The PCI Express configuration address register contains address information for accesses to PCI Express internal and external configuration registers. Both root complex (RC) and endpoint (EP) configuration headers contain 4096 bytes of address space. To access a register within the header, both the extended register number and the register number fields are concatenated to form the 4-byte aligned address of the register. That is, the register address is:

extended register number || register number || 0b00.

The fields of the PCI Express configuration address register are described in **Table 17-16**.

Table 17-16. PEX_CONFIG_ADDR Field Descriptions

Bits	Reset	Description	Settings
EN 31	0	**Enable** This bit allows a PCI Express configuration access when PEX_CONFIG_DATA is accessed.	0 Writing to PEX_CONFIG_DATA has no effect and reading PEX_CONFIG_DATA returns unknown data. 1 PCI Express configuration access allowed when PEX_CONFIG_DATA is accessed.
— 30–28	0	Reserved. Write to zero for future compatibility.	
EXTREGN 27–24	0	**Extended Register Number** This field allows access to extended PCI Express configuration space (that is, the registers in the offset range from 0x100 to 0xFFF).	
BUSN 23–16	0	**BUS Number** PCI bus number to access.	
DEVN 15–11	0	**Device Number** Device number to access on specified bus.	
FUNCN 10–8	0	**Function Number** Function to access within specified device.	
REGN 7–2	0	**Register Number** 32-bit register to access within specified device	
— 1–0	0	Reserved. Write to zero for future compatibility.	

17.5.1.1.2 PCI Express Configuration Data Register (PEX_CONFIG_DATA)

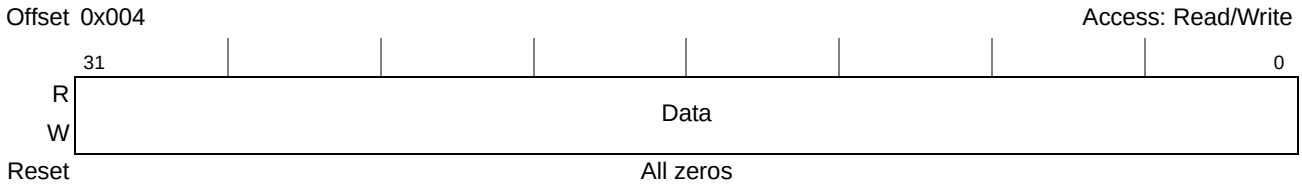

Figure 17-13. PCI Express Configuration Data Register (PEX_CONFIG_DATA)

The PCI Express configuration data register, show in **Figure 17-13**, is a 32-bit port for internal and external configuration access. Note that accesses of 1, 2, or 4 bytes to the PCI Express configuration data register are allowed. Also note that accesses to the little-endian PCI Express configuration space must be properly formatted. See **Section 17.4.1.2**, *Byte Order for Configuration Transactions*, on page 17-10 for more information. The fields of the PCI Express configuration data register are described in **Table 17-17**.

Table 17-17. PEX_CONFIG_DATA Field Descriptions

Bits	Name	Description
310	Data	A read or write to this register starts a PCI Express configuration cycle if the PEX_CONFIG_ADDR enable bit is set (PEX_CONFIG_ADDR[EN] = 1).

17.5.1.1.3 PCI Express Outbound Completion Timeout Register (PEX_OTB_CPL_TOR)

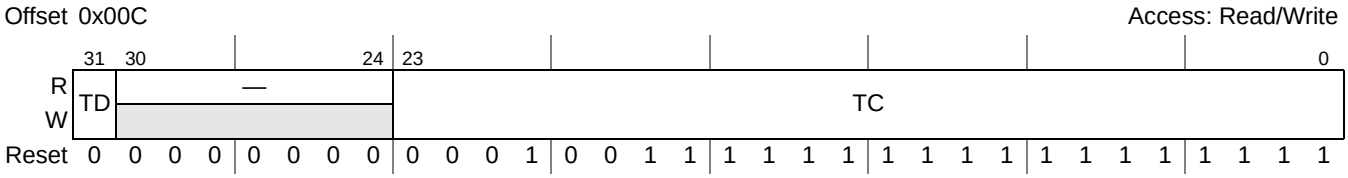

Figure 17-14. PCI Express Outbound Completion Timeout Register (PEX_OTB_CPL_TOR)

The PCI Express outbound completion timeout register, shown in **Figure 17-14**, contains the maximum wait time for a response to come back as a result of an outbound non-posted request before a timeout condition occurs. This register is also used for timeout requests that were not acknowledged (PEX_ERR_DET[PAT] which is a unrecoverable error. The outbound completion timeout register is a programmable register that represents 1/8 timeout period of a response from PCI Express. The logic uses this register's programmed value as an input to a running counter. This counter gets loaded with the timeout counter value every time a non-posted request is scheduled to PCI Express. While waiting for the response to come back, the counter gets decremented. If the response did not come back when the timer expires, then a timeout error has occurred. The specification requires a minimum of 10 ms and a maximum of 50 ms before timeout. The fields of the PCI Express outbound completion timeout register are described in **Table 17-18**.

Table 17-18. PEX_OTB_CPL_TOR Field Descriptions

Bits	Name	Description
31	TD	Timeout disable. This bit controls the enabling/disabling of the timeout function. 0 Enable completion timeout 1 Disable completion timeout
30–24	—	Reserved
23–0	TC	Timeout counter. This is the value that is used to load the response counter. of the completion timeout. The completion timeout is determined by TC and the setting of the completion timeout disable bit (CPL_TOD) in the Device Control 2 Register. **Note:** The maximum computed timeout value based on TC cannot exceed 1.072 s at 500 MHz. When Device_Control _2[CPL_TOD] is set, the timeout the TC unit is 8 x the PCI Express controller clock period; that is, one TC unit is 16 ns at 500 MHz. The following are examples of timeout periods based on 500 MHz: • 0x000_0000 Reserved • 0x010_FFFF 17.82 ms at 500 MHz controller clock. • 0xFFF_FFFF 268.43 ms at 500 MHz controller clock When Device Control 2[CPL_TOD] is cleared, the timeout value is based on TC and Device Control 2[CPL_TO_VAL]. When completion timeout value (CPL_TO_VAL) is: • 0000 the timeout value is TC • 0001 the timeout value is TC/64 • 0010 the timeout value is TC/4 • 0101 the timeout value is TC • 0110 the timeout value is TC×4 • 1001 the timeout value is TC×16 • 1010 the timeout value is TC×64 For all other values of completion timeout the timeout value is TC.

17.5.1.1.4 PCI Express Configuration Retry Timeout Register (PEX_CONF_RTY_TOR)

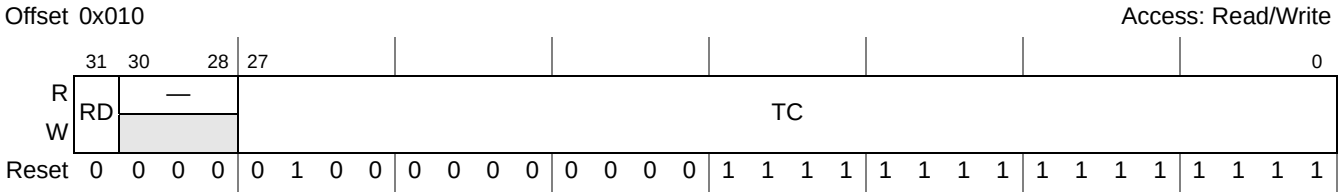

Figure 17-15. PCI Express Configuration Retry Timeout Register (PEX_CONF_RTY_TOR)

The PCI Express configuration retry timeout register, shown in **Figure 17-3**, contains the maximum time period during which retries of configuration transactions which resulted in a CRS response occur. This register is a programmable register that represents 1/8 timeout period of a configuration request is scheduled to PCI Express and a CRS response is received. While waiting for the response to come back, the counter is decremented. If a CRS response continues to be received when the timer expires, then a timeout error occurs. The logic continues to issue the same configuration request with a CRS status completion until a status other than CRS is returned or it has exceed the Configuration Timeout period. A minimum of 2^{26} PCI Express clocks is required before timeout. The fields of the PCI Express configuration retry timeout register are described in **Table 17-19**.

Table 17-19. PEX_CONF_RTY_TOR Field Descriptions

Bits	Name	Description
31	RD	Retry disable. This bit disables the retry of a configuration transaction that receives a CRS status response packet. 0 Enable retry of a configuration transaction in response to receiving a CRS status response until the timeout counter (defined by the PEX_CONF_RTY_TOR[TC] field) has expired. 1 Disable retry of a configuration transaction regardless of receiving a CRS status response.
30–28	—	Reserved
27–0	TC	Timeout counter. This is the value that is used to load the response counter. The value is 1/8 of the total timeout value. One TC unit is 8 times the PCI Express controller clock, that is, one TC unit is 16 ns at 500 MHz. The following are examples of timeout periods based on 500 MHz: • 0x000_0000 Reserved • 0x010_FFFF 1.07 s at 500 MHz controller clock. • 0xFFF_FFFF 4.30 s at 500 MHz controller clock

17.5.1.1.5 PCI Express Configuration Register (PEX_CONFIG)

Figure 17-16. PCI Express Configuration Register (PEX_CONFIG)

The PCI Express configuration register, shown in **Figure 17-4**, contains various control switches for the controller. The fields of the PCI Express configuration register are described in **Table 17-20**.

Table 17-20. PEX_CONFIG Field Descriptions

Bits	Name	Description
31–14	—	Reserved
13	OB_CK	Outbound transaction address checking enable. 0 Disable checking for all outbound transaction addresses (memory and I/O) against the base/limit registers. There is no checking of outbound addresses. This setting is compatible with the previous generation PCI Express controller behavior. 1 Enable checking for all outbound addresses (memory and I/O) against the base/limit registers. If an outbound transaction address does not hit into the base/limit registers, it will cause an error.
12–5	—	Reserved
4	SAC	Sense ASPM Control. This bit controls the default value of ASPM of PEX Link Control Register's bit 0. See **Section 17.5.1.12.11**, *PCI Express Link Control Register—0x5C,* on page 17-103 for more information.
3–2	—	Reserved
1	SP	Slot Present. This bit controls the default value of the PCI Express capabilities register [slot] bit. See **Section 17.5.1.12.6**, *PCI Express Capabilities Register—0x4E,* on page 17-99 for more information.
0	SCC	Slot Clock Configuration. This bit controls the default value of the PCI Express link status register [SCC] bit. See **Section 17.5.1.12.12**, *PCI Express Link Status Register—0x5E,* on page 17-103 for more information.

17.5.1.1.6 PCI Express Interrupt Status Register (PEX_INT_STAT)

Reset	All zeros											

Figure 17-18. PCI Express PME and Message Detect Register (PEX_PME_MES_DR)

The PCI Express PME and message detect register, shown in **Figure 17-5**, logs inbound messages and PME events that are detected by the PCI Express controller. This register is a write-1-to-clear type register.The fields of the PCI Express PME and message detect register are described in **Table 17-22**.

Table 17-22. PEX_PME_MES_DR Field Descriptions

Bits	Name	Description
31–16	—	Reserved
15	PTO	PME turn off. This bit indicates the detection of a PME_Turn_Off message. This bit is only valid in EP mode. 1 A PME_Turn_Off_message is detected 0 No PME_Turn_Off message detected
14	—	Reserved. Note that during normal operation, this bit may be set (falsely). The bit may be ignored and cleared (w1c) without consequence.
13	ENL23	Entered L2/L3 ready state. This bit indicates that the PCI Express controller has entered L2/L3 state. This is only valid in RC mode. 1 L2/L3 ready state has been entered 0 L2/L3 ready state has not been entered
12	EXL23	Exit L2/L3 ready state. This bit indicates that the PCI Express controller has exited the L2/L3 state. This is only valid in RC mode. 1 Exit L2/L3 state has been detected 0 Exit L2/L3 state not detected
11	—	Reserved. Note that during normal operation, this bit may be set (falsely). The bit may be ignored and cleared (w1c) without consequence.
10	HRD	Hot reset detected. This bit indicates that the PCI Express controller has detected a hot reset condition on the link. The controller will be reset and will clean up all outstanding transactions. Link retraining will take place once hot reset state is exited. This is valid only in EP mode. 1 Hot reset request has been detected 0 Hot reset request not detected
9	LDD	Link down detected. This bit indicates that a link down condition has been detected. The controller will be reset and then will clean up all outstanding transactions. Link retraining will take place once the controller has cleaned itself up. 1 Link down has been detected 0 Link down not detected
8	AILDD	Ack-timeout induced link down detected. This bit indicates that a link down condition has been detected due to an internal timeout condition. The controller is reset and then cleans up all outstanding transactions. Link retraining takes place once the controller has cleaned itself up. No LDD will be set if this bit is set. 1 Ack timeout link down has been detected 0 Ack timeout link down not detected
7	LUD	Link up detected. This bit indicates that a link up condition has been detected. It means that link training has been successful. 1 Link up detected 0 Link up not detected

Table 17-22. PEX_PME_MES_DR Field Descriptions (Continued)

Bits	Name	Description
6–0	—	Reserved

17.5.1.2.2 PCI Express PME and Message Disable Register (PEX_PME_MES_DISR)

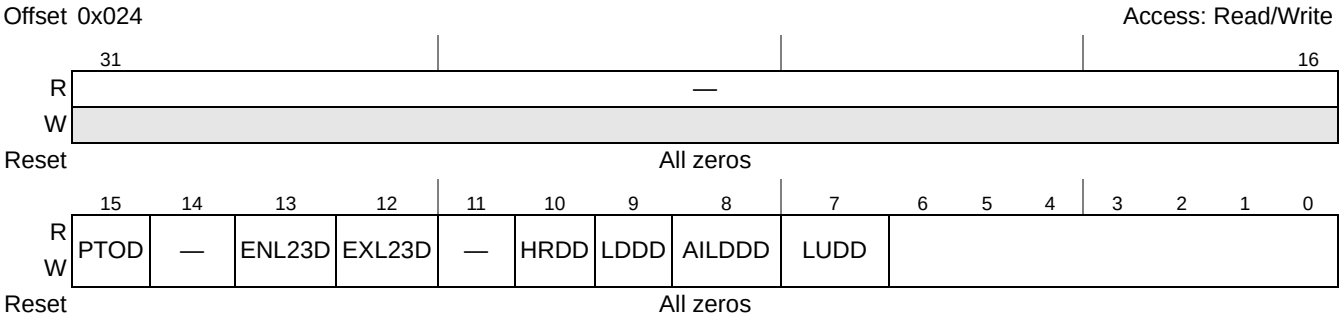

Figure 17-19. PCI Express PME and Message Disable Register (PEX_PME_MES_DISR)

The PCI Express PME and message disable register, shown in Figure 17-19, when set, prevents the detection of the corresponding bits in the PCI Express PME and message detect register. The fields of the PCI Express PME and message disable register are described in **Table 17-23**.

Table 17-23. PEX_PME_MES_DISR Field Descriptions

Bits	Name	Description
31–16	—	Reserved
15	PTOD	PME turn off disable. When set will disable the setting of PEX_PME_MES_DR[PTO] bit. 1 Disable PME_Turn_Off_message detection 0 Enable PME_Turn_Off message detection
14	—	Reserved
13	ENL23D	Entered_L2/L3 ready disable. When set will disable the setting of PEX_PME_MES_DR[ENL23] bit. 1 Disable Entered_L2/L3 ready state detection 0 Enable Entered_L2/L3 ready state detection
12	EXL23D	Exited_L2/L3 ready disable. When set will disable the setting of PEX_PME_MES_DR[EXL23] bit. 1 Disable Exited_L2/L3 ready state detection 0 Enable Exited_L2/L3 ready state detection
11	—	Reserved
10	HRDD	Hot reset detected disable. When set will disable the setting of PEX_PME_MES_DR[HRD] bit. 1 Disable hot reset state detection 0 Enable hot reset state detection
9	LDDD	Link down detected disable. When set will disable the setting of PEX_PME_MES_DR[LDD] bit. 1 Disable link down state detection 0 Enable link down state detection
8	AILDDD	Ack time-out induced link down detected disable. When set, this bit disables the setting of PEX_PME_MES_DR[AILDD] bit. 1 Disable ack time-out link down state detection 0 Enable ack time-out link down state detection
7	LUDD	Link up detected disable. When set, this bit disables the setting of PEX_PME_MES_DR[LUD] bit. 1 Disable link up detection 0 Enable link up detection
6–0	—	Reserved

17.5.1.2.3 PCI Express PME and Message Interrupt Enable Register (PEX_PME_MES_IER)

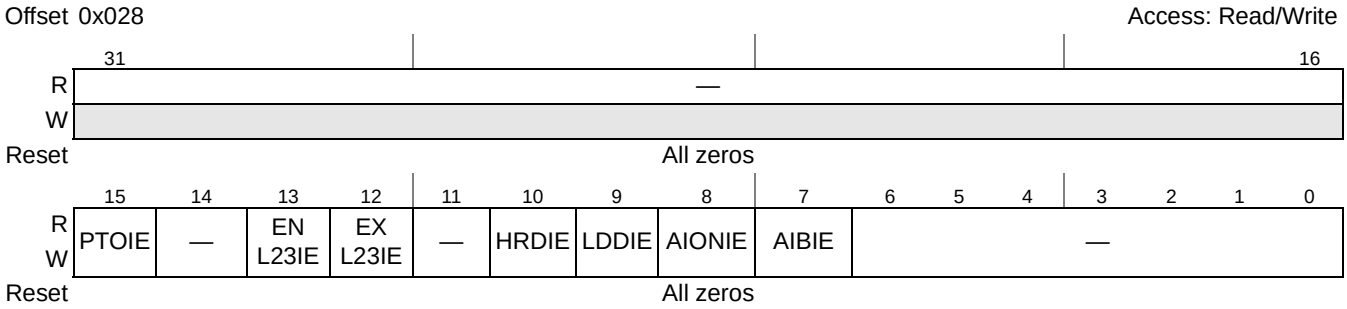

Figure 17-20. PCI Express PME and Message Interrupt Enable Register (PEX_PME_MES_IER)

The PCI Express PME and message interrupt enable register, shown in **Figure 17-7**, allows for the detection of a message or a PME event to generate an interrupt, provided that the corresponding bit in the PCI Express PME and message detect register is set. **Table 17-24** shows the fields of the PCI Express PME and message interrupt enable register.

Table 17-24. PEX_PME_MES_IER Field Descriptions

Bits	Name	Description
31–16	—	Reserved
15	PTOIE	PME turn off interrupt enable. When set and PEX_PME_MES_DR[PTO]=1 will generate an interrupt. 1 Enable PME_Turn_Off_message interrupt generation 0 Disable PME_Turn_Off message interrupt generation
14	—	Reserved
13	ENL23IE	Entered L2/L3 ready interrupt enable. When set and PEX_PME_MES_DR[ENL23]=1 will generate an interrupt. 1 Enable Entered_L2/L3 ready state interrupt generation 0 Disable Entered_L2/L3 ready state interrupt generation
12	EXL23IE	Exited L2/L3 ready interrupt enable. When set and PEX_PME_MES_DR[EXL23]=1 will generate an interrupt. 1 Enable Exited_L2/L3 ready state interrupt generation 0 Disable Exited_L2/L3 ready state interrupt generation
11	—	Reserved
10	HRDIE	Hot reset detected interrupt enable. When set and PEX_PME_MES_DR[HRD]=1 will generate an interrupt. 1 Enable hot reset state interrupt generation 0 Disable hot reset state interrupt generation
9	LDDIE	Link down detected interrupt enable. When set and PEX_PME_MES_DR[LDD]=1 will generate an interrupt. 1 Enable link down state interrupt generation 0 Disable link down state interrupt generation
8	AILDDIE	Ack time-out induced link down detected interrupt enable. When set and PEX_PME_MES_DR[AILDD]=1 generates an interrupt. 1 Enable ack time-out link down state interrupt generation 0 Disable ack time-out link down state interrupt generation
7	LUDIE	Link up detected interrupt enable. When set and PEX_PME_MES_DR[LUD]=1 generates an interrupt. 1 Enable link up detected interrupt generation 0 Disable link up detected interrupt generation
6–0	—	Reserved

17.5.1.2.4 PCI Express Power Management Command Register (PEX_PMCR)

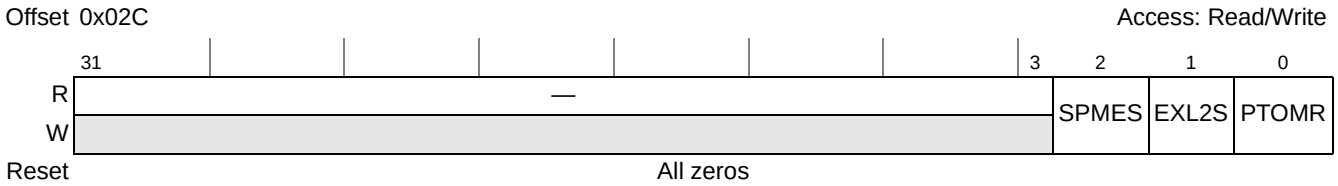

Figure 17-21. PCI Express Power Management Command Register (PEX_PMCR)

The PCI Express power management command register, shown in **Figure 17-8**, provides software a mechanism to allow the PCI Express controller to get back to L0 link state. The fields of the PCI Express power management command register are described in **Table 17-25**.

Table 17-25. PEX_PMCR Field Descriptions

Bits	Name	Description
31–3	—	Reserved
2	SPMES	Set PME status. This sets the PME status bit and if PME is enabled (see **Section 17.5.1.12.3**, *PCI Express Power Management Status and Control Register—0x48*, on page 17-98, for more information) it transmits a PM_PME message upstream. This bit should not be used when in RC mode. This bit is self-clearing.
1	EXL2S	Exit L2 state. When set exits the link state out of L2/L3 ready state in order to send new requests. The request is only made when entered_L2/L3 ready state is active. This bit is self-clearing. When the link has exited L2/L3 ready state, the status bit Exit_L2/L3 ready state is set. This bit should not be used when in EP mode.
0	PTOMR	PME_Turn_Off message request. When set broadcasts a PME turn_off message. This bit should not be used when in EP mode. This bit is self-clearing

17.5.1.3 PCI Express Link Width Control Register (PEX_LWCR)

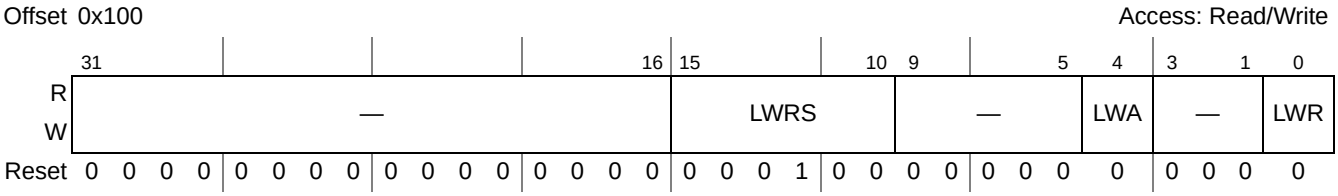

Figure 17-22. PCI Express Link Width Control Register (PEX_LWCR)

The PCI Express link width control register provides software a mechanism to dynamically changing the link width.

Table 17-26. PEX_LWCR Field Descriptions

Bits	Name	Description
31–16	—	Reserved
15–10	LWRS	Link width request size. These bits indicate the size of the link width request. Software should first read the PEX_LWSR[LD] bits to determine what are the valid lanes to request before initializing this field. 000001 - x1 link 000010 - x2 link 000100 - x4 link 001000 - x8 link All other encodings are reserved and should not be used.

Table 17-26. PEX_LWCR Field Descriptions (Continued)

Bits	Name	Description
9–5	—	Reserved
4	LWA	Link width auto. This bit is settable by software.
3–1	—	Reserved
0	LWR	Link width request. This bit when set by software will initiate a change in link width as indicated by LWRS. Once the link width operation finishes, this bit is cleared by hardware.

17.5.1.4 PCI Express Link Width Status Register (PEX_LWSR)

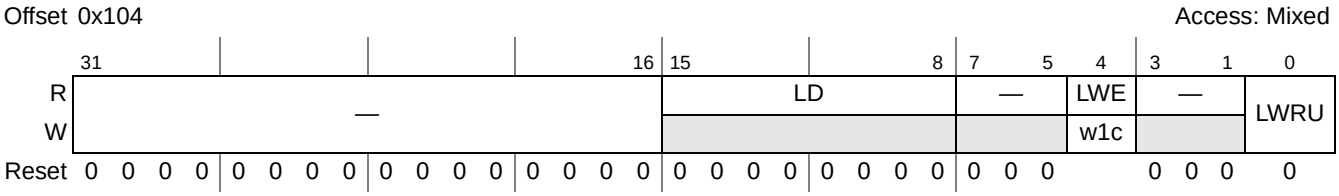

Figure 17-23. PCI Express Link Width Status Register (PEX_LWSR)

The PCI Express link width status register provides software a mechanism to dynamically changing the link width.

Table 17-27. PEX_LWSR Field Descriptions

Bits	Name	Description
31–16	—	Reserved
15–8	LD	Lane detected. Each bit indicates a corresponding lane was detected when coming out of the Detect state. For example, a value of 00000001 means only one lane was detected; a value of 00000011 means 2 lanes were detected.
7–5	—	Reserved
4	LWE	Link width error. An error has been detected when making a link width change request. 0 no error 1 error has been detected. The following conditions will cause an error to be detected. • PEX_LWCR[LWR]=1 and PEX_LWCR[LWA]=1 and Hardware Autonomous Width Disable bit is set in Link Control 2 register • PEX_LWCR[LWR] = 1 and PEX_LWCR[LWRS] > current link width and not upconfig capable • PEX_LWCR[LWR] = 1 and PEX_LWCR[LWRS] width is not to available lanes • PEX_PME_MES_DR[LWD]=1 and current width != PEX_LWCR[LWRS]
3–1	—	Reserved
0	LWU	Link width upconfiguration capable. It means that the link is capable of a size up request.

17.5.1.5 PCI Express Link Speed Control Register (PEX_LSCR)

Offset 0x108 Access: Read/Write

	31–16	15–12	11–5	4	3–2	1	0
R W	—	LSRS	—	LSA	—	LSM	LSR
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 1 0	0 0 0 0 0 0 0	0	0 0	0	0

Figure 17-24. PCI Express Link Speed Control Register (PEX_LSCR)

The PCI Express link speed control register provides software a mechanism to dynamically changing the link speed.

Table 17-28. PEX_LSCR Field Descriptions

Bits	Name	Description
31–16	—	Reserved
15–12	LSRS	Link speed request size. These bits indicate the size of the link speed request. Its default value is set by configuration pins. Software should first determine the link partner's advertised speed by reading PEX_LSSR[LPAS] bits before initializing these bits. 0001 - 2.5 Gb/s speed 0010 - 5.0 Gb/s speed All other encodings are reserved and should not be used.
11–5	—	Reserved
4	LSA	Link speed auto. This bit is settable by software. It is gated with the Hardware Autonomous Speed Disable bit.
3-2	—	Reserved
1	LSM	Link speed mask. This bit when set indicate that 5.0 Gb/s speed is not supported. Its default value is set by configuration signals. If the controller is advertising that 5.0 Gb/s is supported and its link partner is also supporting 5.0Gb/s, then it is not possible to train down to 2.5 Gb/s unless this bit is set.
0	LSR	Link speed request. This bit when set by software will initiate a change in link speed as indicated by LSRS. Once the link speed operation finishes, this bit is cleared by hardware.

Note: The RCW bit PFREQ has no effect on the speed at which the PCI Express runs after power-on reset. The PCI Express controller runs at 5 Gbaud after the system exits reset if the external PCI Express controller is a Gen2 device and the PCI Express controller cannot train to 2.5 Gbaud after exiting power-on reset if the external device supports Gen2 speed even if value of RCW Bit PFREQ = 1 (2.5 Gbaud). To run the PCI Express controller at 2.5 Gbaud, write the specified values to the following fields in PEX_LSCR (offset 0x108):

- PEX_LSCR[LSRS] = 0b0001
- PEX_LSCR[LSM] = 0b1
- PEX_LSCR[LSR] = 0b1

This allows the PCI Express controller to train to 2.5 Gbaud.

17.5.1.8 PCI Express ATMU Registers

17.5.1.8.1 PCI Express Outbound ATMU Registers

The outbound address translation windows must be aligned based on the granularity selected by the size fields. Outbound window misses use the default outbound register set (outbound ATMU window 0). Overlapping outbound windows are not supported and will cause undefined behavior. Note that for RC mode, all outbound transactions post ATMU must hit either into the memory base/limit range or the prefetchable memory base/limit range defined in the PCI Express type 1 header. For EP mode, there is no such requirement.

Note that in RC mode, when PEX_CONFIG[OB_CK] is set, the translated address of an outbound transaction must fall into either the memory base/limit range, the prefetchable memory base/limit range, or I/O base/limit range. The transaction will be terminated if the translated address does not fall within these ranges.

Figure 17-28 shows the outbound transaction flow.

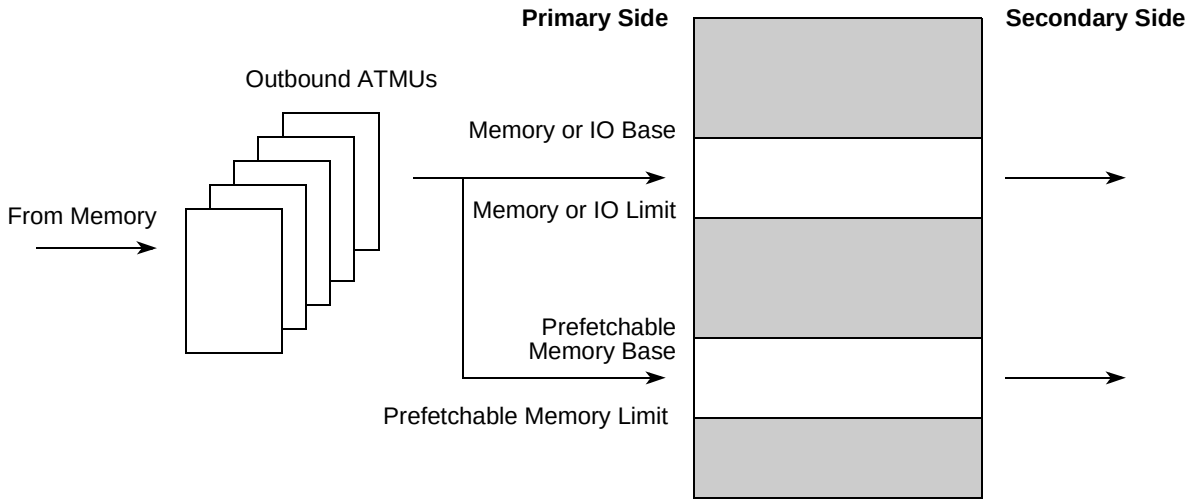

Figure 17-28. RC Outbound Transaction Flow

However, accesses that miss all other windows and hit outside the default window will be aliased to the default window. 000000 Reserved ... 001011 4-Kbyte window size 001100 8-Kbyte window size ... 011111 4-Gbyte window size 100000 8-Gbyte window size 100001 16-Gbyte window size 100010 32-Gbyte window size 100011 64-Gbyte window size 100100 Reserved ... 111111 Reserved

17.5.1.8.6 PCI Express Inbound ATMU Registers

There are differences between RC and EP implementations of inbound ATMU registers as described in the following sections.

17.5.1.8.7 EP Inbound ATMU Implementation

All base address registers (BARs) reside in the PCI Express type 0 configuration header space which is accessible via PEX_CONFIG_ADDR/PEX_CONFIG_DATA mechanism. Note that host software must program these BAR using configuration type 0 cycles. There are 4 inbound BARs.

- Default inbound window BAR0 at configuration address 0x10 (32-bit). Also known as PEXCSRBAR. This window can be used as either a fixed Mbyte window used for inbound memory transactions that access memory-mapped registers or it can be programmed as a general purpose window for local memory access.
- Inbound window BAR1 at configuration address 0x14 (32-bit)
- Inbound window BAR2 at configuration address 0x18-0x1c (64-bit)
- Inbound window BAR3 at configuration address 0x20-0x24 (64-bit)

The PCI Express controller does not implement a shadow of the inbound BARs in the memory-mapped register set. However, when there is a hit to the BAR(s), the PCI Express controller uses the corresponding translation and attribute registers in the memory-mapped register set for the translation. If the transaction hits multiple BARs, then the lowest-numbered BAR will be used.

17.5.1.8.8 RC Inbound ATMU Implementation

In RC mode, the PEXIWBAR[1–3] registers reside outside of the type 1 header; PEXIWBAR0 is the only inbound BAR that resides in the Type 1 header (at offset 0x10).

If the transaction hits any window, the translation is performed and then the transaction is sent to memory. If there is no hit to any one of the BARs, then a UR completion will be returned for non-posted transactions. All posted transactions with no BAR hit are ignored.

Figure 17-34 shows the inbound transaction flow in RC mode.

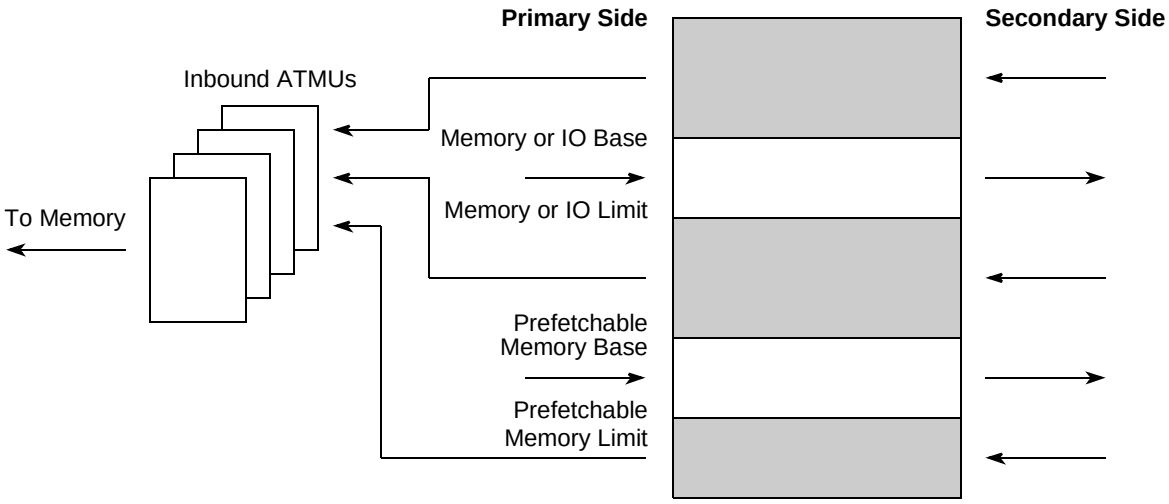

Figure 17-34. RC Inbound Transaction Flow

Figure 17-36. PCI Express Inbound Window Base Address Registers (PEXIWBAR*n*)

The PCI Express inbound window base address registers select the base address for the windows that are translated to an alternate target address space. In root complex (RC) mode, addresses for inbound transactions are compared to these windows. In RC mode, PEXIWBAR0 is located in the PCI Express type 1 configuration header space and PEXIWBAR[1–3] registers are implemented as described in this section. In endpoint (EP) mode, these registers are not implemented in the memory-mapped space. Reading these registers in EP mode returns all zeros and writing to these offsets has no effect. All base address registers in EP are located in the PCI Express type 0 configuration header space. Note that PEXIWBAR1 only supports 32-bit PCI Express address space.

Table 17-37 describes the fields of the PCI Express inbound window base address registers.

Table 17-37. PEXIWBAR*x* Field Descriptions

Bit	Name	Description
WBEA 31–20	WBEA	Window base extended address. This field corresponds to PCI Express address bits [31:20]. Note that the extended address is supported for windows 2 and 3 only; for PEXIWBAR0 and PEXIWBAR1, these bits are reserved and must be 0.
WBA 19–0	WBEA	Window base extended address. This field corresponds to PCI Express address bits [19:0].

The PCI Express inbound window attributes registers define the window sizes to translate and other attributes for the translations. 64 Gbytes is the largest window size allowed. **Table 17-39** describes the fields of the PCI Express inbound window attributes registers.

Table 17-39. PEXIWAR*x* Field Descriptions

Bit	Description	Settings
EN 31	**Enable Address Translation** Set to 1 and read-only for default window 0.	0 Disable inbound window translation. 1 Enable inbound window translation.
— 30	Reserved. Write to zero for future compatibility.	
PF 29	**Prefetchable** This bit indicates that the address space is prefetchable. This bit corresponds to the prefetchable bit in the BAR in the PCI Express type 0 header. This bit drives the BAR prefetchable bit in EP mode.	0 Not prefetchable 1 Prefetchable
— 28–24	Reserved. Write to zero for future compatibility.	
TRGT 23–20	**Target Interface** This field selects the interface to which the inbound transaction is sent. See **Section 15.4** for information about the OCN-to-MBus bridges.	0000 OCN-to-MBus Bridge 1 1110 OCN-to-MBus Bridge 0 1111 CCSR space All others reserved.
RTT 19–16	**Read Transaction Type** Transaction type to run on the local memory if the access is a read.	Not a local memory space access: 0100 Read. All others reserved.
WTT 15–12	**Write Transaction Type** Transaction type to run on local memory if access is a write.	Not a local memory space access: 0100 Write All others reserved.

Table 17-39. PEXIWAR*x* Field Descriptions (Continued)

Bit	Description	Settings
— 11–6	Reserved. Write to zero for future compatibility.	
IWS 5–0	**Window Size** Inbound translation window size N which is the encoded $2^{(N+1)}$-bytes window size. The smallest window size is 4 Kbytes. For EP mode, this field directly controls the size of the BARs.	001011 4-Kbyte window size 001100 8-Kbyte window size to in 4-Kbyte increments 011111 4-Gbyte window size 100000 8-Gbyte window size 100001 16-Gbyte window size 100010 32-Gbyte window size 100011 64-Gbyte window size All others reserved.

Note: When using the same OCN-to-MBus (O2M) for Read and Write transactions, the write transactions may write incorrect data for specific access sequences. To preclude this scenario, use one bridge for Write transactions and the other bridge for read transactions.

17.5.1.8.13 PCI Express MSI Inbound Translation Address Register (PEXMSIITAR)—RC Mode Only

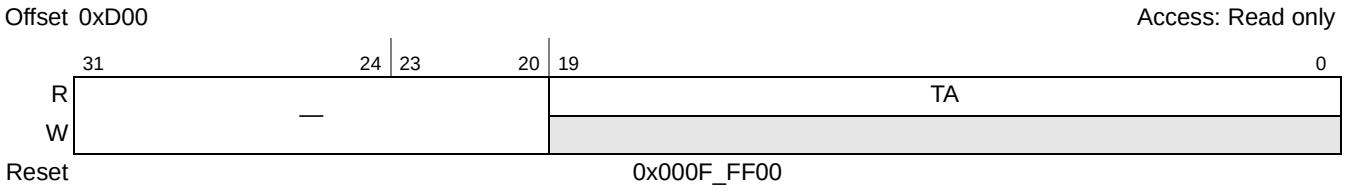

Figure 17-37. PCI Express MSI Inbound Translation Address Register (PEXMSIITAR)

The PCI Express MSI inbound translation address register, shown in **Figure 17-37**, contains the translated internal platform address to be used. The translated address is always mapped to CCSR space similarly to PEXITAR0. This register only applies in RC mode.**Table 17-40** describes the fields of the PCI Express MSI inbound translation address register.

Table 17-40. PCI Express MSI Inbound Translation Address Register Field Descriptions

Bits	Name	Description
31–20	—	Reserved
19–0	TA	Translation address. Target address which indicates the starting point of the inbound translated address. Mapped to the CCSR range.

17.5.1.8.14 PCI Express MSI Inbound Window Base Address Register (PEXMSIIWBAR)—RC Mode Only

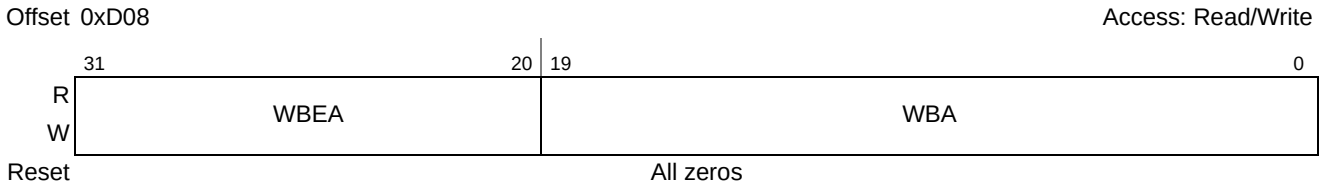

Figure 17-38. PCI Express MSI Inbound Window Base Address Register (PEXMSIIWBAR)

The PCI Express MSI inbound window base address register, shown in **Figure 17-38**, selects the base address for the windows which are translated to an alternate target address space. In root complex (RC) mode, addresses for the 64-bit MSI inbound transactions are compared to this window. This register only applies in RC mode. **Table 17-41** describes the fields of the PCI Express MSI inbound window base address registers.

Table 17-41. PCI Express MSI Inbound Window Base Address Register Field Descriptions

Bits	Name	Description
31–20	WBEA	Window base extended address. This field corresponds to PCI Express address bits [43:32].
19–0	WBA	Window base address. Source address which is the starting point for the inbound translation window. The window must be aligned based on the size selected in the window size bits. This corresponds to PCI Express address bits [31:12].

17.5.1.8.15 PCI Express MSI Inbound Window Base Extended Address Registers (PEXMSIIWBEAR)—RC Mode Only

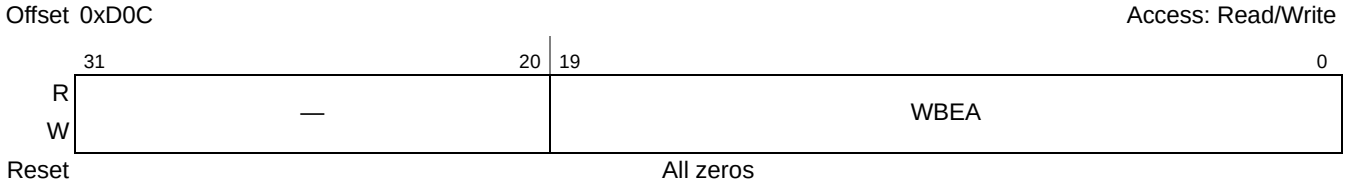

Figure 17-39. PCI Express MSI Inbound Window Base Extended Address Register (PEXMSIIWBEAR)

The PCI Express MSI inbound window base extended address register, shown in **Figure 17-39**, contains the most-significant bits of a 64-bit MSI base address. This register only applies in RC mode. **Table 17-42** describes the fields of the PCI Express MSI inbound window base extended address registers.

Table 17-42. PCI Express MSI Inbound Window Base Extended Address Register Field Descriptions

Bits	Name	Description
31–20	—	Reserved
19–0	WBEA	Window base extended address. This field corresponds to PCI Express address bits [63:44]

17.5.1.8.16 PCI Express MSI Inbound Window Attributes Registers (PEXMSIIWAR)—RC Mode Only

Figure 17-40. PCI Express MSI Inbound Window Attributes Register (PEXMSIIWAR)

The PCI Express MSI inbound window attributes register, shown in **Figure 17-40**, defines the window sizes to translate and other attributes for the translations. The size is fixed at -M window. This register only applies in RC mode. **Table 17-43** describes the fields of the PCI Express MSI inbound window attributes register.

Table 17-43. PCI Express MSI Inbound Window Attribute Register Field Descriptions

Bits	Name	Description
31	EN	Enable. This bit controls the enabling/disabling of the MSI translation window. 0 Disable inbound window translation 1 Enable inbound window translation
30	—	Reserved
29	PF	Prefetchable. This bit indicates that the address space is prefetchable. This bit corresponds to the prefetchable bit in the BAR in the PCI Express type 0 header. This bit drives the BAR's prefetchable bit in EP mode. 0 Not prefetchable 1 Prefetchable
28–24	—	Reserved
23–20	.TRGT	Target Interface. This field selects the interface to which the inbound transaction is sent. 1111 CCSR space All others reserved.
19–16	RTT	Read transaction type. Read transaction type to send to target interface. 0100 Read All others reserved.
15–12	WTT	Write transaction type. Write transaction type to send to target interface. 0100 Write All others reserved.

Table 17-43. PCI Express MSI Inbound Window Attribute Register Field Descriptions

Bits	Name	Description
11–6	—	Reserved
5–0	IWS	Inbound window size. Inbound translation window size N which is the encoded $2^{(N + 1)}$-bytes window size. The smallest window size is 4 Kbytes. For EP mode, this field directly controls the size of the BARs. This field is driven by config pin 000000 Reserved ... 001010 Reserved 001011 4-Kbyte window size 001100 8-Kbyte window size ... 011111 4-Gbyte window size 100000 8-Gbyte window size 100001 16-Gbyte window size 100010 32-Gbyte window size 100011 64-Gbyte window size 100100 Reserved ... 111111 Reserved

Figure 17-41. PCI Express Error Detect Register (PEX_ERR_DR)

The PCI Express error detect register, shown in **Figure 17-41**, contains error status bits that are detected by hardware.The detected error bits are write-1-to-clear type registers. Reading from these registers occurs normally; however, write operations can clear but not set bits. A bit is cleared whenever the register is written, and the data in the corresponding bit location is a 1. For example, to clear bit 6 and not affect any other bits in the register, the value 0b0200_0000 is written to the register. When an error is detected the appropriate error bit is set. Subsequent errors will set the appropriate error bits in the error detection registers, but only the first error for a particular unit will have any relevant information captured. The interrupt enable bits are used to allow or block the error reporting to the interrupt mechanism while the disable bits are used to prevent or allow the setting of the status bits.**Table 17-44** describes the fields of the PCI Express error detect register.

