00 (the function power state is D0) or PCI Express PM Control Register[8] (PME enable) is set.
PCI Express Slot Status Register[3] (presence detect changed) is set	PCI Express Slot Control Register[3] (presence detect changed enable) is set and PCI Express Slot Control Register[5] (hot plug interrupt enable) is set and either PCI Express PM Control Register[1–0] = 00 (the function power state is D0) or PCI Express PM Control Register[8] (PME enable) is set.
PCI Express Slot Status Register[4] (command completed) is set	PCI Express Slot Control Register[4] (command completed interrupt enable) is set and PCI Express Slot Control Register[5] (hot plug interrupt enable) is set.

17.4.3.3 Error Conditions

Table 17-10 describes specific error types and the action taken for various transaction types.

Table 17-10. Error Conditions

Transaction Type	Error Type	Action
Inbound response	PEX response time out. This case happens when the internal platform sends a non-posted request that did not get a response back after a specific amount of time specified in the outbound completion timeout register (PEX_OTB_CPL_TOR)	Log error (PEX_ERR_DR[PCT]) and send interrupt to PIC, if enabled.
Inbound response	Unexpected PEX response. This can happen if, after the response times out and the internal queue entry is deallocated, the response comes back.	Log unexpected completion error (PCI Express Uncorrectable Status Register[16]) and send interrupt to PIC, if enabled.

Table 17-10. Error Conditions (Continued)

Transaction Type	Error Type	Action
Inbound response	Unsupported request (UR) response status	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request. Log the error (PEX_ERR_DR[CDNSC] and PCI Express Uncorrectable Status Register[20]) and send interrupt to PIC, if enabled.
Inbound response	Completer abort (CA) response status	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request. Log the error (PEX_ERR_DR[PCAC, CDNSC] and PCI Express Uncorrectable Status Register[15] and send interrupt to PIC, if enabled.
Inbound response	Poisoned TLP (EP=1)	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request. Log the error (PCI Express Uncorrectable Status Register[12]) and send interrupt to PIC, if enabled.
Inbound response	ECRC error	Depending upon whether the initial internal request was broken up, the error is not sent until all responses come back for all portions of the internal request. Log the error (PCI Express Uncorrectable Status Register[19]) and send interrupt to PIC, if enabled.
Inbound response	Configuration Request Retry Status (CRS) timeout for a configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1.The controller always retries the transaction as soon as possible until a status other than CRS is returned. However, if a CRS status is returned after the configuration retry timeout (PEXCONF_RTY_TOR) timer expires, then the controller aborts the transaction and sends all 1s (0xFFFF_FFFF) data back to requester. 2. Log the error (PEX_ERR_DR[PCT]) and send interrupt to the PIC, if enabled.
Inbound response	UR response for configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1. Send back all 1s (0xFFFF_FFFF) data. 2. Log the error (PEX_ERR_DR[CDNSC] and PCI Express Uncorrectable Status Register[20]) and send interrupt to PIC, if enabled.
Inbound response	CA response for Configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1. Send back all 1s (0xFFFF_FFFF) data. 2. Log the error (PEX_ERR_DR[PCAC, CDNSC] and PCI Express Uncorrectable Status Register[15]) and send interrupt to PIC, if enabled.
Inbound response	Poisoned TLP (EP=1) response for Configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1. Send back all 1s (0xFFFF_FFFF) data. 2. Log the error (PCI Express Uncorrectable Status Register[12]) and send interrupt to PIC, if enabled.
Inbound response	ECRC error response for Configuration transaction that originates from PEX_CONFIG_ADDR/ PEX_CONFIG_DATA	1. Send back all 1s (0xFFFF_FFFF) data. 2. Log the error (PCI Express Uncorrectable Status Register[19]) and send interrupt to PIC, if enabled.
Inbound response	Configuration Request Retry Status (CRS) response for Configuration transaction that originates from ATMU	1.The controller always retries the transaction as soon as possible until a status other than CRS is returned. However, if a CRS status is returned after the configuration retry timeout (PEXCONF_RTY_TOR) timer expires, then the controller aborts the transaction. 2. Log the error (PEX_ERR_DR[CRST]) and send interrupt to the PIC, if enabled.