Table 17-44. PCI Express Error Detect Register Field Descriptions

Bits	Name	Description
31	ME	Multiple errors. Detecting multiple errors of the same type. An error is considered as multiple error when its detect bit is set and the same error is occurring again. Note that this bit does not track the ordering of when the error occurs. 1 Multiple errors were detected. 0 Multiple errors were not detected.
30–24	—	Reserved
23	PCT	PCI Express completion time-out. A completion time-out condition was detected for a non-posted, outbound PCI Express transaction. An error response is sent back to the requestor. Note that a completion timeout counter only starts when the non-posted request was able to send to the link partner. 1 A completion time-out on the PCI Express link was detected. Note that a completion timeout error is a fatal error. If a completion timeout error is detected, the system has become unstable. Hot reset is recommended to restore stability of the system 0 No completion time-out on the PCI Express link detected.
22	PAT	PCI Express Ack time-out. An internal request timeout was seen. This is considered as a internal fatal error. Once this bit is set, all outstanding transactions will be canceled. No new transactions will be accepted until this bit is clear. It is expected that software needs to perform the proper clean-up operation (that is, hot reset) to get the link to function again before clearing this bit. 1 An Ack time-out on the PCI Express link was detected. 0 No Ack time-out on the PCI Express link detected.

Table 17-44. PCI Express Error Detect Register Field Descriptions (Continued)

Bits	Name	Description
21	PCAC	PCI Express completer abort (CA) completion. A completion with CA status was received. 1 A completion with CA status was detected. 0 No completion with CA status detected.
20	PNM	PCI Express no map. Detect an inbound transaction that was not mapped to any inbound windows. In RC mode, a completion without data (CPL) packet with a UR completion status is sent back to the requester and this bit is set. For EP mode, a CPL packet with a UR completion status is sent back to the requester but will not set this bit. 1 A no-map transaction was detected in RC mode. 0 No no-map transaction detected.
19	CDNSC	Completion with data not successful. A completion with data packet was received with a non successful status (that is, UR, CA or CRS status). 1 Completion with data non successful packet was detected. 0 No completion with data non successful packet detected.
18	CRSNC	CRS non configuration. A completion was detected for a non configuration cycle and with CRS status. 1 CRS non configuration packet was detected. 0 No CRS non configuration packet detected.
17	ICCA	Invalid PEX_CONFIG_ADDR/PEX_CONFIG_DATA configuration access. Access to an illegal configuration space from PEX_CONFIG_ADDR/PEX_CONFIG_DATA was detected. 1 Invalid CONFIG_ADDR/PEX_CONFIG_DATA access detected 0 No invalid PEX_CONFIG_ADDR/PEX_CONFIG_DATA access detected
16	IACA	Invalid ATMU configuration access. Access to an illegal configuration space from an ATMU window was detected. 1 Invalid ATMU configuration access was detected 0 No invalid ATMU configuration access detected
15	CRST	CRS thresholded. An outbound configuration transaction was retried and thresholded due to a CRS completion status. An error response is sent back to the requestor. See **Section 17.5.1.1.4**, *PCI Express Configuration Retry Timeout Register (PEX_CONF_RTY_TOR),* on page 17-33 for more information. 1 A CRS threshold condition was detected for an outbound configuration transaction 0 No CRS threshold condition detected
14	MIS	Message invalid size. An outbound message transaction that is greater than 4 bytes or crosses a 4-byte boundary was detected. See **Section 17.4.2.1**, *Outbound ATMU Message Generation,* on page 17-13 for more information. 1 An invalid size outbound message transaction was detected 0 No invalid size outbound message transaction detected
13	IOIS	I/O invalid size. An outbound I/O transaction that is greater than 4 bytes or crosses a 4-byte boundary was detected. 1 an invalid size outbound I/O transaction was detected 0 no invalid size outbound I/O transaction detected
12	CIS	Configuration invalid size. An outbound configuration transaction that is greater than 4 bytes or crosses a 4-byte boundary was detected. 1 An invalid size outbound configuration transaction was detected 0 No invalid size outbound configuration transaction detected
11	CIEP	Configuration invalid EP. An outbound ATMU configuration transaction request was seen when in EP mode. 1 An outbound configuration transaction while in EP was detected 0 No outbound configuration transaction in EP detected
10	IOIEP	I/O invalid EP. An outbound I/O transaction request was seen when in EP mode. 1 An outbound I/O transaction while in EP was detected 0 No outbound I/O transaction in EP detected

Table 17-44. PCI Express Error Detect Register Field Descriptions (Continued)

Bits	Name	Description
9	OAC	Outbound ATMU crossing. An outbound crossing ATMU transaction was detected. 1 An outbound transaction that hits in one window and crosses overing it was detected 0 No outbound ATMU crossing condition detected
8	IOIA	I/O invalid address. An outbound I/O transaction with a translated address of greater than 4 Gbytes was detected. 1 A greater than 4-Gbyte I/O address was detected 0 No greater than 4-Gbyte I/O address detected
7	IMBA	Invalid memory base address. An outbound memory transaction with a translated address not hitting into the Memory Base/Limit register or Prefetchable Memory Base/Limit register. Only valid in RC mode. This feature is enabled by setting PEX_CONFIG[OB_CK]. 1 Invalid memory base address was detected 0 No invalid memory base address detected
6	IIOBA	Invalid I/O base address. An outbound I/O transaction with a translated address not hitting into the IO Base/Limit register or IO Upper Base/Limit register. Only valid in RC mode. This feature is enabled by setting PEX_CONFIG[OB_CK]. 1 Invalid I/O base address was detected 0 No invalid I/O base address detected
5	LDDE	Link down data error. An outbound read transaction was issued through an ATMU window when the link was down. 1 Link down data error detected 0 No Link down data error detected
4–0	—	Reserved

Figure 17-42. PCI Express Error Interrupt Enable Register (PEX_ERR_EN)

The PCI Express error interrupt enable register, shown in **Figure 17-42**, allows interrupts to be generated when the corresponding PCI Express error detect register bits are set. **Table 17-45** describes the fields of the PCI Express error interrupt enable register.

Table 17-45. PCI Express Error Interrupt Enable Register Field Descriptions

Bits	Name	Description
31–24	—	Reserved
23	PCTIE	PCI Express completion time-out interrupt enable. When set and PEX_ERR_DR[PCT]=1 will generate an interrupt. 1 Enable PCI Express completion time-out interrupt generation 0 Disable PCI Express completion time-out interrupt generation
22	PATIE	PCI Express Ack time-out interrupt enable. When set and PEX_ERR_DR[PAT]=1 will generate an interrupt. 1 Enable PCI Express ack time-out interrupt generation 0 Disable PCI Express ack time-out interrupt generation
21	PCACIE	PCI Express CA completion interrupt enable. When set and PEX_ERR_DR[PCAC]=1 will generate an interrupt. 1 Enable completion with CA status interrupt generation 0 Disable completion with CA status interrupt generation
20	PNMIE	PCI Express no map interrupt enable. When set and PEX_ERR_DR[PNM]=1 will generate an interrupt. 1 Enable no map PCI Express packet interrupt generation 0 Disable no map PCI Express packet interrupt generation
19	CDNSCIE	Completion with data not successful interrupt enable. When this bit is set and PEX_ERR_DR[CDNSC] = 1 will generate an interrupt. 1 Enable completion with data non successful interrupt generation 0 Disable completion with data non successful interrupt generation
18	CRSNCIE	CRS non configuration interrupt enable. When this bit is set and PEX_ERR_DR[CRSNC] = 1 will generate an interrupt. 1 Enable CRS non configuration interrupt generation 0 Disable CRS non configuration interrupt generation
17	ICCAIE	Invalid PEX_CONFIG_ADDR/PEX_CONFIG_DATA configuration access interrupt enable. When set and PEX_ERR_DR[ICCA]=1 will generate an interrupt. 1 Enable invalid PEX_CONFIG_ADDR/PEX_CONFIG_DATA access interrupt generation 0 Disable invalid PEX_CONFIG_ADDR/PEX_CONFIG_DATA access interrupt generation.

Table 17-45. PCI Express Error Interrupt Enable Register Field Descriptions (Continued)

Bits	Name	Description
16	IACAIE	Invalid ATMU configuration access. When set and PEX_ERR_DR[IACA]=1 will generate an interrupt. 1 Enable invalid ATMU configuration access interrupt generation 0 Disable invalid ATMU configuration access interrupt generation
15	CRSTIE	CRS thresholded interrupt enable. When set and PEX_ERR_DR[CRST]=1 will generate an interrupt. 1 Enable CRS threshold interrupt generation 0 Disable CRS threshold interrupt generation
14	MISIE	Message invalid size interrupt enable. When set and PEX_ERR_DR[MIS]=1 will generate an interrupt. 1 Enable invalid outbound message size interrupt generation 0 Disable invalid outbound message size interrupt generation
13	IOISIE	I/O invalid size interrupt enable. When set and PEX_ERR_DR[IOIS]=1 will generate an interrupt. 1 Enable invalid outbound I/O size interrupt generation 0 Disable invalid outbound I/O size interrupt generation
12	CISIE	Configuration invalid size interrupt enable. When set and PEX_ERR_DR[CIS]=1 will generate an interrupt. 1 Enable invalid outbound configuration size interrupt generation 0 Disable invalid outbound configuration size interrupt generation
11	CIEPIE	Configuration invalid EP interrupt enable. When set and PEX_ERR_DR[CIEP]=1 will generate an interrupt. 1 Enable outbound configuration transaction while in EP mode interrupt generation 0 Disable outbound configuration transaction in EP mode interrupt generation
10	IOIEPIE	I/O invalid EP interrupt enable. When set and PEX_ERR_DR[IOIEP]=1 will generate an interrupt. 1 Enable outbound I/O transaction EP mode interrupt generation 0 Disable outbound I/O transaction EP mode interrupt generation
9	OACIE	Outbound ATMU crossing interrupt enable. When set and PEX_ERR_DR[OAC]=1 will generate an interrupt. 1 Enable outbound crossing ATMU interrupt generation 0 Disable outbound crossing ATMU interrupt generation
8	IOIAIE	I/O address invalid enable. When set and PEX_ERR_DR[IOIA]=1 will generate an interrupt. 1 Enable greater than 4G I/O address interrupt generation 0 Disable greater than 4G I/O address interrupt generation
7	IMBAIE	Invalid memory base address interrupt enable. When set and PEX_ERR_DR[IMBA]=1 will generate an interrupt. 1 Enable memory base address interrupt generation 0 Disable memory base address interrupt generation
6	IIOBAIE	Invalid I/O base address interrupt enable. When set and PEX_ERR_DR[IIOBA]=1 will generate an interrupt. 1 Enable I/O base address interrupt generation 0 Disable I/O base address interrupt generation
5	LDDEIE	Link down data error interrupt enable. When set and PEX_ERR_DR[LDDEIE]=1 will generate an interrupt. 1 Enable link down data error interrupt generation 0 Disable link down data error interrupt generation
4–0	—	Reserved

4–0	—	Reserved

17.5.1.9.4 PCI Express Error Capture Status Register (PEX_ERR_CAP_STAT)

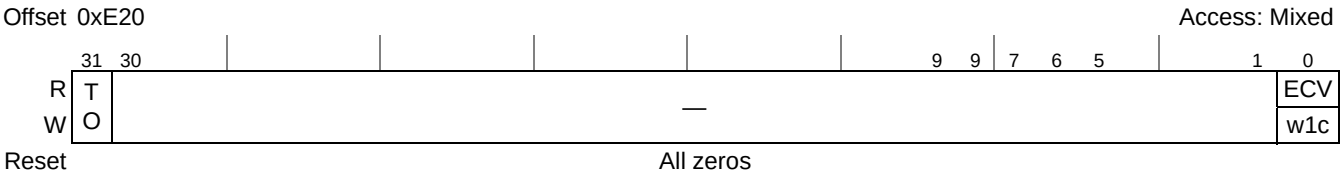

Figure 17-44. PCI Express Error Capture Status Register (PEX_ERR_CAP_STAT)

The PCI Express error capture status register, shown in **Figure 17-44**, allows vital error information to be captured when an error occurs. Note that no further error capturing is performed until the ECV bit is cleared. **Table 17-47** describes the fields of the PCI Express error capture status register.

Table 17-47. PCI Express Error Capture Status Register Field Descriptions

Bits	Name	Description
31	TO	Transaction originator. This field Indicates whether the originator of the transaction is from PEX_CONFIG_ADDR/PEX_CONFIG_DATA. 1 Transaction originated from PEX_CONFIG_ADDR/PEX_CONFIG_DATA. 0 Transaction not originated from PEX_CONFIG_ADDR/PEX_CONFIG_DATA.
30–1	—	Reserved
0	ECV	Error capture valid. This bit indicates that the capture registers 0-3 contain valid info. This bit when set indicates that the captured registers contain valid capturing information. No new capturing will be done unless this bit is cleared by writing a 1 to it.

17.5.1.9.5 PCI Express Error Capture Register 0 (PEX_ERR_CAP_R0)

Together with the other PCI Express error capture registers, PEX_ERR_CAP_R0 allows vital error information to be captured when an error occurs. Different error information is reported depending on whether the error source is from an outbound transaction from an internal source or from an inbound transaction from an external source; the source of the captured error is reflected in PEX_ERR_CAP_STAT[GSID]. Note that after the initial error is captured, no further capturing is performed until the PEX_ERR_CAP_STAT[ECV] bit is clear.

PEX_ERR_CAP_R0 for the case when the error is caused by an outbound transaction from an internal source (that is, PEX_ERR_CAP_STAT[GSID] ≠ 0h02), is shown in **Figure 17-45**.

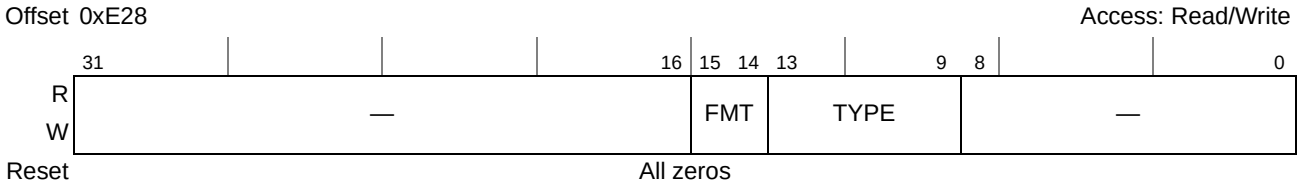

Figure 17-45. PCI Express Error Capture Register 0 (PEX_ERR_CAP_R0) Internal Source, Outbound Transaction

Table 17-48 describes the fields of the PCI Express error capture register 0 for the case when the error is caused by an outbound transaction from an internal source.

Table 17-48. PCI Express Error Capture Register 0 Field Descriptions Internal Source, Outbound Transaction

Bits	Name	Description
31–16	—	Reserved
15–14	FMT	PCI Express format. This field indicates the PCI Express packet format. See PCI Express Spec 2.0 for more information on 3 or 4 DW (4-byte) header format.
13–9	TYPE	PCI Express type. This field indicates the PCI express packet type. See PCI Express Spec 2.0 for more information on 3 or 4 DW (4-byte) header format.
8–0	—	Reserved

PEX_ERR_CAP_R0 for the case when the error is caused by an inbound transaction from an external source (that is, PEX_ERR_CAP_STAT[GSID] = 0h02 for controller 1), is shown in **Figure 17-46**.

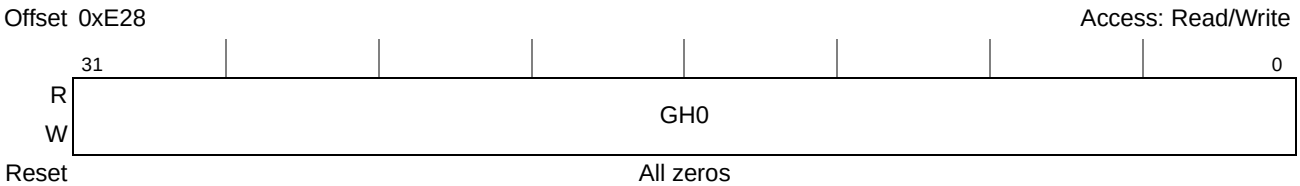

Figure 17-46. PCI Express Error Capture Register 0 (PEX_ERR_CAP_R0) External Source, Inbound Transaction

Table 17-49 describes the fields of PEX_ERR_CAP_R0 for the case when the error is caused by an inbound transaction from an external source.

Table 17-49. PCI Express Error Capture Register 0 Field Descriptions
External Source, Inbound Transaction

Bits	Name	Description
31–0	GH0	PCI Express 1st DW (4-byte) header. This field contains the PCI Express error packet's 1st DW (4-byte) header. 27–31 type 26–26 fmt 20–24 Rsv 17–19 TC 16 Rsv 14–15 length[9:8] 12–13 Rsv 10–11 Attr 9 EP 8 TD 0–7 length[7:0]

17.5.1.9.6 PCI Express Error Capture Register 1 (PEX_ERR_CAP_R1)

Together with the other PCI Express error capture registers, PEX_ERR_CAP_R1 allows vital error information to be captured when an error occurs. Different error information is reported depending on whether the error source is from an outbound transaction from an internal source or from an inbound transaction from an external source; the source of the captured error is reflected in PEX_ERR_CAP_STAT[GSID]. Note that after the initial error is captured, no further capturing is performed until the PEX_ERR_CAP_STAT[ECV] bit is clear.

PEX_ERR_CAP_R1 for the case when the error is caused by an outbound transaction from an internal source (that is, PEX_ERR_CAP_STAT[GSID] ≠ 0h02), is shown in **Figure 17-47**.

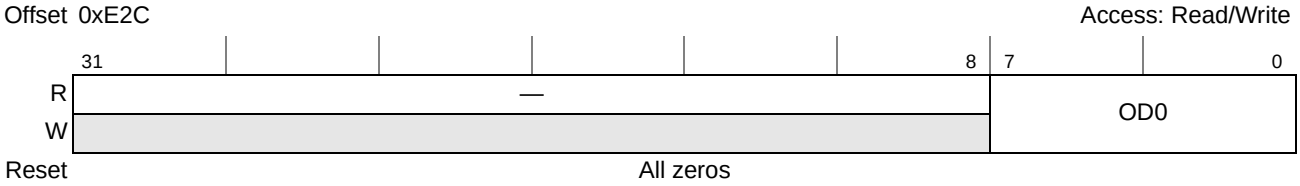

Figure 17-47. PCI Express Error Capture Register 1 (PEX_ERR_CAP_R1)
Internal Source, Outbound Transaction

Table 17-50 describes the fields of PEX_ERR_CAP_R1 for the case when the error is caused by an outbound transaction from an internal source.

Table 17-50. PCI Express Error Capture Register 1 Field Descriptions
Internal Source, Outbound Transaction

Bits	Name	Description
31–8	—	Reserved
7–0	OD0	Internal platform transaction information. Reserved for factory debug.

PEX_ERR_CAP_R1 for the case when the error is caused by an inbound transaction from an external source (that is, PEX_ERR_CAP_STAT[GSID] = 0h02 for controller 1), is shown in **Figure 17-48**.

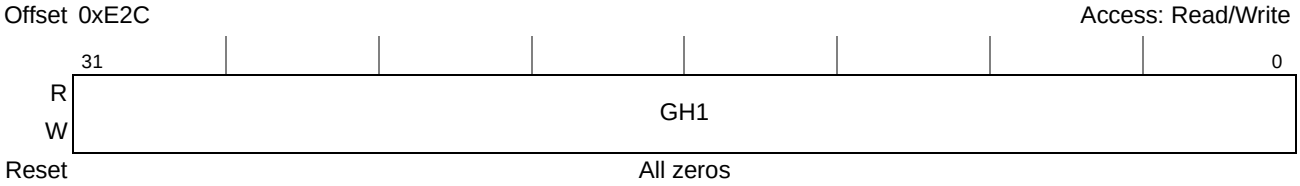

Figure 17-48. PCI Express Error Capture Register 1 (PEX_ERR_CAP_R1)
External Source, Inbound Transaction

Table 17-51 describes the fields of PEX_ERR_CAP_R1 for the case when the error is caused by an inbound transaction from an external source.

Table 17-51. PCI Express Error Capture Register 1 Field Descriptions
External Source, Inbound Transaction

Bits	Name	Description
31–0	GH1	PEX 2nd DW (4-byte) header. This field contains the PCI Express error packet's 2nd DW (4-byte) header. 24–31 Comp ID[15:8] 16–23 Comp ID[7:0] 13–15 Comp Status 12 BCM 8–11 Byte Count[11:8] 0–7 Byte Count[7:0]

17.5.1.9.7 PCI Express Error Capture Register 2 (PEX_ERR_CAP_R2)

Together with the other PCI Express error capture registers, PEX_ERR_CAP_R2 allows vital error information to be captured when an error occurs. Different error information is reported depending on whether the error source is from an outbound transaction from an internal source or from an inbound transaction from an external source; the source of the captured error is reflected in PEX_ERR_CAP_STAT[GSID]. Note that after the initial error is captured, no further capturing is performed until the PEX_ERR_CAP_STAT[ECV] bit is clear.

PEX_ERR_CAP_R2 for the case when the error is caused by an outbound transaction from an internal source (that is, PEX_ERR_CAP_STAT[GSID] ≠ 0h02), is shown in **Figure 17-49**.

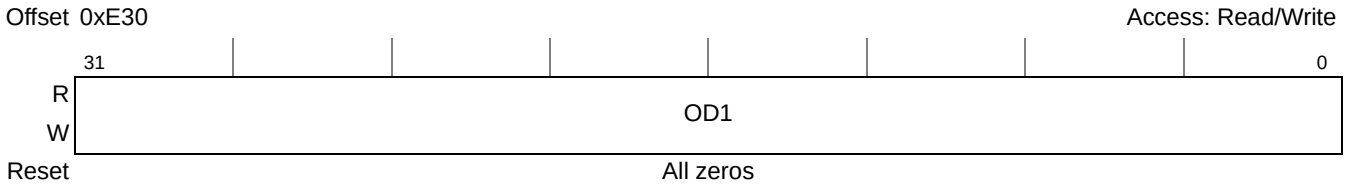

Figure 17-49. PCI Express Error Capture Register 2 (PEX_ERR_CAP_R2) Internal Source, Outbound Transaction

Table 17-50 describes the fields of PEX_ERR_CAP_R2 for the case when the error is caused by an outbound transaction from an internal source.

Table 17-52. PCI Express Error Capture Register 2 Field Descriptions Internal Source, Outbound Transaction

Bit	Name	Description
31–0	OD1	Internal platform transaction information. Reserved for factory debug.

PEX_ERR_CAP_R2 for the case when the error is caused by an inbound transaction from an external source (that is, PEX_ERR_CAP_STAT[GSID] = 0h02 for controller 1), is shown in **Figure 17-48**.

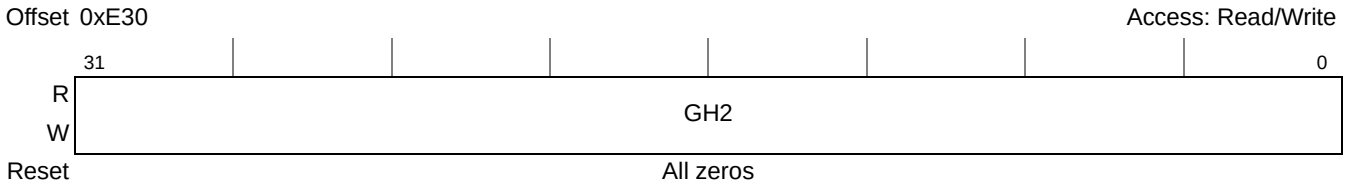

Figure 17-50. PCI Express Error Capture Register 2 (PEX_ERR_CAP_R2) External Source, Inbound Transaction

Table 17-51 describes the fields of PEX_ERR_CAP_R2 for the case when the error is caused by an inbound transaction from an external source.

Table 17-53. PCI Express Error Capture Register 2 Field Descriptions
External Source, Inbound Transaction

Bits	Name	Description
31–0	GH2	PCI Express 3rd DW (4-byte) header. This field contains the PCI Express error packet's 3rd DW (4-byte) header. 24–31 Req ID[15:8] 16–23 Req ID[7:0] 8–15 Tag[7:0] 1–7 Lower Address[6:0] 0 Rsv

17.5.1.9.8 PCI Express Error Capture Register 3 (PEX_ERR_CAP_R3)

Together with the other PCI Express error capture registers, PEX_ERR_CAP_R3 allows vital error information to be captured when an error occurs. Different error information is reported depending on whether the error source is from an outbound transaction from an internal source or from an inbound transaction from an external source; the source of the captured error is reflected in PEX_ERR_CAP_STAT[GSID]. Note that after the initial error is captured, no further capturing is performed until the PEX_ERR_CAP_STAT[ECV] bit is clear.

PEX_ERR_CAP_R3 for the case when the error is caused by an outbound transaction from an internal source (that is, PEX_ERR_CAP_STAT[GSID] ≠ 0h02), is shown in **Figure 17-51**.

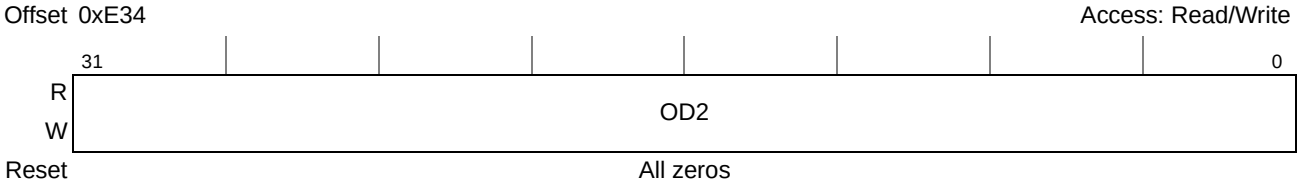

Figure 17-51. PCI Express Error Capture Register 3 (PEX_ERR_CAP_R3)
Internal Source, Outbound Transaction

Table 17-50 describes the fields of PEX_ERR_CAP_R3 for the case when the error is caused by an outbound transaction from an internal source.

Table 17-54. PCI Express Error Capture Register 3 Field Descriptions
Internal Source, Outbound Transaction

Bits	Name	Description
31–0	OD2	Internal platform transaction information. Reserved for factory debug.

PEX_ERR_CAP_R3 for the case when the error is caused by an inbound transaction from an external source (that is, PEX_ERR_CAP_STAT[GSID] = 0h02 for controller 1), is shown in **Figure 17-48**.

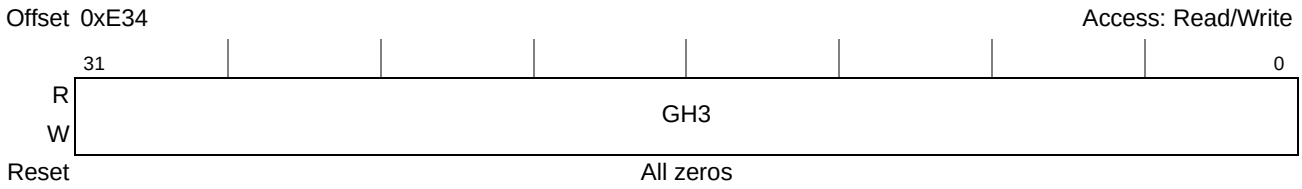

Figure 17-52. PCI Express Error Capture Register 3 (PEX_ERR_CAP_R3)
External Source, Inbound Transaction

Table 17-51 describes the fields of PEX_ERR_CAP_R3 for the case when the error is caused by an inbound transaction from an external source.

Table 17-55. PEX Error Capture Register 3 Field Descriptions
External Source, Inbound Transaction

Bits	Name	Description
31–0	GH3	PEX 4th DW (4-byte) header. This field is a don't care.

17.5.1.10 PCI Express Configuration Space Access

There are two methods of accessing the PCI Express configuration header:

- PCI Express outbound ATMU window
- PCI Express configuration access registers (PEX_CONFIG_ADDR/PEX_CONFIG_DATA)

17.5.1.10.1 RC Configuration Register Access

To access internal configuration space, software must rely on the PCI Express configuration access register (PEX_CONFIG_ADDR/ PEX_CONFIG_DATA) mechanism. To access external configuration space, software can either use configuration access registers or the outbound ATMU mechanism. For the configuration access register method, a value must be written to the PEX_CONFIG_ADDR register that specifies the PCI Express bus, the device on that bus, the function within the device, and the configuration register in that device that should be accessed. The PCI Express controller's bus number is obtained from the PCI Express configuration header (type 1). Then either a write or a read to the PEX_CONFIG_DATA register triggers the actual write or read cycle to the configuration space. Note that accesses to the little-endian PCI Express configuration space must be properly formatted. See **Section 17.4.1.2**, *Byte Order for Configuration Transactions*, on page 17-10 for more information.

Note that external configuration transactions should not be attempted until the link has successfully trained.

17.5.1.10.2 PCI Express Configuration Access Register Mechanism

There are two types of configuration transactions (Type 0 and Type 1) needed to support hierarchical bridges.

- If the bus number, and device number equal to the PCI Express controller's bus number and device number, and the function number is zero, then an internal PCI Express configuration cycle access is performed.
- If the bus number does not equal the PCI Express controller's bus number, but does equal the secondary bus number (from the type 1 header) and the device number is 0, then a Type 0 configuration transaction is sent to the PCI Express link.
- If the bus number does not equal the PCI Express controller's bus number, and does not equal the secondary bus number (from the type 1 header), and the bus number is less than or equal to the subordinate bus number (from the type 1 header), then a Type 1 configuration transaction is sent to the PCI Express link.
- If none of the above conditions occur, then the PCI Express controller returns all 1s for reads and ignores writes.

17.5.1.10.3 Outbound ATMU Configuration Mechanism (RC-Only)

Software can also program one of the outbound ATMU windows to perform a configuration access. This is accomplished by programming the ReadTType or WriteTType field of the desired PEXOWAR to 0x2. Software must only issue 4-byte or less access to the ATMU configuration window and the access cannot cross a 4-byte boundary. The bus number, device number, function number, register, and extended register number sent are decoded from the outbound translated PCI Express address.

- bus number[7:0] = PCI Express address[27:20]
- device number[4:0] = PCI Express address[19:15]
- function number[2:0] = PCI Express address[14:12]
- extended register number[3:0] = PCI Express address[11:8]
- register number[5:0] = PCI Express address[7:2]

A Type 0 configuration cycle is sent to the link if the bus number equals the secondary bus number (from the type 1 header) and device number is 0. A Type 1 configuration cycle is sent to the link if bus number does not equal primary bus and secondary bus numbers and it is less than or equal to the subordinate bus number (from the type 1 header). For all other cases, the PCI Express controller squashes the write and read will result in a response with error returned.

Note that the PCI Express controller does not support access to its internal configuration registers using the outbound ATMU mechanism. That is, the outbound ATMU mechanism must not be used to program the internal registers.

17.5.1.10.4 EP Configuration Register Access

When the PCI Express controller is configured as an EP device it responds to remote host generated configuration cycles. This is indicated by decoding the configuration command along with type 0 access in the packet. A remote host can access up to 4096 bytes of the PCI Express configuration area. While in EP mode, the PCI Express controller does not support generating configuration accesses as a master. The PCI Express Controller Internal CSR registers are not accessible by inbound PCI Express configuration transactions. Attempts to access these registers return all zeros.

All accesses to PEX_CONFIG_ADDR/PEX_CONFIG_DATA cause the device to access the internal configuration registers regardless of the bus number or device number programmed in the PEX_CONFIG_ADDR register. There is no configuration mechanism supported in EP mode using the ATMU window. If the outbound ATMU window is configured to issue a configuration transaction, all posted transactions hitting this window are ignored and all non-posted transactions will get a response with an error.

17.5.1.11 PCI Compatible Configuration Headers

The first 64 bytes of the 256-byte PCI compatible configuration space consists of a predefined header that every PCI Express device must support. The first 16 bytes of the predefined header are defined the same for all PCI Express devices. These common registers are shown in **Figure 17-53**.

Reserved

				Address Offset (Hex)
Device ID		Vendor ID		00
Status		Command		04
Class Code			Revision ID	08
BIST	Header Type	Latency Timer	Cache Line Size	0C

Figure 17-53. PCI Express PCI-Compatible Configuration Header Common Registers

The remaining 48 bytes of the header may have differing layouts depending on the function of the device. There are two header types applicable to PCI Express. Type 0 headers are typically used by endpoints; Type 1 headers are used by root complexes and switches/bridges.

17.5.1.11.1 Common PCI Compatible Configuration Header Registers

This section details the registers that are common to both type 0 and type 1 configuration headers.

17.5.1.11.2 PCI Express Vendor ID Register—Offset 0x00

The vendor ID register, shown in **Figure 17-54**, is used to identify the manufacturer of the device.

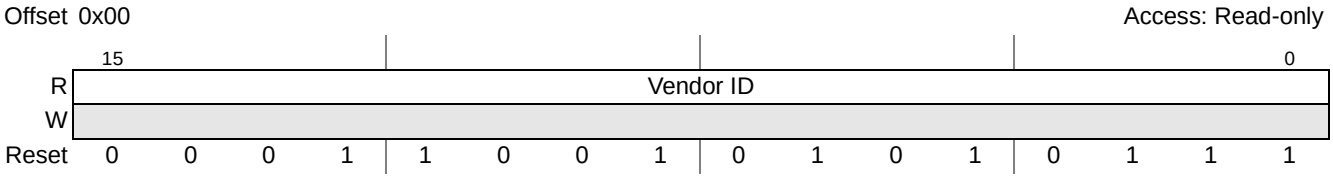

Figure 17-54. PCI Express Vendor ID Register

Table 17-56 describes the vendor ID register fields.

Table 17-56. PCI Express Vendor ID Register Field Description

Bits	Name	Description
15–0	Vendor ID	0x1957 (Freescale)

17.5.1.11.3 PCI Express Device ID Register—Offset 0x02

The device ID register, shown in **Figure 17-55**, is used to identify the device.

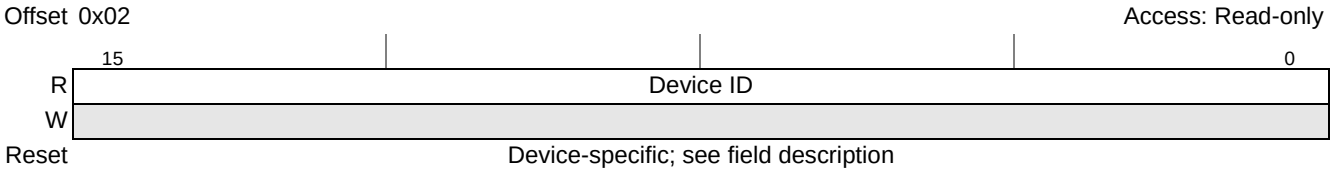

Figure 17-55. PCI Express Device ID Register

Table 17-57 describes the device ID register fields.

Table 17-57. PCI Express Device ID Register Field Description

Bits	Name	Description
15–0	Device ID	Value is 0x182A

17.5.1.11.4 PCI Express Command Register—Offset 0x04

The command register, shown in **Figure 17-56**, provides control over the ability to generate and respond to PCI Express cycles.

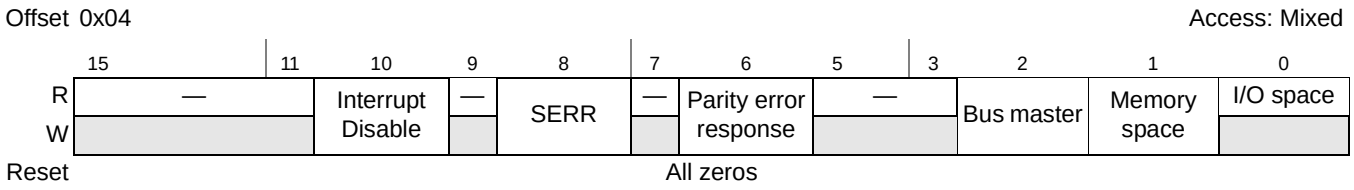

Figure 17-56. PCI Express Command Register

Table 17-58 describes the bits of the command register.

Table 17-58. PCI Express Command Register Field Descriptions

Bits	Name	Description
15–11	—	Reserved
10	Interrupt Disable	Controls the ability to generate INTx interrupt messages. 0 Enables INTx interrupt messages 1 Disables INTx interrupt messages Any INTx emulation interrupts already asserted by this device must be deasserted when this bit is set.
9	—	Reserved
8	SERR	Controls the reporting of fatal and non-fatal errors detected by the device to the root complex. 0 Disables reporting 1 Enables reporting **Note:** The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI Express device control register described in **Section 17.5.1.12.8**, *PCI Express Device Control Register—0x54,* on page 17-101 and the advance error reporting capability structure described in **Section 17.5.1.13.1** through **Section 17.5.1.13.12**.
7	—	Reserved
6	Parity error response	Controls whether this PCI Express controller responds to parity errors. 0 Parity errors are ignored and normal operation continues. 1 Parity errors cause the appropriate bit in the PCI Express status register to be set. However, note that errors are reported based on the values set in the PCI Express error enable and detection registers. **Note:** The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI Express device control register described in **Section 17.5.1.12.8**, *PCI Express Device Control Register—0x54,* on page 17-101 and the advance error reporting capability structure described in **Section 17.5.1.13.1** through **Section 17.5.1.13.12**.
5–3	—	Reserved
2	Bus master	Indicates whether this PCI Express device is configured as a master. 0 Disables the ability to generate PCI Express accesses 1 Enables this PCI Express controller to behave as a PCI Express bus master EP mode: Clearing this bit prevent the device from issuing any memory or I/O transactions. Because MSI interrupts are effectively memory writes, clearing this bit also disables the ability of the device to issue MSI interrupts. RC mode: Clearing this bit disables the ability of the device to forward memory transactions upstream. This causes any inbound memory transaction to be treated as an unsupported request.
1	Memory space	Controls whether this PCI Express device (as a target) responds to memory accesses. 0 This PCI Express device does not respond to PCI Express memory space accesses. 1 This PCI Express device responds to PCI Express memory space accesses. EP mode: Clearing this bit will prevent the device from accepting any memory transaction. RC mode: This bit is ignored. It does not affect outbound memory transaction
0	I/O space	I/O space. 0 This PCI Express device (as a target) does not respond to PCI Express I/O space accesses. 1 This PCI Express device (as a target) does respond to PCI Express I/O space accesses. EP mode: Clearing this bit will prevent the device from accepting any IO transaction. Note that this bit is a don't care in EP mode since the device does not support IO transaction. RC mode: This bit is ignored. It does not affect outbound IO transaction.

17.5.1.11.5 PCI Express Status Register—Offset 0x06

The status register, shown in **Figure 17-57**, is used to record status information for PCI Express related events.

Offset 0x06 Access: Mixed

	15	14	13	12	11	10	9	8
R	Detected parity error	Signaled system error	Received master-abort	Received target-abort	Signaled target-abort	—		Master data parity error
W	w1c	w1c	w1c	w1c	w1c			w1c
Reset	All zeros							

	7	6	5	4	3	2		0
R	—	—	—	Capabilities list	Interrupt Status	—		
W								
Reset	0	0	0	1	0	0	0	0

Figure 17-57. PCI Express Status Register

The definition of each bit is given in **Table 17-59**.

Table 17-59. PCI Express Status Register Field Descriptions

Bits	Name	Description
15	Detected parity error[1]	Set whenever a device receives a poisoned TLP regardless of the state of bit 6 in the command register.
14	Signalled system error[1]	Set whenever a device sends a ERR_FATAL or ERR_NONFATAL message and the SERR enable bit in the command register is set.
13	Received master-abort[1]	Set whenever a requestor receives a completion with unsupported request completion status.
12	Received target-abort[1]	Set whenever a device receives a completion with completer abort completion status.
11	Signalled target-abort[1]	Set whenever a device completes a request using completer abort completion status.
10–9	—	Reserved
8	Master data parity error detected[1]	Set by the requestor (primary side for Type1 headers) when either the requestor receives a completion marked poisoned or the requestor poisons a write request. Note that the parity error enable bit (bit 6) in the command register must be set for this bit to be set.
7–5	—	Reserved
4	Capabilities List	All PCI Express devices are required to implement the PCI Express capability structure.
3	Interrupt Status	Set when an INTx interrupt message is pending internally to the device. Note that this bit is associated with INTx messages and not Message Signaled Interrupts.
2–0	—	Reserved

1. The error control and status bits in the command and status registers control PCI-compatible error reporting. PCI Express advanced error reporting is controlled by the PCI Express device control register described in **Section 17.5.1.12.8**, *PCI Express Device Control Register—0x54,* on page 17-101 and the advance error reporting capability structure described in **Section 17.5.1.13.1** through **Section 17.5.1.13.12**.

17.5.1.11.6 PCI Express Revision ID Register—Offset 0x08

The revision ID register, shown in **Figure 17-58**, is used to identify the revision of the device.

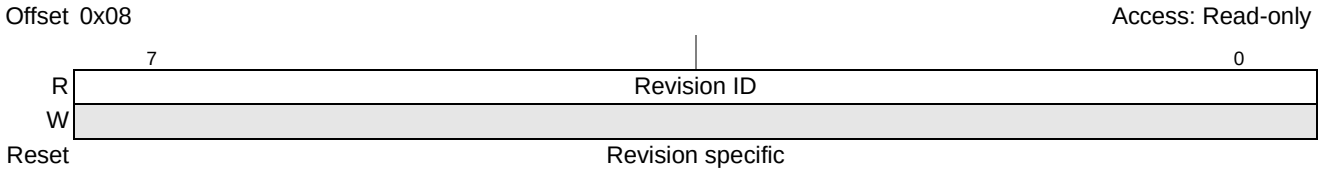

Figure 17-58. PCI Express Revision ID Register

Table 17-60 describes the revision ID register fields.

Table 17-60. PCI Express Revision ID Register Field Descriptions

Bits	Name	Description
7–0	Revision ID	Revision specific.

17.5.1.11.7 PCI Express Class Code Register—Offset 0x09

The class code register, shown in **Figure 17-59**, is comprised of three single-byte fields—base class (offset 0x0B), sub-class (offset 0x0A), and programming interface (offset 0x09)—that indicate the basic functionality of the function.

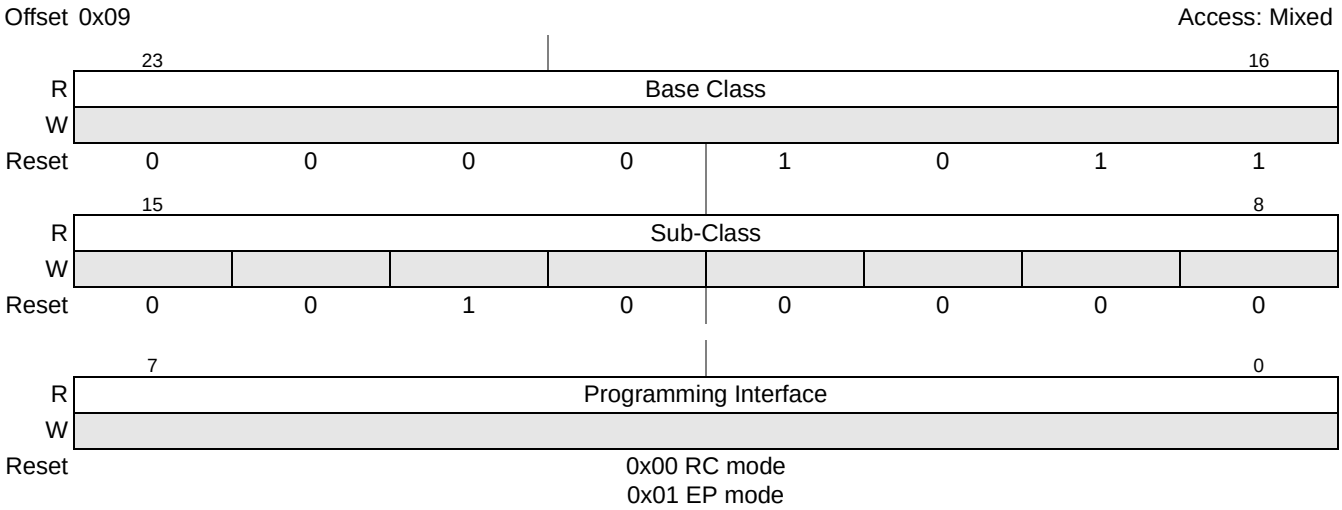

Figure 17-59. PCI Express Class Code Register

Table 17-61 describes the class code register fields.

Table 17-61. PCI Express Class Code Register Field Descriptions

Bits	Name	Description
23–16	Base Class	0x0B—Processor
15–8	Sub-Class	0x20—PowerPC
7–0	Programming Interface	0x00—RC mode 0x01—EP mode

17.5.1.11.8 PCI Express Cache Line Size Register—Offset 0x0C

The cache line size register, shown in **Figure 17-60**, is provided for legacy compatibility purposes (PCI 2.3); it is not used for PCI Express device functionality.

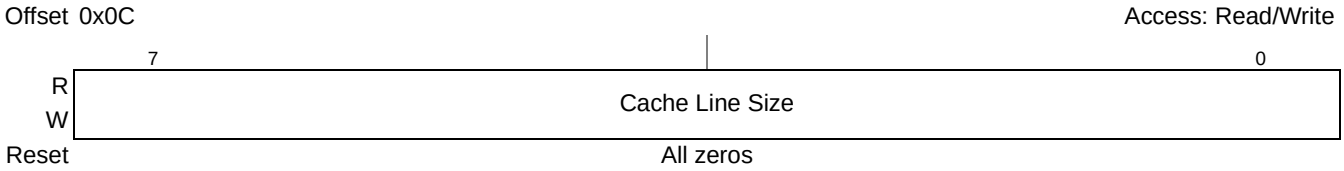

Figure 17-60. PCI Express Bus Cache Line Size Register

Table 17-62 describes the cache line size register.

Table 17-62. PCI Express Bus Cache Line Size Register Field Descriptions

Bits	Name	Description
7–0	Cache Line Size	Represents the cache line size of the processor in terms of 32-bit words (8 32-bit words = 32 bytes). Note that for PCI Express operation this register is ignored.

17.5.1.11.9 PCI Express Latency Timer Register—0x0D

The latency timer register, shown in **Figure 17-61**, is provided for legacy compatibility purposes (PCI 2.3); it is not used for PCI Express device functionality.

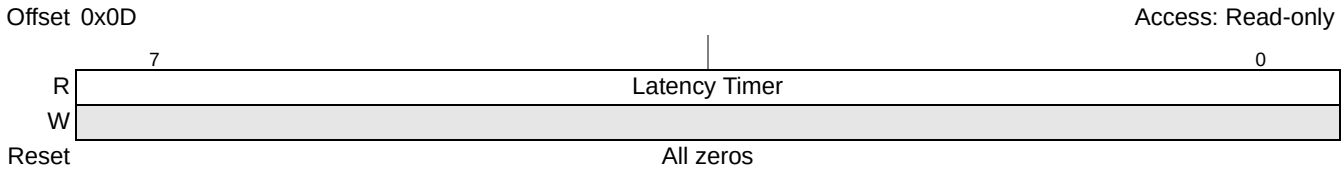

Figure 17-61. PCI Express Bus Latency Timer Register

Table 17-63 describes the PCI Express latency timer register (PLTR).

Table 17-63. PCI Express Bus Latency Timer Register Field Descriptions

Bits	Name	Description
7–0	Latency Timer	Note that for PCI Express operation this register is ignored.

17.5.1.11.10 PCI Express Header Type Register—0x0E

The PCI Express header type register, shown in **Figure 17-60**, is used to identify the layout of the PCI compatible header.

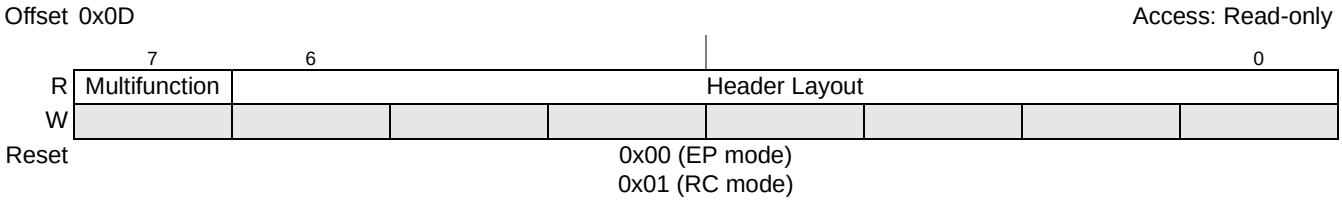

Figure 17-62. PCI Express Bus Latency Timer Register

Table 17-63 describes the PCI Express header type register.

Table 17-64. PCI Express Bus Latency Timer Register Field Descriptions

Bits	Name	Description
7	Multifunction	Identifies whether a device supports multiple functions 0 Single function device 1 Multiple function device
6–0	Header Layout	0x00 Endpoint. See **Figure 17-63** for type 0 layout. 0x01 Root Complex. See **Figure 17-75** for type 1 layout. All other encodings reserved.

17.5.1.11.11 PCI Express BIST Register—0x0F

The BIST register is optional and reserved on the PCI Express controller.

17.5.1.11.12 Type 0 Configuration Header

The type 0 header is shown in **Figure 17-63**.

Reserved			Address Offset (Hex)
Device ID		Vendor ID	00

MAX_LAT	MIN_GNT	Interrupt Pin	Interrupt Line	3C

Figure 17-63. PCI Express PCI-Compatible Configuration Header—Type 0

Section 17.5.1.11.1, *Common PCI Compatible Configuration Header Registers*, on page 17-73 describes the registers in the first 16 bytes of the header. This section describes the registers that are unique to the type 0 header beginning at offset 0x10.

17.5.1.11.13 PCI Express Base Address Registers—0x10–0x27

The PCI Express base address registers (BARs) point to the beginning of distinct address ranges which the device should claim. In EP mode, the device supports a configuration space BAR, a 32-bit memory space BAR, and two 64-bit memory space BARs. In RC mode, the device only supports the configuration space BAR in the header; the other memory spaces are defined by the inbound ATMUs. Refer to **Section 17.5.1.8.6**, *PCI Express Inbound ATMU Registers*, on page 17-50 for more information. Base address register 0 at offset 0x10 is a special fixed 1-Mbyte window that is used for inbound configuration accesses. This window is called the PCI Express configuration and status register base address register (PEXCSRBAR). Note that PEXCSRBAR cannot be updated through the inbound ATMU registers. The PEXCSRBAR is shown in **Figure 17-64**.

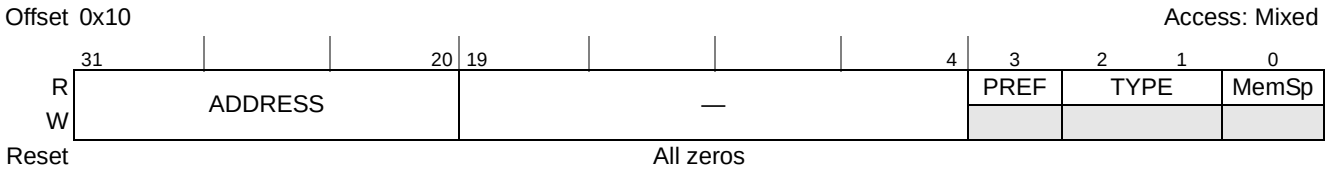

Figure 17-64. PCI Express Base Address Register 0 (PEXCSRBAR)

Table 17-65 describes the PCI Express configuration and status register base address register.

Table 17-65. PEXCSRBAR Field Descriptions

Bits	Name	Description
31–20	ADDRESS	Indicates the base address that the inbound configuration window occupies. This window is fixed at 1 Mbyte.
19–4	—	Reserved
3	PREF	Prefetchable
2–1	TYPE	Type. 00 Locate anywhere in 32-bit address space.
0	MemSp	Memory space indicator

Base address register 1 at offset 0x14 is used to define the inbound memory window in the 32-bit memory space. The 32-bit memory BAR is shown in **Figure 17-65**.

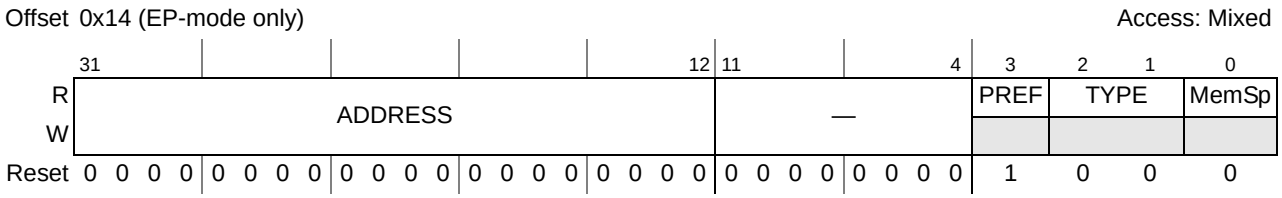

Figure 17-65. 32-Bit Memory Base Address Register (BAR1)

Table 17-66 describes the PCI Express 32-bit memory BAR fields.

Table 17-66. 32-Bit Memory Base Address Register (BAR1) Field Descriptions

Bits	Name	Description
31–12	ADDRESS	Indicates the base address where the inbound memory window begins. The number of upper bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes register (PEXIWAR1).
11–4	—	Reserved. The device allows a 4 Kbyte window minimum.
3	PREF	Prefetchable. This bit is determined by PEXIWAR1[PF].
2–1	TYPE	Type. 00 Locate anywhere in 32-bit address space.
0	MemSp	Memory space indicator.

Base address register 2 at offset 0x18 and base address register 4 at offset 0x20 are used to define the lower portion of the 64-bit inbound memory windows. The 64-bit low memory BARs are shown in **Figure 17-66**.

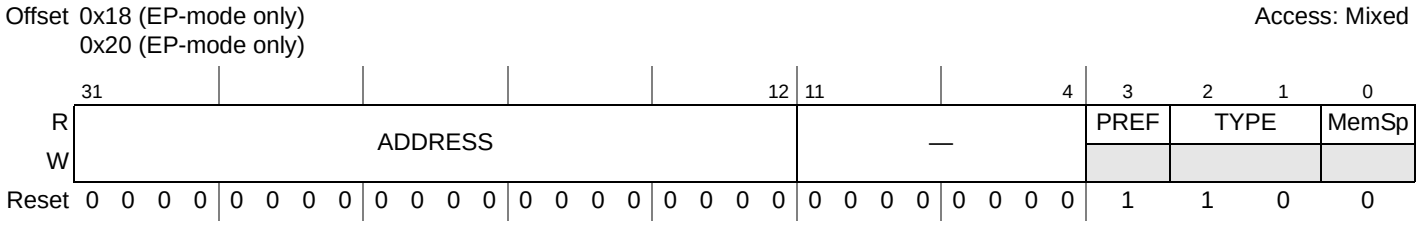

Figure 17-66. 64-Bit Low Memory Base Address Register

Table 17-67 describes the PCI Express 64-bit low memory BAR fields.

Table 17-67. 64-Bit Low Memory Base Address Register Field Descriptions

Bits	Name	Description
31–12	ADDRESS	Indicates the lower portion of the base address where the inbound memory window begins. The number of bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes registers (PEXIWAR2 for offset 0x18 and PEXIWAR3 for offset 0x20).
11–4	—	Reserved. The device allows a 4 Kbyte window minimum.
3	PREF	Prefetchable. This bit is determined by PEXIWAR*n*[2].
2–1	TYPE	Type. 0b10 Locate anywhere in 64-bit address space.
0	MemSp	Memory space indicator

Base address register 3 at offset 0x1C and base address register 5 at offset 0x24 are used to define the upper portion of the 64-bit inbound memory windows. The 64-bit high memory BARs are shown in **Figure 17-67**.

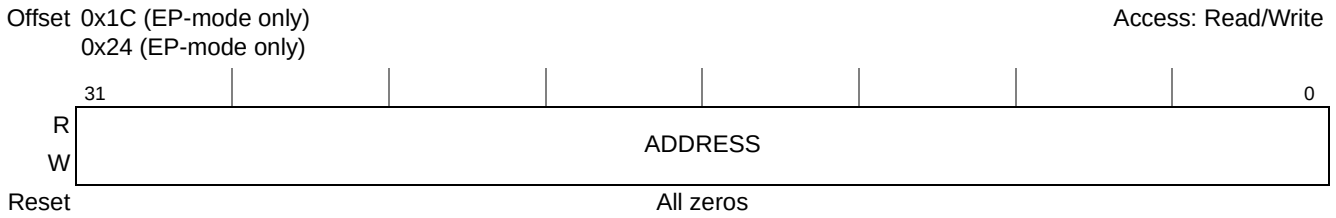

Figure 17-67. 64-Bit High Memory Base Address Register

Table 17-68 describes the PCI Express 64-bit low memory BAR fields.

Table 17-68. Bit Setting for 64-Bit High Memory Base Address Register

Bits	Name	Description
31–0	ADDRESS	Indicates the upper portion of the base address where the inbound memory window begins. The number of bits that the device allows to be writable is selected through the inbound window size in the inbound window attributes registers (PEXIWAR2 for offset 0x1C and PEXIWAR3 for offset 0x24). If no access to local memory is to be permitted by external requestors, then all bits are programmed.

17.5.1.11.14 PCI Express Subsystem Vendor ID Register (EP-Mode Only)—0x2C

The PCI Express subsystem vendor ID register is used to identify the subsystem.

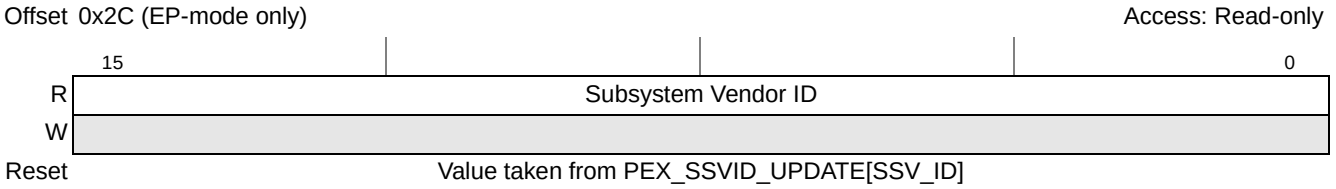

Figure 17-68. PCI Express Subsystem Vendor ID Register

Table 17-69. PCI Express Subsystem Vendor ID Register Field Description

Bits	Name	Description
15–0	Subsystem Vendor ID	The value for subsystem vendor ID is determined by the PCI Express subsystem vendor ID update register. See **Section 17.5.1.13.17**, *PCI Express Subsystem Vendor ID Update Register (EP Mode Only)—0x478,* on page 17-126 for more information.

17.5.1.11.15 PCI Express Subsystem ID Register (EP-Mode Only)—0x2E

The PCI Express subsystem ID register is used to identify the subsystem.

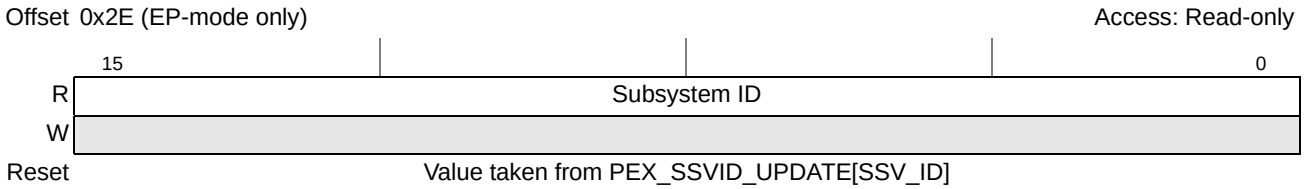

Figure 17-69. PCI Express Subsystem ID Register

Table 17-70. PCI Express Subsystem ID Register Field Description

Bits	Name	Description
15–0	Subsystem ID	The value for subsystem ID is determined by the PCI Express subsystem vendor ID update register. See **Section 17.5.1.13.17**, *PCI Express Subsystem Vendor ID Update Register (EP Mode Only)—0x478,* on page 17-126 for more information.

17.5.1.11.16 Capabilities Pointer Register—0x34

The capabilities pointer identifies additional functionality supported by the device.

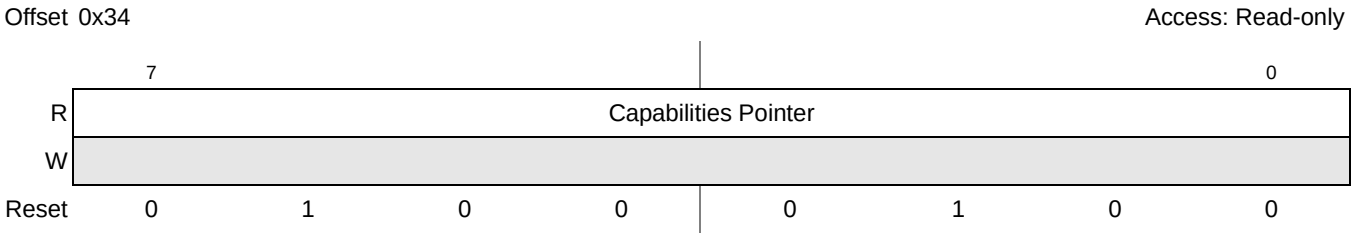

Figure 17-70. Capabilities Pointer Register

Table 17-71. Capabilities Pointer Register Field Description

Bits	Name	Description
7–0	Capabilities Pointer	The capabilities pointer provides the offset (0x44) for additional PCI-compatible registers above the common 64-byte header. Refer to **Section 17.5.1.12**, *PCI Compatible Device-Specific Configuration Space,* on page 17-96 for more information.

17.5.1.11.17 PCI Express Interrupt Line Register (EP-Mode Only)—0x3C

The interrupt line register is used by device drivers and OS software to communicate interrupt line routing information. Values in this register are programmed by system software and are system specific.

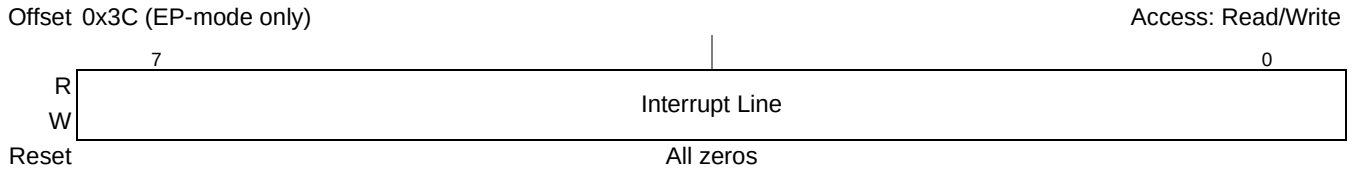

Figure 17-71. PCI Express Interrupt Line Register

Table 17-72. PCI Express Interrupt Line Register Field Description

Bits	Name	Description
7–0	Interrupt Line	Used to communicate interrupt line routing information.

17.5.1.11.18 PCI Express Interrupt Pin Register—0x3D

The interrupt pin register identifies the legacy interrupt (INTx) messages the device (or function) uses.

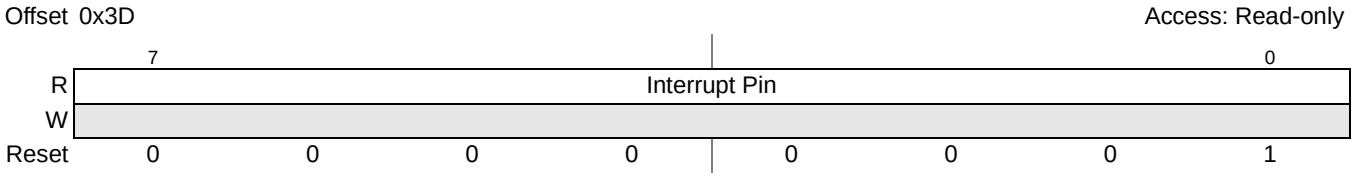

Figure 17-72. PCI Express Interrupt Pin Register

Table 17-73. PCI Express Interrupt Pin Register Field Description

Bits	Name	Description
7–0	Interrupt pin	Legacy INTx message used by this device. 0x00 This device does not use legacy interrupt (INTx) messages. 0x01 INTA 0x02 INTB 0x03 INTC 0x04 INTD all others Reserved.

17.5.1.11.19 PCI Express Minimum Grant Register (EP-Mode Only)—0x3E

This register does not apply to PCI Express. It is present for legacy purposes.

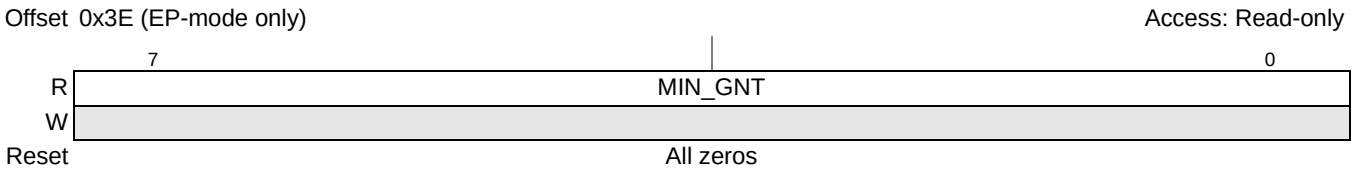

Figure 17-73. PCI Express Maximum Grant Register (MAX_GNT)

Table 17-74. PCI Express Maximum Grant Register Field Description

Bits	Name	Description
7–0	MIN_GNT	Does not apply for PCI Express.

17.5.1.11.20 PCI Express Maximum Latency Register (EP-Mode Only)—0x3F

This register does not apply to PCI Express. It is present for legacy purposes.

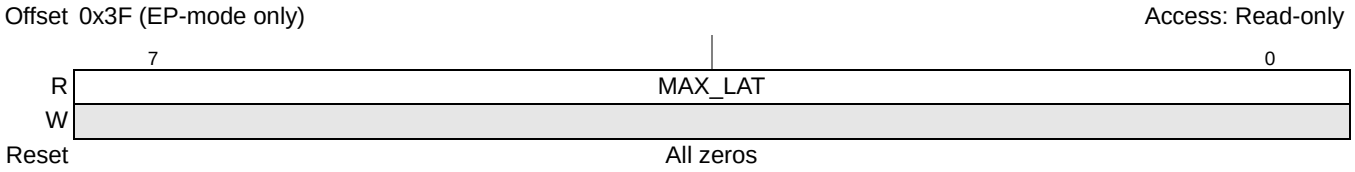

Figure 17-74. PCI Express Maximum Latency Register (MAX_LAT)

Table 17-75. PCI Express Maximum Latency Register Field Description

Bits	Name	Description
7–0	MAX_LAT	Does not apply for PCI Express.

17.5.1.11.21 Type 1 Configuration Header

The type 1 header is shown in **Figure 17-75**.

Section 17.5.1.11.1, *Common PCI Compatible Configuration Header Registers*, on page 17-73 describes the registers in the first 16 bytes of the header. This section describes the registers that are unique to the type 1 header beginning at offset 0x10.

17.5.1.11.22 PCI Express Base Address Register 0—0x10

Base address register 0 at offset 0x10 is a special fixed 1-Mbyte window that is used for inbound configuration accesses. This window is called the PCI Express configuration and status register base address register (PEXCSRBAR). Note that PEXCSRBAR cannot be updated through the inbound ATMU registers. The PEXCSRBAR is shown in **Figure 17-64**.

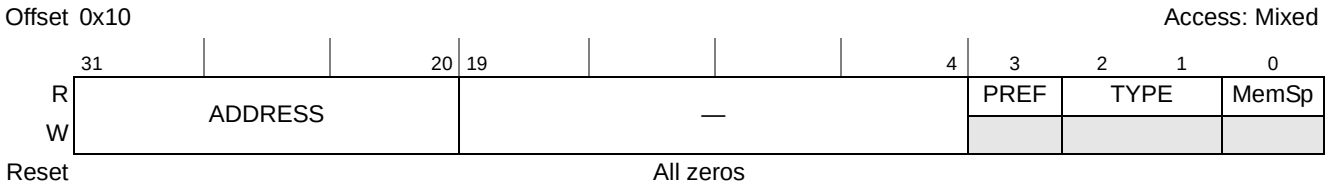

Figure 17-76. PCI Express Base Address Register 0 (PEXCSRBAR)

Table 17-65 describes the PCI Express configuration and status register base address register.

Table 17-76. PEXCSRBAR Field Descriptions

Bits	Name	Description
31–20	ADDRESS	Indicates the base address that the inbound configuration window occupies. This window is fixed at 1 Mbyte.
19–4	—	Reserved
3	PREF	Prefetchable
2–1	TYPE	Type. 00 Locate anywhere in 32-bit address space.
0	MemSp	Memory space indicator

17.5.1.11.23 PCI Express Primary Bus Number Register—Offset 0x18

The primary bus number register is shown in **Figure 17-77**.

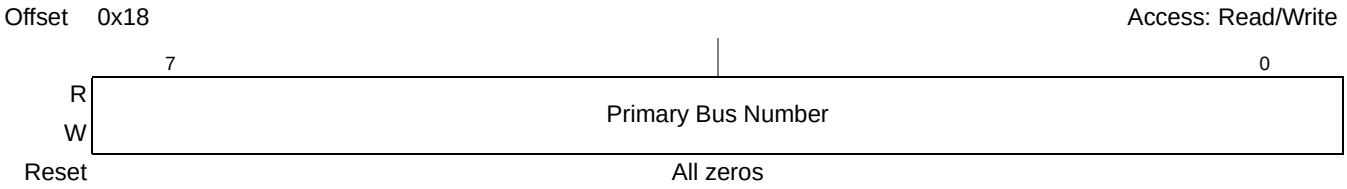

Figure 17-77. PCI Express Primary Bus Number Register

Table 17-77 describes the primary bus number register fields.

Table 17-77. PCI Express Primary Bus Number Register Field Description

Bits	Name	Description
7–0	Primary Bus Number	Bus that is connected to the upstream interface. Note that this register is programmed during system enumeration; in RC mode this register should remain 0x00.

17.5.1.11.24 PCI Express Secondary Bus Number Register—Offset 0x19

The secondary bus number register is shown in **Figure 17-78**.

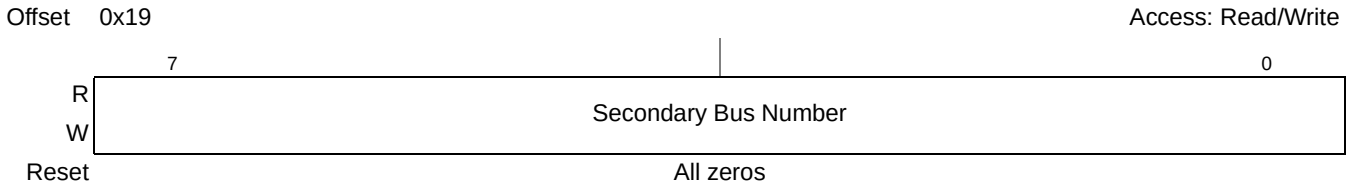

Figure 17-78. PCI Express Secondary Bus Number Register

Table 17-78 describes the secondary bus number register fields.

Table 17-78. PCI Express Secondary Bus Number Register Field Description

Bits	Name	Description
7–0	Secondary Bus Number	Bus that is directly connected to the downstream interface. Note that this register is programmed during system enumeration; in RC mode, this register is typically programmed to 0x01.

17.5.1.11.25 PCI Express Subordinate Bus Number Register—Offset 0x1A

The subordinate bus number register is shown in **Figure 17-79**.

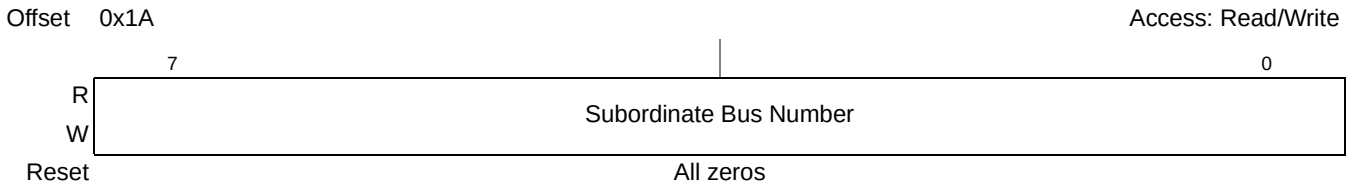

Figure 17-79. PCI Express Subordinate Bus Number Register

Table 17-79 describes the subordinate bus number register fields.

Table 17-79. PCI Express Subordinate Bus Number Register Field Description

Bits	Name	Description
7–0	Subordinate Bus Number	Highest bus number that is on the downstream interface.

17.5.1.11.26 PCI Express Secondary Latency Timer Register—0x1B

The secondary latency timer register does not apply to PCI Express. It must be read-only and return all zeros when read.

17.5.1.11.27 PCI Express I/O Base Register—0x1C

Note that this device does not support inbound I/O transactions. The I/O base register is shown in **Figure 17-79**.

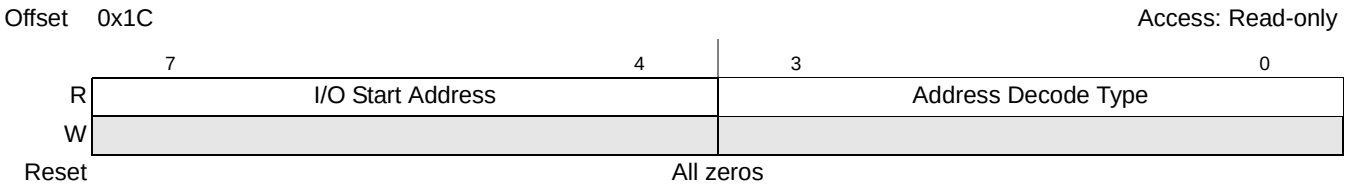

Figure 17-80. PCI Express I/O Base Register

Table 17-79 describes the I/O base register fields.

Table 17-80. PCI Express I/O Base Register Field Description

Bits	Name	Description
7–4	I/O Start Address	Specifies bits 15:12 of the I/O space start address
3–0	Address Decode Type	Specifies the number of I/O address bits. 0x00 16-bit I/O address decode 0x01 32-bit I/O address decode All other settings reserved.

17.5.1.11.28 PCI Express I/O Limit Register—0x1D

Note that this device does not support inbound I/O transactions. The I/O limit register is shown in **Figure 17-79**.

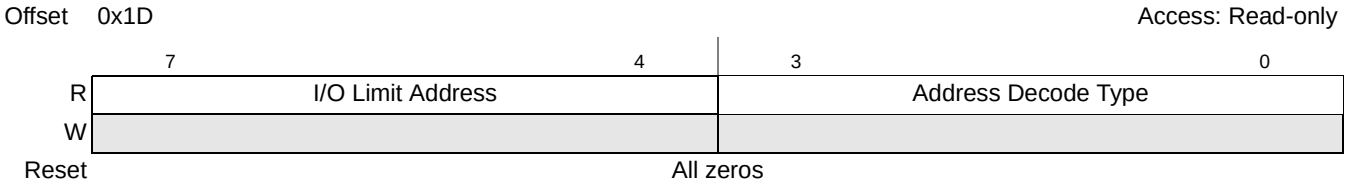

Figure 17-81. PCI Express I/O Limit Register

Table 17-79 describes the I/O limit register fields.

Table 17-81. PCI Express I/O Limit Register Field Description

Bits	Name	Description
7–4	I/O Limit Address	Specifies bits 15:12 of the I/O space ending address
3–0	Address Decode Type	Specifies the number of I/O address bits. 0x00 16-bit I/O address decode 0x01 32-bit I/O address decode All other settings reserved.

17.5.1.11.29 PCI Express Secondary Status Register—0x1E

The PCI Express secondary status register is shown in **Figure 17-82**. Note that the errors in this register may be masked by corresponding bits in the secondary status interrupt mask register (PEX_SS_INTR_MASK) and that by default all of the errors are masked. See **Section 17.5.1.13.20**, *Secondary Status Interrupt Mask Register (RC-Mode Only)—0x5A0,* on page 17-129 for more information.

Offset 0x1E Access: Mixed

Reset	All zeros									

Figure 17-82. PCI Express Secondary Status Register

Table 17-82 describes the PCI Express secondary status register fields.

Table 17-82. PCI Express Secondary Status Register Field Description

Bits	Name	Description
15	DPE	Detected parity error. This bit is set whenever the secondary side receives a poisoned TLP regardless of the state of the parity error response bit.
14	SSE	Signaled system error. This bit is set when a device sends a ERR_FATAL or ERR_NONFATAL message, provided the SERR enable bit in the command register is set to enable reporting.
13	RMA	Received master abort. This bit is set when the secondary side receives an unsupported request (UR) completion.
12	RTA	Received target abort. This bit is set when the secondary side receives a completer abort (CA) completion.
11	STA	Signaled target abort. This bit is set when the secondary side issues a CA completion.
10–9	—	Reserved
8	MDPE	Master data parity error. This bit is set when the parity error response bit is set and the secondary side requestor receives a poisoned completion or poisons a write request. If the parity error response bit is cleared, this bit is never set.
7–0	—	Reserved

Note: After Gen2 training and before initiating any transactions toward the PCI Express controller, always clear the DPE bit to clear any receive packet errors caused by the training.

17.5.1.11.30 PCI Express Memory Base Register—0x20

The memory base register is shown in **Figure 17-83**.

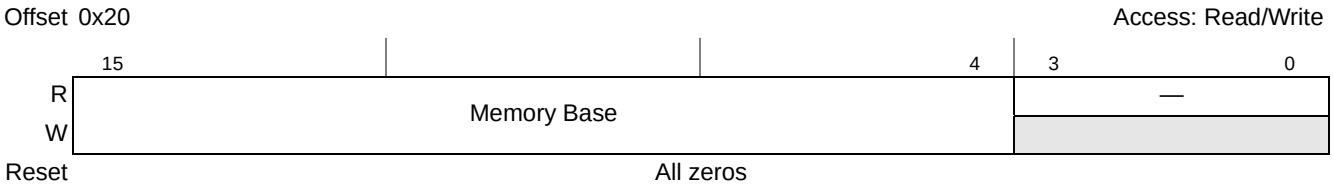

Figure 17-83. PCI Express Memory Base Register

Table 17-83 describes the memory base register fields.

Table 17-83. PCI Express Memory Base Register Field Description

Bits	Name	Description
15–4	Memory Base	Specifies bits 31:20 of the non-prefetchable memory space start address. Typically used for specifying memory-mapped I/O space. **Note:** Inbound posted transactions hitting into the mem base/limit range are ignored; inbound non-posted transactions hitting into the mem base/limit range results in an unsupported request response.
3–0	—	Reserved

17.5.1.11.31 PCI Express Memory Limit Register—0x22

The memory limit register is shown in **Figure 17-84**.

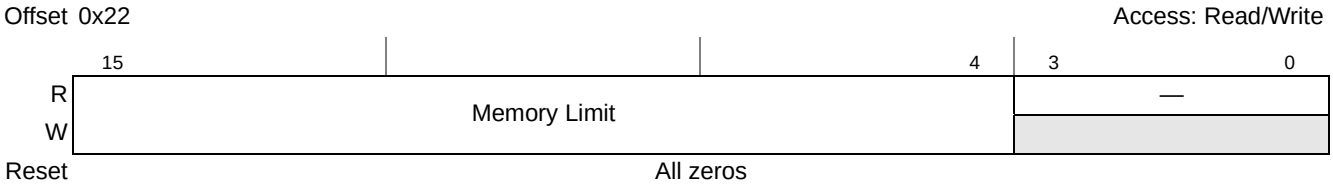

Figure 17-84. PCI Express Memory Limit Register

Table 17-84 describes the memory base register fields.

Table 17-84. PCI Express Memory Limit Register Field Description

Bits	Name	Description
15–4	Memory Limit	Specifies bits 31:20 of the non-prefetchable memory space ending address. Typically used for specifying memory-mapped I/O space. **Note:** Inbound posted transactions hitting into the mem base/limit range are ignored; inbound non-posted transactions hitting into the mem base/limit range will result in unsupported request response.
3–0	—	Reserved

17.5.1.11.32 PCI Express Prefetchable Memory Base Register—0x24

The prefetchable memory base register is shown in **Figure 17-85**.

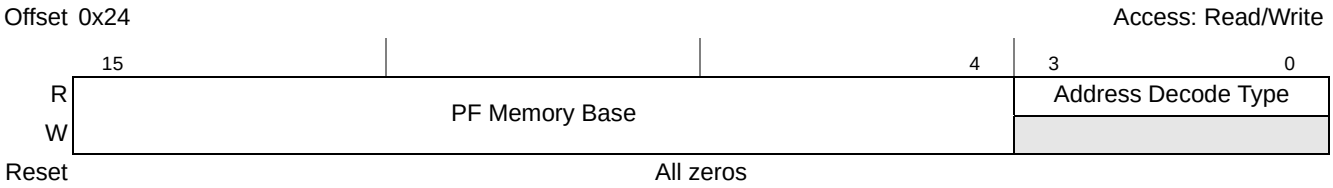

Figure 17-85. PCI Express Prefetchable Memory Base Register

Table 17-85 describes the prefetchable memory base register fields.

Table 17-85. PCI Express Prefetchable Memory Base Register Field Description

Bits	Name	Description
15–4	PF Memory Base	Specifies bits 31:20 of the prefetchable memory space start address.
3–0	Address Decode Type	Specifies the number of prefetchable memory address bits. 0x00 32-bit memory address decode 0x01 64-bit memory address decode All other settings reserved.

17.5.1.11.33 PCI Express Prefetchable Memory Limit Register—0x26

The prefetchable memory limit register is shown in **Figure 17-86**.

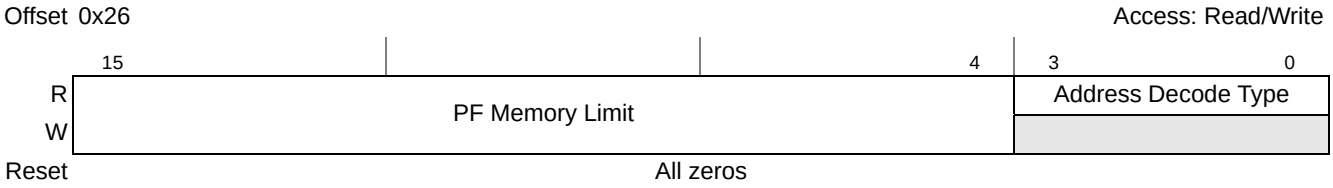

Figure 17-86. PCI Express Prefetchable Memory Limit Register

Table 17-86 describes the prefetchable memory limit register fields.

Table 17-86. PCI Express Prefetchable Memory Limit Register Field Description

Bits	Name	Description
15–4	PF Memory Limit	Specifies bits 31:20 of the prefetchable memory space ending address.
3–0	Address Decode Type	Specifies the number of prefetchable memory address bits. 0x00 32-bit memory address decode 0x01 64-bit memory address decode All other settings reserved.

17.5.1.11.34 PCI Express Prefetchable Base Upper 32 Bits Register—0x28

The PCI Express prefetchable memory base upper 32 bits register is shown in **Figure 17-87**.

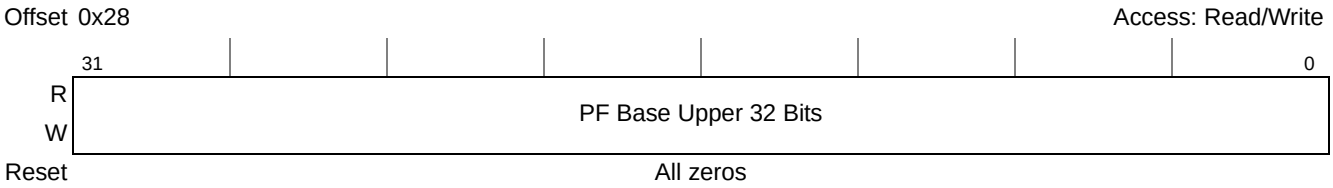

Figure 17-87. PCI Express Prefetchable Base Upper 32 Bits Register

Table 17-87 describes the PCI Express prefetchable memory base upper 32 bits register fields.

Table 17-87. PCI Express Prefetchable Base Upper 32 Bits Register

Bits	Name	Description
31–0	PF Base Upper 32 Bits	Specifies bits 64:32 of the prefetchable memory space start address when the address decode type field in the prefetchable memory base register is 0x01.

17.5.1.11.35 PCI Express Prefetchable Limit Upper 32 Bits Register—0x2C

The PCI Express prefetchable memory base upper 32 bits register is shown in **Figure 17-88**.

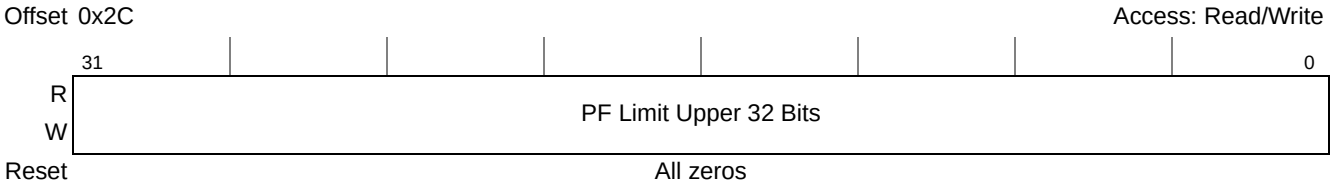

Figure 17-88. PCI Express Prefetchable Limit Upper 32 Bits Register

Table 17-88 describes the PCI Express prefetchable memory limit upper 32 bits register fields.

Table 17-88. PCI Express Prefetchable Limit Upper 32 Bits Register

Bits	Name	Description
31–0	PF Limit Upper 32 Bits	Specifies bits 64–32 of the prefetchable memory space ending address when the address decode type field in the prefetchable memory limit register is 0x01.

17.5.1.11.36 PCI Express I/O Base Upper 16 Bits Register—0x30

Note that this device does not support inbound I/O transactions. The I/O base upper 16 bits register is shown in **Figure 17-89**.

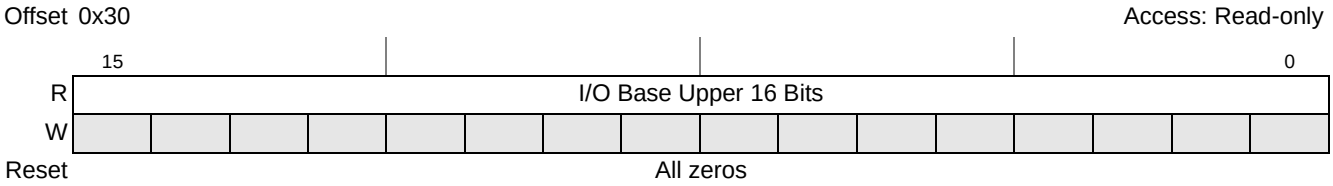

Figure 17-89. PCI Express I/O Base Upper 16 Bits Register

Table 17-89 describes the I/O base upper 16 bits register fields.

Table 17-89. PCI Express I/O Base Upper 16 Bits Register Field Description

Bits	Name	Description
15–0	I/O Base Upper 16 Bits	Specifies bits 31–16 of the I/O space start address when the address decode type field in the I/O base register is 0x01.

17.5.1.11.37 PCI Express I/O Limit Upper 16 Bits Register—0x32

Note that this device does not support inbound I/O transactions. The I/O limit upper 16 bits register is shown in **Figure 17-90**.

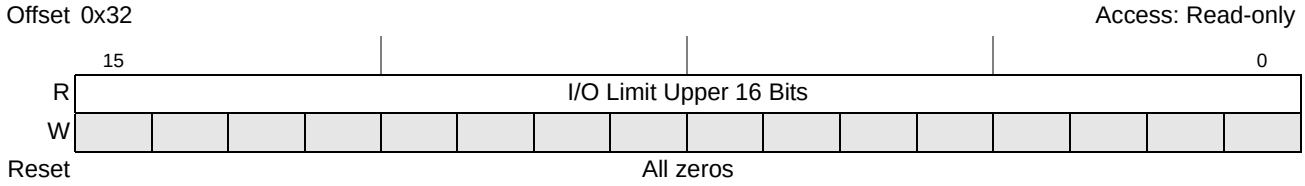

Figure 17-90. PCI Express I/O Limit Upper 16 Bits Register

Table 17-90 describes the I/O limit upper 16 bits register fields.

Table 17-90. PCI Express I/O Limit Upper 16 Bits Register Field Description

Bits	Name	Description
15–0	I/O Limit Upper 16 Bits	Specifies bits 31–16 of the I/O space ending address when the address decode type field in the I/O limit register is 0x01.

17.5.1.11.38 Capabilities Pointer Register—0x34

The capabilities pointer identifies additional functionality supported by the device.

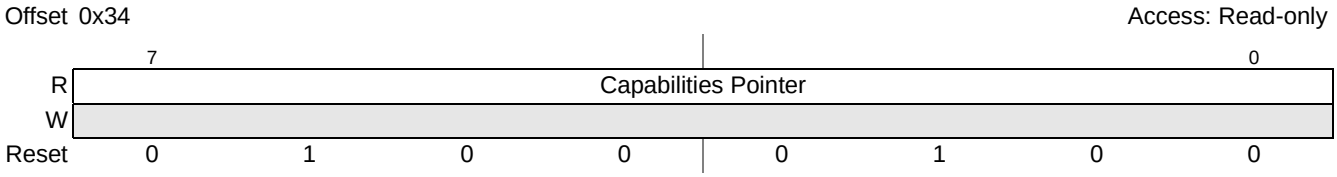

Figure 17-91. Capabilities Pointer Register

Table 17-91. Capabilities Pointer Register Field Description

Bits	Name	Description
7–0	Capabilities Pointer	The capabilities pointer provides the offset (0x44) for additional PCI-compatible registers above the common 64-byte header. Refer to **Section 17.5.1.12**, *PCI Compatible Device-Specific Configuration Space,* on page 17-96," for more information.

17.5.1.11.39 PCI Express Interrupt Line Register—0x3C

The interrupt line register is used by device drivers and OS software to communicate interrupt line routing information. Values in this register are programmed by system software and are system specific.