Table 17-10. Error Conditions (Continued)

Transaction Type	Error Type	Action
Inbound response	UR response for Configuration transaction that originates from ATMU	Log the error (PEX_ERR_DR[CDNSC] and PCI Express Uncorrectable Status Register[20]) and send interrupt to PIC, if enabled.
Inbound response	CA response for Configuration transaction that originates from ATMU	Log the error (PEX_ERR_DR[PCAC, CDNSC] and PCI Express Uncorrectable Status Register[15]) and send interrupt to PIC, if enabled.
Inbound response	Malformed TLP response	PCI Express controller does not pass the response back to the core. Therefore, a completion timeout error eventually occurs.
Inbound request	Poisoned TLP (EP=1)	1. If it is a posted transaction, the controller drops it. 2. If it is a non-posted transaction, the controller returns a completion with UR status. 3. Release the proper credits
Inbound request	ECRC error	1. If it is a posted transaction, the controller drops it. 2. If it is a non-posted transaction, the controller returns a completion with UR status. 3. Release the proper credits
Inbound request	PCI Express nullified request	The packet is dropped.
Outbound request	Outbound ATMU crossing	Log the error (PEX_ERR_DR[OAC]). The transaction is not sent out on the link.
Outbound request	Illegal message size	Log the error (PEX_ERR_DR[MIS]). The transaction is not sent out on the link.
Outbound request	Illegal I/O size	Log the error (PEX_ERR_DR[IOIS]). The transaction is not sent out on the link.
Outbound request	Illegal I/O address	Log the error (PEX_ERR_DR[IOIA]). The transaction is not sent out on the link.
Outbound request	Illegal configuration size	Log the error (PEX_ERR_DR[CIS]). The transaction is not sent out on the link.
Outbound request	Internal platform memory write/read requests that do not hit either Memory Base/Limit or Pref Memory Base/Limit register.	Log the error in error detect register. The controller will drop the transaction.
Outbound request	Internal platform I/O write/read requests that do not hit either Memory Base/Limit or Pref Memory Base/Limit register.	Log the error in error detect register. The controller will drop the transaction.
Outbound response	Internal platform response with error (for example, an ECC error on a DDR read or the transaction maps to unknown address space).	Send poisoned TLP (EP=1) completion(s) for data that are known bad. If the response is the final response, then deallocate resource. If the response is not the final response, wait for all responses to come back before deallocate resource.If the poison data happens in the middle of the packet, the rest of the response packet(s) is also poisoned.
Link speed change request	1. Auto request with Auto speed disable bit set or 2. Link partner incapable of 5.0 Gb/s and request speed is 5.0 Gb/s	Clear link speed request and set interrupt in PME Message Detect register. Additionally, log error in link speed status register.
Link width change request	1. Auto request with Auto width disable bit set or 2. Upconfiguration not capable and request was to size-up the width or 3. Not enough detected lanes for a given request	Clear link width request and set interrupt in PME Message Detect register. Additionally, log error in link width status register.

Table 17-10. Error Conditions (Continued)

Transaction Type	Error Type	Action
Link speed change request	1. Auto request with Auto speed disable bit set or 2. Link partner incapable of 5.0 Gb/s and request speed is 5.0 Gb/s	Clear link speed request and set interrupt in PME Message Detect register. Additionally, log error in link speed status register.
Link width change request	1. Auto request with Auto width disable bit set or 2. Upconfiguration not capable and request was to size-up the width or 3. Not enough detected lanes for a given request	Clear link width request and set interrupt in PME Message Detect register. Additionally, log error in link width status register.

17.4.4 Interrupts

Handling of INTx and message signalled interrupts (MSI) depends on whether the PCI Express controller is configured as an RC or EP device. As an RC device, the PCI Express controller responds to interrupts from the system. As a EP device, the controller can generate interrupt signals. **Table 17-11** and **Table 17-12** summarize the interrupt functionality for EP and RC devices, respectively.

Table 17-11. EP Device INTx and MSI Handling

Interrupt Action	EP Device
INTx Message Generation	
• Hardware	Not supported.
• Software	Not supported.
MSI Generation	
• Hardware:	When configured to handle this operation, the PCI Express controller can generate MSI transactions automatically to the RC. The PCI Express controller uses the GCR5[PEX_IRQ_OUT] bit (see **Chapter 8**, *General Configuration Registers* for details). to trigger the generation of the MSI. The remote RC must set up the MSI capability structure for all endpoints during system initialization by writing the appropriate values to the Message Address and Message Data registers and setting the MSIE bit in the MSI Message Control register. When configured properly, the PCI Express controller detects when the GCR5[PEX_IRQQ_OUT] bit sets (= 1) and generates a PCI Express memory write transaction to the address specified in the MSI Message Address register (and MSI Message Upper Address register) with a data payload as specified in the MSI Message Data register (with leading zeros appended).
• Software	The core must set up the MSI capability registers to enable MSI mode, and write the correct values to the MSI address and data register. Then, local software must read the MSI address in the MSI capability register and configure the outbound ATMU window to map the translated address to the MSI address (see **Chapter 8**, *General Configuration Registers* for details on programming the ATMU window). Software must determine the number of allocated messages in the MSI capability register and allocate the appropriate data values to use. A write to the ATMU window containing the MSI address with the appropriate data value generates the desired MSI transaction to the remote RC.