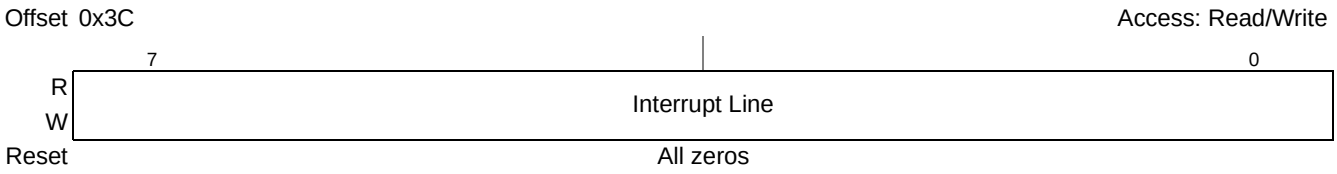

Figure 17-92. PCI Express Interrupt Line Register

Table 17-92. PCI Express Interrupt Line Register Field Description

Bits	Name	Description
7–0	Interrupt Line	Used to communicate interrupt line routing information.

17.5.1.11.40 PCI Express Interrupt Pin Register—0x3D

The interrupt pin register identifies the legacy interrupt (INTx) messages the device (or function) uses.

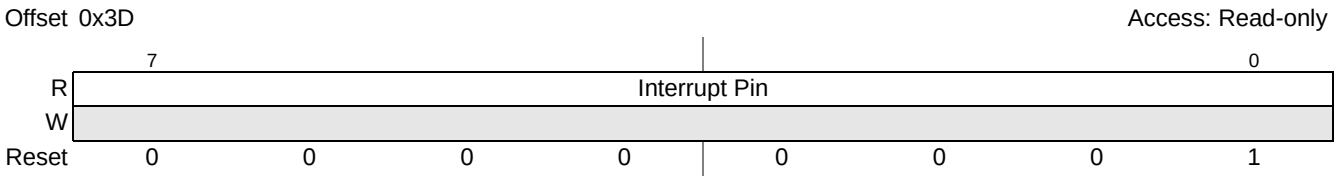

Figure 17-93. PCI Express Interrupt Pin Register

Table 17-93. PCI Express Interrupt Pin Register Field Description

Bits	Name	Description
7–0	Interrupt pin	Legacy INTx message used by this device. 0x00 This device does not use legacy interrupt (INTx) messages. 0x01 INTA 0x02 INTB 0x03 INTC 0x04 INTD all others Reserved.

17.5.1.11.41 PCI Express Bridge Control Register—0x3E

The PCI Express bridge control register is shown in **Figure 17-94**.

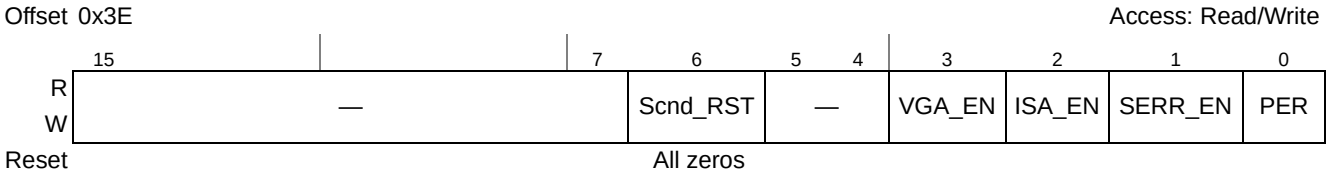

Figure 17-94. PCI Express Bridge Control Register

Table 17-94 describes the PCI Express bridge control register fields.

Table 17-94. PCI Express Bridge Control Register Field Description

Bits	Name	Description
15–7	—	Reserved
6	Scnd_RST	Secondary bus reset
5–4	—	Reserved
3	VGA_EN	VGA enable
2	ISA_EN	ISA enable
1	SERR_EN	SERR enable. This bit controls the propagation of ERR_COR, ERR_NONFATAL, and ERR_FATAL responses received on the secondary side.
0	PER	Parity error response.

17.5.1.12 PCI Compatible Device-Specific Configuration Space

The PCI compatible device-specific configuration space is a PCI compatible configuration space from 0x40 to 0xFF (just above the 64-byte PCI-compatible configuration header).

Reserved

			Address Offset (Hex)
PCI-Compatible Configuration Header (See **Section 17.5.1.11**, *PCI Compatible Configuration Headers* for more information.)			00 3F

The PCI Express capabilities register is shown in **Figure 17-101**.

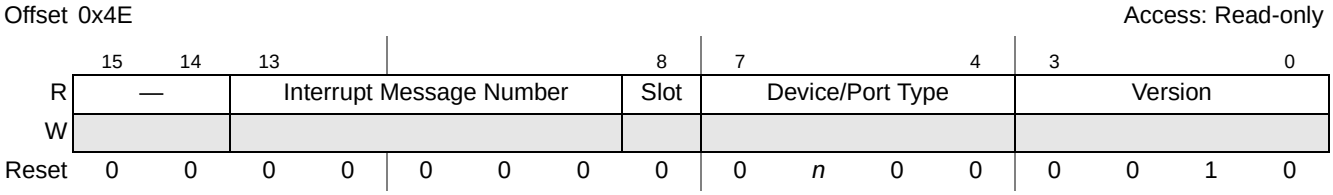

Figure 17-101. PCI Express Capabilities Register

Table 17-100. PCI Express Capabilities Register Field Description

Bits	Name	Description
15–14	—	Reserved
13–9	Interrupt Message Number	If this function is allocated more than one MSI interrupt number, then this register is required to contain the offset between the base Message Data and the MSI Message that is generated when any of the status bits in either the Slot Status register or the Root Port Status register, of this capability structure, are set.
8	Slot	Slot Implemented (RC mode only)
7–4	Device/Port Type	0100 (RC mode) 0000 (EP mode)
3–0	Capability Version	Indicates the defined PCI Express capability structure version number. Must be 1h for this specification.

17.5.1.12.7 PCI Express Device Capabilities Register—0x50

The PCI Express device capabilities register is shown in **Figure 17-102**.

Offset 0x50 Access: Read-only

Bits	Name	Description
15	—	Reserved
14–12	MAX_READ_SIZE	Maximum read request size
11	NSE	No snoop enable
10	APE	AUX power PM enable
9	PFE	Phantom functions enable
8	ETE	Extended tag field enable
7–5	MAX_PAYLOAD_SIZE	Maximum payload size
4	RO	Relaxed ordering
3	URR	Unsupported request reporting
2	FER	Fatal error reporting
1	NFER	Non-fatal error reporting
0	CER	Correctable error reporting

17.5.1.12.9 PCI Express Device Status Register—0x56

The PCI Express device status register is shown in **Figure 17-104**.

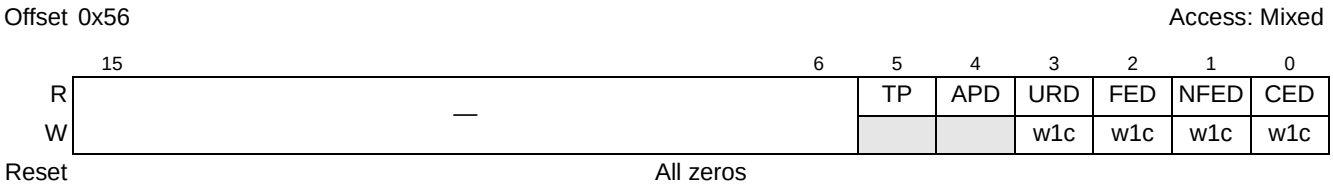

Figure 17-104. PCI Express Device Status Register

Table 17-103. PCI Express Device Status Register Field Description

Bits	Name	Description
15–6	—	Reserved
5	TP	Transactions pending
4	APD	AUX power detected
3	URD	Unsupported request detected
2	FED	Fatal error detected
1	NFED	Non-fatal error detected
0	CED	Correctable error detected

Note: After training and before initiating any transactions toward the PCI Express controller, always clear the CED bit.

17.5.1.12.10 PCI Express Link Capabilities Register—0x58

The PCI Express link capabilities register is shown in **Figure 17-105**.

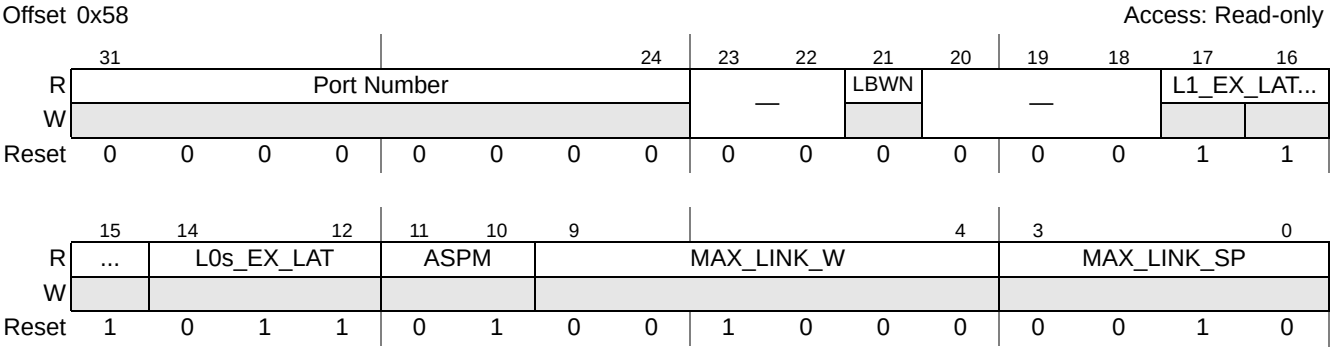

Figure 17-105. PCI Express Link Capabilities Register

Table 17-104. PCI Express Link Capabilities Register Field Description

Bits	Name	Description
31–24	Port Number	
23–22	—	Reserved
21	LBWN	Link bandwidth notification capable.
20–18	—	Reserved
17–15	L1_EX_LAT	L1 exit latency

Table 17-104. PCI Express Link Capabilities Register Field Description (Continued)

Bits	Name	Description
14–12	L0s_EX_LAT	L0s exit latency
11–10	ASPM	Active state power management (ASPM) Support
9–4	MAX_LINK_W	Maximum link width
3–0	MAX_LINK_SP	Maximum link speed

17.5.1.12.11 PCI Express Link Control Register—0x5C

The PCI Express link control register is shown in **Figure 17-106**.

Offset 0x5C — Access: Read/Write

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

13	—	Reserved
12	SCC	Slot clock configuration
11	LT	Link training
10	—	Reserved.
9–4	NEG_LINK_W	Negotiated link width
3–0	LINK_SP	Link speed

17.5.1.12.13 PCI Express Slot Capabilities Register—0x60

The PCI Express slot capabilities register is shown in **Figure 17-108**.

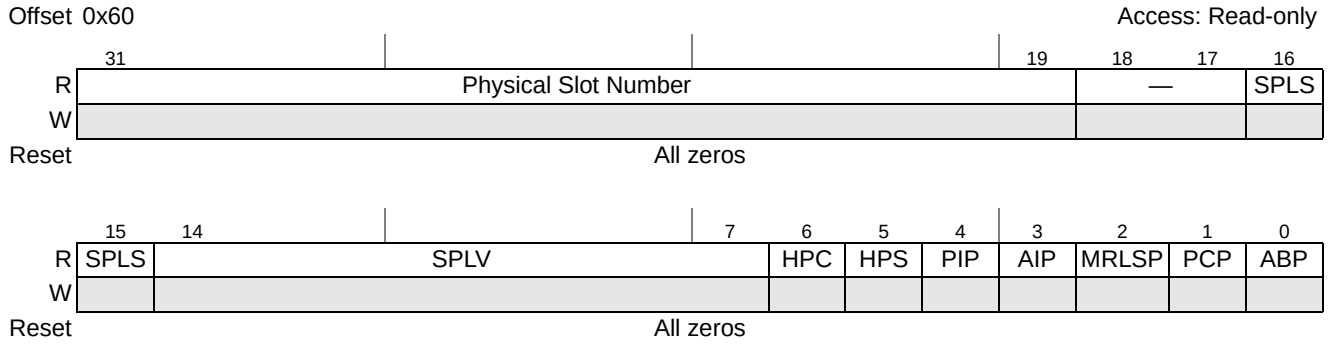

Figure 17-108. PCI Express Slot Capabilities Register

Table 17-107. PCI Express Slot Capabilities Register Field Description

Bits	Name	Description
31–19	Physical Slot Number	This hardware initialized field indicates the physical slot number attached to this Port. This field must be hardware initialized to a value that assigns a slot number that is globally unique within the chassis. These registers should be initialized to 0 for Ports connected to devices that are either integrated on the system board or integrated within the same silicon as the Switch device or Root Port.
18–17	—	Reserved
16–15	SPLS	Slot power limit scale.
14–7	SPLV	Slot power limit value.
6	HPD	Hot plug capable.
5	HPS	Hot plug surprise.
4	PIP	Power indicator present.
3	AIP	Attention indicator present.
2	MRLSP	MRL sensor present.
1	PCP	Power controller present.
0	ABP	Attention button present.

17.5.1.12.14 PCI Express Slot Control Register—0x64

The PCI Express slot control register is shown in **Figure 17-109**.

Offset 0x64 Access: Read/Write

15–0	Error Source ID	ERR_FATAL/NONFATAL source ID

17.5.1.13.13 LTSSM State Status Register—0x404

The PCI Express link training and status state machine (LTSSM) state status register, shown in **Figure 17-135**, provides detailed information about link training status. This register is useful for debugging link training failures.

Note: The Status Code in PEX_LTSSM_STAT changes while reacting to the link status. Therefore, software may need to read PEX_LTSSM_STAT multiple times to ensure the value has stabilized.

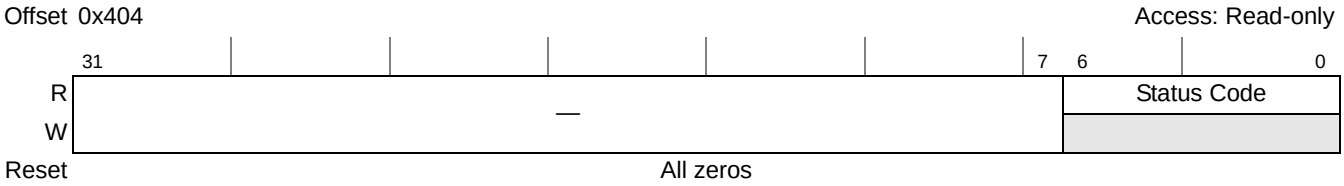

Figure 17-135. PCI Express LTSSM State Status Register (PEX_LTSSM_STAT)

The fields of the PCI Express LTSSM state status register are described in **Table 17-133**.

Table 17-133. PEX_LTSSM_STAT Field Descriptions

Bits	Name	Description
31–7	—	Reserved
6–0	Status code	Status code. See **Table 17-134** for encodings.

Table 17-134 provides the encodings for the status code field of the PEX_LTSSM_STAT register.

Table 17-134. PEX_LTSSM_STAT Status Codes

Status Code (Hex)	LTSSM State Description	Status Code (Hex)	LTSSM State Description
00	Detect quiet	27	TX L0s FTS; RX L0s FTS
01	Detect active (0)	28	L0 to L1 (0)
02	Detect active (1)	29	L0 to L1 (1)
03	Detect active (2)	2A	L1 entry
04	Polling active (0)	2B	L1 idle (0)
05	Polling active (1)	2C	L1 idle (1)
06	Polling config (0)	2D	L0 to L2 (0)
07	Polling config (1)	2E	L0 to L2 (1)
08	Polling compliance	2F	L2 entry
09	Configuration link width start (0)	30	L2 idle (0)
0A	Configuration link width start (1)	31	L2 idle (1)
0B	Configuration link width accept (0)	32	Recovery lock (0)

Table 17-134. PEX_LTSSM_STAT Status Codes (Continued)

Status Code (Hex)	LTSSM State Description	Status Code (Hex)	LTSSM State Description
0C	Configuration link width accept (1)	33	Recovery lock (1)
0D	Configuration lane number wait (0)	34	Recovery lock (2)
0E	Configuration lane number wait (1)	35	Recovery cfg (0)
0F	Configuration lane number wait (2)	36	Recovery cfg (1)
10	Configuration lane number wait (3)	37	Recovery idle (0)
11	Configuration lane number accept	38	Recovery idle (1)
12	Configuration complete (0)	39	Recovery to configuration
13	Configuration complete (1)	3A	Recovery cfg to configuration
14	Configuration idle (0)	3F	L0 no training
15	Configuration idle (1)	7F	Detect quiet EI
16	L0	49	Configuration link width start—RC
17	TX L0; RX L0s entry	4A	Configuration link width accept—RC
18	TX L0; RX L0s idle	4B	Configuration lane number wait—RC
19	TX L0; RX L0s fast training sequence (FTS)	4C	Configuration lane number accept—RC
1A	TX L0s entry (0); RX L0	60	Loopback slave active (0)
1B	TX L0s entry (0); RX L0s idle	61	Loopback slave active (1)
1C	TX L0s entry (0); RX L0s FTS	62	Loopback slave exit
1D	TX L0s entry (1); RX L0	68	Hot reset (0)
1E	TX L0s entry (1); RX L0s idle	69	Hot reset (1)
1F	TX L0s entry (1); RX L0s FTS	6A	Hot reset (0)—RC
20	TX L0s idle; RX L0	6B	Hot reset (1)—RC
21	TX L0s idle; RX L0s entry	75	Disabled (0)
22	TX L0s idle; RX L0s idle	71	Disabled (1)
23	TX L0s idle; RX L0s FTS	72	Disabled (2)
24	TX L0s FTS; RX L0	73	Disabled (3)
25	TX L0s FTS; RX L0s entry	74	Disabled (4)
26	TX L0s FTS; RX L0s idle	78	L0 to L1/L2—RC

17.5.1.13.14 PCI Express Controller Core Clock Ratio Register—0x440

The PCI Express controller core clock ratio register, shown in **Figure 17-136**, is used to program the ratio of the actual PCI Express controller clock frequency to the default controller core frequency (333 MHz). This is required only when a PCI Express controller clock frequency other than the default 333 MHz has to be used.

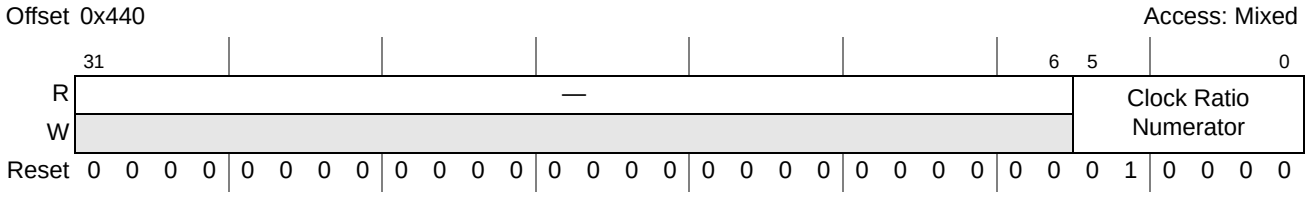

Figure 17-136. PCI Express IP Block Core Clock Ratio Register (PEX_GCLK_RATIO)

The fields of the PCI Express IP block core clock ratio register are described in **Table 17-135**.

Table 17-135. PEX_GCLK_RATIO Field Descriptions

Bits	Name	Description
31–6	—	Reserved
5–0	Clock Ratio Numerator	The numerator of the ratio of the actual PCI Express controller clock frequency used to the default core clock frequency of 333 MHz. The denominator of the ratio is fixed at 16. The default value of this register is 0x10 (16 decimal), which corresponds to a ratio of 1:1 (or 16/16)

As an example of programming PEX_GCLK_RATIO, consider the case where the actual PCI Express controller clock is 250 MHz, the ratio of the actual clock to the default clock (333 MHz) is 3:4. that is, the default core clock has to be multiplied by the ratio (3/4, which is equivalent to 12/16). So the register has to be programmed with the decimal numerator value 12 or 0x0000_000C.

17.5.1.13.15 PCI Express Power Management Timer Register—0x450

The PCI Express power management timer register, shown in **Figure 17-137**, is used to program the time-in values for entering L0s and L1 power management states.

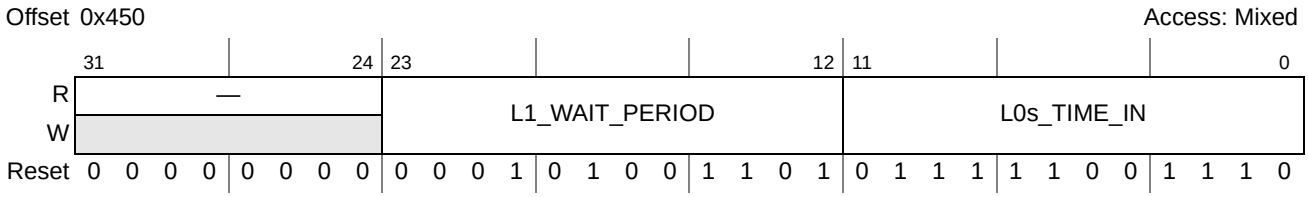

Figure 17-137. PCI Express Power Management Timer Register (PEX_PM_TIMER)

The fields of the PCI Express power management timer register are described in **Table 17-136**.

Table 17-136. PEX_PM_TIMER Field Descriptions

Bits	Name	Description
31–24	—	Reserved
23–12	L1_WAIT_PERIOD	Wait period (in PCI Express controller core clock cycles) before entering L1 power state after all functions are in a non-D0 power state. The value is calculated as: Time (in µsec) × PCI Express controller core clock frequency (in MHz) The time value must be less than 2 µs; the default value (0x14D) is 1 µs for the default clock frequency of 333 MHz.
11–0	L0s_TIME_IN	Time in value (in PCI Express controller core clock cycles) for entering L0s power state. The value is calculated as: Time (in µsec) × PCI Express controller core clock frequency (in MHz) The maximum time value is 7 µs; the default value (0x7CE) is 6 µs for the default clock frequency of 333 MHz.

17.5.1.13.16 PCI Express PME Time-Out Register (EP-Mode Only)—0x454

The PCI Express PME time-out register, shown in **Figure 17-138**, is used to program the time-out value that the controller uses before re-sending a PME message to the host. If PME is requested by a function and the host does not clear the associated PME_STAT bit even after this time-out has expired, the PME message is sent again to the host by the PCI Express controller. This register is supported only for EP mode.

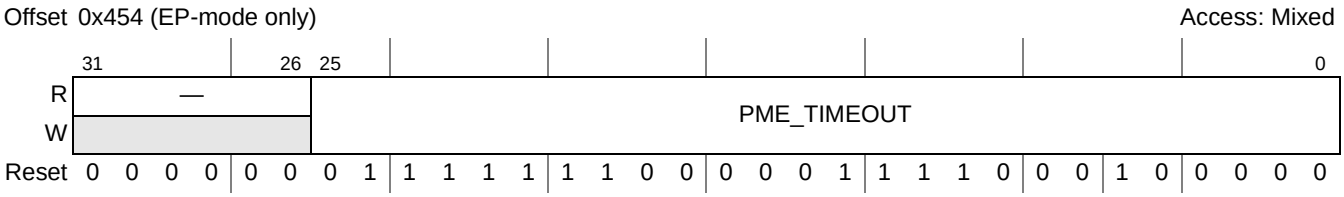

Figure 17-138. PCI Express PME Time-Out Register (PEX_PME_TIMEOUT)

The fields of the PCI Express PME time-out register are described in **Table 17-136**.

Table 17-137. PEX_PME_TIMEOUT Field Descriptions

Bits	Name	Description
31–26	—	Reserved
25–0	PME_TIMEOUT	The PME time-out value specifies the interval before PME messages are resent by the controller, provided the PME_STAT bit in the PCI Express power management status and control register (offset 0x48) is not cleared by the host. The value for PME_TIMEOUT is specified in terms of PCI Express controller core clock cycles. The value is calculated as: Time (in µsec) × PCI Express controller core clock frequency (in MHz) The minimum time value is 100 ms; the default value (0x1FC1E20) is 100 ms for the default clock frequency of 333 MHz.

17.5.1.13.17 PCI Express Subsystem Vendor ID Update Register (EP Mode Only)—0x478

The PCI Express subsystem vendor ID update register, shown in **Figure 17-139**, is used to set the values for the Subsystem ID and Subsystem Vendor ID registers in the Type 0 configuration header.

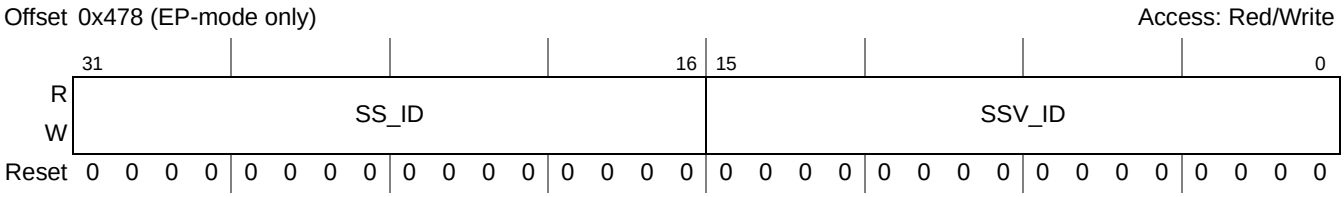

Figure 17-139. PCI Express Subsystem Vendor ID Update Register (PEX_SSVID_UPDATE)

The fields of the PCI Express subsystem vendor ID update register are described in **Table 17-138**.

Table 17-138. PEX_SSVID_UPDATE Field Descriptions

Bits	Name	Description
31–16	SS_ID	Subsystem ID [15–0] value
15–0	SSV_ID	Subsystem vendor ID [15–0] value

When used as an endpoint, the controller's initialization software programs the desired subsystem ID and subsystem vendor ID values in PEX_SSVID_UPDATE before setting the CFG_READY bit in the PEX_CFG_READY register (see **Section 17.5.1.13.18**, *Configuration Ready Register—0x4B0*, on page 17-127). That way, when the host begins system enumeration, the correct values will be present in the Type 0 configuration header.

17.5.1.13.18 Configuration Ready Register—0x4B0

The PCI Express configuration ready register, shown in **Figure 17-140**, is used to indicate configuration complete status to the transaction layer. The transaction layer handles configuration requests from external hosts only after the CFG_READY bit is set. All the configuration requests received from external hosts before the CFG_READY bit is set are completed with configuration request retry status (CRS). The CFG_READY bit in this register should be set after all relevant configuration registers have been programmed. This makes sure the external host reads the correct capability advertisements during enumeration.

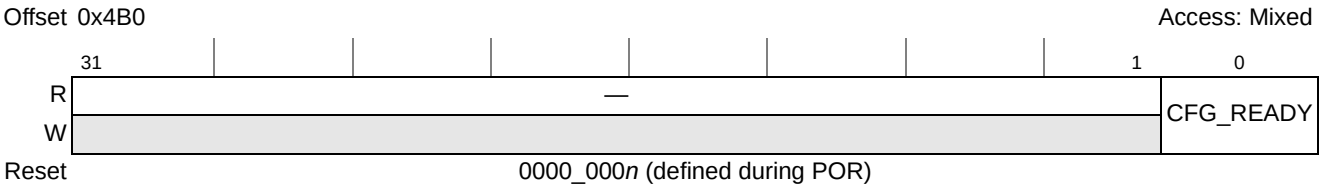

Figure 17-140. PCI Express Configuration Ready Register (PEX_CFG_READY)

The fields of the PCI Express configuration ready register are described in **Table 17-139**.

Table 17-139. PEX_CFG_READY Field Descriptions

Bits	Name	Description
31–1	—	Reserved
0	CFG_READY	Configuration ready 1 The transaction layer will accept inbound configuration requests. 0 The transaction layer will respond to all inbound configuration requests with retry (CRS) Note that the reset state of this bit is determined during POR.

17.5.1.13.19 Flow Control Update Timeout Register—0x4B8

The PCI Express flow control update timeout register, shown in **Figure 17-141**, is used to program the timeout value for update-FC DLLP reception in terms of PCI Express controller core clock cycles.

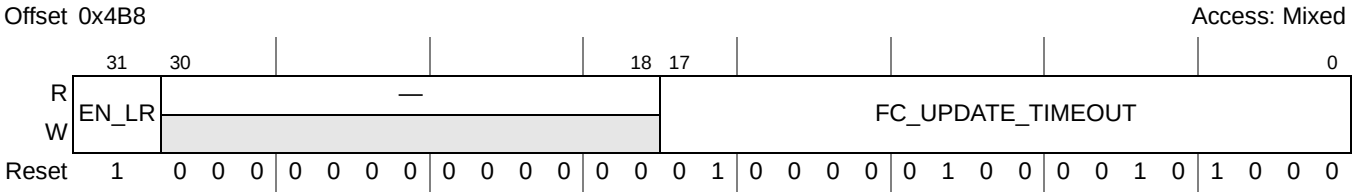

Figure 17-141. PCI Express Flow Control Update Timeout Register (PEX_FC_UPDATE_TOR)

The fields of the PCI Express flow control update timeout register are described in **Table 17-140**.

Table 17-140. PEX_FC_UPDATE_TOR Field Descriptions

Bits	Name	Description
31	EN_LR	Enable link retraining on FC update timeout error. The PCI Express protocol allows for optional link retraining by a device if FC updates are not received from the remote device within the timeout period programmed in bits [17–0] of this register. If the FC updates were lost due to link error issues, this retraining will help to restore normal operation. By default, this retraining is enabled. Since this is an optional feature, the user is allowed to disable such automatic retraining, if desired.
30–18	—	Reserved
17–0	FC_UPDATE_TIMEOUT	FC update timeout value specifies the interval (in PCI Express controller core clock cycles) to wait for the reception of consecutive FC-update DLLPs before indicating a flow-control protocol error. The value is calculated as: Time (in µsec) × PCI Express controller core clock frequency (in MHz) The maximum time value is 200 µsec; the default value (0x10428) is 200 µsec for the default clock frequency of 333 MHz.

17.5.1.13.20 Secondary Status Interrupt Mask Register (RC-Mode Only)—0x5A0

The PCI Express secondary status interrupt mask register, shown in **Figure 17-142**, can be used to disable sideband interrupt generation when error bits in the PCI Express secondary status register are set. See **Section 17.5.1.11.29**, *PCI Express Secondary Status Register—0x1E*, on page 17-89 for more information. By default, interrupt generation due to secondary status errors is disabled.

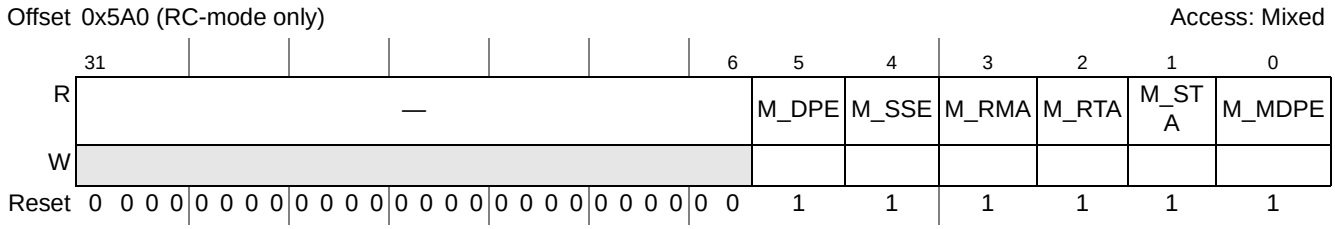

Figure 17-142. PCI Express PCI Interrupt Mask Register (PEX_SS_INTR_MASK)

The fields of the PCI Express secondary status interrupt mask register are described in **Table 17-141**.

Table 17-141. PEX_SS_INTR_MASK Field Descriptions

Bits	Name	Description
31–6	—	Reserved
5	M_DPE	Mask detected parity error
4	M_SSE	Mask signaled system error
3	M_RMA	Mask received master abort
2	M_RTA	Mask received target abort
1	M_STA	Mask signaled target abort
0	M_MDPE	Mask master data parity error

17.5.1.13.21 Gen2 Control Register—0x640

The PEX Gen2 control register, shown in **Figure 17-143**, can be used to control the MAC in Gen2 device.

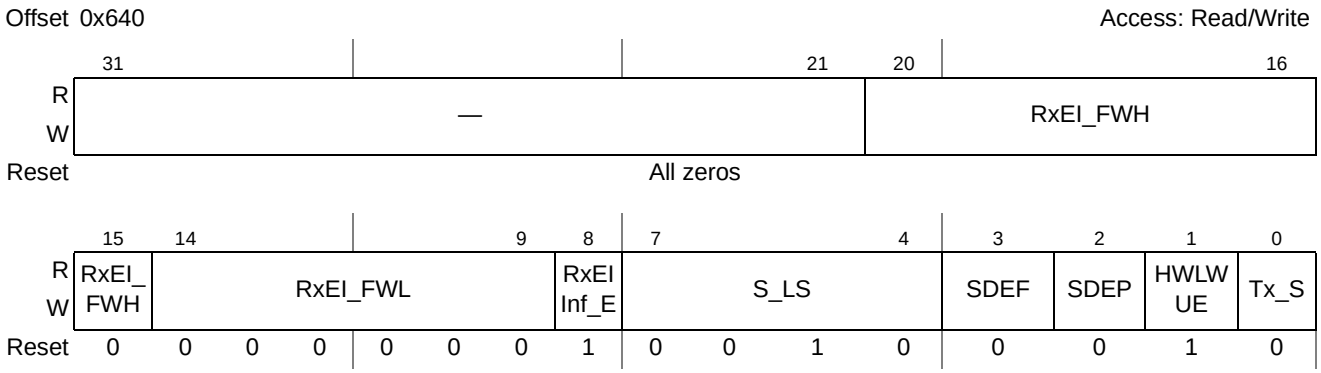

Figure 17-143. PEX Gen2 Control Register (PEX_GEN2_CONTROL)

The fields of the PEX Gen2 control register are described in **Table 17-142**.

Table 17-142. PEX_GEN2_CONTROL Field Descriptions

Bits	Name	Description
31–21	—	Reserved
20–15	RxEI_FWH	RxEI filter width high
14–9	RxEI_FWL	RxEI filter width low
8	RxEI_Inf_E	RxEI inferring enable
7–4	S_LS	Supported link speeds
3	SDEF	Select de-emphasis forced
2	SDEP	Select de-emphasis preferred
1	HWLWUE	Hardware link width upconfiguration enable
0	Tx_S	Transmit swing

18 Common Public Radio Interface (CPRI) Complex

The CPRI complex enables communication among radio devices (REC or RE) over a CPRI bus. The CPRI subsystems located at the baseband processing side are called Radio Equipment Control (REC) and the subsystems located at the radio module are called Radio Equipment (RE). The subsystems (RE and REC) are also called nodes. A radio basestation must have at least two nodes, with at least one of each type (RE and REC). RE nodes can be local or remote.The nodes are connected by one or more interface links, where each link connects two ports which have asymmetrical functions and roles: a master port and a slave port. At least one REC node in a radio basestation must have at least one master port with optional ports that can be slave or master. Typically, a basestation has one master port and one slave port.

The CPRI complex in the MSC8157E is designed to support the CPRI version v.4.1 specification and can be configured to support several air interface standards, including WiMAX, LTE, and WCDMA. Each complex supports up to six CPRI links with each link configurable as a master or slave port.

Each CPRI link supports three types of service access points (SAP):

- IQ samples for antenna transferred through the SAP IQ Interface
- CPRI frames synchronized by the SAP synchronization interface
- CPRI link control and management (C&M) data transferred between SAPs in both CPRI master and slave ports. The fast C&M channel follows the same Ethernet standards as a slow C&M channel (HDLC).

Figure 18-1 shows the CPRI complex block diagram and external interfaces. The CPRI Framer modules construct CPRI frame structures and manage transmission of CPRI frames to a serial link using the ten-bit interface (TBI) protocol. The CPRI Framer also extracts the data fields from the received CPRI frames, and the C&M data is transferred to the system memory via the Ethernet HDLC integrated engines. The receive and transmit IQ data is transferred by the CPRI DMA to/from antenna carrier buffers in the main memory. The VSS, HDLC, and fast Ethernet also transfer the data to buffers in the system memory using DMA. Auxiliary interfaces are required to support chain topologies.

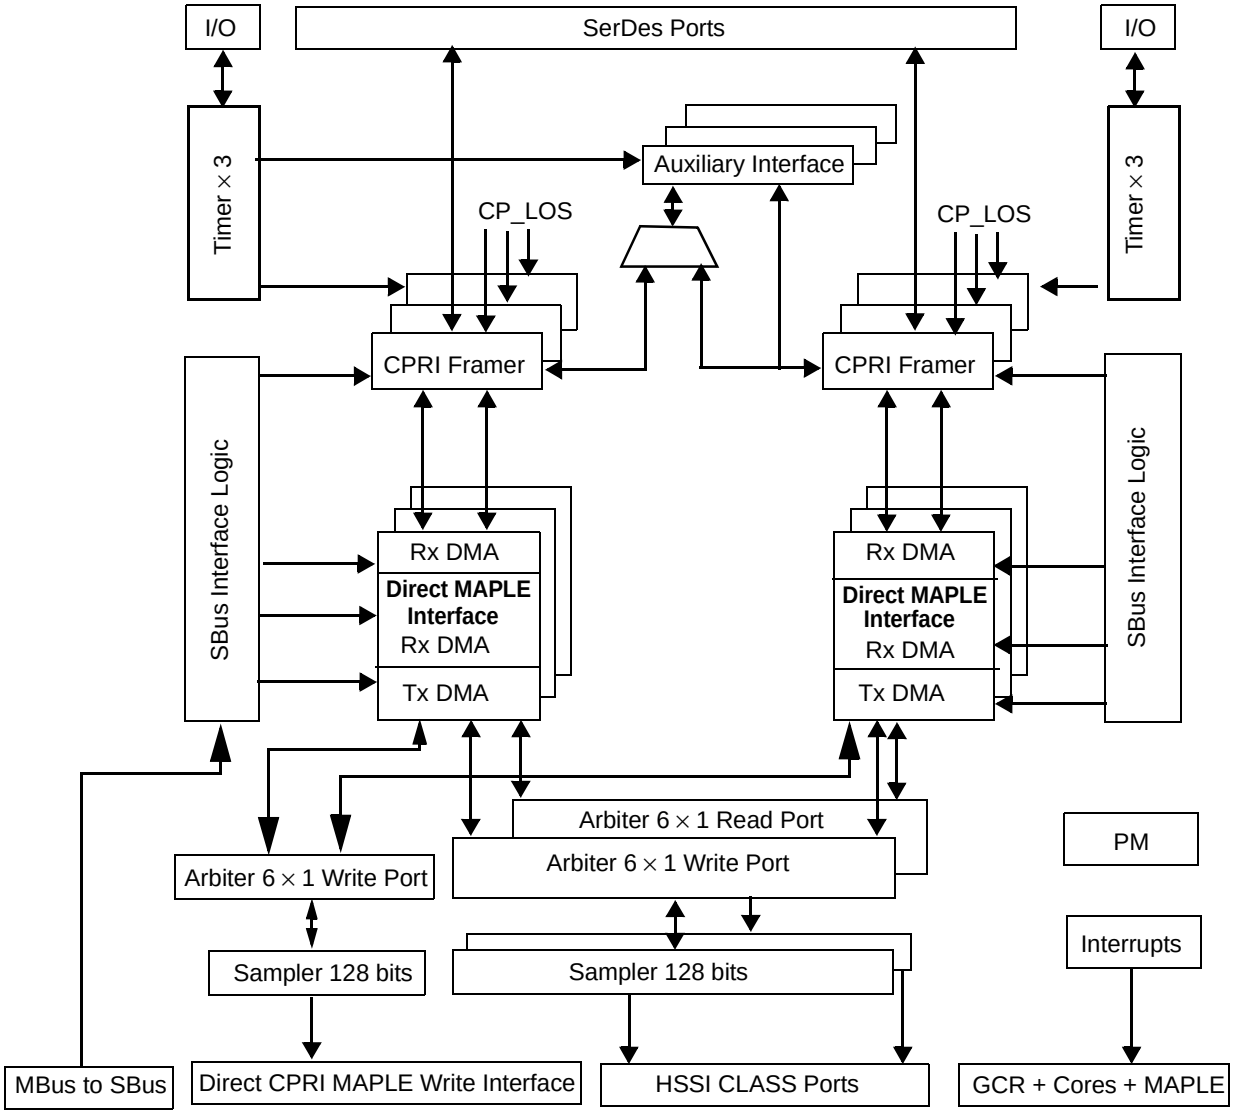

Figure 18-1. CPRI Complex Block Diagram

18.1 Features

The CPRI complex has the following features:

- Supports the following CPRI link rates:
  - 1228.8 Mbps
  - 2457.6 Mbps
  - 3072.0 Mbps
  - 4915.2 Maps
  - 6144.0 Mbps

Note: All the CPRI units must be configured to the same link rate

- Supports up to 6 lanes
- Supports the following topologies
  - Single point-to-point link between one REC and one RE (figure 3 in the CPRI Specification V4.1)
  - Multiple point-to-point link between one REC and one RE (Figure 4 in the CPRI Specification V4.1)
  - Multiple point-to-point links between one REC and several REs—Star topology (Figure 5 in the CPRI Specification V4.1)
  - Chain topology (figure 5A in the CPRI Specification V4.1)
  - Tree topology (figure 5B in the CPRI Specification V4.1)
  - Multiple point-to-point links between several RECs and one RE (figure 5D in the CPRI Specification V4.1)
  - Chain topology of multiple RECs (figure 5E in the CPRI specification V4.1)
- Supports the following mapping methods:
  - LTE mapping method 1 (IQ sample based) and method 3 (Backward compatible)
  - WiMAX mapping method 3 (Backward compatible).
  - WCDMA mapping method 3 (Backward compatible)
- Supports packed position and flexible position of each AxC container
- Each port supports up to 24 antenna carriers.
- All carriers of a CPRI unit should run with the same sampling rate. In order to support different radio interfaces running in different sampling rates on the same link, auxiliary interface must be used.
- Sample width supported: 8- (with double oversampling), 15- and 16-bit sample width.
- All the following LTE sampling rates:
  - 1.92 MHz (channel BW 1.25 MHz).
  - 3.84 MHz (channel BW 2.5 MHz).
  - 7.68 MHz (channel BW 5 MHz).
  - 15.36 MHz (channel BW 10 MHz).
  - 23.04 MHz (channel BW 15 MHz).
  - 30.72 MHz (channel BW 20 MHz).

Note: All the following LTE sampling rates: 1.92 MHz, 3.84 MHz, …, 1.92 * k MHz, …, 30.72 MHz (that is, any multiple of 1.92 MHz from 1.92 MHz through 30.72 MHz (inclusive) is supported

- Different WiMAX sampling rates like:
  - 4 MHz.
  - 5.6 MHz.
  - 8 MHz.
  - 10 MHz.
  - 11.2 MHz.
- Transparent mode (all the CPRI frames transfer to a single buffer in the main memory)
- Fast Control and Management MAC (Ethernet):
  - Three different MAC address filters:

  - Unicast filtering.
  - Multicast filtering (up to 32 different addresses).
  - Broadcast filtering.
- — 4b5b decoding and encoding
- — CRC.

- Slow Control and Management MAC (HDLC)
- Vendor Specific Data (VSS)
- L1 InBand.
- Link start-up and speed negotiation by software.
- Accurate delay measurement and calibration integrated.
- 32-bit Bus interface for register and memory configuration.
- Interrupts. Edge and level.
- Scrambling (optional) for non-daisy-chain topologies.

18.2 Modes of Operation

- Normal operation mode
- Transparent mode

18.3 Functional Description

18.3.1 CPRI Framer

The CPRI complex contains six identical CPRI Framers. The CPRI Framers are built of two main parts: receive and transmit. The transmit part constructs the CPRI frame structure and handles transmission of CPRI frames to the serial link. The receive part of the CPRI Framer extracts data fields from the received CPRI frames and transfers it to the CPRI DMA module. The CPRI Framer supports packed position and flexible position of the AxC container in the CPRI basic frame as defined in the CPRI standard. The CPRI Framer provides synchronization service access points (SAPs), using hyper frame number (HFN) and radio frame number (BFN) fields to provide timing information.

The CPRI framer handles the transmission and reception of all IQ data, C&M (Ethernet, HDLC) and VSS data.

In the transmit direction the framer constructs the CPRI frame structure, executes a 8b/10b encoding and parallel to serial conversion.

In the receive direction the framer executes serial to parallel conversion, comma/byte alignment, 8b/10b decoding, phase alignment and extracts the data from the frame.

Each instantiation of the CPRI framer is designed to provide a complete set of features required to support current and future standard evolutions. The principle followed by the development

process has been to keep it simple, optimized, and complete. This design supports the following basestation standards:

- UTRA-FDD Support (UMTS/WCDMA).
- E-UTRA Support (3GPP LTE)
- WiMAX Support (**IEEE** 802.16 standard)

Each framer contains the following functional blocks:

- CPRI Transmitter
- CPRI Receiver
- CPRI MAP Transmitter
- CPRI MAP Receiver
- Fast C&M interface (Ethernet MAC 10/100 MHz)
- Slow C&M interface (HDLC MAC)
- C&M Channels
  - VSS
  - L1 Inband
  - Alarms
- Register interface
- Delay measurement and calibration

The CPRI standard is based on a frame structure built of 10 ms radio frames. Each radio frame is built of 150 hyperframes and each hyperframe is built of 256 basic frames. There are 16 words in each basic frame; the first is a control word and the others are IQ data. The size of the words depends on the link rate as defined in the standard (at 1.228 Gbps link rate each word is 16 bits and at 6.144 Gbps link rate each word is 80 bits).