Table 17-12. RC Device INTx and MSI Handling

Interrupt Action	RC Device
INTx Message	MSIs are the preferred interrupt signalling mechanism for PCI Express. However, in RC mode, the PCI Express controller supports the INTx virtual-wire interrupt signalling mechanism (as described in the PCI Express specification). Whenever the controller receives an inbound INTx (INTA, INTB, INTC, or INTD) asserted or deasserted message, it asserts or deasserts an equivalent internal INTx signal (*inta*, *intb*, *intc*, or *intd*) to the EPIC in each core. If a PCI Express INTx interrupt is used, then the EPIC must be configured so that these interrupts are level-sensitive (see **Chapter 13**, *Interrupt Handling*).
MSI	An inbound MSI should be handled by using one of the virtual interrupts or virtual NMIs (see **Chapter 13**, *Interrupt Handling*). **Note:** It is the responsibility of the host software to configure the EP MSI capability registers such that an MSI cycle generated from the EP device generates an appropriate interrupt to the DSP cores.

17.4.5 Initial Credit Advertisement

To prevent overflowing of the receiver buffers and for ordering-compliance purposes, the transmitter cannot send transactions unless it has enough flow control (FC) credits to send. Each device maintains an FC credit pool. The FC information is conveyed between the two link partners by DLLPs during link training (initial credit advertisement). The transaction layer performs the FC accounting functions. One FC unit is four DWs (16-bytes) of data.

Table 17-13. Initial credit advertisement

Credit Type	Initial Credit Advertisement
PH (Memory Write, Message Write)	4
PD (Memory Write, Message Write)	(256/16) x 4 = 64
NPH (Memory Read, IO Read, Cfg Read, Cfg Write)	8
NPD (IO Write, Cfg Write)	2
CPLH (Memory Read Completion, IO R/W Completion, Cfg R/W Completion)	Infinite
CPLD (Memory Read Completion, IO Read Completion, Cfg Read Completion)	Infinite

17.4.6 Power Management

All device power states are supported with the exception of D3cold with Vaux. In addition, all link power states are supported with the exception of L2 states. Only L0s ASPM mode is supported if enabled by configuring the Link Control register's bits 1–0 in configuration space. Note that there is no power saving in the controller when the device is put into a non-D0 state. The only power saving is the I/O drivers when the controller is put into a non-L0 link state.

Table 17-14. Power Management State Supported

Component D-State	Permissible Interconnect State	Action
D0	L0, L0s	In full operation.
D1	L0, L0s, L1	All outbound traffics are stalled. All inbound traffics will be thrown away. The only exceptions are PME messages and configuration transactions. If the device is in RC mode, it is permissible to send a PM_Turn_Off message via the PEX Power Management Command register.
D2	L0, L0s, L1	All outbound traffics are stalled. All inbound traffics will be thrown away. The only exceptions are PME messages and configuration transactions. If the device is in RC mode, it is permissible to send a PM_Turn_Off message via the PEX Power Management Command register.
D3hot	L0, L0s, L1, L2/L3 Ready	All outbound traffics are stalled. All inbound traffics will be thrown away. The only exceptions are PME messages and configuration transactions. If the device is in RC mode, it is permissible to send a PM_Turn_Off message via the PEX Power Management Command register. Note that if a transition of D3hot->D0 occurs, a reset is performed to the controller's configuration space. In addition, link training will restart.
D3cold	L3	Completely off.

The PCI Express controller includes support for an L0 low-power interconnection state in which the link is taken to an electrical idle condition and can be taken back to the L0 state without a full device reset. The controller and the PHY should be able to negotiate exiting from the electrical idle state without errors. However, a correctable replay timer time-out may occur and be detected after exit from electrical idle. The error is indicated by the RTTO bit in the PCI Express Correctable Error Status Register. The condition only affects the controller when configured for x2 or x4 PCI Express link widths. Use one of the following methods to prevent this error:

- Disable ASPM by configuring the PCI Express Link Control Register ASPM_CTL field to 0b00.
- The ACK Replay Timeout Register is at offset 0x438 from the CCSR base. Change the RTV (Replay Timeout Value) field (bits 27:13) to 0xFFF.

17.4.7 L2/L3 Ready Link State

The L2/L3 Ready link state is entered after the EP device is put into a D3hot state followed by a PME_Turn_Off/PME_TO_Ack message handshake protocol. Exiting this state requires a POR reset or a $\overline{\text{WAKE}}$ signal from the EP device. The PCI Express controller (in EP mode) does not support the generation of beacon; therefore, the device can use one of the GPIO signals as an enable to an external tristate buffer to generate a $\overline{\text{WAKE}}$ signal, shown in **Figure 17-12**.

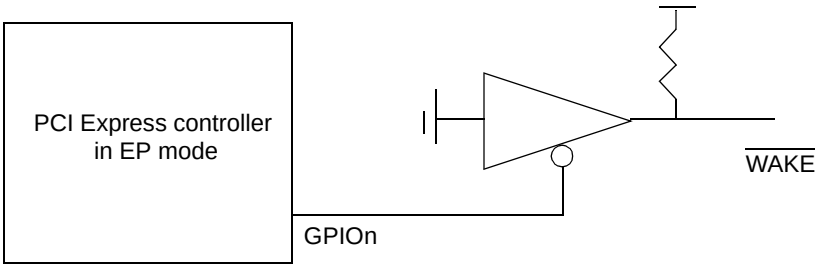

Figure 17-12. $\overline{\text{WAKE}}$ Generation Example

In RC mode, the $\overline{\text{WAKE}}$ signal from the EP device can be connected to one of the external interrupt inputs to service the $\overline{\text{WAKE}}$ request.

17.4.8 Hot Reset

When a hot reset condition occurs, the controller (in both RC and EP mode) initiates a clean-up of all outstanding transactions and returns to an idle state. All non-sticky configuration register bits are cleared. Link training then occurs. The device can generate a hot reset condition on the bus when it is configured as an RC device by setting the “Secondary Bus Reset” bit in the Bridge Control Register in the configuration space. As an EP device, it cannot generate a hot reset condition; it can only detect a hot reset condition and initiate the appropriate clean-up procedure.

17.4.8.1 Hot Reset During Training and Polarity

During training, the PCI Express controller detects the proper lane polarity and records it in the CSR Link Status Register (offset 0x420). If the link partner initiates a hot reset sequence, after the sequence is finished, the detected polarity status is cleared, and the PCI Express controller is not able to complete the training if the polarity inversion is required. If link training is unsuccessful following a hot reset sequence, software should perform the following:

- Write the value 0x88400000 to address 0xFFFB7F00 to reset the PCI controller.
- Wait 1 ms.
- Write the value 0x80400000 to address 0xFFFB7F00 to allow the link training process to start from the DETECT state for proper detection of polarity inversion.

17.4.8.2 Hot Reset During EP Mode

When a hot reset event is detected while the PCI Express Controller is configured in EP mode, the following may occur:

- The TLP received right before the Hot Reset event may be discarded
- Data corruption may occur on the first inbound memory transaction received after the Hot Reset event.

Depending on the type of the first inbound memory transaction received after Hot Reset, data corruption may occur as follows:

- If it is a memory write, the transaction may finish with data corruption at the target.
- If it is a memory read, the transaction may be decoded incorrectly and the return data might be incorrect.

To prevent this occurrence, do the following:

- When possible, before issuing the Hot Reset, the upstream RC or Switch should quiesce the system first to ensure no inbound traffic is flowing into the Freescale PCI Express EP controller. This prevents the above mentioned “inbound memory write followed immediately by Hot Reset event” sequence from occurring. The exact requirement and action required to quiesce the system depends on the system, application and software used. For example, some requirements may include, but are not be limited to, using a software semaphore at the RC system side to stop the new memory requests targeting the downstream Freescale PCI Express EP controller from the RC system's software API layer or DMA controller. Once such “quiescing system” actions have been finished, the RC system can send a configuration write cycle to clear the Memory Space bit in the Freescale PCI Express EP controller Command Register, followed by a several microsecond delay to allow all previously received inbound memory writes to propagate through the EP controller. A Hot Reset command can then be applied.
- If an “inbound memory write followed immediately by Hot Reset event” sequence cannot be avoided, do the following: immediately after the Hot Reset event, the upstream RC can issue a dummy memory write followed by another write or read to the read-only PEX_IP_BLK_REV1 memory-mapped register in the downstream Freescale device with PCI Express controller configured in EP Mode. The RC can then re-transfer the last memory write TLP that occurred right before the Hot Reset event and resume other normal traffic.

17.4.9 Link Down

Typically, a link down condition occurs after a hot reset event; however, it is possible for the link to go down unexpectedly without a hot reset event. When this occurs, a link down condition is detected (PEX_PME_MSG_DR[LDD]=1). Link down is treated similarly to a hot reset condition.