The following sections describe the framer components that process the frames:

- **Section 18.3.1.1** provides the basic description of the Framer Transmitter.
- **Section 18.3.1.2** provides the basic description of the Framer Receiver.
- **Section 18.3.1.3** describes the auto negotiation process.
- **Section 18.3.1.4** describes the way the IQ data is mapped in the IQ data words.
- **Section 18.3.1.5** describes the transmission and reception of the control words.

18.3.1.1 CPRI Framer Transmitter

Figure 18-2 shows the functions of the CPRI TX module inside the CPRI Framer. After the software driver initializes the system and enables the CPRI, the TX framer starts to negotiate versus the RE or REC connected to it (autonegotiation flow is described in **Section 18.3.1.3**). At the end of the autonegotiation phase, the user can enable the DMA and the DMA begins to read the data into its Memory (IQ, Ethernet, HDLC, and VSS).

As long as the Framer is enabled, it reads the IQ samples, Ethernet data, HDLC data, and other control data from the DMA memory and multiplexes them together to form the CPRI frame structure. If the DMA does not contain any data to be transmitted, the Framer keeps sending “0” instead of IQ, Ethernet, HDLC, and VSS. All transmit data from the Framer goes through the 8b/10 encoder and parallel to the serial module towards the physical interface.

It is possible to scramble the CPRI frames (as specified in the CPRI v4.1 specification) for rates greater than 3.072 Mbps for non-daisy-chain topologies. The scrambling is enabled using the CPRIn_TX_PROT_VER register with the scrambler seed configured in the CPRIn_TX_SCR_SEED register.

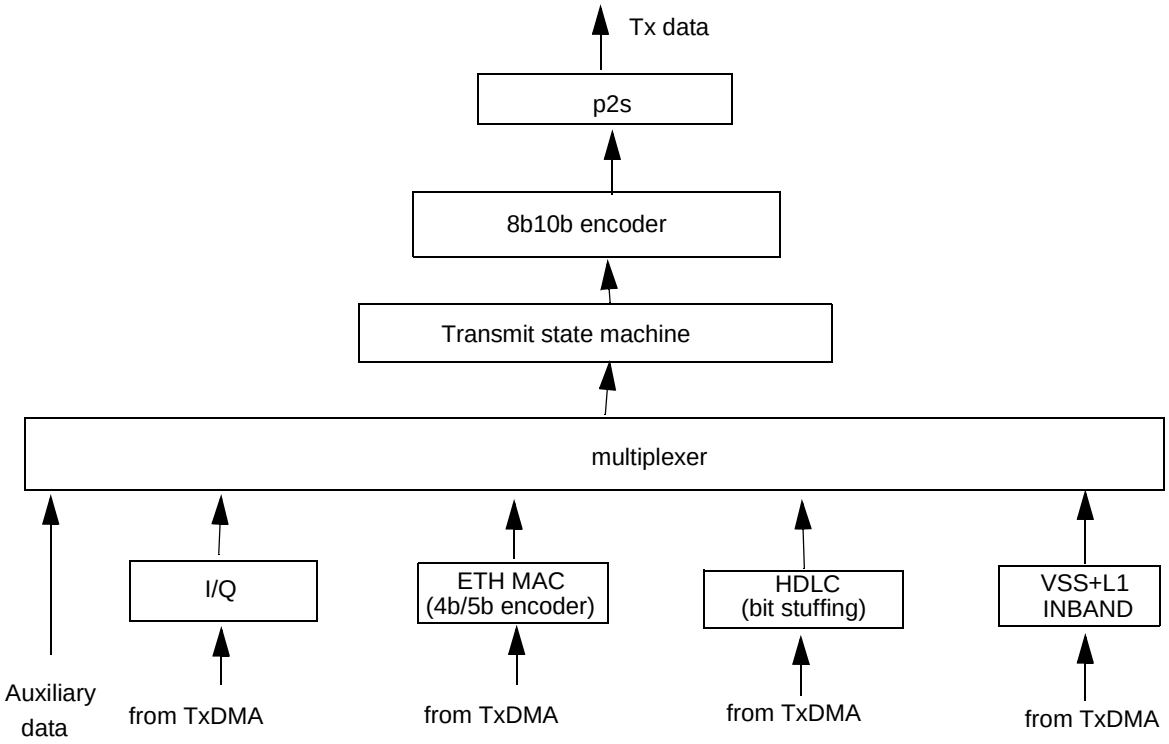

Figure 18-2. CPRI Framer TX Path Architecture

18.3.1.2 CPRI Framer Receiver

Figure 18-3 shows the functions of the CPRI framer RX module.

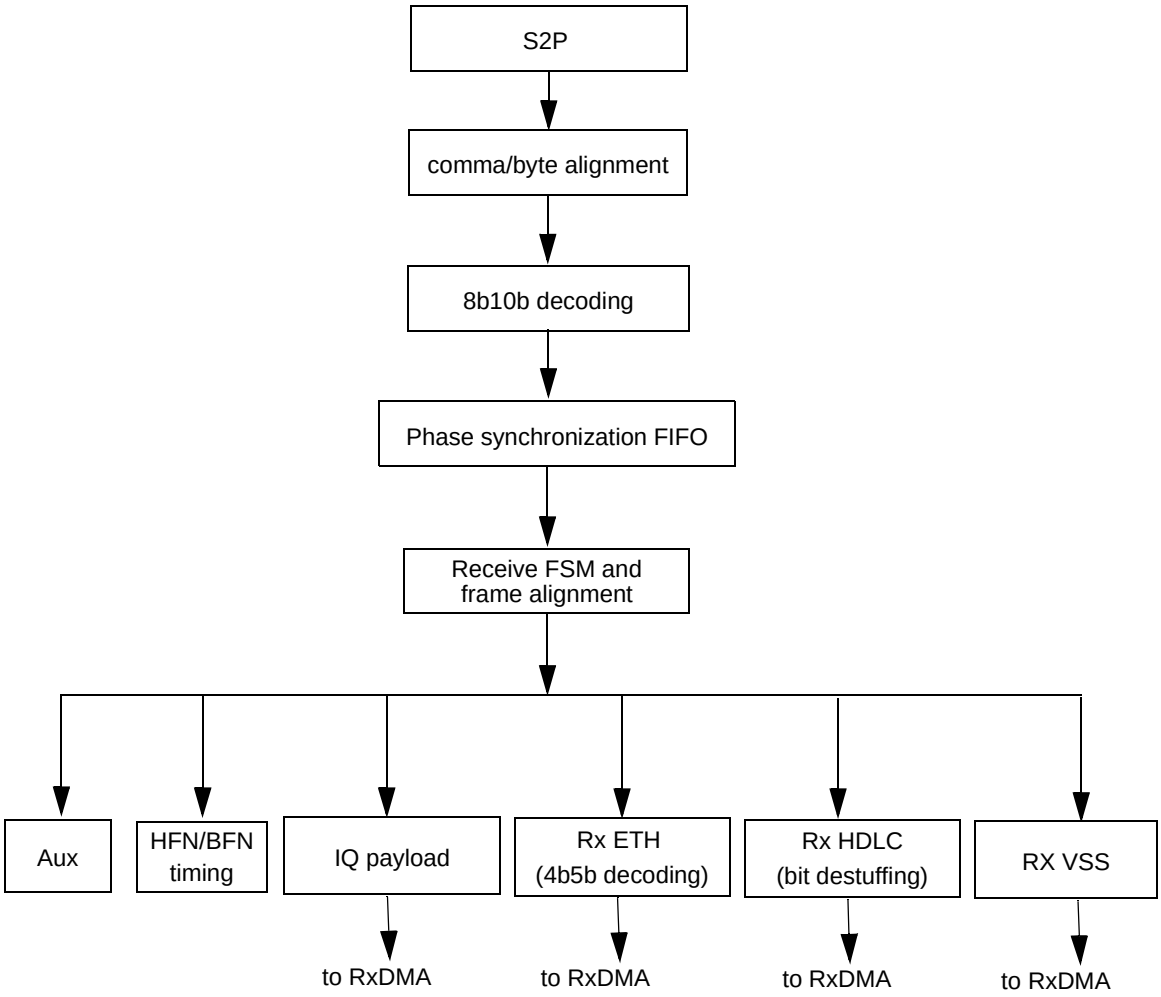

Figure 18-3. CPRI RX Module Path Architecture

In the receive path, the role of the SerDes is to recover the clock from the received data and both clock and data are then moved towards the Framer. The data is first converted from serial to parallel followed by comma alignment and 8b10b decoding. Then, the framer extracts the IQ, Ethernet, HDLC, and VSS from the received frames as follows:

- IQ data are forwarded to the CPRIn_RX_MAP module for extraction of IQ data streams. This data is written through the RX IQ DMA to the configured system memories.
- Ethernet data is extracted according to the pointer p (Z.194.0). Pointer p value is recovered (new pointer accepted when 4 consecutive equal values are received) and used to identify control words carrying Ethernet data. These control words are 4b5b decoded and forwarded to the Ethernet termination module. The Ethernet packets are written through the RX Ethernet DMA to the relevant system memory location.

- The HDLC bit rate information is recovered (new rate accepted when 4 consecutive equal values are received) and used to identify control words carrying HDLC data. These control words are bit-destuffed symbols and are forwarded to the HDLC termination module. The HDLC packets are written through the RX HDLC DMA to the relevant system memory location.
- VSS data extraction uses the recovered pointer p and it is used to identify control words carrying VSS. The VSS data is written through the RX VSS DMA to the relevant system memory location.

The Recovered Receive Clock (CDR clock) that is used to sample the receive data from the SerDes must be frequency synchronous with the internal Framer Clock (TBI clock divided by 4). If there is a difference in the frequency (due to system problem like uplink generated by using different clock frequency), the synchronization buffer can overflow or underflow and resynchronization executes automatically. The RX_FREQ_ALARM_HOLD field in the CPRIn_STATUS register can be used to monitor whether the CDR Clock is synchronous to the Framer Clock. If a frequency difference of more than ±4 clock cycles is detected, the alarm bit is flagged. The alarm bit is cleared when reading the CPRIn_STATUS register. If the alarm is reset, it requires a new drift of 4 cycles to set the alarm again. After clock synchronization, the CPRI frame detection is performed.

As specified in CPRI v4.1, auto detection of scrambled data is performed for rates above 3.072 Gbps based upon the received number in the protocol version field (Z.2.0). The scrambler seed is automatically extracted and is made available through the register CPRIn_RX_SCR_SEED. In case data is scrambled, it automatically descrambles before further processing.

A state machine performs CPRI hyper frame alignment in the receive direction expecting the K28.5 synchronization control word always in the first basic frame of each hyperframe. The HFN and BFN alignments are recovered when 4 matching sequences are received, respectively Alignment is considered lost after 4 consecutive mismatches. RX_HFN_STATE and RX_BFN_STATE status can be read in the CPRIn_STATUS register. The recovered CPRI frame timing is available to the system via the timing output interface. The RX_STATE bit in the CPRIn_STATUS register is set after completion of the full synchronization flow as described previously.

It can as many as 6 hyperframes to achieve rx sync. 6 hyperframes = 6 * 256 (basic frames in a hyperframe) * 40 (clock cycles in a basic frame @ 6.144 Gbps line rate) Framer Clock cycles. The count starts when the first K28.5 is seen on the TBI/4 Framer Clock side of the Rx Synchronization Buffer.It takes two K28.5 (spaced correctly) to exit LOS, and it then takes another 4 K28.5s with correct spacing to enter rx sync state.

18.3.1.3 Auto Negotiation (Setup)

The Autonegotiation flow has three stages:

- Sets up the link rate between the devices.
- Sets up a common protocol version
- Sets up a common C&M channel rate if needed

The auto negotiation flow is done by software according to the flow described below. The flow is for a single CPRI link.

All the CPRI lanes must be configured to the same link rate even if they are not enabled. it means that fields RRAT_SEL and TRAT_SEL in registers LEGCR0– LJGCR0 should be configured with the same value.

The auto negotiation reset is done by writing to bit SDRST in register SRDSB2RSTCTL located outside the CPRI complex. It resets the PLL inside the SerDes which it shared between all the CPRI modules.

The auto negotiation reset has the following effects:

- Resets all the CPRI Framer registers
- Resets all the CPRI DMA operation registers (pointers, counters, and so on)
- All the state machines return to their idle state.
- All the registers are reset.
- The CPRI memories are not affected.

18.3.1.3.1 Autonegotiation (Setup) Flow

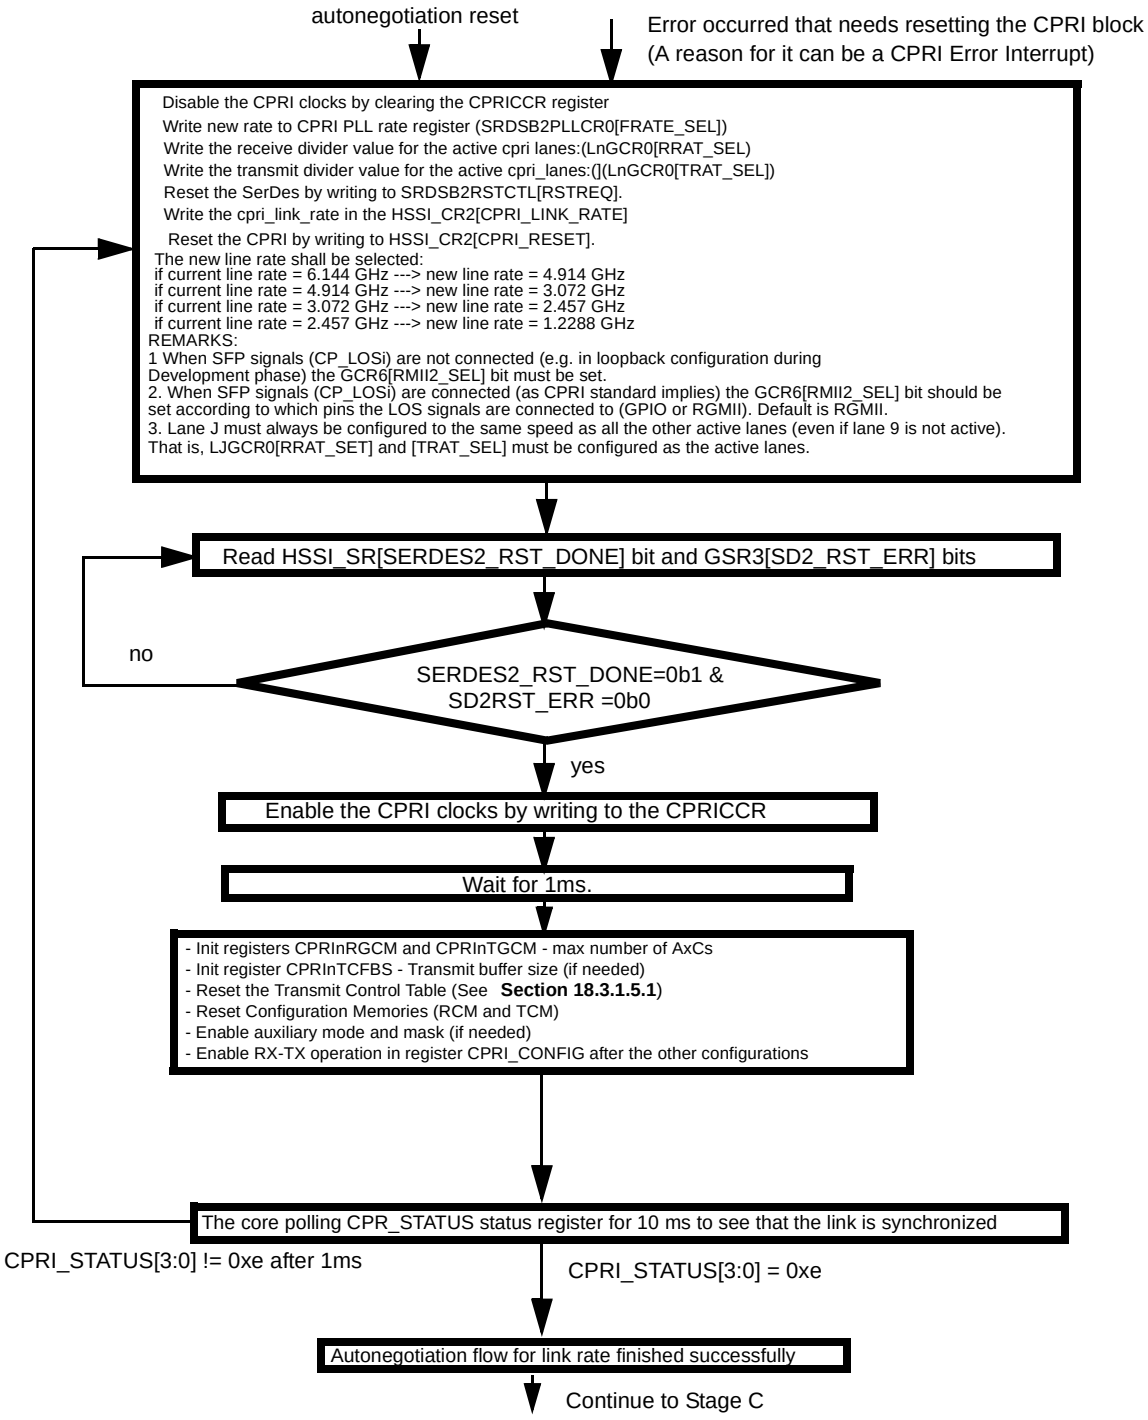

Figure 18-4. Autonegotiation Setup Flow

18.3.1.3.2 Protocol Setup (State C)

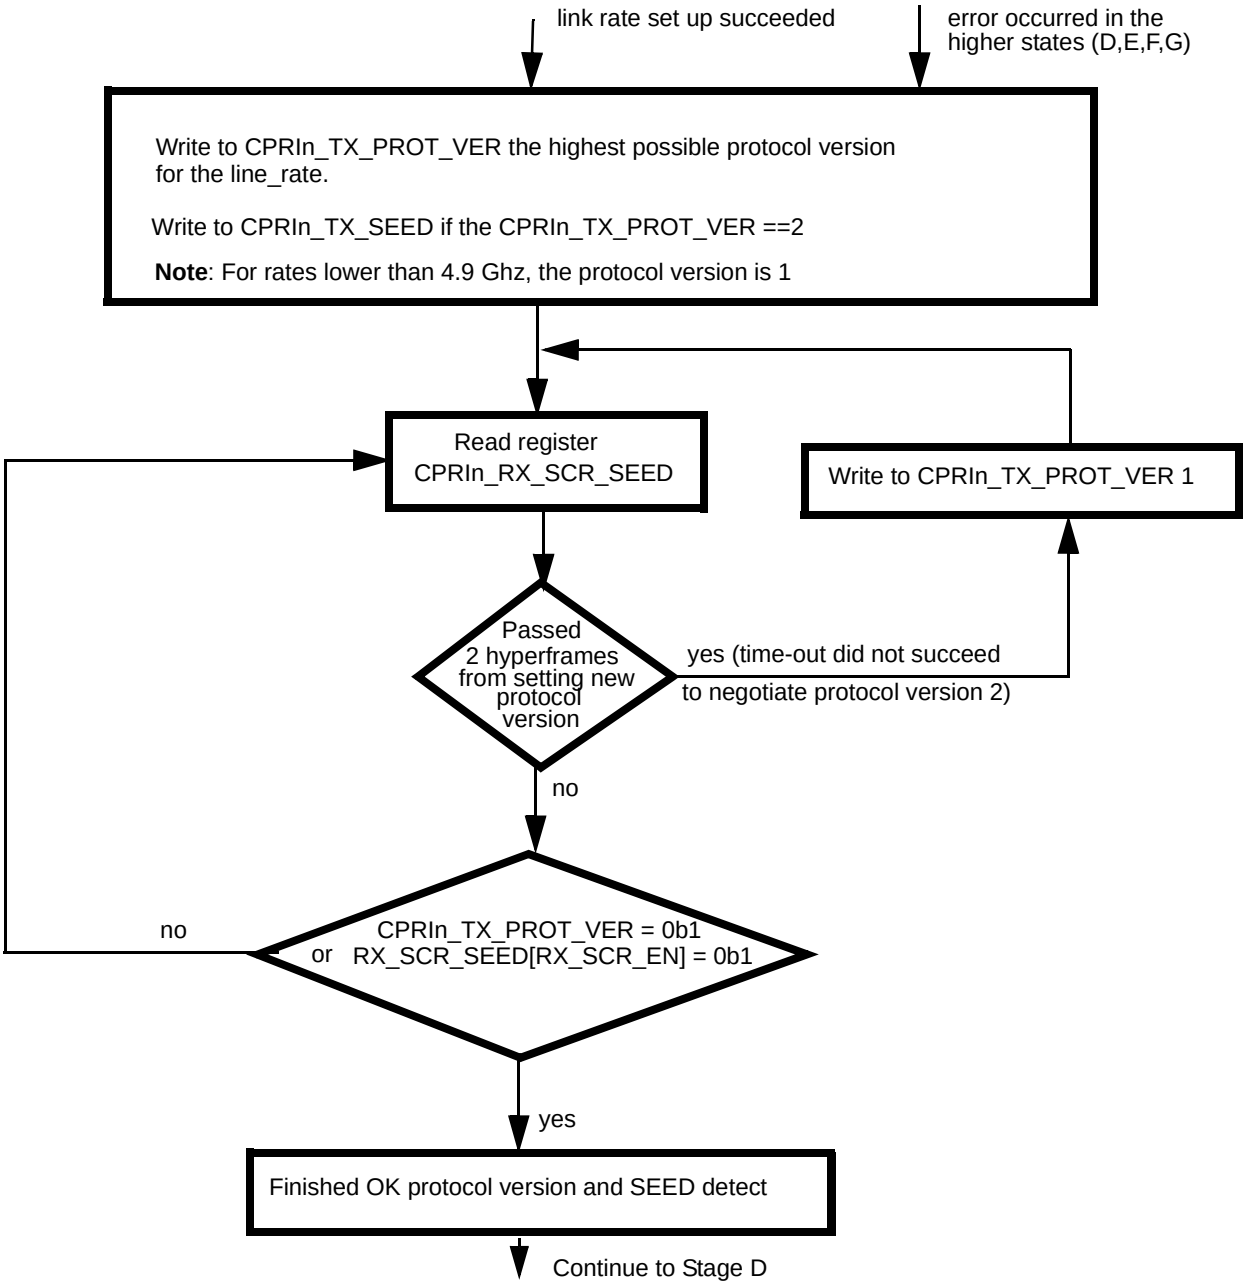

Figure 18-5. Protocol Setup

18.3.1.3.3 C&M Channel Rate Setup (State D)

During this state a common C&M channel bit rate is determined (at least one control rate)

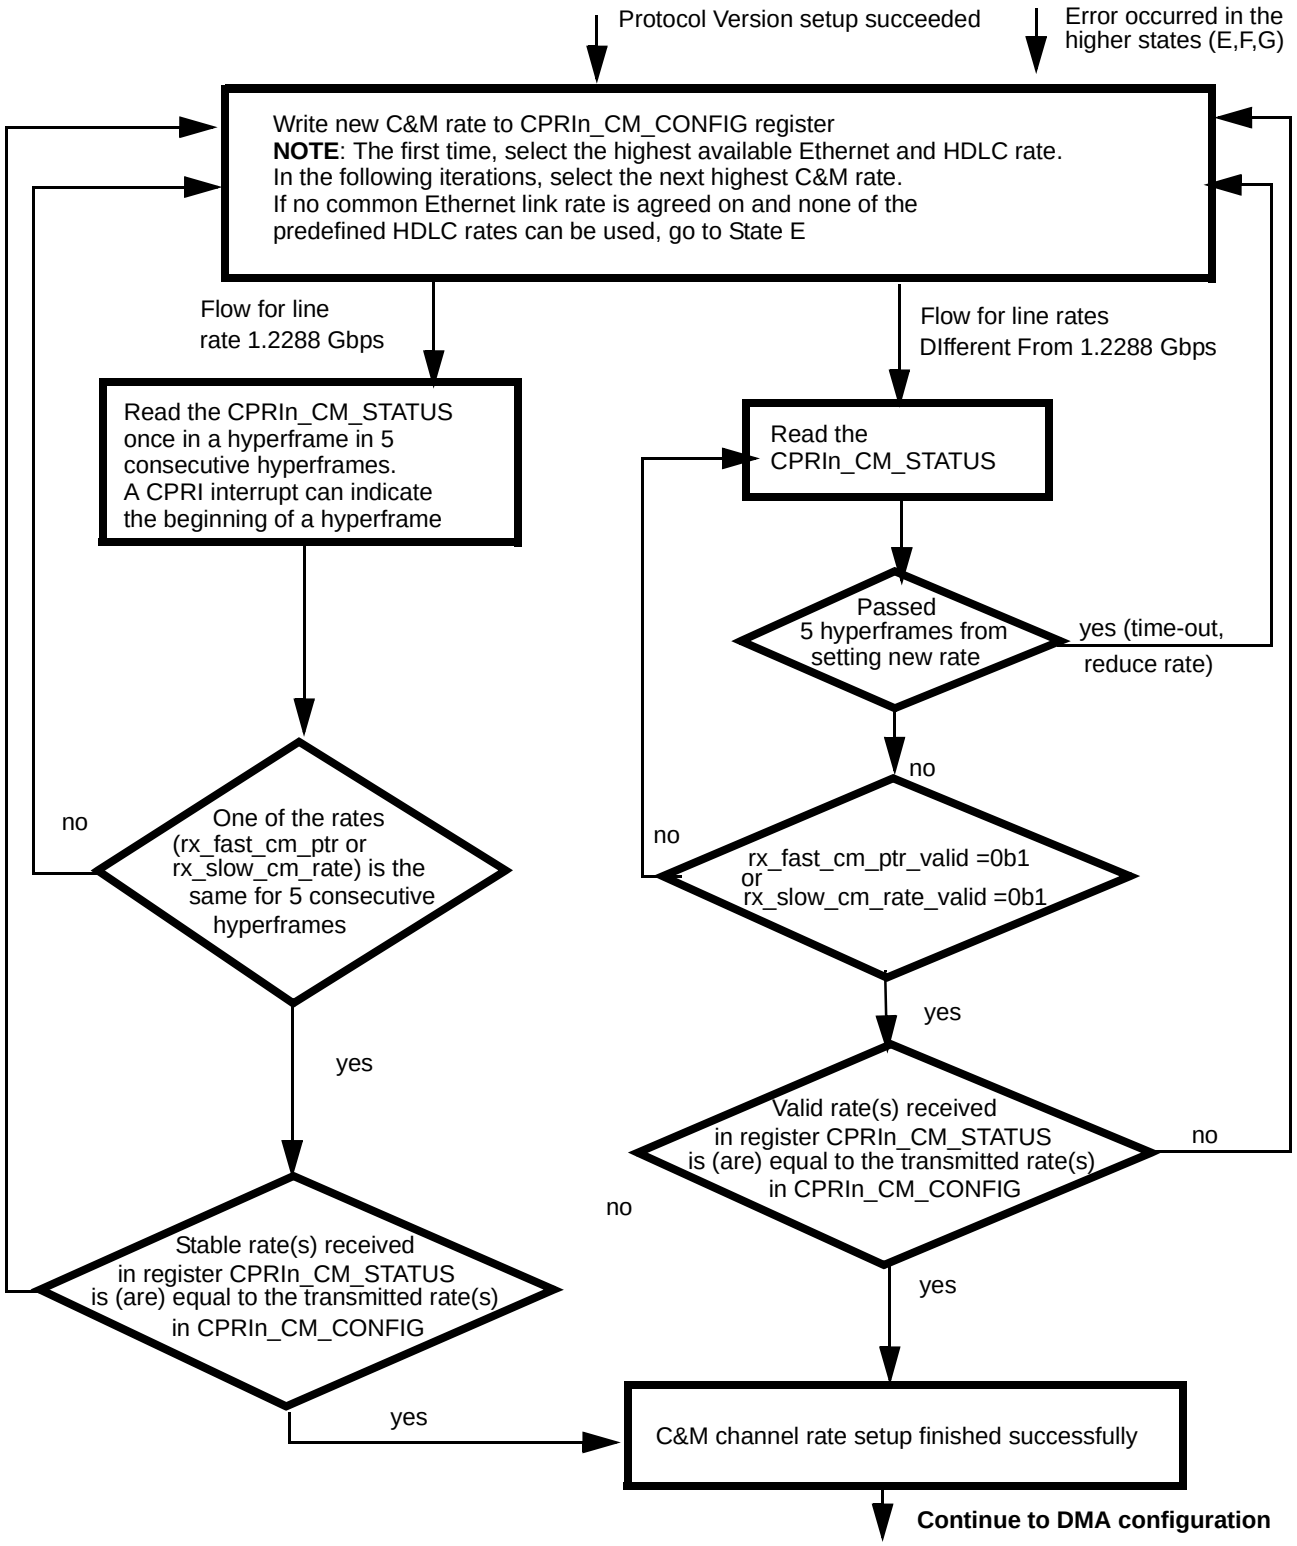

Figure 18-6. C&M Channel Rate Setup

18.3.1.3.4 DMA Configuration

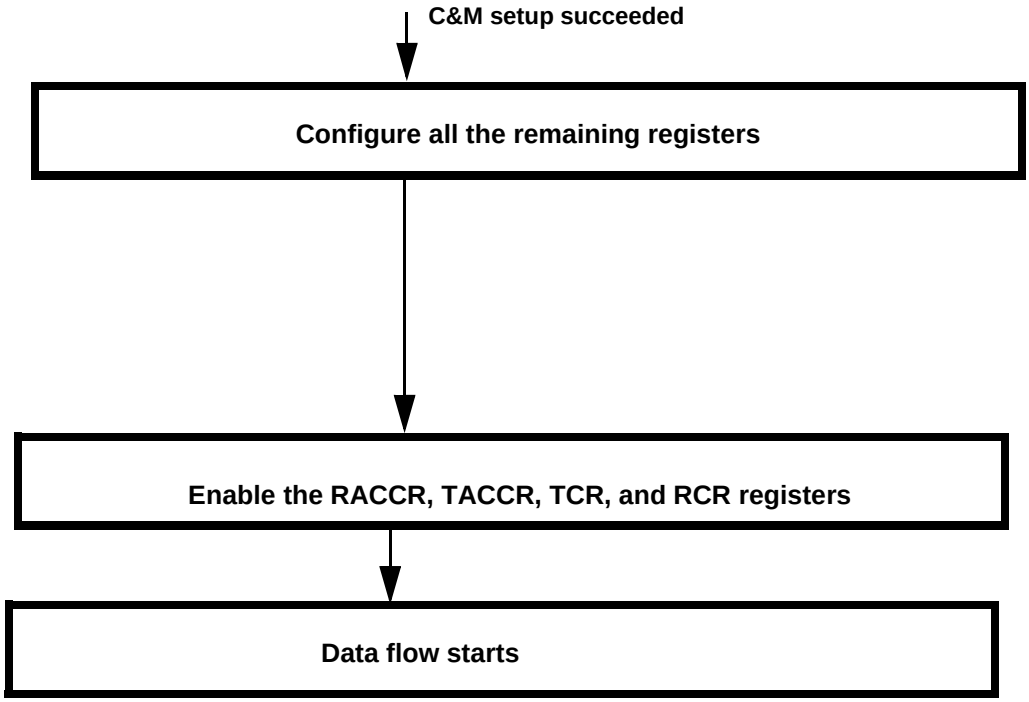

Figure 18-7. Configuring and Enabling the DMA Logic

18.3.1.3.5 State E—Interface and Vendor Specific Negotiation

During the E state, the application for the master and slave ports negotiates the CPRI usage. If a common bit rate for the Ethernet link is agreed to in state D, it is used. Otherwise, the HDLC link is used. In this state, negotiation to a HDLC bit rate that is not one of the pre-defined bit rates may occur. After the negotiation, the core sets the TX_SLOW_CM_RATE field in register CPRIn_CM_CONFIG to 0x007 to indicate to the slave port that a new HDLC bit rate is used. The characteristics of the negotiated HDLC channel is vendor-specific and is outside of the specifications defined for the CPRI.

18.3.1.4 CPRI AxC Mapping

The IQ mapping modules perform mapping of I/Q samples of the different AxCs into the CPRI frame structure. The MAP_MODE field of the CPRIn_MAP_CONFIG register selects between different mapping schemes available.

18.3.1.4.1 Basic AxC Mapping Mode

The basic mapping scheme is selected by setting MAP_MODE to 00 and applies to UMTS/LTE standards in which all the AxCs use the same sample rate. This mapping scheme follows the description given in CPRI Sections 4.2.7.2.2 and 4.2.7.2.3 Option 1 (Packed Position) in Figure #13 of the CPRI specifications.

IQ samples are mapped into Basic Frames as shown on **Figure 18-8**. The mapping is controlled by MAP_AC and MAP_N_AC fields in register CPRI Mapping Counter Configuration (CPRIn_MAP_CNT_CONFIG). For each AxC stream, IQ samples are mapped into AxC Containers, which are consecutively mapped into the IQ Data Block of the Basic Frames. The maximum number of AxC containers (NMAP) is 24. Each AxC Container contains samples only from one AxC mapping stream.

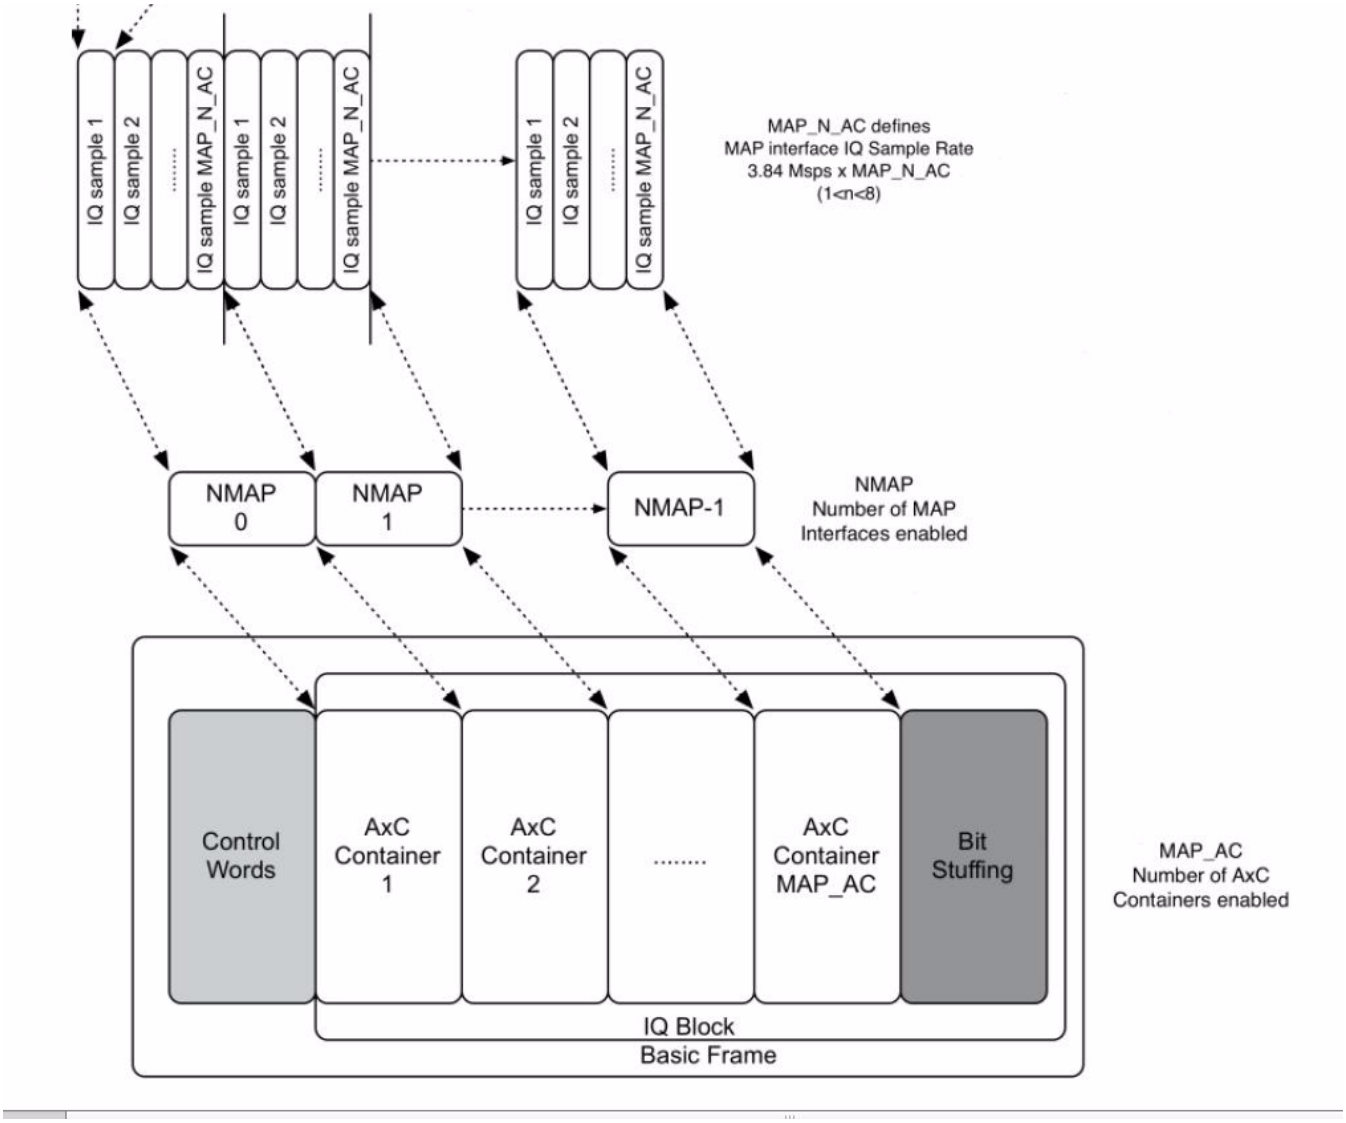

Figure 18-8. Example of Mapping of 16bits IQ samples

The number of IQ samples mapped into each AxC Container is given by the oversampling ratio MAP_N_AC. The sampling rate per AxC interface is computed in the following way:

$$\text{Sampling rate} = \text{MAP\_N\_AC} \times 3.84\ \text{MSPS}$$

The Oversampling Ratio factor is an integer value up to 8 so the maximal sampling rate, thus maximum 8 × 3.84 Msps = 30.72 Msps. **Table 18-1** shows the relation between UMTS/LTE sample rates and channel bandwidth.

Table 18-1. Relation between UMTS/LTE sample rates and RF channel BW

Sampling Rate (Msps)	Channel Bandwidth (MHz)
3.84	2.5 (LTE) & 5 (UMTS)
7.68	5 (LTE)
15.36	10 (LTE)
23.04	15 (LTE)
30.72	20 (LTE)

The number of AxCs and oversampling ratio are configured in the CPRI Mapping Counter Configuration (CPRIn_MAP_CNT_CONFIG) register. The bits in the Basic Frame that are not used for IQ samples are in the end of the Basic Frame and are padded with zeros. Locations of inactive AxCs are also padded with zeros. The active/inactive AxCs are determined by Receive AxC Control Register (CPRInRACCR) and by Transmit AxC Control Register (CPRInTACCR).

Example 18-1. AxC0 and AxC3 with No Oversampling.

2 AxCs (AxC0 and AxC3) used with no oversampling the configuration is:

CPRIn_MAP_CNT_CONFIG = 0x00000401 (MAP_AC=4, MAP_N_AC=1)

CPRInRGCM[MAP_AC] = 4

CPRIn_RACCR= 0x00000009

In case of sample width 16 bits and 2.457 Gbps link rate the Basic frame will be:

Control word, AxC0, {0x0}, {0x0}, AxC3, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}

Example 18-2. AxC0 and AxC3 with Oversampling Ratio 3

2 AxCs (AxC0 and AxC3) used with oversampling ratio 3 the configuration is:

CPRIn_MAP_CNT_CONFIG = 0x00000301 (MAP_AC=4, MAP_N_AC=3)

CPRInRGCM[MAP_AC] = 4

CPRIn_RACCR= 0x00000009

In case of sample width 16 bits and 3.072 Gbps link rate the Basic frame will be:

Control word, AxC0, AxC0, AxC0, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, AxC3, AxC3, AxC3, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}, {0x0}

Sample width inside the framer is programmable to 15-bit or 16-bit for each I and Q. The register CPRI Mapping Configuration (CPRIn_MAP_CONFIG) has the field MAP_15BIT_MODE that can select whether 15-bit or 16-bit samples are mapped. Note that 8-bit sample width and double oversampling (typically used in UL) can be also supported by transferring two samples at a time on the IQ mapping interface. 8-bit sample width and double oversampling can be configured in the CPRInRGCM register.

The maximum number of AxCs is limit to 24 AxCs but it is also limited by the sample width and the link rate **Table 18-2** describes the number of IQ bits in basic frame as function of link rate.

Table 18-2. Bits in IQ Data Blocks

"Rate" Configuration	Transmission Bit-rate	Number of Bits in IQ Data Block of BF
"0010"	1228.8 Mbps	240
"0100"	2457.6 Mbps	480
"0101"	3072.0 Mbps	600
"1000"	4915.2 Mbps	960
"1010"	6144 Mbps	1200

The maximum number of AXCs is determined by the formula below:

```
2 × <sample width > × MAP_N_AC × MAP_AC <= Bits in IQ Data Block
```

Table 18-3. AxC Link Capacity for 16-bit IQ sample

Channel BW LTE (Sample Rate)	2.5 MHz (3.84 Msps)	5 MHz (7.68 Msps)	10 MHz (15.36 Msps)	15 MHz (23.04 Msps)	20 MHz (30.72 Msps)
1228.8 Mbps	7	3	1	1	—
2457.6 Mbps	15	7	3	2	1
3072 Mbps	18	9	4	3	2
4915.2 Mbps	24 (limited by maximum number of supported AxCs)	15	7	5	3
6144 Mbps	24 (limited by maximum number of supported AxCs)	18	9	6	4

Table 18-3 shows AxC link capacity for sample width 16. As an example for a CPRI link at 3072.0 Mbps, there are 600 bits for IQ in each basic frame; therefore, in the case of LTE 5MHz (that is, oversampling ratio = 2), there is bandwidth to transfer nine LTE 5 MHz carriers in each Basic Frame. The IQ data takes only 2*16*2*9= 576 bits so there are always 24 bits of padding in the end of the basic frame that cannot be used in this mapping mode. This bandwidth can be also used to transfer up to 18 AxC channels at 3.84 Msps UMTS rates or up to 2 AxC at 30.72 Mbps LTE rates or anything in between, as long the available bandwidth relation is not violated. For the 15-bit sample size, the total number of required bits must be less than or equal to the following number:

```
2 × 15 × MAP_N_AC × MAP_AC <= Bits in IQ Data Block
```

Table 18-4. AxC Link Capacity for 15-bit IQ Sample

Channel BW LTE (Sample Rate)	2.5 MHz (3.84 Msps)	5 MHz (7.68 Msps)	10 MHz (15.36 Msps)	15 MHz (23.04 Msps)	20 MHz (30.72 Msps)
1228.8 Mbps	8	4	2	1	1
2457.6 Mbps	16	8	4	2	2
3072 Mbps	20	10	5	3	2
4915.2 Mbps	32	16	8	5	4

Table 18-4. AxC Link Capacity for 15-bit IQ Sample

Channel BW LTE (Sample Rate)	2.5 MHz (3.84 Msps)	5 MHz (7.68 Msps)	10 MHz (15.36 Msps)	15 MHz (23.04 Msps)	20 MHz (30.72 Msps)
6144 Mbps	40	20	10	6	5

Note: Configurations requiring more bit bandwidth than available transfer the first AxC channels correctly until all AxC segments (timeslots) in the Basic Frame are used; the last AxC channels are not transferred correctly.

18.3.1.4.2 Advanced AxC Mapping Modes

The advanced AxC mapping modes enable mapping for IQ samples of different rates and different radio standards independently on the interface using auxiliary mode. The sampling rate of all the AxCs in a CPRI unit must be the same.

These modes are enabled by using configuration tables to define mapping of IQ samples to the CPRI IQ block data areas of the basic frame. These tables are static and are configured before link start up. They should not change until the next link start up.

The advanced table based mapping is selected by setting MAP_MODE field in the CPRIn_MAP_CONFIG register, as follows:

- 01 = CPRI v4.1 Standard Section 4.2.7.2.5 Method 1: IQ sample based.
- 10 = CPRI v4.1 Standard 4.2.7.2.7 Method 3: Backward Compatible

Support of the following is available:

- Support for mapping method 3 E-UTRA [CPRI v4.1] is available. Note that in order to achieve it in the case of a 15-bit sample width, use the following:
  - For flexible position, use mapping method 1.
  - For packed position, use mapping method 3.
- Support for mapping method 1 E-UTRA [CPRI v4.1] is available. Note that in order to achieve it in the case of a 15-bit sample width, use the following:
  - For flexible position, use mapping method 1.
  - For packed position, use mapping method 3.
- Support for mapping method 3 WiMAX [CPRI v4.1] is available. Note that in order to achieve it in the case of a 15-bit sample width, use the following:
  - For flexible position, use mapping method 1.
  - For packed position, use mapping method 3.

Supports 15 and 16-bit (including 8b with double oversampling) sample width as in the basic mapping mode.