Subsequently, while the link is down, all new posted outbound transactions are discarded. All new non-posted ATMU transactions are errored out. Non-posted configuration transactions issued using PEX_CONFIG_ADDR/PEX_CONFIG_DATA toward the link returns 0xFFFF_FFFF (all 1s). As soon as the link is up again, the sending of transaction resumes.

Note: In EP mode, a link down condition causes the controller to reset all non-sticky bits in its PCI Express configuration registers as if it had been hot reset.

17.4.10 Initialization/Application Information

In normal boot mode (RCWHR[PRDY] = 0), the DSP cores are expected to boot and configure the device. During this time, the PCI Express interface will retry all inbound PCI Express configuration transactions. When the core has configured the device to a state where it can accept inbound PCI Express configuration transactions, the boot code should set the CFG_READY bit in the PEX_CFG_READY register after which inbound PCI Express configuration transactions are accepted. Refer to **Section 17.5.1.13.18**, *Configuration Ready Register—0x4B0*, on page 17-127 for more information about the CFG_READY bit.

In PCI Express ready mode (RCWHR[PRDY] = 1), the PCI Express interface accepts all inbound PCI Express configuration transactions which allows an external host/RC to configure the device with DSP core intervention.

17.4.11 Enabling Automatic Retraining of Link

As part of the initialization, software should clear PEX_FC_UPDATE_TOR[DIS_LR] to allow automatic retraining of the link if the link partner is down or the device has not received DLLP updates within the interval specified in PEX_FC_UPDATE_TOR[FC_UPDATE_TIMEOUT].

17.4.12 Spread Spectrum Reference Clock Feature

Spread spectrum is supported by PCI Express. However, spread spectrum for the PCI Express cannot use the PLL that serves the SRIO or SGMII interfaces when they are not turned off. Moreover, the PCI Express lane can accept a spread spectrum input even if its own reference clock (REF_CLK) is not spread; that is, you can connect two devices, one with a spread spectrum reference clock and the other without a spread spectrum reference clock, and they can communicate without failures.

17.5 Programming Model

The PCI Express interface supports the following register types:

- Memory-mapped registers—these registers control PCI Express address translation, PCI error management, and PCI Express configuration register access. These registers are described in **Section 17.5.1**, *PCI Express Memory Mapped Registers*, on page 17-27, and its subsections.
- PCI Express configuration registers contained within the PCI Express configuration space—these registers are specified by the PCI Express specification for every PCI Express device. These registers are described in **Section 17.5.1.10**, *PCI Express Configuration Space Access* and its subsections.

17.5.1 PCI Express Memory Mapped Registers

The PCI Express memory mapped registers are accessed by reading and writing to an address comprised of the base address (specified by the CCSR base address on the local side or the PEXCSRBAR on the PCI Express side) plus the block base address, plus the offset of the specific register to be accessed. Note that all memory-mapped registers (except the PCI Express configuration data register, PEX_CONFIG_DATA) must only be accessed as 32-bit quantities.

Table 17-15 lists the memory-mapped registers. In this table and in the register figures and field descriptions, the following access definitions apply:

- Reserved fields are always ignored for the purposes of determining access type.
- R/W, R, and W (read/write, read only, and write only) indicate that all the non-reserved fields in a register have the same access type.
- w1c indicates that all of the non-reserved fields in a register are cleared by writing ones to them.
- Mixed indicates a combination of access types.
- Special is used when no other category applies. In this case the register figure and field description table should be read carefully.

Table 17-15. PCI Express Memory-Mapped Register Map

Offset	Register	Access	Reset	Page
PCI Express Controller Memory-Mapped Registers—Block Base Address 0x0A000				
PCI Express Configuration Access Registers				
0x000	PEX_CONFIG_ADDR—PCI Express configuration address register	R/W	0x0000_0000	**page 17-30**
0x004	PEX_CONFIG_DATA—PCI Express configuration data register	R/W	0x0000_0000	**page 17-31**
0x00C	PEX_OTB_CPL_TOR—PCI Express outbound completion timeout register	R/W	0x0013_FFFF	**page 17-32**
0x010	PEX_CONF_RTY_TOR—PCI Express configuration retry timeout register	R/W	0x0400_FFFF	**page 17-33**
0x014	PEX_CONFIG—PCI Express configuration register	R/W	0x0004_0028	**page 17-34**
0x018	PEX_INT_STAT—PCI Express interrupt status register	R	0x0000_0000	**page 17-35**