In addition to the Basic Mapping mode the Advanced Mapping mode supports:

- WiMAX
- Mapping tables to map the IQ samples to the frames
- Flexible position. It is possible to configure the number of stuffing bits between samples or in the beginning of a Basic Frame or AxC Container Block
- Individual sample rates per AxC interface for multiple standards or rates via auxiliary mode. **Note that each unit supports only one sample rate**.
- Supporting K>1
- It is possible to configure an IQ sample rate different from n $\times$ 3.84 Msps. For example, the WiMAX sample rates and E-UTRA sample rate at 1.92 Msps can be configured easily.

K value:

IQ samples are mapped into AxC Container Blocks with a duration of K basic frames, where K is defined in the register CPRI Mapping Table Configuration (CPRIn_MAP_TBL_CONFIG). The K value is common for all AxC interfaces, and the number S of samples allocated to an AxC interface must be also the same. K is typically set to one of the values defined in CPRI v4.1 which are 1, 2, 12, 24 or 48.

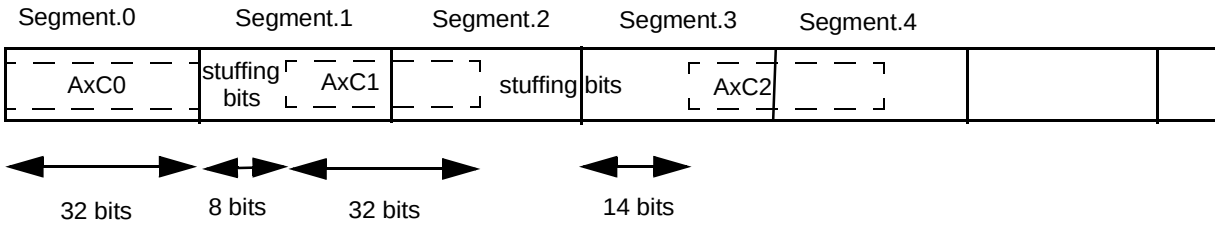
Mapping Table:

Separate mapping tables for RX side and TX side are used to define position of samples in the AxC Container Block. The tables have an entity for each 2*16 bits or 2*15 bits segments of the AxC Container Block depending on the mapping method and if 15-bit sample mode is selected. In case of sample width 15 bits and mapping method 3 the segments are of 30 bits otherwise 32 bits.

Each a table entity contains the following attributes:

- Enable bit, which must be asserted to map an IQ sample into the segment
- AxC number to select the A&C interface
- Bit position to select bit-offset relative to first bit position of the segment
- Sample width to define number of sample bits mapped into the CPRI frame.

Figure 18-9 shows an example for mapping method 3, 16-bit sample width, and how the mapping table should be configured.



Mapping table configuration:

Segment 0: Enable bit =0x1, AxC number=0x0, Width=0x10, Position =0x0
Segment 1: Enable bit =0x1, AxC number=0x1, Width=0x10, Position =0x4
Segment 2: Enable bit =0x0, AxC number=0x0, Width=0x0, Position =0x0
Segment 3: Enable bit =0x1, AxC number=0x2, Width=0x10, Position =0x7

Mapping method 3, Sample width 16 bits

Figure 18-9. Mapping Table Configuration with Sample Width 16 bits

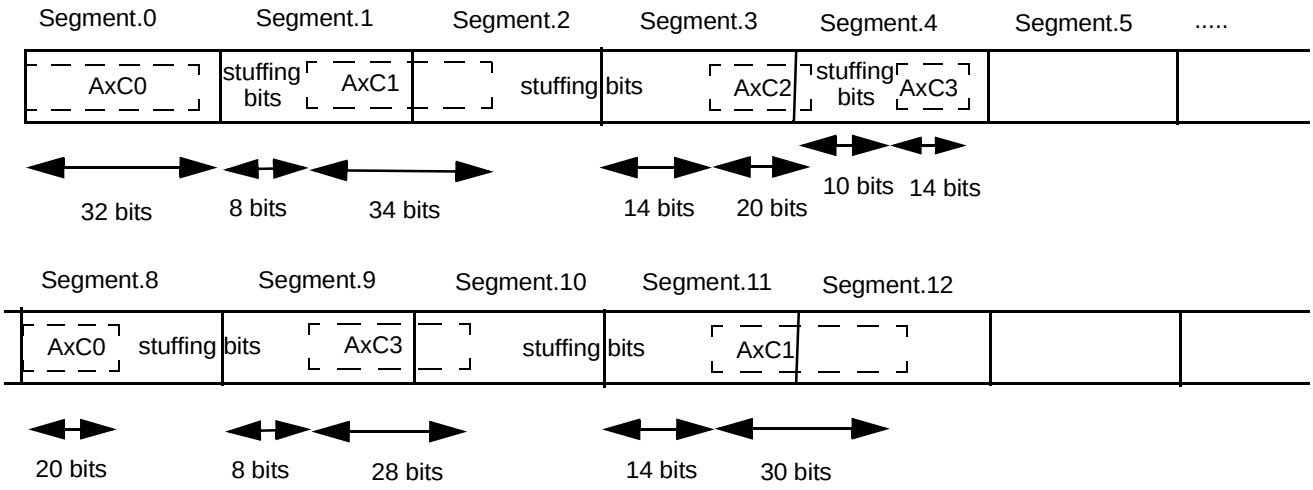
The receive memory fields are described by Receive Configuration Memory (CPRInRCM_<i>) and transmit memory fields are described by Transmit Configuration Memory (CPRInTCM_<i>).

The bit position field can be used for 16-bit sample width in both mapping methods (map_modes “01” and “10”). For 15-bit sample width, the bit position field can be used only in mapping method 1 (map_mode “01”). This makes it possible to define the exact bit offset position relative to the samples default position, such that a sample can be placed on any even bit position of the AxC Container Block.

In Mapping Mode 3, 15-bit sample width, exactly n IQ samples can be mapped into each Basic Frame, and all n*K entries of the table can be used. (n = 4*RATE)

In Mapping Method 1, the width field can be used as well to determine the number of bits used for each segment in the mapping table. This means that a segment may not contain exactly one sample. It could contain less than one sample (in this case that remainder of the sample is transmitted in the next segment enabling the AxC in question), or it can contain more (in this case some bits from the following sample are transmitted).

Figure 18-10 shows an example for mapping method 1, 15 bit sample width, and how the mapping table should be configured.



Mapping table configuration:

Segment 0: Enable bit =0x1, AxC number=0x0, Width=0xf, Position =0x0
Segment 1: Enable bit =0x1, AxC number=0x1, Width=0x11, Position =0x4
Segment 2: Enable bit =0x0, AxC number=0x0, Width=0x0, Position =0x0
Segment 3: Enable bit =0x1, AxC number=0x2, Width=0xa, Position =0x7
Segment 4: Enable bit =0x1, AxC number=0x3, Width=0x7, Position =0x5
Segment 5: Enable bit =0x0, AxC number=0x0, Width=0x0f, Position =0x0
Segment 6: Enable bit =0x0, AxC number=0x0, Width=0x0, Position =0x0
Segment 7: Enable bit =0x0, AxC number=0x0, Width=0x0, Position =0x0
Segment 8: Enable bit =0x1, AxC number=0x0, Width=0xa, Position =0x0
Segment 9: Enable bit =0x1, AxC number=0x3, Width=0xef, Position =0x4
Segment 10: Enable bit =0x0, AxC number=0x0, Width=0x0, Position =0x0
Segment 11 Enable bit =0x1, AxC number=0x1, Width=0x10, Position =0x7

Mapping method 1, Sample width 15 bits

Figure 18-10. Mapping Table Configuration for Sample Width 15 Bits

In 16-bit sample mode, there is no integer number of samples per AxC interface for most of the line rates (see **Table 18-5**). Stuffing bytes are placed by default at the end of each basic frame for mapping methods 1 and 3. The bit position field makes it is possible to place stuffing bits at the beginning of the basic frame or AxC Container Block or distribute them between samples.

Table 18-5. Capacity for 16-bit Mapping Mode

RATE	Line rate	n Number of Segments (timeslots)	Basic frame payload size	Samples	Spare bytes
2	1228Mbps	8	30 bytes	7	2
4	2457Mbps	16	60 bytes	15	0
5	3072Mbps	20	75 bytes	18	3
8	4915Mbps	32	120 bytes	30	0
10	6144Mbps	40	150 bytes	37	2

Segment numbering:

Depending on the mapping mode selected (map_mode and MAP_15BIT_MODE), there are entries of the mapping table that cannot be used. For mapping methods 1 and 3, unused table entries are always placed at the end of each group of n entries, where n is number of 32-bit words per Basic Frame shown in **Table 18-5** (n is also equal to 4*RATE).

For mapping methods 1 and 3, n segments are available for a basic frame, regardless of whether using 15 or 16 bit sample widths. For 15 bit samples in mapping mode 3, all the segments can be used but for 16 bit samples, there are a few segments at the end of each basic frame that cannot be used.

For example, for a 16 bit sample width and 3.072 Gbps line rate (rate=5) with K set to 2, there are 18 AxC Containers per Basic frame. In this case, n = 20 segments are available per basic frame so a second basic frame runs from segment number 20 to segment 37. See **Figure 18-8** for explanation. The total tables required is 40, but two groups of 18 are used.

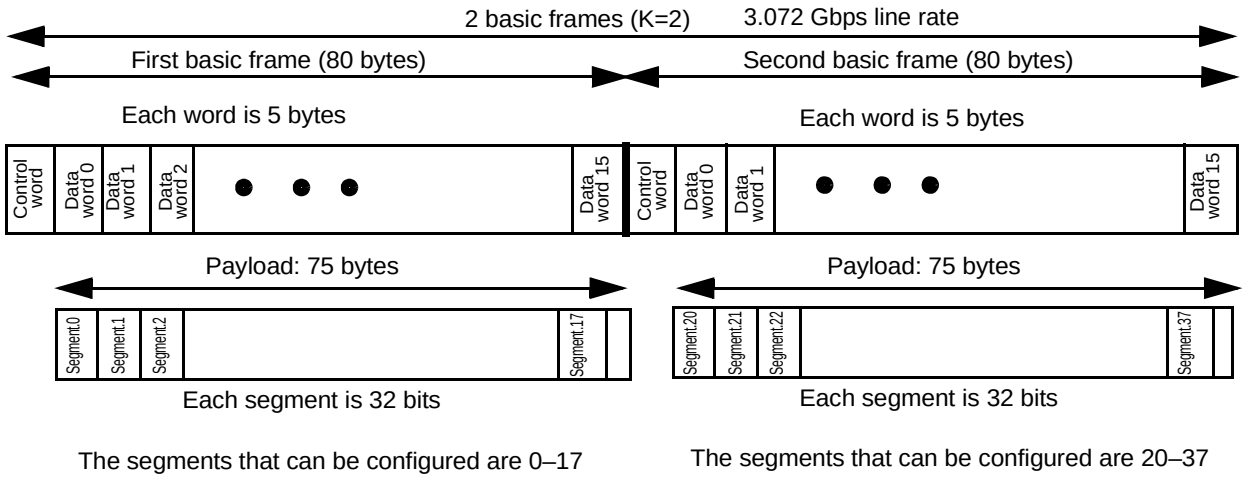


Figure 18-11. Use of Segments

18.3.1.4.3 CPRI IQ MAP Interface Synchronization

The AxC Container Block is synchronized to the start of the 10 ms CPRI frame with a frame offset defined in the CPRIn_MAP_OFFSET_RX and CPRIn_MAP_OFFSET_TX registers. The CPRI RX AxC Container Mapping Block Offset (CPRIn_MAP_OFFSET_RX) register defines where the first receive IQ sample is mapped relative to the start of the radio frame or CPRI Hyper Frame. This enables extraction of the CPRI frame sample position for the different AxCs.

The CPRI TX AxC Container Mapping Block Offset (CPRIn_MAP_OFFSET_TX) register defines the location of the first IQ sample in the transmit CPRI frame. The offset is defined relative to the start of the radio frame or CPRI hyper frame. This enables controlling the start of AxC container block when using advance mapping modes. This position is typically aligned with the WiMAX frame as defined in the CPRI Standard section 4.2.8.2, such that the offset register points at the first basic frame of the first AxC Container block in the WiMAX frame.

The values in the CPRIn_MAP_OFFSET_RX and CPRIn_MAP_OFFSET_TX registers also select the buffer synchronization done for every 10 ms CPRI Radio Frame or for every 67 µs CPRI Hyper Frame.

Typically, the CPRIn_START_OFFSET_TX register is set to an offset that is the number of basic frames before the offset of the CPRIn_MAP_OFFSET_TX register in which the number of basic frames is equal to the Transmit Buffer Size (as defined in the CPRInTCFBS register). For example, if CPRIn_MAP_OFFSET_TX is configured to 0x0 it means that the first IQ sample should be placed at the beginning of Radio frame (10 ms frame) in Hyperframe No 0, Basic frame No 0.

If the transmit buffer size is 16, then CPRIn_START_OFFSET_TX register should be configured as:

CPRIn_START_OFFSET_TX.START_TX_OFFSET_X = 0xF0 (Buffer size (16) before basic frame No 0)

CPRIn_START_OFFSET_TX.START_TX_OFFSET_Z = 0x95 (the1st hyperframe before hyperframe No 0).

See **Figure 18-12** describing the example

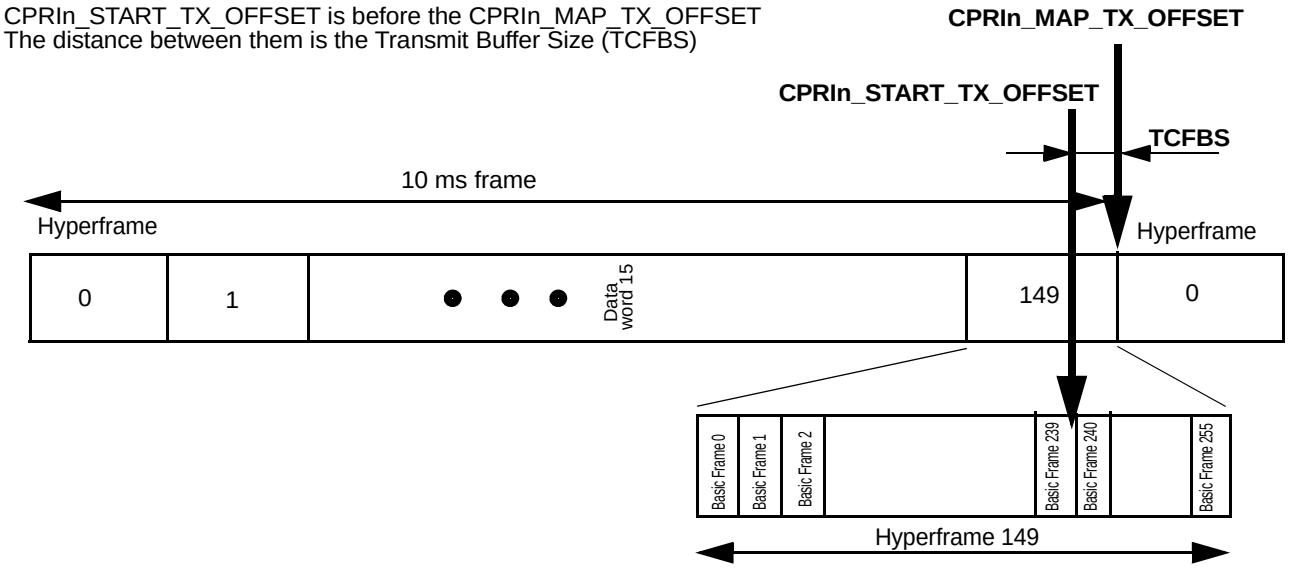

Figure 18-12. Use of Offset registers

18.3.1.5 Control Words

The following sections describe how the control words are processed.

18.3.1.5.1 Control Words Transmission

The following CPRI transmit control data is inserted by the CPRI module:

- Synchronization control byte (K28.5) and filling bytes (D16.2) in the synchronization control word
- HFN
- BFN
- HDLC bit rate
- Fast C&M pointer
- 4b5b encoded Fast C&M Ethernet frames
- Bit-stuffed Slow C&M HDLC frames

- VSS
- L1 Inband
- Alarms

Other control bytes (#Z.X.0.Y) can be inserted via the control transmit table. Programing the control transmit table is done by using the following registers:

- TX_CTRL_INSERT_EN CPRIn_CONFIG
- Transmit Control Data Register 0 (CPRInTCD0)
- Transmit Control Data register 1(CPRInTCD1)
- Transmit Control Data Register 2 (CPRInTCD2)
- Transmit Control Attribute Register (CPRInTCA)
- Transmit Control Table Insert Enable 1(TCTIE1)
- Transmit Control Table Insert Enable 2(TCTIE2)

The transmit table has an entry for each of the 256 control words, each up to 10 bytes values.

The VSS, Ethernet and HDLC data is managed by the DMA, but the other control words (words 0–15, 64–79,192–207,128–143) can be managed through registers mentioned above.

For example, to insert control word number 130, use the following steps:

1. Set bit 2 of TCTIE2 register.
2. Write the required data to TCD0,TCD1 and TCD2 registers.
3. Write the following to the TCA register: {0x0000000000000, 0x1, 0x00000082, 0x0000000000}

To read control word <x>, use the following steps:

1. Write the following to the TCA register: {0x0000000000000, 0x0, <x>, 0x0000000000}
2. Read the TCD0, TCD1, and TCD2 registers.

As the Transmit Control Table is a memory, it must be reset before use during the autonegotiation flow. The way to reset the Transmit Control Table is:

1. Write 0 to Transmit Control Data Register 0 (CPRInTCD0)
2. Write 0 to Transmit Control Data register 1 (CPRInTCD1)
3. Write 0 to Transmit Control Data Register 2 (CPRInTCD2)
4. Write to the Transmit Control Attribute Register (CPRInTCA) the following values in a loop ($0 \le i \le 255$) {0b0000000000000, 0b1, M, 0b1111111111} where M is an 8-bit number equal to i. (The first value of CPRInTCA is 0x00040000, the last is 0x0007FC00)

18.3.1.5.2 Control Words Reception

All received control bytes (#Z.X.Y) can be inspected via the control receive table, which is accessed using the following registers:

- Receive Control Attribute Register (CPRInRCA)
- Receive Control Data register 0 (CPRInRCD0)
- Receive Control Data Register 1 (CPRInRCD1)
- Receive Control Data Register 2 (CPRInRCD2)

The receive table has an entry for each of the 256 control words of a hyperframe containing 256 X × (up to) 10 Y (bytes) values. The table is continuously updated with received control bytes. To read a control byte first write to Receive Control Attribute Register (CPRInRCA) registers and than read the data from Receive Control Data register 0 (CPRInRCD0), Receive Control Data Register 1 (CPRInRCD1) and Receive Control Data Register 2 (CPRInRCD2).

The L1 inband data and the receive VSS can be read from the receive control table, but the received VSS data can be also transferred to internal memory by the receive DMA.

Note: The receive table is only updated when the receive state machine performing CPRI hyper frame alignment in the receive direction reflects alignment. Using the control word access tables, the user can also read the Ethernet and HDLC locations if using the wrong index.

18.3.1.5.3 Fast C&M Channel (Ethernet)

The Ethernet MAC is connected to the Ethernet interface of the CPRIn_RX and CPRIn_TX modules with a synchronous MII. The number of CPRI control words used for Ethernet frame transfer is controlled by the Fast C&M pointer, which is mapped into control byte Z.194.0. This pointer can be set to values from 0x14 to 0x3F. When the Ethernet channel is not used, set the pointer to 0x3F, which means that 4 control words are dedicated for Ethernet and 188 for VSS. To block reception of Ethernet packets, write all zeros to register CPRIn_ETH_CONFIG_1. To prevent transmission of Ethernet packets, do not prepare any BDs. The size of each control word depends on the link rate. Ethernet transfer uses all the bytes of the relevant control words so the achieved Ethernet bit rate depends on both the link rate and the Fast C&M pointer.

The Fast C&M pointer is set up during State D of the autonegotiation flow (See **Section 18.3.1.3.3**) The CPRIn_ETH_CONFIG_1, CPRIn_ETH_CONFIG_2 and CPRIn_ETH_CONFIG_3 registers are used for general Ethernet configurations.

When an Ethernet packet is received, the Ethernet MAC destination address is checked, and, if it does not pass the address filter, the BD reflects that the packet is aborted. The MAC address check can be disabled using the MAC_CHECK field of the CPRIn_ETH_CONFIG_1 register.

MAC address filtering assumes that MAC destination address is the first 6 bytes of the CPRI encapsulated frame. For other frame formats, all MAC address filtering must be disabled. In that case, no particular packet format is expected, and the packet format can be controlled from software. MAC address filtering is configured in the CPRIn_ETH_CONFIG_1 register. If the MAC_CHECK field is cleared (0), all received packets pass (Accept All Mode).

Three different Ethernet MAC address filtering are supported:

- Unicast (single) filtering: The received DMAC (Destination MAC) address is compared with MAC address specified in the CPRIn_ETH_ADDR_LSB and CPRIn_ETH_ADDR_MSB registers.
- Multicast filtering: An Ethernet multicast address is an address with LSB of the first MAC address byte set to one. A very simple HASH table is used to filter multicast mac addresses. It is important that this multicast address filtering is used in combination with full address validation in software. This function is enabled using the MULTICAST_FLT_EN_FIELD of the CPRIn_ETH_CONFIG_1 register.
- Broadcast filtering: An Ethernet broadcast address is an address with all bits set to one. Enable/disable of broadcast mode is via the BROADCAST_EN field of the CPRIn_ETH_CONFIG_1 register

The current packet received can be aborted by setting RX_DISCARD field of the CPRIn_ETH_RX_CONTROL register. After a packet is discarded the next read from the Ethernet RX buffer will be start of a new packet.

The data transfer between the framer and the DMA is based on triggers. Bits 18–17 and 14–10 of register CPRIn_ETH_CONFIG_1 managing the triggering must be set.

The size of the Ethernet buffers is indicated by the CPRInRETHBS register. If the size of an arrived Ethernet packet is larger than the defined Ethernet buffer size, the current received packet is aborted and the ABORT bit is set in the buffer descriptor. If the size of an arrived Ethernet packet is equal to the defined Ethernet buffer size, the current received packet is accepted, but the ABORT bit is set in the buffer descriptor and the packet is aborted.

If the start of packet has been already read by the DMA from the Framer, abort is indicated the next time the CPRIn_ETH_RX_STATUS register is read; otherwise, the previously received part of the packet is just removed without further notice. The CPRIn_ETH_RX_STATUS register indicates if a packet was aborted and the reason of it (for example, CRC error, buffer overflow, and so forth).

Note: Always make sure that the Ethernet buffer size definition in the CPRInRETHBS register is larger than the expected Ethernet packet size.

18.3.1.5.4 Slow C&M Channel (HDLC)

The number of CPRI control bytes used for HDLC frame transfer is controlled by the HDLC rate, which is mapped into control byte Z.66.0. Table 18-6 shows the possible rate configurations; see also CPRI standard Section 4.2.7.6. Setting HDLC bit-rate Minimum CPRI rate.

Table 18-6. HDLC Rate Setting

Setting	HDLC bit-rate in Kbps	Minimum CPRI rate
0	No HDLC	Any rate
1	240	Any rate
2	480	Any rate
3	960	>= 1228.8 Mbps
4	1920	>= 2457.6 Mbps
5	2400	>= 3072.0 Mbps
6	HIghest possible. For link rate 4915 Mbps: 3840. For link rate 6144 Mbps: 4800	>= 4915.2 Mbps

The slow C&M channel functions as follows:

- On the transmit side, the HDLC rate is configured in the CPRIn_CM_CONFIG register.
- On the receive side, the accepted HDLC rate can be read in the CPRIn_CM_STATUS register.
- The HDLC rate setting is negotiated as described in **Section 18.3.1.3** The CPU control interface for HDLC packet transfer is equal to the interface for Ethernet transfer.
- The data transfer between the framer and the DMA is based on triggers. Bits 18–17 and 14–10 of the CPRIn_HDLC_CONFIG_1 register managing the triggering must be set.

18.3.2 The CPRI Clocks

Table 18-7 describes the CPRI complex input clocks.

Table 18-7. CPRI Complex Input Clocks

Clock Name	Clock Frequency	Clock Description
Recovered Receive Clock (CDR Clock)	line_rate/10	The CDR clock is used to receive the incoming CPRI frame. There are six different CDR clocks supplied by the SerDes to CPRI Framer modules. The CDR Clock is asynchronous to the other clocks.
TBI Clock (Ten Bit Interface Clock)	line rate/10	The TBI clock drives the 10 bit transmit data toward the SerDes. This clock is also used by the CPRI Framer module for delay measurement. The TBI clock is common for all the CPRI Framer modules and is synchronous to the Framer Clock
Framer Clock	line rate/40	Framer Clock is the main processing clock of the CPRI Framer module. The Framer Clock is common for all the CPRI Framer modules and it is synchronous to the TBI clock
System Clock	HSSI clock	The System Clock is the system clock of the chip. It is used by the CPRI DMA to transfer data between the system memories and the CPRI Framer modules, to configure the memories and registers of the CPRI complex. The System Clock is asynchronous to other clocks.

18.3.3 CPRI DMA Controller

The CPRI DMA is composed of 6 identical DMA modules where each DMA module is connected to a single CPRI Framer. Each CPRI DMA controller contains a receive DMA module that transfers the received VSS, Ethernet, HDLC, and IQ data from the CPRI Framer to buffers in the system memory via the write MBus bus. The CPRI DMA block also contains transmit DMA module that transfers the VSS, Ethernet, HDLC, and IQ data from the buffers in the system memory to the CPRI Framer via the read MBus bus. The CPRI DMA block also contains an additional receive DMA module that transfers the IQ data from the CPRI Framer to buffers in the MAPLE in multicast mode through a direct bus.

All the six receive DMA modules are connected to an arbiter that controls write accesses between the different receive DMA modules to the MBus. The arbiter simultaneously performs a Pseudo Round Robin arbitration algorithm for each of the priority levels and chooses the highest level request. The priority level of a write accesses depends on how full its DMA buffer is. All six transmit DMA modules also connect to an arbiter that controls read accesses to the MBus bus by the different transmit DMA modules. As for write access, the arbiter simultaneously performs a Pseudo Round Robin arbitration algorithm for each of the priority levels and chooses the highest level request. The priority level of a read accesses depends on how empty its DMA buffer is.

Each receive CPRI DMA module and transmit CPRI DMA module contains four sub modules:

- rec_vss/trn_vss: handles the receive/transmit VSS data
- rec_eth/trn_eth: handles the receive/transmit Ethernet data
- rec_hdlc/trn_hdlc: handles the receive/transmit HDLC data
- rec_IQ/trn_IQ: handles the receive/transmit IQ data.

Figure 18-4 describes the CPRI DMA block diagram.

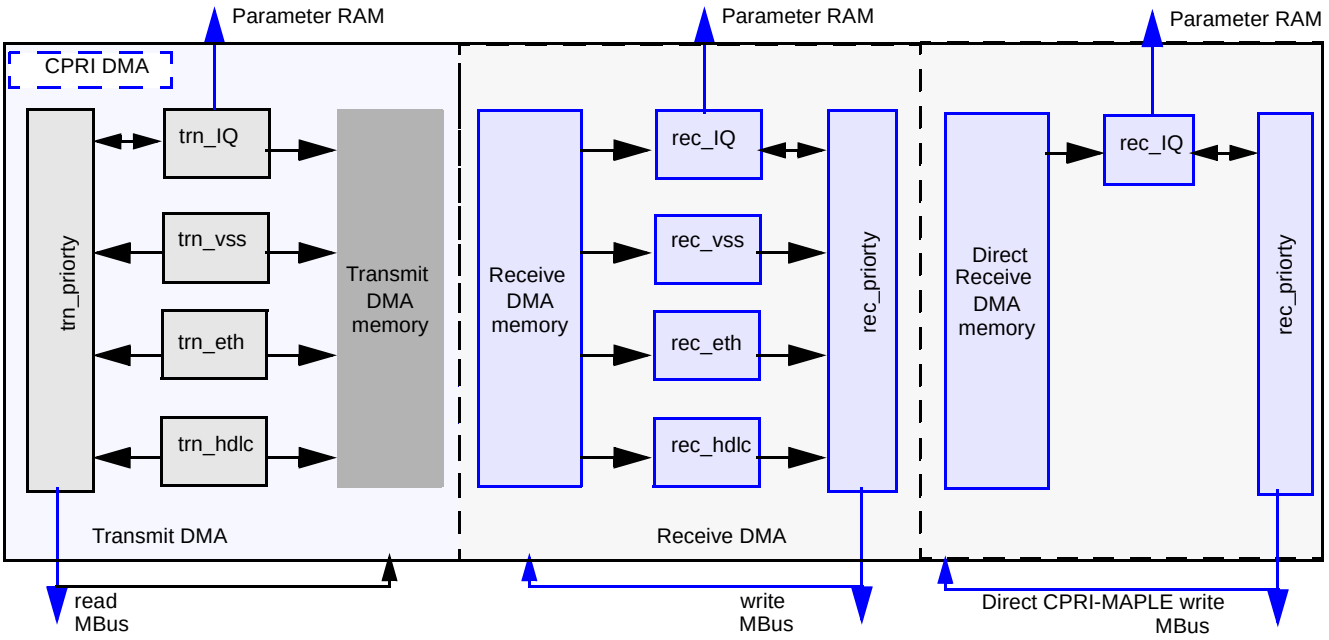

Figure 18-13. CPRI DMA Block Diagram

18.3.3.1 Receive DMA and Transmit DMA Memories

The receive DMA module contains receive DMA memory that temporarily stores the received IQ, VSS, HDLC, and Ethernet data. Similarly, the transmit DMA modules also contains transmit DMA memory that temporarily stores the transmit IQ, VSS, HDLC, and Ethernet data. The receive DMA memory and transmit DMA memory use the same partitioning, which is described in **Table 18-8 on page 18-29**.

Table 18-8. Receive DMA/Transmit DMA Memory Partition

Memory Section	Number of Bytes Allocated for each section
IQ data	256 bytes × 24(maximum number of AxC)
VSS data	256 bytes
ETH data	256 bytes
HDLC data	256 bytes

The IQ data section in the Receive DMA memory is divided into 96 buffers of 64 bytes each. The buffers for each antenna carrier are consecutive in the Receive DMA memory. The number of buffers allocated for each antenna carrier depends on the total number of antenna carriers. For example, if the number of antenna carriers is 3, then each AxC has 2048 bytes (64 bytes × 32(number of buffers)). The number of antenna carriers is described by CPRInRGCM[MAP_AC] field.

Table 18-9 on page 18-30 describes the memory configuration as a function of the number of antenna carriers.

Table 18-9. Memory Configuration As Function of Number of Antenna Carriers

Number of Antenna Carriers	Number of Buffers (of 64 bytes) for Each Antenna Carrier	Valid MBus Transaction Size	Notes
1	96	2048 bytes, 1024 bytes, 512 bytes, 256 bytes, 128 bytes or 64 bytes	The MBus transaction size is configurable as 64 bytes, 128 bytes, 256 bytes, 512 bytes, 1024 bytes or 2048 bytes. If the transaction size is 64 bytes, then MBus request is generated only if at least 1 64 bytes buffers for each Antenna Carriers are full If the transaction size is 128 bytes, then MBus request is generated only if at least 2 64 bytes buffers for each Antenna Carriers are full If the transaction size is 256 bytes, then MBus request is generated only if at least 4 64 bytes buffers for each Antenna Carriers are full If the transaction size is 512 bytes, then MBus request is generated only if at least 8 64 bytes buffers for each Antenna Carriers are full If the transaction size is 1024 bytes, then MBus request is generated only if at least 16 64 bytes buffers for each Antenna Carriers are full If the transaction size is 2048 bytes, then MBus request is generated only if at least 32 64 bytes buffers for each Antenna Carriers are full
2	48	1024 bytes, 512 bytes, 256 bytes, 128 bytes or 64 bytes	
3	32

18.3.3.2 Receive IQ Data Flow

The receive CPRI Framer module extracts the antenna carrier data from the CPRI frame and transfers it to the receive DMA. The received antenna carrier data is temporarily stored in the receive DMA memory until it is transferred to the received antenna carrier buffers mapped in the system memory. A single transactions from the receive DMA memory to system memory is done via the MBus interface with minimal access size of at least 64 bytes. The receive MBus transaction size is programmable by the CPRInRIQMTS register (for details, see **Section 18.4.2.1**, *Receive IQ MBus Transaction Size (CPRInRIQMTS)*, on page 18-97). Small

MBus transaction size reduces the system latency but it may impact on the overall DSP device performance.

Note: The maximum valid transaction size is determined by CPRInRGCM[RMAP_AC] and CPRInRIQMTS[RSM] fields.

Each receive antenna carrier is stored in a different buffer mapped in the system memory. This buffer can be located in any location in the system memories. The antenna carrier n buffer base address is determined by Receive Antenna Carrier Parameter Register n (CPRInRACPRy) register. The antenna carrier buffer base address should be aligned to 16 bytes.

The buffers can be located in the DDR, M3, or any of the M2 memories. Also part of the buffers can be in one memory and other buffers in another memory, the only constraint is that if M2 memory is used all the buffers of a given CPRI unit must be in the same M2 memory.

The antenna carriers buffer size is identical for all the receive antenna carrier belonging to a CPRI link and is defined by Receive IQ Buffer Size (CPRInRIQBS) register. The antenna carrier buffer size should be aligned to MBus transaction size.

The antenna carriers have the same sample rate therefore the IQ buffers write pointer is identical for all the receives antenna carriers and it's described by the status register Receive IQ Buffer Displacement Register (CPRInRIQBDR). Adding this register to the Receive Antenna Carrier Base Address (CPRInRACPRy[RACBA]) field indicates the location to which CPRI writes next.

Figure 18-14 shows how the samples are stored in the system antenna carrier (IQ) buffer. Note that when the sample width is 15 bits, then Q0 and I0 are clear.

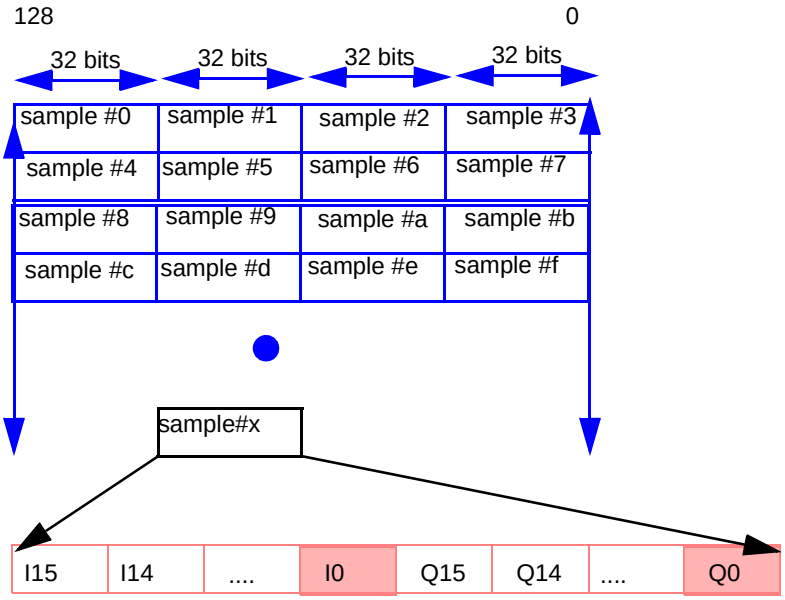

Figure 18-14. Antenna Carrier (IQ) Buffer in the Main Memory

The receive IQ buffers in the system memory share two threshold levels. The CPRI notifies the cores each time it fills the receive buffers up to a threshold level. The first threshold level is determined by Receive IQ First Threshold (CPRInRIQFT) and the second receive threshold level is determined by Receive IQ Second Threshold (CPRInRIQST).

When the CPRI DMA receiver fills the receive buffer through the MBus interface up to an offset defined by the first threshold defined by the CPRInRIQFT[RIQFT] field, the CPRInRER[RIQFTE] bit is set. If the bit CPRIICRy[RIQFTE] is also set and CPRInRER register is selected, a first threshold interrupt is generated. When the interrupt is asserted in the EPIC, then the SC3850 core can read all the receive buffers from their beginning up to the first threshold (RIQFT) point. Meanwhile, the CPRI DMA keeps writing new data to the second part of the buffer

When the CPRI DMA receiver fills the receive buffer through the MBus interface up to an offset defined by the second threshold defined by the CPRInRIQST[RIQST] field, the CPRInRER[RIQSTE] bit is set. If the bit CPRIICRy[RIQSTE] is also set and CPRInRER register is selected, a second threshold interrupt is generated.

The threshold interrupts can be generates as pulse or level, as determined by CPRIICRy[LEVEL] bit. If the interrupt is level, then the ISR should clear the appropriate bit in the CPRInRER register by writing a 1 to it. If the interrupt is pulse, there is no need to clear the status bit.

Figure 18-15 illustrates the pointers associated with receive AxC buffers that are mapped on the system memory.

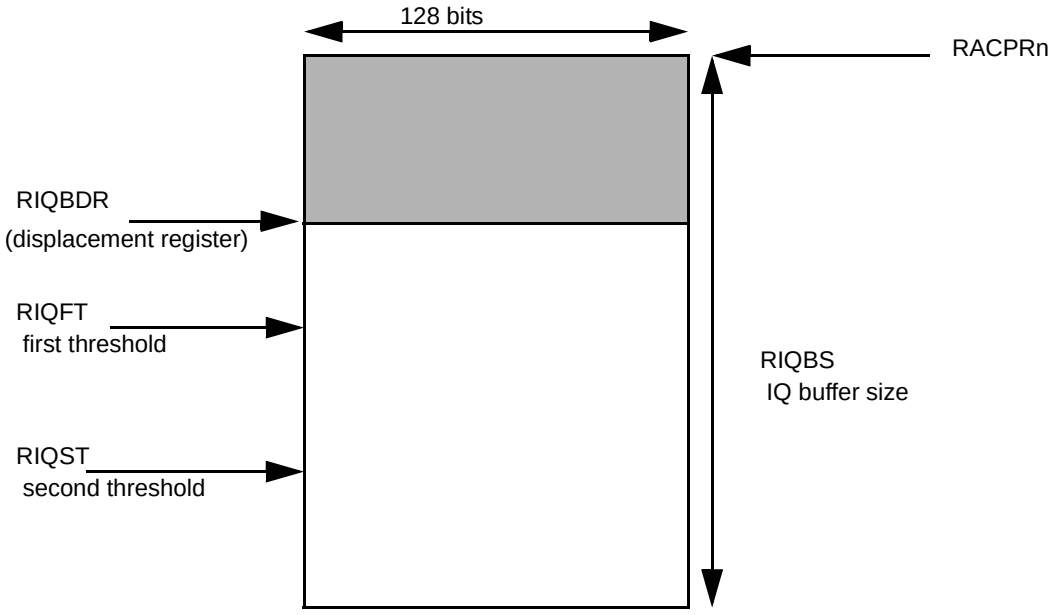

Figure 18-15. System Memory Receive IQ Buffers Threshold Pointers

It is also possible to generate an interrupt when a given number of bytes were written to the system memory as defined by register CPRInRIQT.

When the CPRI DMA cannot transfer data to AxC buffers in the system memory an overrun occurs and the CPRInEER[RIQOV] bit is set and if the CPRInEIER[RIQOVE] bit is also set, an error interrupt is generated. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the system interface, and, therefore, cannot write the data into the destination memory (the AxC buffers).

The receive DMA transfers received data to system memory only if the Receive Control Register (CPRInRCR) [RIQE] bit set. The Receive AxC Control Register (CPRInRACCR) determines which received antenna carrier is active.

18.3.3.3 Transmit IQ Data Flow

AxC data transmitted from the buffer mapped on system memory is temporarily stored in the CPRI transmit DMA memory until it is transmitted via the CPRI Framer.The data is transferred from the system memory to CPRI transmit DMA memory via the MBus. The transmit MBus transaction size is programmable by the CPRInTIQMTS register. For details, see **Section 18.4.2.3**, *Transmit IQ MBus Transaction Size (CPRInTIQMTS)*

Each transmit antenna carrier is stored in a different buffer mapped in the system memory. This buffer can be located in any location in the system memories. The antenna carrier n transmit buffer base address is determined by CPRInTACPRy register. The antenna carrier transmit buffer base address should be aligned to 16 bytes.

The antenna carrier buffer size is identical for all the transmit antenna carriers belonging to a CPRI and is defined by Transmit IQ Buffer Size (CPRInTIQBS) register. The transmit AxC buffer size should be aligned to the transmit MBus transaction size.

Figure 18-14 shows how the samples are stored in the system antenna carrier (IQ) buffer. Note that when the sample width is 15 bits, then Q0 and I0 should be clear.

The transmit AxC buffers share the same read pointer since the sample rate of all the AxC is the same. The read pointer is describes by the status register Transmit IQ Buffer Displacement Register (CPRInTIQBDR)). Adding this register to the transmit AxC buffer base address (CPRInTACPRy[TACBA]) field indicates the location to which the CPRI DMA reads next.This register can be used to show which data is already read from the buffer so that the buffer can be filled with new data.

The transmit AxC buffers also share two threshold levels. The CPRI notifies the SC3850 core each time it reads from the transmit buffer up to a threshold level. The first transmit threshold level is determined by Transmit IQ First Threshold (CPRInTIQFT) register and the second threshold level is determined by the Transmit IQ Second Threshold (CPRInTIQST)). If the transmit CPRI DMA reads the data until the first threshold, then the status bit CPRInTER[TIQFTE] bit is set and if it reads the data until the second threshold level, then the status bit CPRInTER[TIQSTE] is set. If the CPRIICRy[IQFTE] bit is set and CPRInTER is selected by the CPRIICRy[ERS] field, then a first threshold interrupt is generated. If the

CPRIICRy[IQFSE] bit is set and CPRInTER is selected by the CPRIICRy[ERS] field, then a second threshold interrupt is generated.The interrupt can configured as pulse or level, as determined by the CPRIICRy[LEVEL] bit. If the interrupt is level, then the ISR should clear the CPRInTER[TIQFTE/TIQSTE] bit by writing a 1 to it. If the interrupt is pulse, there is no need to clear the status bit.

Figure 18-16 illustrates the pointers associated with transmit AxC buffers that are mapped on the system memory.

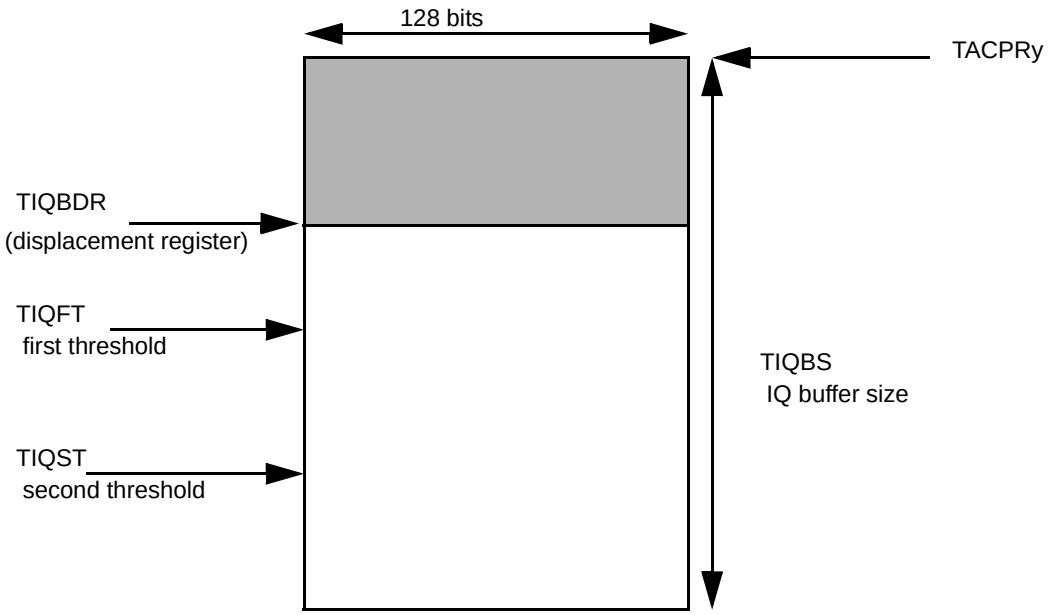

Figure 18-16. System Memory Transmit IQ Buffers Threshold Pointers

It is also possible to generate an interrupt when a given number of bytes are read from the system memory as defined by register CPRInTIQT.

When the CPRI DMA cannot transfer data from AxC buffers to CPRI DMA transmit memory, an underrun occurs. When the CPRI transmit DMA memory is empty, the CPRInEER[TIQUR] bit is set and if the CPRInEIER[TIQURE] bit is also set, an error interrupt is generated. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the system interface, and, therefore, cannot read the data from the system memory into CPRI transmit DMA memory.

The transmit DMA transfers transmit data from the system memory only if the Transmit Control Register (CPRInTCR)[TIQE] bit is set. The Transmit AxC Control Register (CPRInTACCR) determines which transmit antenna carrier is active.

18.3.3.4 Receive VSS (Vendor Specific Data) Data Flow

The receive CPRI Framer module extracts the VSS data from the CPRI frame and writes it to control memory in the CPRI Framer. The receive DMA reads the VSS data from the control

memory and stores the VSS data temporarily in the VSS section of the receive DMA memory until it is transferred to the VSS buffer in the system memory.

The received VSS data can be also read directly from the receive control table by the core. The Receive Control Register (CPRInRCR)[RVSSE] bit enables the writing of the received VSS data to VSS buffer in the system memory.

The VSS data is aligned to a hyperframe and the amount of VSS bytes during one hyper frame is determined by the Ethernet pointer. The minimum number of VSS control words during one hyperframe is 16. The maximum number of VSS control words during one hyperframe is 192.

The VSS data is transferred to VSS buffer via the MBus bus. The VSS MBus transaction size is configurable by register and it can be 16 bytes, 32 bytes, 64 bytes or128 bytes. The VSS data is stored in the VSS buffer in the system memory. This buffer can be located in any location in the system memories. The VSS buffer base address is determined by the Receive VSS Base Address (CPRInRVSSBA) and its size is also configurable. This size is determined by the Receive VSS Buffer Size (CPRInRVSSBS) register. The VSS buffer size should be aligned to the receive VSS MBus transaction size.

The VSS buffer write pointer is defined by the status register CPRInRVSSBDR. Adding this register to the VSS buffer base address (Receive VSS Base Address (CPRInRVSSBA)) field indicates the location to which the CPRI writes next.

The receive DMA notifies the cores each time that it fills the VSS buffer with N VSS data bytes. The number N is determined by CPRInRVSST register. CPRI_INTy interrupt is generated if the CPRIICRy[EVSSTE] bit is set and CPRInRER register is selected by CPRIICRy[ESR] field. This interrupt can be configured as pulse or level as determined by the CPRIICRy[LEVEL] bit. The control interrupt CPRIn_RX_control is also generated if the CPRInRCIER[RVSSEE] bit is set. The interrupt can be pulse or level and it is determined by CPRInRCIER[LEVEL] bit.

When the CPRI DMA cannot transfer the VSS data to VSS buffer in system memory, an overrun occurs and bit CPRInEER[RVSSOV] is set. If CPRInEIER[RVSSOVE] bit is also set, an error interrupt is generated. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the system interface, and, therefore, cannot write the data into the VSS buffer in the system memory.

18.3.3.5 Transmit VSS (Vendor Specific Data) Data Flow

The VSS data is transmitted from the VSS buffer mapped in system memory and is temporarily stored in the VSS section of the transmit DMA memory. The transmit DMA reads the VSS data from the transmit DMA memory and writes it to the transmit control table in the CPRI Framer. The CPRI Framer reads the VSS data from the control table and transfers it externally. The transmit VSS data can be also written directly to the transmit control table by the core via. The Transmit Control Register (CPRInTCR)[TVSSE] bit enables the reading of the transmit VSS data via the MBus bus.

The VSS MBus transaction size is configurable by Transmit VSS MBus Transaction Size (CPRInTVSSMTS) register and it can be 16 bytes, 32 bytes, 64 bytes or 128 bytes.

The transmit VSS data is stored in the VSS buffer in the system memory. This buffer can be located in any location in the system memories. The VSS buffer base address is determined by Transmit VSS Base Address (CPRInTVSSBA). Its size is also configurable and is determined by Transmit VSS Buffer Size (CPRInTVSSBS) register. The VSS buffer size should be aligned to the transmit VSS MBus transaction size.

The VSS buffer read pointer is defined by the status register CPRInTVSSBDR. Adding this register to the transmit VSS buffer base address field indicates the location that CPRI reads next.

The transmit DMA notifies the cores each time that it read N bytes of VSS data from the VSS buffer. The number N is determined by CPRInTVSST register. An interrupt is generated if the CPRIICRy[EVSSTE] bit is set and CPRInTER register is selected by CPRIICRy[ESR] field. This interrupt can be configured as pulse or level as determined by the CPRIICRy[LEVEL] bit. The control interrupt CPRIn_tx_control is also generated if the CPRInTCIER[TVSSEE] bit is set. The interrupt can be pulse or level as determined by CPRInTCIER[LEVEL] bit.

When the CPRI DMA cannot transfer the VSS data from the VSS buffer in the system memory, an underrun occurs and the CPRInEER[TVSSUN] bit is set. If the CPRInEIER[TVSSUNE] bit is also set, an error interrupt is generated. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the system interface, and, therefore, cannot read the data from the VSS buffer in the system memory.

18.3.3.6 Receive Ethernet Data Flow

The CPRI Framer extracts the Ethernet packets from the CPRI frame and transfers them to an integrated Ethernet MAC in the CPRI Framer. The MAC decodes the 4B5B Ethernet frame and checks the destination MAC address. If the destination MAC address passes the address filter, the data is transferred to system memory via the MBus. Otherwise, the Buffer Descriptor reflects an aborted packet.

The Ethernet MAC supports three different MAC address filters:

- Unicast filtering
- Multicast filtering
- Broadcast filtering

Each Ethernet packet is stored in a different buffer in the system memory where the Ethernet data buffer location is described by RDBP pointer field of CPRInRETHBD register. The size of the receive Ethernet buffers is indicated by the CPRInRETHBS register. If the size of an arrived Ethernet packet is equal to or greater than the Ethernet buffer size, the packet is aborted and the ABORT bit in the buffer descriptor is set.

For the case of overrun for Ethernet RX, the RX BD does not reflect that the data in the relevant packet is corrupted. The CPRI generates an error interrupt (if enabled) that indicates that an Ethernet RX overrun has occurred. Overrun and underrun cases should only occur during system development and not during normal operation.

The receive buffer descriptors are located in the system memory in consecutive order. The base address of the buffer descriptor ring is determined by the Receive Ethernet BD Ring Base Address (CPRInREBDRBA) register and the number of buffer descriptors in the ring is determined by the Receive Ethernet BD Ring Size (CPRInREBDRS) register. The minimum number of buffer descriptors that the ring supports is four and the maximum number of buffer descriptors in the ring is 256.

The receive DMA has a CPRInREWPR register that indicates the next written buffer descriptor number. This register is updated only by the core each time that a new receive buffer descriptor (or some buffer descriptor) is updated in the system memory. It is the core responsibility to ensure that a Buffer Descriptor underrun (lack of receive descriptors) does not occur. Each time that the core wraps to the beginning of the buffer descriptor ring, the core should update the wrap bit.

The receive DMA Ethernet controller also contains a status register CPRInRERPR that indicates the next buffer descriptor to be read by the receive DMA Ethernet controller. This register is updated only by the receive DMA.

Figure 18-17 shows the Ethernet buffer descriptors rings.

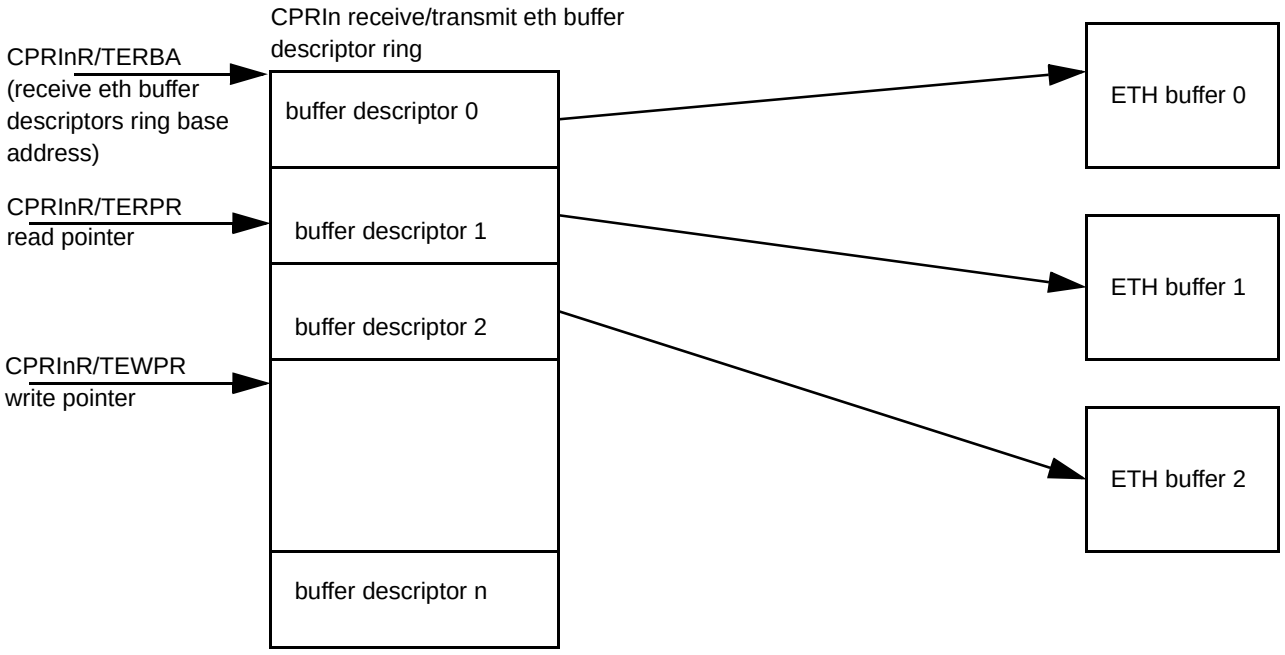

Figure 18-17. Ethernet Buffer Descriptor Ring

18.3.3.7 Receive Ethernet Interrupts

The receive DMA can notify the cores each time that a packet is transferred to the system memory or after a programmable number of packets are transferred to the system memory. The number of packets is determined by the CPRInRETHCT register. The number of packets transferred is indicated by the coalescing counter status register (CPRInRETHCS). In unicast and multicast MAC address filtering, an interrupt is generated not only when a programmed number of packets are transferred to system memory, but also when part or all of the packets do not fit the MAC filter. In this case, the BD of the packets reflects that the packet is aborted.

When the coalescing counter reaches its threshold value, the status bit RETHE in CPRInRER is set, an interrupt is generated if the CPRIICRy[EETHE] bit is set, and the CPRInRER event register is selected by the ESR field. This interrupt can be configured as pulse or level as determined by CPRIICRy[LEVEL] bit. The control interrupt CPRIn_Rx_control is also generated if the CPRInRCIER[RETHEE] bit is set. The interrupt can be pulse or level and it is determined by CPRInRCIER[LEVEL] bit.

When the CPRI DMA can no longer transfer the Ethernet packets to buffers in the system memory, an overrun occurs and the CPRInEER[RETHOV] bit is set. If the CPRInEIER[RETHOVE] bit is also set, an error interrupt is generated. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the system interface, and, therefore, cannot write the data into the Ethernet buffer in the system memory.

When a new packet arrives and the buffer descriptor ring does not contain a valid buffer descriptor, a buffer descriptor underrun occurs. In this case, the CPRInEER[REBDUN] bit is set and, if CPRInEIER[REBDUNE] bit is also set, an error interrupt is generated.

18.3.3.8 Transmit Ethernet Data Flow

The Ethernet packet is transmitted from the Ethernet buffer on the system memory and is temporarily stored in the Ethernet section of the transmit DMA data memory. The transmit DMA transfers the Ethernet packets to an integrated Ethernet MAC in the CPRI Framer module. The Ethernet MAC decodes 4b5b the Ethernet frame and transfers the packets externally. Each Ethernet packet is stored in different buffers in the system memory in the location described by the transmit Ethernet data buffer location in the TDBP pointer field of CPRInTETHBD register.

The transmit buffer descriptors are located in the main memory in a consecutive order. The base address of the buffer descriptor ring is determined by the Transmit Ethernet BD Ring Base Address (CPRInTEBDRBA) register and the number of buffer descriptors in the ring is determined by the Transmit Ethernet BD Ring Size (CPRInTEBDRS) register. The minimum number of supported buffer descriptors in the ring is four and the maximum number of buffer descriptor in the ring is 256.

The transmit DMA Ethernet controller contains a status register CPRInTEWPR that indicates the next written buffer descriptor number. This register is updated only by the core and is updated each time that the core writes a new buffer descriptor (or some buffer descriptors). When there are no valid buffer descriptors the CPRI doesn't transmit Ethernet packets. Each time that the core wraps to the beginning of the buffer descriptor ring, the core should update the wrap bit.

The transmit DMA Ethernet controller contains also a status register CPRInTERPR that indicates the next buffer descriptor that should be read by the transmit DMA Ethernet controller. This register is updated only by the transmit DMA Ethernet controller. **Figure 18-17 on page 18-37** shows the Ethernet buffer descriptors ring.

18.3.3.9 Ethernet Transmit Interrupts

The transmit DMA can notify the cores each time that a packet is transferred from the system memory or after that a programmable number of packets are transferred from the system memory. The number of packets transferred is indicated by the coalescing counter status register (CPRInTETHCS).

When the coalescing counter reaches its threshold value, the status bit TETHE in the CPRInTER is set and an interrupt is generated if the CPRIICRy[EETHE] bit is set and the CPRInTER event register is selected by the ESR field.This interrupt can be configured as pulse or level as determined by the CPRIICRy[LEVEL] bit.

The control interrupt CPRIn_Tx_control is also generated if the CPRInTCIER[TETHEE] bit is set. The interrupt can be pulse or level as determined by the CPRInRCIER[LEVEL] bit.

When the CPRI DMA can no longer transfer the Ethernet packets from buffers in the system memory, an overrun occurs and the CPRInEER[TETHUN] bit is set. If the CPRInEIER[TETHUNE] bit is also set, an error interrupt is generated. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the system interface, and, therefore, cannot read the data from the Ethernet buffer in the system memory.

18.3.3.10 Receive HDLC Data Flow

The CPRI Framer extracts the HDLC packets from the CPRI frame and transfers them to an integrated HDLC MAC in the CPRI Framer. Each HDLC packet is stored in a different buffer in the system memory in the HDLC data buffer location described by the RDBP pointer field of the CPRInRHDLCBD register. The size of the receive HDLC buffers is determined by the CPRInRHDLCBS register. If the size of an HDLC packet that arrives exceeds the HDLC buffer size, then the packet is aborted and the ABORT bit in the buffer descriptor is set.

For HDLC RX overruns, the RX BD does not reflect that the data of the relevant packet is corrupted. The CPRI generates an error interrupt (if enabled) to reflect that the RX overrun has

occurred. Overrun and underrun cases should occur only during system development and not during normal operation.\

The receive buffer descriptors are located in the system memory in consecutive order. The base address of the buffer descriptor ring is determined by the CPRInRHBDRBA register and the number of buffer descriptors in the ring is determined by Receive HDLC BD Ring Size (CPRInRHBDRS) register. The minimum number of buffer descriptors that the ring supports is four and the maximum number of buffer descriptors in the ring is 256.

The receive DMA contains a CPRInRHWPR register that indicates the next written buffer descriptor number. This register is updated only by the core each time that a new receive buffer descriptor (or some buffer descriptors) is updated in the system memory. It is the core responsibility to ensure that a buffer descriptor underrun does not occur. Each time that the core wraps to the beginning of the buffer descriptor ring, the core should update the wrap bit.

The receive DMA HDLC contains also a status register CPRInRHRPR that indicates the next buffer descriptor that should be read by the receive DMA. This register is updated only by the receive DMA. The structure of the HDLC buffer descriptor ring is similar to the Ethernet buffer descriptor ring described in **Figure 18-17 on page 18-37**

18.3.3.11 Receive HDLC Interrupts

Whenever an HDLC packet is transferred to system memory, then the RHDLCE bit in the CPRInRER register is set. A CPRI_INTy interrupt is generated if the CPRIICRy[EHDLCE] bit is set and the CPRInRER event register is selected by the ESR field. This interrupt can be pulse or level as determined by CPRIICRy[LEVEL] bit. The control interrupt CPRIn_RX_control is generated if the bit CPRInRCIER[RHDLCEE] bit is set. The interrupt can be pulse or level as determines by CPRInRCIER[LEVEL].

When the CPRI DMA can no longer transfer the HDLC packets to buffers in the system memory, an overrun occurs and the CPRInEER[RHDLCOV] bit is set. If the CPRInEIER[RHDLCOVE] bit is also set, an error interrupt is generated. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the system interface, and, therefore, cannot write the data into the HDLC buffer in the system memory.

If a new packet arrives and the buffer descriptors ring does not contain a valid buffer descriptor, a buffer descriptor underrun occurs. In this case, the CPRInEER[RHBDUN] bit is set and if CPRInEIER[RHBDUNE] bit is also set, an error interrupt is generated.

18.3.3.12 Transmit HDLC Data Flow

The HDLC packet is transmitted from the HDLC buffers on the system memory and it is temporarily stored in the HDLC section of the transmit DMA memory. The transmit DMA transfers the HDLC packets to an integrated HDLC MAC in the CPRI Framer module.

Each HDLC packet is stored in a different buffer in the system memory for which the transmit HDLC data buffer location is described by TDBP pointer field of CPRInTHDLCBD register.

The transmit buffer descriptors are located in the main memory in consecutive order. The base address of the buffer descriptor ring is determined by the CPRInTHBDRBA register and the number of buffer descriptors in the ring is determined by the Transmit HDLC BD Ring Size (CPRInTHBDRS) register. The minimum number of supported buffer descriptors in the ring is four and the maximum number of buffer descriptors in the ring is 256.

The transmit DMA contains a status register CPRInTHWPR that indicates the next written buffer descriptor number. This register is updated only by the core and it updates each time that the core writes a new buffer descriptor (or some buffer descriptors). When there are no valid buffer descriptors the CPRI doesn't transmit HDLC packets. Each time that the core wraps to the beginning of the buffer descriptor ring, the core should update the wrap bit.

The transmit DMA contains also has a status register CPRInTHRPR that indicates the next buffer descriptor for the transmit DMA to read. This register is updated only by the transmit DMA. The structure of the HDLC buffer descriptor ring is similar to the Ethernet buffer descriptor ring described in **Figure 18-17 on page 18-37.**

18.3.3.13 HDLC Transmit Interrupts

The transmit DMA notifies the core each time that an HDLC packet is transferred from the system memory. The THDLCE bit in the CPRInTER register is set and a CPRI_INTy interrupt is generated if the CPRIICRy[EHDLCE] bit is set and the CPRInTER event registers is selected by the ESR field. A control interrupt (CPRIn_tx_control) can be also generated if the bit CPRInTCIER[THDLCEE] bit is set. The interrupt can be pulse or level as determined by the CPRInTCIER[CLEVEL] bit.

18.3.4 Transparent Mode

The CPRI supports transparent mode in both directions (receive and transmit). Each can be enabled independently. When the CPRIn_MAP_CONFIG[CPRIn_MAP_RX_TR_MODE] bit and CPRInRGCM[TM] bit are set, the received CPRI frames are directed to one shared IQ buffer in the system memory through the MBus interface. The buffer location is described by CPRInRACPR0 register and the buffer size is described by CPRInRIQBS register.

When the CPRIn_MAP_CONFIG[CPRIn_MAP_TX_TR_MODE] bit and CPRInTGCM[TM] bit are set, all the CPRI frames (including the control words) are transmitted directly from a single buffer in the system memory. The buffer location is described by CPRInTACPR0 register and the buffer size is described by the CPRInTIQBS register

Note: In transparent mode the buffer size should be aligned to CPRI basic frame size. For example, if the link rate is 3.072 GHz then each word in the basic frame is 5 bytes and

the buffer size must be 80 × X, where X is an integer number. In transparent mode, the HDLC and Ethernet MACs are disabled.

Figure 18-18 on page 18-42 shows how the CPRI frames are stored in the system memory.

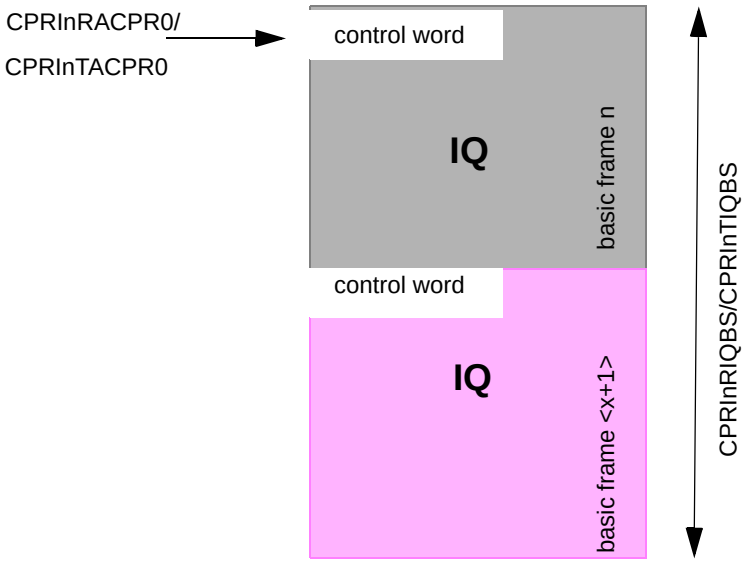

Figure 18-18. CPRI Buffer in the System Memory in Transparent Mode

18.3.5 Chip Rate Mode

Chip rate processing can be performed on uplink and downlink data.

18.3.5.1 Uplink Functional Description in Chip Rate Mode

The uplink data in chip rate mode use an 8-bit sample width with double oversampling. The oversampling data that belongs to the same AxC must be located back-to-back in the same CPRI frame. The CPRI module can separate the oversampling data to two different buffers. Bit ROVS in the CPRInRGCM register determines whether the received data that belongs to the same AxC is separated into two different buffers. In this case, the sample width should be set to 8 (the RSW field in the CPRInRGCM register should be 0x2).

The oversampling data is transferred to system memory and also to MAPLE-B memory. The transactions from the receive DMA memory to system memory and to MAPLE-B memory is done in parallel via different Mbus ports. The transactions toward the MAPLE-B memory are generated when there are 64 bytes of data for each AxC (for 16-byte transactions) whereas the transaction size toward the system memory is programmable by the Receive IQ MBus Transaction Size (CPRInRIQMTS) register. The small MBus transaction size reduces the system latency but it may impact device performance. The RMCM bit in the CPRInRGCM register determines whether the received data is sent in parallel to MAPLE memory and to system memory.

If synchronization between some CPRI links is required, then the CPRInRCR[RIQS] bit should be set for the relevant units, but the data transfer between the Framer and the receive DMA only starts when the GRIQS bit in the CPRIGRSR register is also set. The CPRIGRSR register is common for all the CPRI links, and it should be set only after that all the relevant CPRI lanes are synchronized.

18.3.5.2 AxC Data Buffers

Each receive oversampling antenna carrier is stored in a different buffer mapped on the system memory. The AxC<n> oversampling0 buffer can be located in any location in the system memories and the AxC<n> oversampling buffers are locate in consecutive locations. The antenna carrier <n> buffer base address is determined by the Receive Antenna Carrier Parameter Register n (CPRInRACPRy). The antenna carrier buffer base address should be aligned to 16 bytes.

The oversampling antenna carrier buffer size is identical for all the receive antenna carrier belonging to a CPRI link and is defined by Receive IQ Buffer Size (CPRInRIQBS) register. The antenna carriers buffer size should be aligned to MBus transaction size (CPRInRIQMTS[RIQMTS]).

The antenna carriers have the same sample rate; therefore, the IQ buffers write pointer is identical for all the receive oversampling antenna carriers and is described by the status register Receive IQ Buffer Displacement Register (CPRInRIQBDR). Adding this register to the receive AxC oversampling base address indicates the location to which CPRI writes next in the system memory. The location of AxCn OVS0 is described by Receive Antenna Carrier Base Address (CPRInRACPRy[RACBA]) field and the location of AxCn OVS1 is equal to CPRInRACPRy[RACBA] + CPRInRIQBS[RIQBS] +1.

In addition to a displacement status register, each CPRI module contains a status register that indicates the number of 2560 chips per OVS buffer that are written to the OVS buffers in the device. The status register Receive Chips Counter Register (CPRInRCCR) indicates the number of chips in a resolution of 2560 chips.

In Chip Rate mode, the CPRI complex supports up to 24 AxCs. The number of the AxCs handled by all the CPRI units in chip rate (multicast) mode can be up to 24.

When only one pair is used for chip-rate mode:

- If the pair operates in shared mode (when only one CPRI unit operates in a pair), this unit can handle all 24 AxCs.
- If the pair does not operate in shared mode (both CPRI units can operate in a pair), each unit can handle a maximum of 12 AxCs.

Figure 18-19 describes the AxC data buffer locations in the system memory.

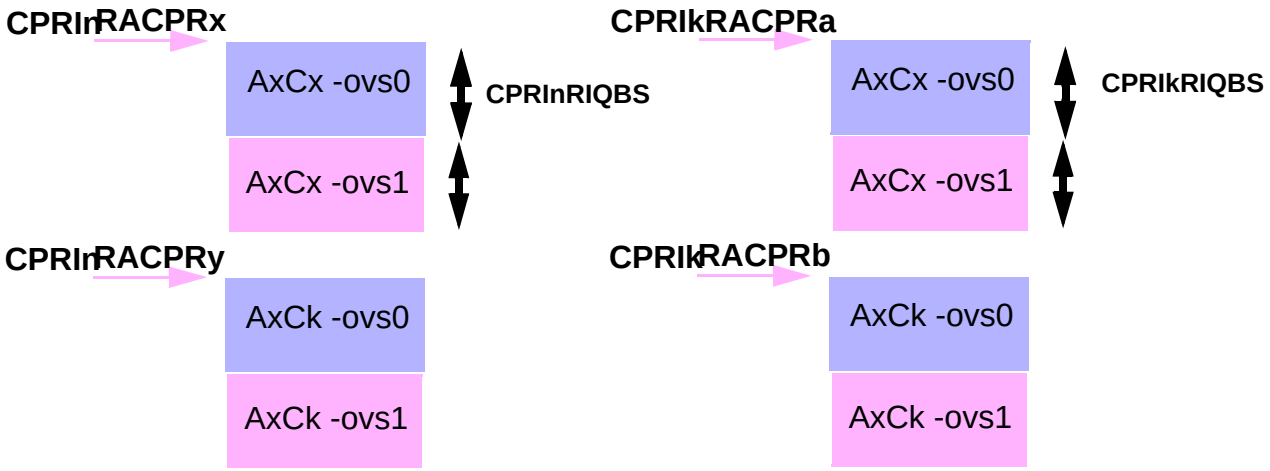

Figure 18-19. AxC Data Buffers Location in the System Memory

In the case in which the RMCM bit of Receive General CPRI Mode (CPRInRGCM) is set, then the received oversampling antenna carriers are also stored in a different buffer mapped in the MAPLE memory. The AxC buffers that belong to the same CPRI link are located in consecutive order in the MAPLE memory where the first active AxC location is determined by the Receive IQ Second Destination Base Address register (CPRInRIQSDBA). This base address in MAPLE must be aligned to 16 bytes.

The OVS antenna carrier buffer size is identical for all the receive antenna carrier belonging to a CPRI link and is indicated by the Receive IQ Second Destination Buffer Size register (CPRInRIQSDBS).The AxCn ovs buffer size must be aligned to 64 bytes.

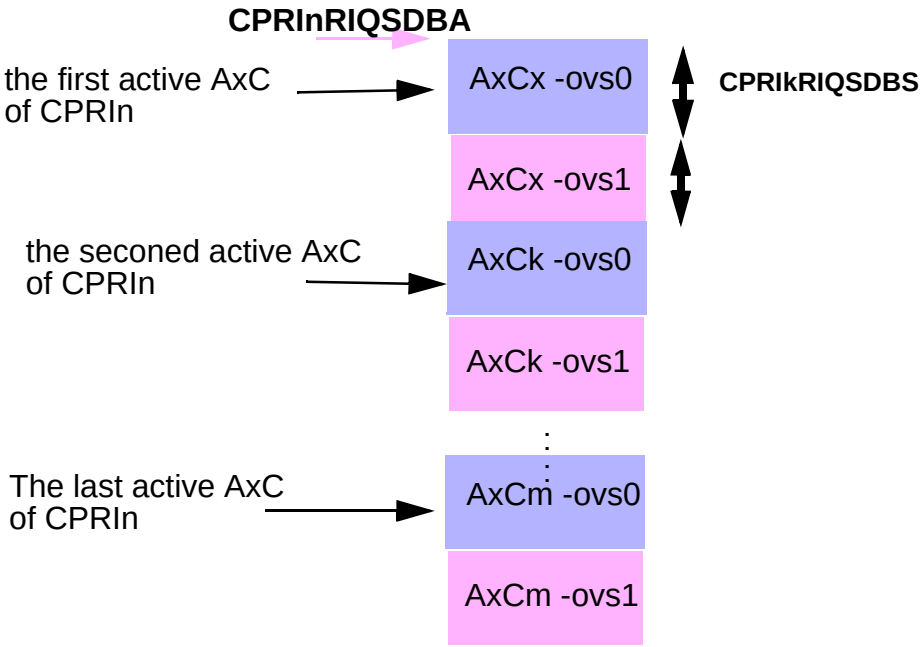

Figure 18-20. AxC Data Buffer Locations in the MAPLE Memory

Figure 18-20 shows how the oversampling data is stored in the MAPLE buffers in chip rate mode. Note the sample width is 8 bits. **Figure 18-21** shows the AxC oversampling buffer in the MAPLE-B.

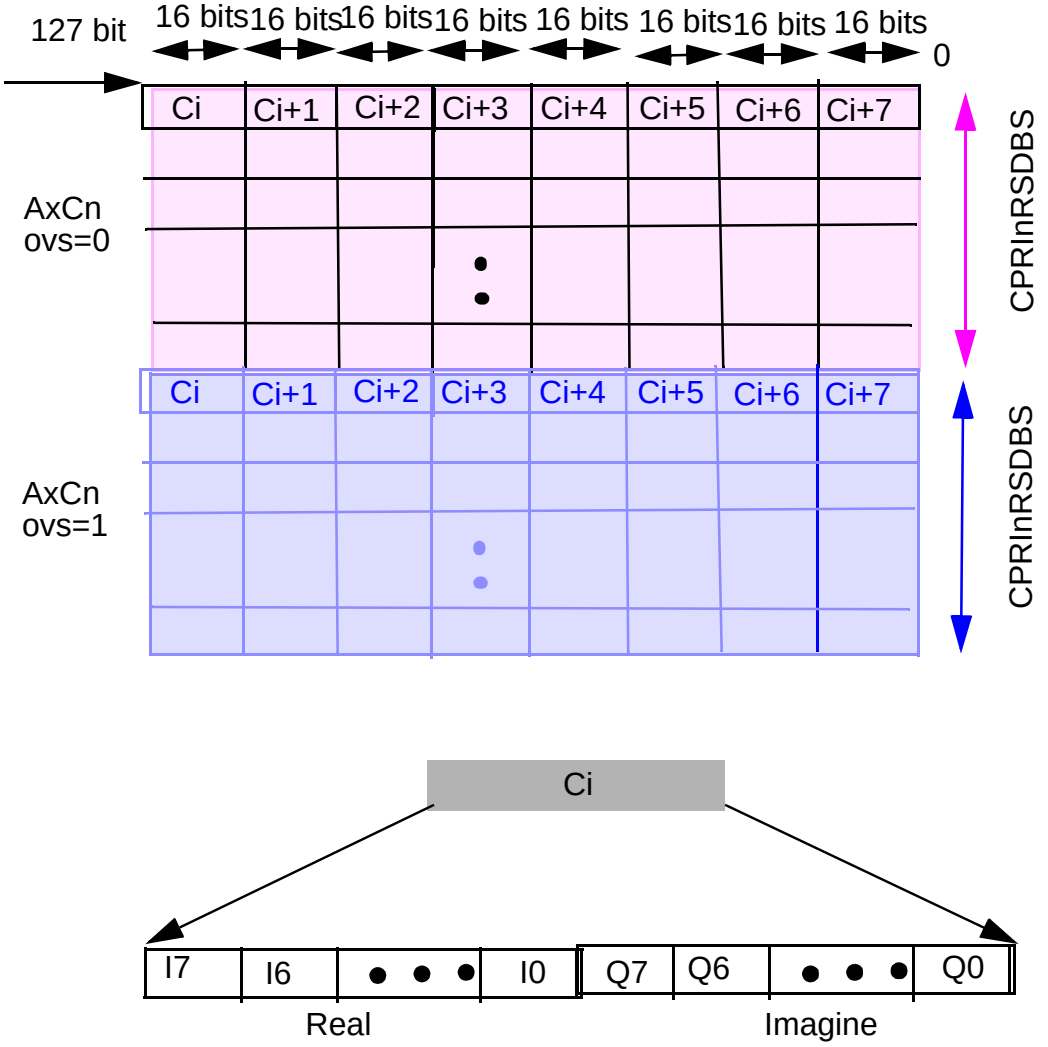

Figure 18-21. Antenna Carrier Oversampling Buffer

The CPRI can notify the cores each time that it transfers <x> bytes to the buffers or each time it fill the buffers up to threshold levels. The number of bytes is determined by the Receive IQ Threshold register (CPRInRIQT) and the threshold levels defined by CPRInRIQFT and CPRInRIQST registers.

18.3.5.3 Uplink Delay in Chip Rate Mode

The uplink delay in chip rate mode is determined based on the delay of the receive buffers located in the CPRI module.

- Receive IQ shared memory (buffer inside the CPRI framer). The delay of the IQ shared memory is 4 chips
- Receive DMA memory. The latency of this memory depends on the transactions size.
  - Latency toward the MAPLE buffers. The transaction size toward the MAPLE is 64 bytes, therefore the latency is 32 chips
  - Latency to ward the SOC buffers. The transaction toward the DSP system is configurable by the Receive IQ MBus Transaction Size (CPRInRIQMTS) register therefore the delay is RIQMTS*32
- The maximum uplink latency toward the MAPLE in chip rate mode: 4 + 32 = 36 chips
- The maximum uplink latency toward the DSP system in chip rate mode is: 4 + RIQMTS*32

18.3.5.4 Downlink Functional Description in Chip Rate Mode

The transmit DMA data flow in chip rate mode is identical to the flow in normal mode, but some configurations and the order of enabling is more limited. Downlink can be done using one or more CPRI lanes. When multiple lanes are used, each CPRI controller transmits part of the AxCs, but they read the data from the MAPLE-B2 at the same time. For downlink in chip-rate mode, there is only one IQ sample for each AxC in a basic frame.

The functional description is summarized as follows:

- If more than one CPRI unit is required, all the units should use should use the same Node B frame (10 ms) sync signal. It can be done using the shared mode of the timer. In this case, the pulse is generated by the CPRI1 timer. The CPRI1 sync signal is connected to the other relevant CPRI modules if the CPRInTMRC[SSM] bit is set. The CPRI1 sync signal determines the start of the transmit Node B frame.
- All relevant units should have the same values in the CPRIn_MAP_TX_OFFSET and CPRI_START_TX_OFFSET registers. The value in CPRIn_MAP_TX_OFFSET should be 16 basic frames bigger than the value in the CPRIn_START_TX_OFFSET register.
- The CPRInTIQMTS of all the relevant lanes should be configured to 1.
- All relevant CPRI units should be configured except for the CPRInTCRs. After the MAPLE CPRE prepares the data to be transmitted and fills up its buffers, the TCR of all relevant lanes should be set together. Both the CPRInTCR[TIQE] and CPRInTCR[TIQSYNC] bits should be set.
- Set the relevant bit in the CPRIGTSR one HyperFrame after all CPRInTCRs are enabled. It should occur at least one HyperFrame before reaching the offset value configured in the CPRIn_START_TX_OFFSET register. This can be done by reading the offset value in the

PCRInTXHEN register and checking whether the TX_OFFSET value is within 1 HyperFrame from the offset value configured in CPRIn_START_TX_OFFSET register. If the distance is not at least 1 HyperFrame, the relevant bit in CPRIGTSR should be set later when there is a distance of at least 1 HyperFrame.

- The interrupt to the MAPLE-CRPE indicting that the CPRI started to fetch new data from the MAPLE-CRPE can be generated by any of the relevant CPRI units. The interrupt can be enabled when the CPRIICRy[EIQE] bit is set and the TYER is selected in the ERS field.
- The maximum number of AxCs that can be handled by all the CPRI units is 16.

18.3.5.5 Down Link Latency.

The transmit latency is determined by the latency of the transmit DMA buffers and the transmit buffers inside the CPRI framer module.

- Transmit IQ shared memory (buffer inside the CPRI framer). This delay is configurable and it is determined by the Transmit CPRI Framer Buffer Size (CPRInTCFBS) register. The minimum delay in chip rate mode is 16 chips.
- Transmit DMA memory. The latency imposed by this memory depends on the transmit transactions size; in chip rate mode, the transaction size is 64 bytes and, therefore, the delay is 16 chips.

Latency from the MAPLE buffers to the CPRI frame in chip rate mode = 16 + 16 = 32 chips.

18.3.6 External Implementation

The CPRI complex implements the external interface with 6-high speed serialized links. Each link is connected to a single SerDes lane and they all share the same PLL. These links support 1228.8 MHz, 2457.6 MHz, 3072.0 MHz, 4912.2 MHz, and 6144.0 MHz line rates. The CPRI complex supports the following topologies:

- Single point-to-point link between one REC and one RE (Figure 3 in the CPRI Specification V4.1)
- Single point-to-point link between one REC and one RE (Figure 4 in the CPRI Specification V4.1)
- Multiple point-to-point links between one REC and several REs—Star topology (Figure 5in the CPRI Specification V4.1)
- Chain topology (Figure 5A in the CPRI Specification V4.1)
- Tree topology (Figure 5B in the CPRI Specification V4.1)
- Multiple point-to-point links between several RECs and one RE (Figure 5D in the CPRI Specification V4.1)
- Chain topology of multiple RECs (Figure 5E in the CPRI specification V4.1)

Figure 18-22 describes the CPRI complex system when minimum frames skew is required between the REC links. In order to promise full synchronization between the CPRI links, the connect the Timer1 output to all the CPRI Framer modules.

18.3.6.1 Star Topology

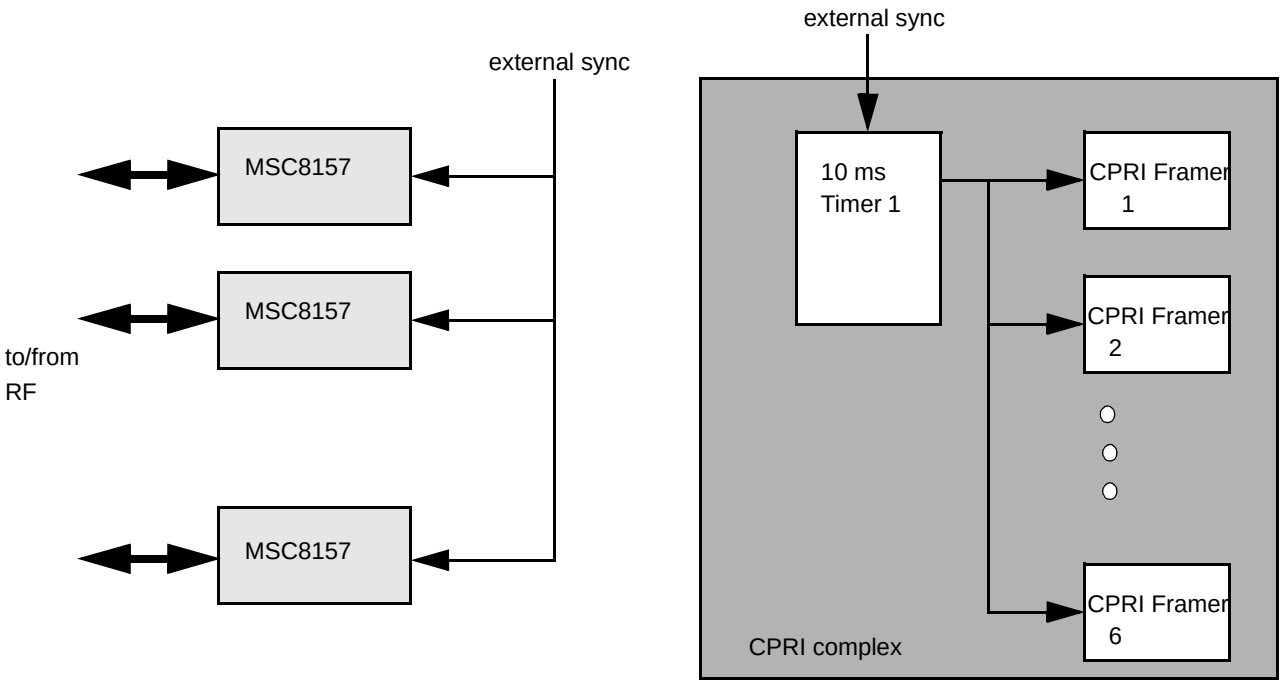

Figure 18-22. Star Topology When Minimum Frame Skew Is Required

18.3.6.2 Chain Topology

The daisy chain topology is supported by the auxiliary ports of the CPRI Framer modules and by the auxiliary modules. The CPRI complex contains three pairs of CPRI units; each pair can be used in auxiliary mode. **Figure 18-23** describes the down link data flow. The “master” device (the last in the chain and the most far from the RE) starts to transfer the CPRI downlink frame where each MSC8157E device in the chain can insert AxC data in any segment (timeslot) in the CPRI frame. The control words are always controlled by the master device. The master device generates the 10 ms pulse of the chain, and both CPRI units of the REC slave in the chain generate their 10 ms pulse using the received 10 ms sync signal of the other CPRI unit in the pair. The REC master can reset the RE using the Reset bit in the #Z.130.0 according to the standard. The reset request from the REC master for the slave REC either can be sent externally (not using the CPRI standard) or can be resolved in software; the software of the REC slave device should poll the Reset bit in #Z.130.0 once in a hyperframe to determine whether the REC master has issued a reset.

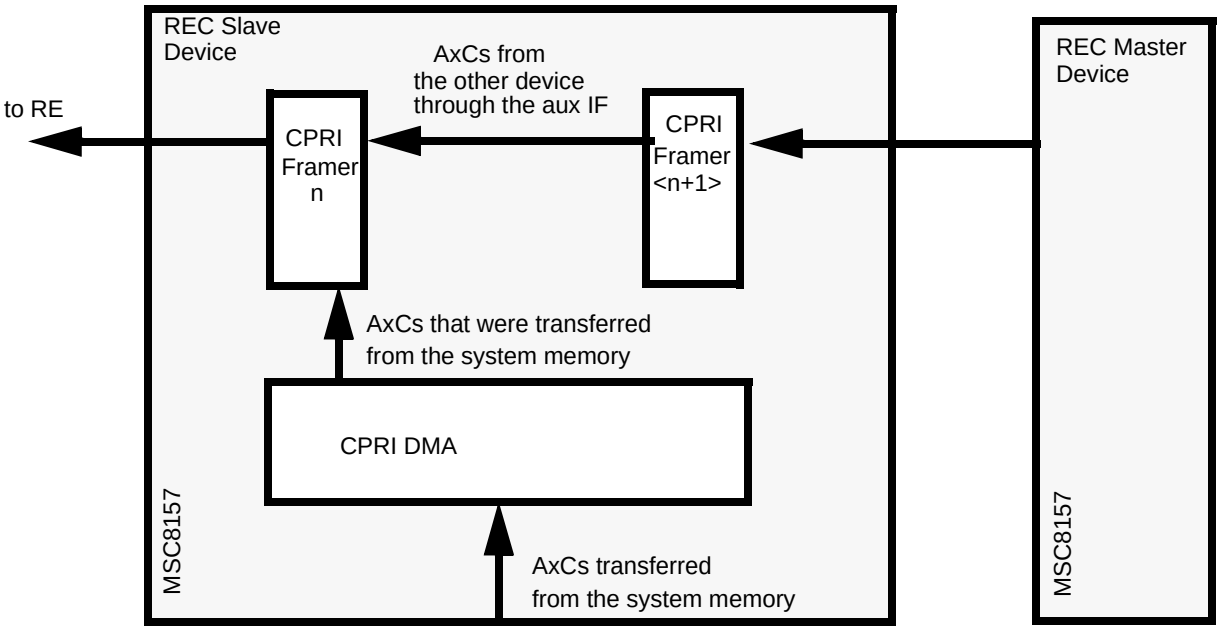

Figure 18-23. Down Link Data Flow in Daisy Chain Topology

The mask registers define for each bit in the frame whether the transmit data should be driven by the auxiliary port or by the CPRI Framer itself. Figure 18-24 describes how the CPRI Framer uses the mask registers.

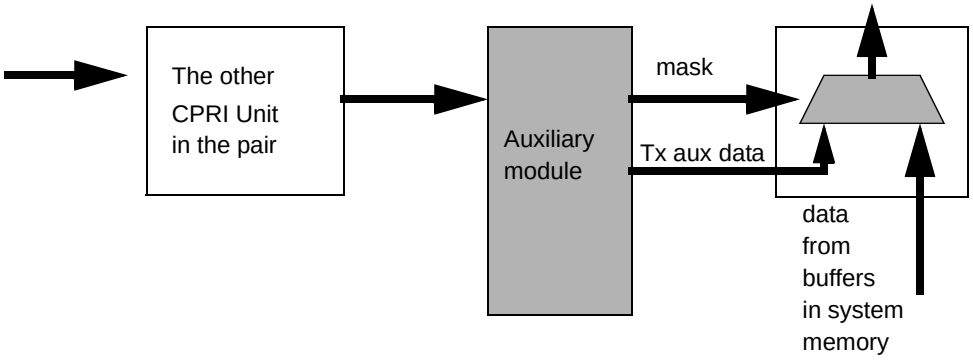

Figure 18-24. Mask Registers Inside the CPRI Framer

Figure 18-25 describes the uplink data flow at daisy chain configuration. The received CPRI frame arrives via the CPRI Framer and the selected antenna carriers and the control data are transferred to the system memory via the MBus bus. In parallel the received CPRI frame is transferred via the receive auxiliary port to the other CPRI Framer in the pair and is transmitted externally to another device in the chain.

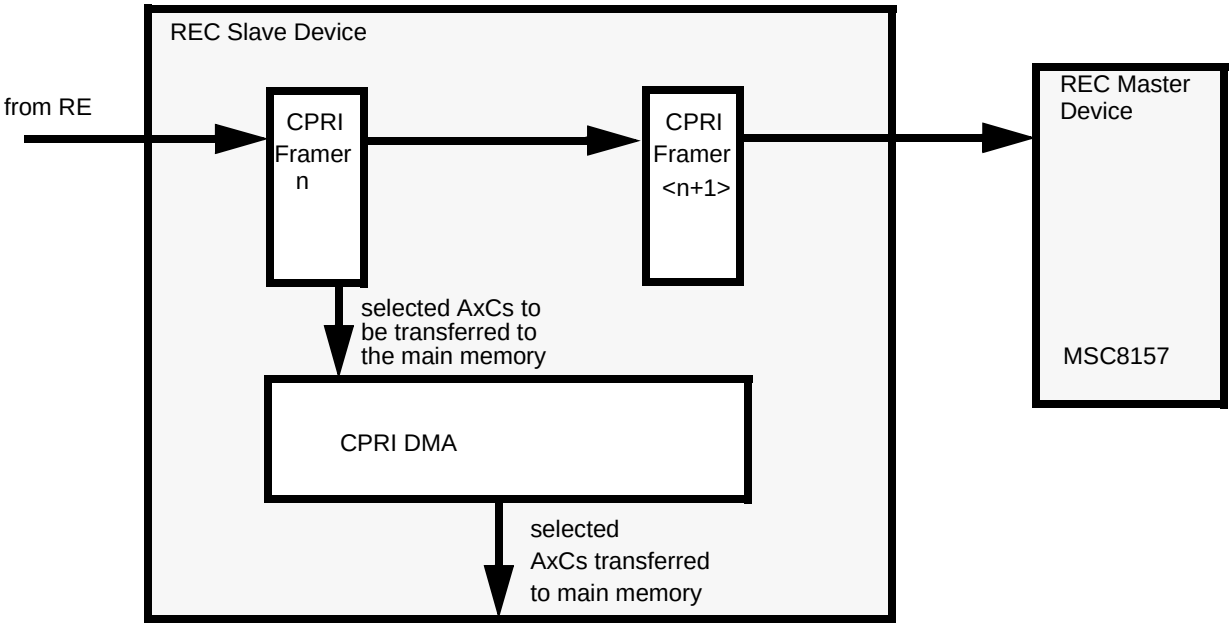

Figure 18-25. Uplink Data Flow in Daisy Chain Configuration

Note: For lanes that operate as pairs in auxiliary mode, when they generate an Error interrupt due to Local Loss of Frame error (bit CPRInEER[LLOF] is set, see **Section 18.4.4.17**), software should disable the CPRInAUXCR[AUX_EN] bit for both lanes of the pair and then immediately reenable both lanes.

18.3.7 CPRI Double Sampling Rate

A single CPRI module supports only one single sampling rate. To support a double sampling rate, three CPRI modules are required. The first CPRI is connected to the RF (CPRI 0 in the figure) and it transfers the AxCs with sampling rate <x> to the system memory. The second CPRI (CPRI 1 in the figure) module receives the RF data from the first CPRI module via the auxiliary interface and it outputs the data directly via the SerDes to the third CPRI module.The third CPRI module transfers the AxCs with sampling rate <y> to the system memory.

In the transmit direction, the third CPRI module fetches the AxCs with sampling rate <y> from the system memory and it transfers the data to the second CPRI module via the SerDes interface. The second CPRI module transfers the transmit data via the auxiliary interface to the first CPRI module which outputs the data toward the RF.

Each CPRI module contains a receive configuration table that determines which AxCs to transfer to the system memory and the AxCs location in the basic frame. The receive configuration table is programable.

Each CPRI module contains a transmit configuration table that determines which AxCs to fetch from system memory and the AxCs location in the basic frame. The transmit configuration table is programable.

Each CPRI module contains receive CPRI mask registers with the masking bits of the auxiliary interface. These registers should be configured for CPRI 0 in the example. If a masking bit is set then the auxiliary data (coming from CPRI 1) is sent out to the RF and if this bit is cleared then the data read by CPRI 0 from the system memory is sent out.

The synchronization between the different CPRI modules is done via internal sync signals (General Transmit Synchronization Register). **Figure 18-26** describes the system connectivity in double sampling rate.

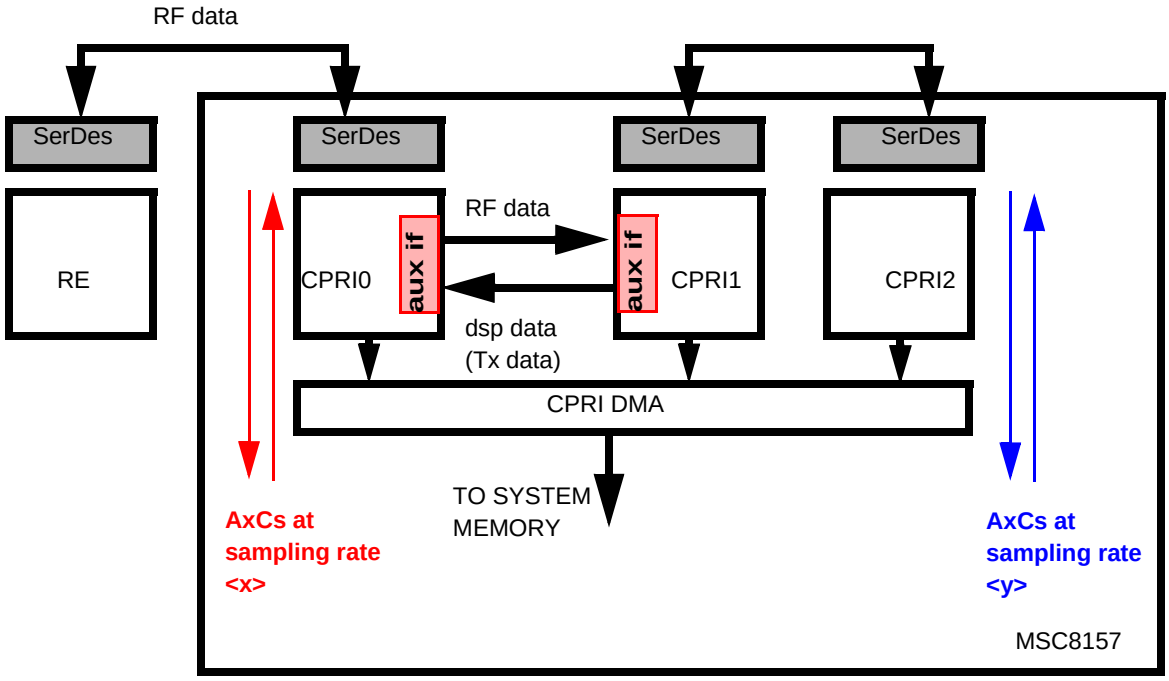

Figure 18-26. CPRI Connectivity in Double Sampling Rate

18.3.8 Timers

Each CPRI Framer has a local timer which generates 10 ms sync signal used by the CPRI Framer to transmit the CPRI frame. The CPRInTMRC register determines the CPRIn timer operation mode. When a minimum skew is required between the CPRI links, then the tsync signal of timer 1 is connected to CPRI Framers 2–6. Field SSM determines whether the CPRI complex works in shared mode or in independent mode.

The timer can generate the 10 ms sync signal in one of the following three modes, depending on field ESA:

- Sync signal generated locally by the timer

- Sync signal is aligned to 10 ms external sync signal and synchronized to Framer Clock. In this case, the maximum skew between the external sync signal and the generated sync is one Framer Clock cycle.
- Sync signal is aligned to received 10 ms sync signal of the CPRI Framer Unit in the pair.

The input sync signal is expected to be a minimum of one Framer Clock period wide, and asserted high. Asynchronous sync signals are double re synchronized to the Framer Clock domain. There is a rising edge detect circuit and an offset generator that can offset the sync signal by up to +16 Framer Clock cycles, or it can offset the sync by –255 Framer Clock cycles. The offset value is defined by SDLY field and its direction (+ or –) by the ESA field. The timer sync_out signal can be driven out externally (outside the device) when the TSO bit is set.

Figure 18-27 describes the frame sync signal when the delay is two cycles. **Figure 18-28** describes the frame sync signal when the delay is negative and is two cycles.

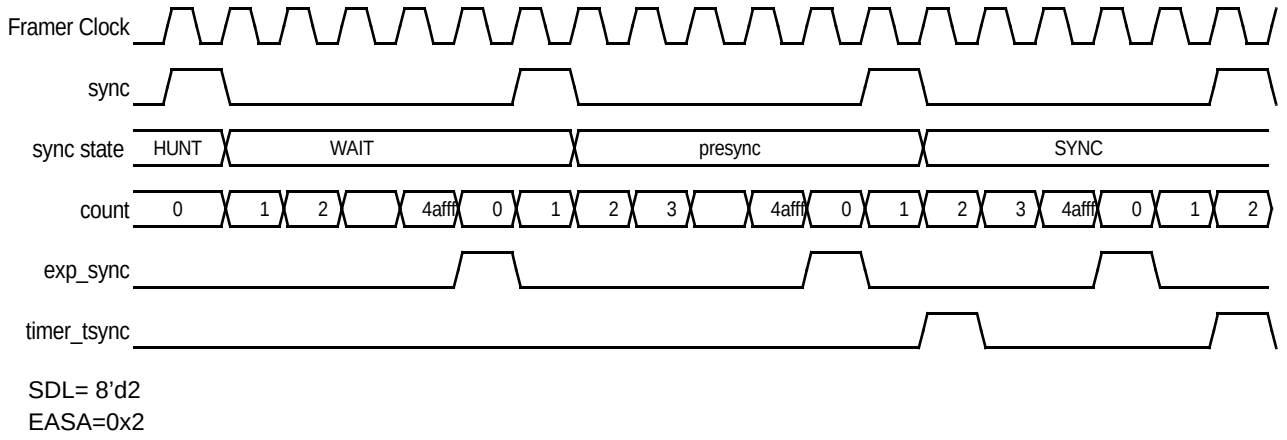

Figure 18-27. Sync Signal Offset is 2 Cycles

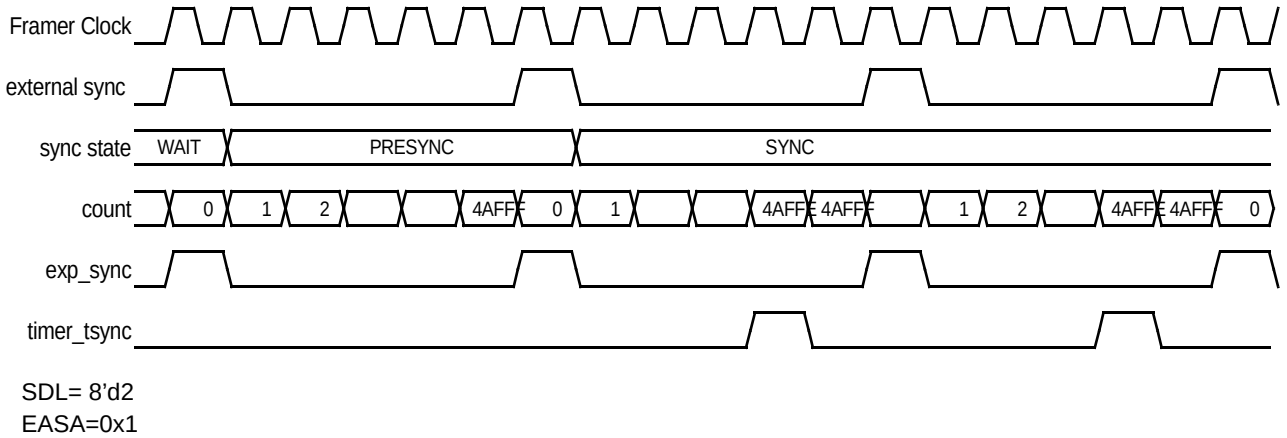

Figure 18-28. Sync Signal Offset Is Negative 2 Cycles

The local timer is clocked by Framer Clock and the number of clock cycles during 10 ms is depends on the link rate as describes in **Table 18-10**.

Table 18-10. The Counter Values as a Function of the Link Rate

Link Rate	Number of Cycles During 10 ms
1228.8 MHz	307200
2457.6 MHz	614400
3072.0 MHz	768000
4915.2 MHz	1228800
6144.0 MHz	1536000

18.3.8.1 Timer Sync State Machine

The timer state machine is required when the sync signal is not generated locally. The state machine is enabled only if the SSME bit in register CPRInTMRC register is set. The timer state machine state is described by the CPRInTMRSR status register. When sync synchronization is lost, then the EXSSLOS bit in the CPRInEER is set and an error interrupt is generated if the CPRInEIER[EXSSLOSE] bit is set.

Following is a list of the states of the sync state machine:

- HUNT (00). A sync event is constantly sought. As soon a sync event is detected, the state machine changes to a WAIT state. During the Hunt state, 10 ms sync signal is not generated.
- WAIT (01). At least one sync has been detected. The next sync event should be accepted after 10 ms.If the sync appears in the correct position after 10 ms the state changes to PRESYNC state. If the sync doesn’t appear the state returns to HUNT. Note that when the input sync is an asynchronous signal (when the ESA field = 01 or 10), then a mistake of up to 2 cycles is accepted. During the WAIT state sync signal is not generated.
- PRESYNC (11). Two sync events have been detected and the distance between the sync signals is 10 ms. If the sync event is recognized not after 10 ms the state returns to the WAIT state. Otherwise, the machine transfers to the SYNC state. During this state sync signal is not generated.
- SYNC (10). At least 3 sync events has appeared exactly where it was expected. This state is maintained as long as the sync event continues to appear where expected. If a sync is missed or a sync event is recognized earlier NUMERR times, the state changes to the HUNT state (00). During the SYNC state, sync signal is generated according to SDLY field of CPRInTMRC.

Figure 18-29 shows the timer state machine

Note: When the input sync is an asynchronous signal, then a mistake of up to two cycles (for each direction) is accepted.

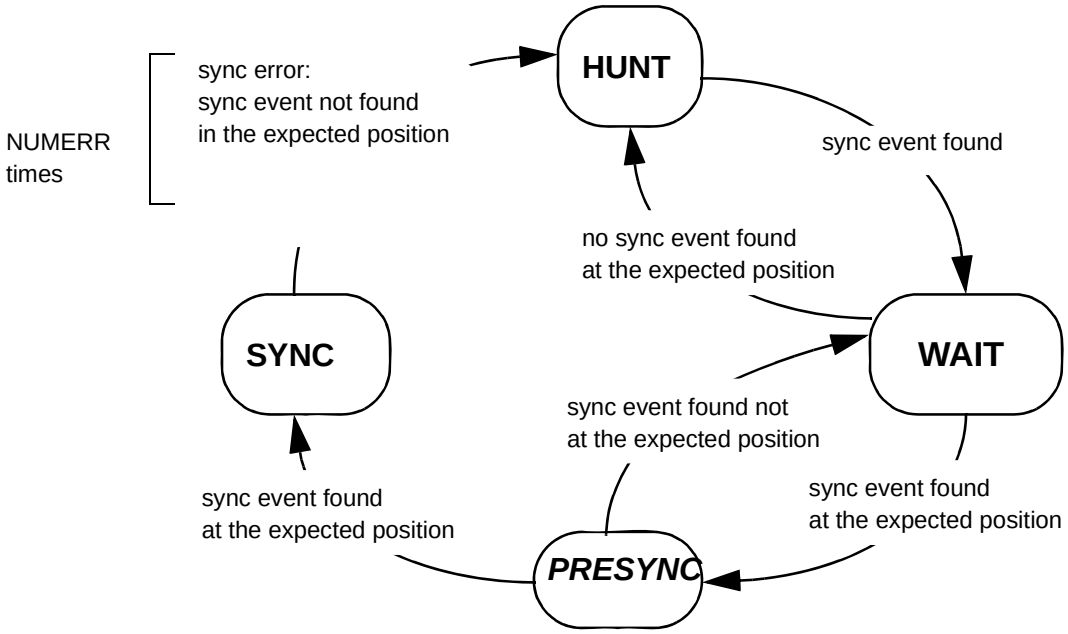

Figure 18-29. Sync State Machine

18.3.9 Interrupts

Table 18-11 shows the different kind of interrupts generated by the CPRI.

Table 18-11. CPRI Interrupts

Interrupt Name		Connectivity in MSC8157E	Description
IPI_INT_CPRIn_INTy	1–12	DSP	These CPRI interrupts are generated during normal operation as a result of any event described in the CPRInRER or CPRInTER registers. The CPRIICRy[ERS] field selects the receive or transmit event register and bits [8–0] of the register enable the interrupts. The interrupt can be generated as pulse or level as determined by the CPRIICRy[LEVEL] bit. **Figure 18-30** describes the CPRI interrupts scheme.
IPI_INT_CPRIn_RX_CONTROL	1–6	GCR	The receive control interrupt can be generated as result of the following events: • Receive Ethernet event (CPRInRER[RETHE] bit is set) • Receive HDLC event (CPRInRER[RHDLCE] bit is set) • Receive VSS event (CPRInRER[RVSSE] bit is set) The interrupt is enabled if at least one of the bits of CPRInRCIER[2:0] register is set. The interrupt can be generated as pulse or level and it is determined by the CPRInRCIER[CLEVEL] bit.

Table 18-11. CPRI Interrupts (Continued)

Interrupt Name		Connectivity in MSC8157E	Description
IPI_INT_CPRIn_TX_CONTROL	1–6	GCR	The transmit control interrupt can be generated as result of the following events: • Transmit Ethernet event (CPRInTER[TETHE] bit is set) • Transmit HDLC event (CPRInTER[THDLCE] bit is set) • Transmit VSS event (CPRInTER[TVSSE] bit is set) The interrupt is enabled if at least one of the bits of CPRInTCIER[2:0] register is set. The interrupt can be generated as pulse or level and it is determined by the CPRInTCIER[CLEVEL] bit.
IPI_INT_CPRIn_RX_FRAME_TIMING	1–6	GCR	Receive BFN/ hyper frame timing interrupt. These interrupt is asserted each time that new hyperframe or BFN frame arrives. These events are indicated by CPRInRER[RBFNE] bit and by CPRInRER[RHFNE]. The interrupt is enabled if CPRInRCIER[RBFE] bit or CPRInRCIER[RHFE] bit is set. The timing interrupt can be pulse or level and it is determined by the CPRInRCIER[RLEVEL] bit
IPI_INT_CPRIn_TX_FRAME_TIMING	1–6	GCR	Transmit BFN/ hyper frame timing interrupt. These interrupt is asserted each time that new hyperframe or BFN frame arrives. These events are indicated by CPRInTER[TBFNE] bit and by CPRInTER[THFNE]. The interrupt is enabled if CPRInTCIER[TBFE] bit or CPRInTCIER[THFE] bit is set. The timing interrupt can be pulse or level and it is determined by the CPRInTCIER[TLEVEL] bit
IPI_INT_CPRI_RX_CPU	1	VSG	CPRI receive CPU control interrupt The receive CPU control interrupt can be generated as result of the following events of any of the CPRI units depending on register CPRIRCCIER. • Receive Ethernet event (CPRInRER[RETHE] bit is set) • Receive HDLC event (CPRInRER[RHDLCE] bit is set) • Receive VSS event (CPRInRER[RVSSE] bit is set) The interrupt can be generated as pulse or level and it is determined by the CPRIRCCIER[RCPULEVEL] bit.
IPI_INT_CPRI_TX_CPU	1	VSG	CPRI transmit CPU control interrupt The transmit CPU control interrupt can be generated as result of the following events of any of the CPRI units depending on register CPRITCCIER. Transmit Ethernet event (CPRInTER[TETHE] bit is set) Transmit HDLC event (CPRInTER[THDLCE] bit is set) Transmit VSS event (CPRInTER[TVSSE] bit is set) The interrupt can be generated as pulse or level and it is determined by the CPRITCCIER[TCPULEVEL] bit.
IPI_INT_CPRI_ERR	1	GCR	CPRI error interrupt This interrupt is asserted if an error occurred in any CPRI module and if its corresponding bit is set in the Mask Register CPRInEIER. Error Status Register CPRIESR indicates which CPRI the error comes from The error events of CPRIn are indicated by the status registers CPRInEER. This interrupt is level.

Table 18-28 describes the CPRI_INTy generation.

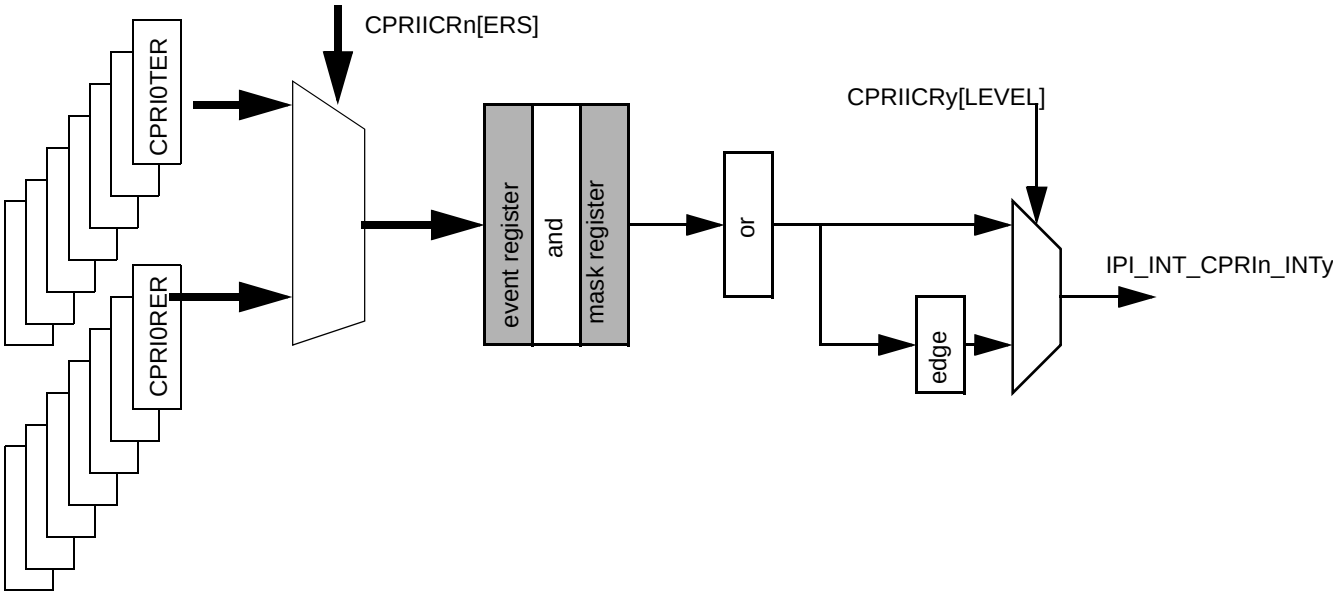

Figure 18-30. IPI_INT_CPRIn_INTy Interrupt Generation

18.3.10 L1 Inband Protocol Errors

Bits of control word Z.130.0 are used for basic Layer 1 functions. The following bits when set in the Receive Control word Z.130.0 can generate an error interrupt depending on the configuration in the CPRInEIER register:

- Bit “1” reflects RAI (Remote Alarm Indication)
- Bit “2” reflects SDI (Remote SAP Defect Indication)
- Bit “3” reflects LOS (Remote Loss of Signal Indication)
- Bit “4” reflects LOF (Remote Loss of Frame Indication)

Bit “0” of control word Z.130.0 reflects Remote Reset Request. It can be set through CPRIn_HW_RESET register.

When the REC sends a reset request to another REC, the second REC can poll this bit in the Control Table from time to time (for example, once in a hyperframe) and initiate an autonegotiation reset.

The REC master can send a reset request to the REC slave or RE through the CPRIn_HW_RESET register. The REC slave cn send a reset acknowledge to the master, but this configuration has the following restraints:

- If the REC slave is an end-point, it can generate the reset acknowledge.

- If the REC slave is not an end-point (but between the REC master and the RE), it must be configured as a master (to support the 10 ms chaining) and the reset request/ack must be managed outside the CPRI protocol.

18.3.11 CP_LOS

There are six CPRI loss-of-signal (LOS) input signals coming from externally-connected smallform-factor pluggable (SFP) optical transceivers that the SFP device uses to indicate that it has lost the CPRI input signal. Receipt of the CPRI LOS signal causes the framer to lose synchronization and can generate a CPRI error interrupt if enabled by the CPRIEIER[LLOSE] bit.

18.3.12 Delay Measurement and Calibration

Measurement and control of the signal delay is required for appropriate recovery of the synchronization references and system configuration. The MSC8157E CPRI provides internal support for accurate delay measurement and calibration. The RX delay measurement and the TX delay calibration values are accessible via the register interface. The CPRI standard contains a number of delay accuracy requirements (see **Sections 3.5** and **3.6** of the CPRI specification), most of which relate to the physical layer functions. The MSC8157E CPRI includes built-in PCS sub-layer functions to ensure meeting the tough requirements. A simple RE networking configuration can use the AUX interface to configure the frame timing to match the CPRI specification requirements.

A basic CPRI configuration has a single REC node and a single RE node with a single link connecting the REC master port to the RE slave port. This is called a single-hop point-to-point connection. As noted in **Section 18.3.6**, *External Implementation*, however, the modules support a number of connection topologies. While the star topology is similar to the basic configuration in that all links are between two nodes, the difference is that it has multiple master ports in the REC node. All the other topologies are considered multi-hop configurations. A multihop configuration is one which has continuously connected hops from the REC that end with a specific RE, but includes all the nodes in between. Delay budgets must be configured for each hop (both for upload and download).

The CPRI standard defines reference points for frame timing and delayed measurements, as shown in **Figure 18-31** (adapted from the CPRI specification. shows the frame timing sequence of these values for a single-hop interface.

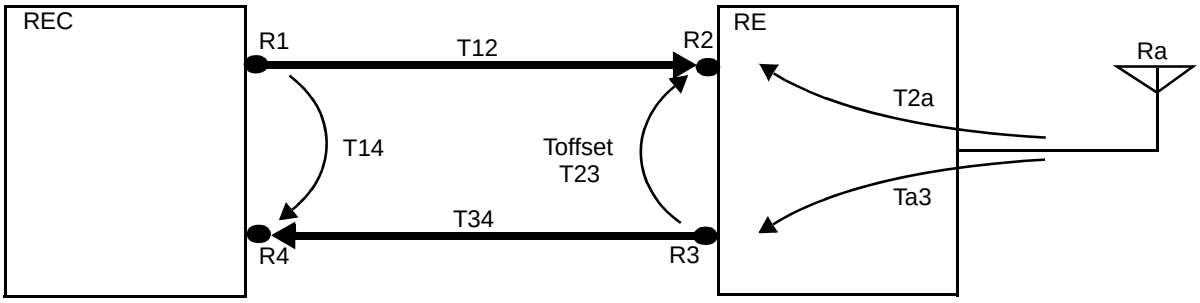

Figure 18-31. Single-Hop Frame Timing Reference Points

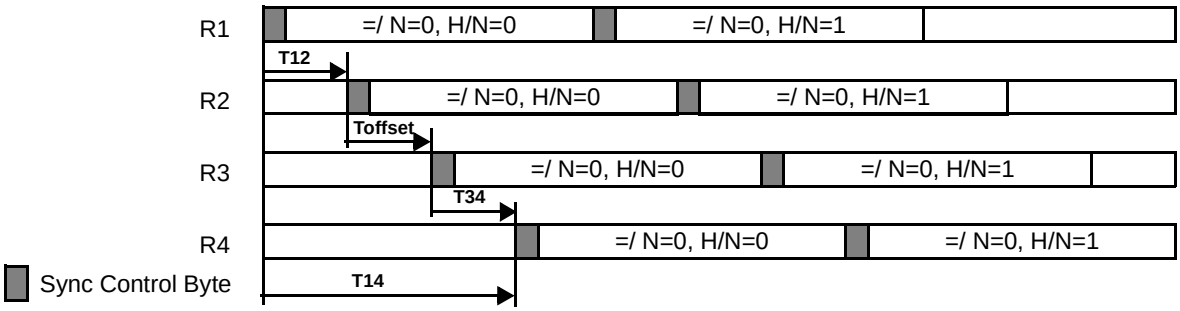

Figure 18-32. Single-Hop CPRI Frame Timing Diagram

The T14, Toffset, T12, and T34 delays can be calculated using the following equations:

- T14 = T_TX = CPRI_ROUND_DELAY * TCLK – (T_T4 + T_EXT + T_R1)
- Toffset(RE) = T23 = T_T4 + T_EXT + T_R1
- T12 = T34 = (T14 – Toffset) / 2

  where,

  — CPRI_ROUND_DELAY is the total round delay from start of internal transmit radio frame to start of internal receive radio frame in the REC node. The value for this variable is measured by the CPRIn_ROUND_DELAY registers (see **Section 18.4.1.10**, *CPRI Round Trip Delay (CPRIn_ROUND_DELAY)*).

  — TCLK is the period of the clock at line_rate/40

  — T_T4 is the transmit delay from the 10 ms synchronization radio frame input signal to the TX AUX counter outputs. See **Section 18.3.12.1**, *CPRI Transmission Delay*.

  — T_EXT = T_EXT_RX + T_EXT_TX—Total external delay is the sum of the SerDes receive delay and the SerDes transmit delay. Optical delays are outside the MSC8157E, and are not compensated. They should be regarded as an extra inaccuracy in the calculation. If these delays (SFP_RX_{REC}, SFP_TX_{REC}, SFP_RX_{RE}, SFP_TX_{RE}) are known, add them to T_EXT to reduce the inaccuracy of the total calculation. These values are stored in the PCVTRCPRInCR0 for T_EXT_RX and PCVTRCPRInCR1

for T_EXT_TX. See **Section 15.10.50**, *CPRIn PCVTR Control Register 0(PCVTRCPRInCR0)* and **Section 15.10.51**, *CPRIn PCVTR Control Register 1(PCVTRCPRInCR1)* for register details.

— T_R1 is the receive delay from the SerDes receive interface until the data is presented to the RX AUX interface. See **Section 18.3.12.2**, *CPRI Reception Delay*.

For these equations, you must consider different values for REC and RE. For example, Toffset (T23) is the total delay in the RE from the SerDes receive to SerDes transmit. This delay is computed using the following formula:

$$T\_R1_{TE} + R\_T4_{RE} + T\_EXT\_RX_{RE} + T\_EXT\_TX_{RE}$$

where, $T\_EXT\_(RX,TX)_{RE}$ are the SerDes delays.

Different REs may use different value for Toffset. The REC node should know the value of Toffset for each RE in advance (for example, by using a predefined value or by having the RE inform the REC by higher layer message).

The total REC SerDes delay is as follows:

$$T\_EXT_{REC} = T\_EXT\_RX_{REC} + T\_EXT\_TX_{REC}.$$

where, $T\_EXT\_(RX, TX)_{REC}$ are the SerDes delays.

Because optical delays are external to the MSC8157E, they do not have compensation and should be regarded as an extra inaccuracy in the calculation. If the delays (SFT_RX_{REC}, SFP_TX_{REC}, SFP_RX_{RE}, and SFP_TX_{RE}) are known, they can be added to T_EXT to reduce the inaccuracy of the total calculation.

Use the following equation according the CPRI specification to calculate T34 and T12:

$$T34 = T12 = (T14 – Toffset) / 2$$

The delay accuracy is discussed in **Section 18.3.12.3**, *Delay Accuracy*,

18.3.12.1 CPRI Transmission Delay

The Transmission delay consists of the innate existing internal delay plus the delay the user can add. The user delay is added mainly to compensate for line delay change (for example, due to temperature changes).

From the start of the transmit 10 ms RF pulse (CPRIn_tx_rfp) there is a delay of T_TX to the start of radio frame (K28_5 symbol) on the output to the SerDes.

- The existing internal delay is equal to 6.75 *T_CLK where T_CLK is a period of clock at line_rate/40

- The user defined delay is configured in the TX_EX_DELAY field of the CPRIn_EX_DELAY_CONFIG register (see **Section 18.4.1.11**, *CPRI Extended Delay Measurement Configuration (CPRIn_EX_DELAY_CONFIG)*). It enables a bit level delay calibration. The delay calibration field can be set between 0 and 39 bit steps. Default calibration on reset is set to zero.

The total delay is: T_TX = 6.75 *T_CLK + TX_EX_DELAY

Figure 18-33 shows the CPRI transmit delay path.

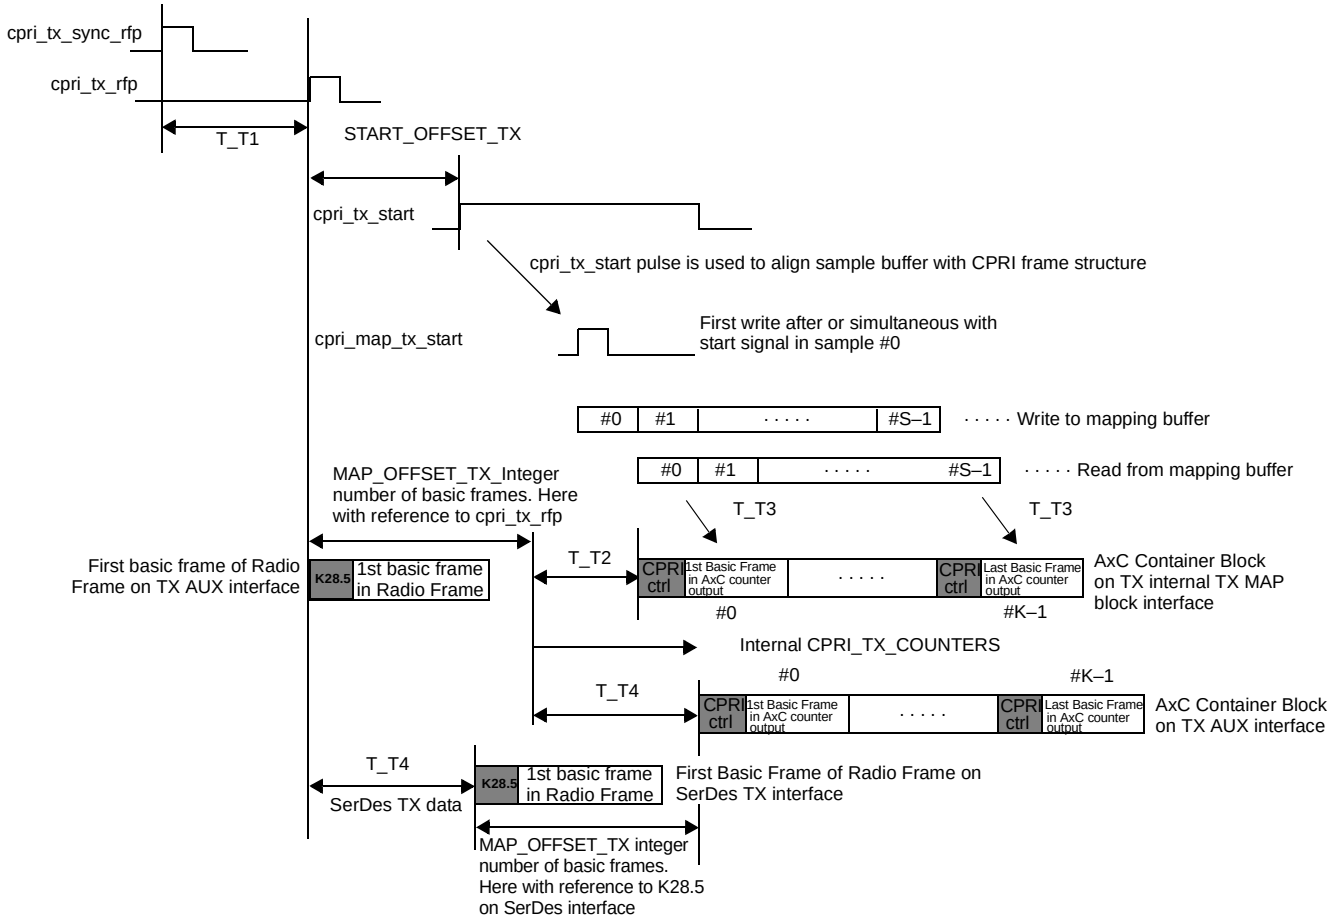

Figure 18-33. CPRI Transmit Delay Path

18.3.12.2 CPRI Reception Delay

The delay from the first serial bit at the receive interface is given by the parameter T_RX. The following equations are used to calculate the T_RX value:

T_RX = (T_RX_BIT_ALIGN + T_8B10B_DEC + T_RX_BUF + T_RX_PHASE + T_RX_BYTE_ALIGN + T_RX_PIPELINE) where

— T_RX_BIT_ALIGN = 2 * T_CLK + CPRIn_RX_DELAY[RX_ALIGN_DELAY] * T_CLK / 40

— T_8B10B_DEC = T_CLK
— T_RX_BUF + T_RX_PHASE is measured in register CPRIn_EX_DELAY_STATUS and computed by: (RX_EX_BUF_DELAY * T_CLK) / N
— T_RX_BYTE_ALIGN = CPRIn_RX_DELAY[RX_BYTE_DELAY] / 4 *T_CLK
— T_RX_PIPELINE = 6 * TCLK
— T_CLK is period of clock at line_rate/40
— N is the value configured in CPRIn_EX_DELAY_CONFIG [RX_EX_DELAY_PERIOD].

The RX_EX_DELAY_PERIOD should be configured depending on the link rate:

- For link rates 6.144 Gbps and 4.914Gbps, RX_EX_DELAY_PERIOD = 40
- For link rates 3.072 Gbps and 2.457Gbps, RX_EX_DELAY_PERIOD = 80
- For link rates 1.228 Gbps, RX_EX_DELAY_PERIOD = 160

Note: See **Section 18.4.1.11**, *CPRI Extended Delay Measurement Configuration (CPRIn_EX_DELAY_CONFIG)*, **Section 18.4.1.12**, *CPRI Extended Delay Measurement Status (CPRIn_EX_DELAY_STATUS)*

Figure 18-34 shows the CPRI receive delay path.

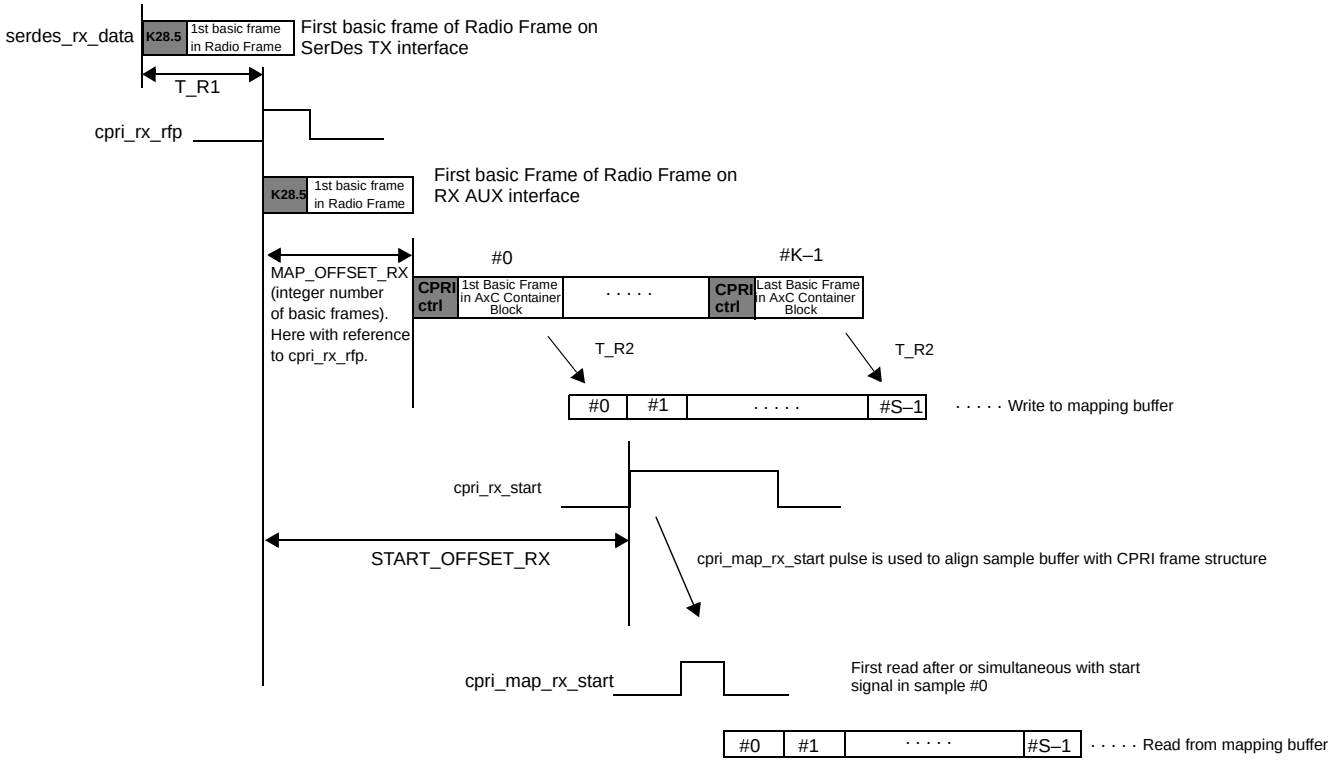

Figure 18-34. CPRI Receive Delay Path

18.3.12.3 Delay Accuracy

The CPRI units fulfill requirement R-19 of the CPRI v4.1 standard defining that the link delay accuracy in downlink between SAPs master port and SAPs slave port excluding the cable length must be ± 8.138 ns.

Requirement R-20 of the CPRI v4.1 standard defines the round trip absolute accuracy excluding cable length to be ± 16.276 ns. In order to comply with this specification, REC chaining using only MSC8157/8 devices can done with up to 6 devices using daisy-chain mode.

18.4 CPRI Programming Model

All the CPRI complex registers are 32-bit registers. The bits are ordered 31 (most-significant bit) to 0 (least-significant bit). All the read and write accesses are executed through a 32-bit bus interface; reads and writes always access all the bits of the register. The registers are categorized as follows:

- *CPRI framer registers.* Configures the data framing operations, including Ethernet and HDLC frame handling. Each of the 6 units has its own registers.
- *CPRI complex registers.* Used to configure the CPRI complex. Each of the 6 units have their own registers
- *Control registers*. Each of the 6 units have their own registers
- *Status registers*. Read-only registers that can be accessed any time. Each of the 6 units have their own registers
- *Configuration memories.* Configures the mapping tables. Each of the 6 units have their own memories.
- *CPRI General Registers.* Registers used by all the 6 units.

The base address of the CPRIn (n=1...6) registers is 0xfff40000 + (n–1)*0x3000.

The address of the registers can be computed by adding the offset from the table to the relevant base address. The General registers use the base address of CPRI1.

For example, the address of CPRIn_HFN register in CPRI3 can be computed by:

0xfff40000 + (3–1)*0x3000 + 0x24 = 0xfff46024.

18.4.1 CPRI Framer Registers

The following sections describe the CPRI Framing registers.

18.4.1.1 CPRI Status Register (CPRIn_STATUS)

address 0x4 (CPRIn_STATUS)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	—															
W																
Reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	—				RX_RFP_HOLD	RX_FREQ_ALARM_HOLD	RX_STATE_HOLD	RX_LOS_HOLD	—				RX_BFN_STATE	RX_HFN_STATE	RX_STATE	RX_LOS
W																
Reset:	0	0	0	0	0	1	1	1	0	0	0	0	0	0	0	1

Figure 18-35. CPRIn_STATUS

Table 18-13. CPRIn_STATUS Bit Descriptions

Name	Reset	Description	Setting
— 31–12	0	Reserved. Write to zero for future compatibility.	
RX_RFP_HOLD 11	0	**Radio Frame Pulse (RFP) Received** Indicates that an RFP was received. This bit is set every 10 ms when hyperframe, basic frame =0,0. This bit is read-to-clear.	0 RFP not detected 1 RFP detected
RX_FREQ_ALARM_HOLD 10	1	**Receive Clock Frequency Alarm Received** This bit indicates that a CPRI CDR Clock is not synchronous with the Framer Clock. The alarm is set every time the phase of the CDR Clock has changed more than 4 clock periods of the Framer Clock. This bit is read-to-clear.After clearing it takes a new drift of 4 cycles to set the alarm again	0 No frequency alarm occurred 1 Frequency alarm occurred

Table 18-13. CPRIn_STATUS Bit Descriptions

Name	Reset	Description	Setting
RX_STATE_HOLD 9	1	**Receive State Hold** Indicates that the internal RX state machine is out of synchronization. It happens when either K.28.5 was at least once not in its expected position or an error occurred in the HFN,BFN counter sequence (If for 4 hyperframes the counter values recovered from the incoming CPRI frame structure do not match the expected values, a loss of SYNC is declared). This bit is read-to-clear.	0 No receive loss of SYNC (LOS). 1 Receive LOS occurred
RX_LOS_HOLD 8	1	**Receive Loss of Signal (LOS) Occurred** Indicates that a loss of SYNC occurred. This bit is a sticky read-to-clear bit.	0 No LOS detected 1 LOS detected
— 7–4	0	Reserved. Write to zero for future compatibility.	
RX_BFN_STATE 3	0	**Receive NodeB Frame (BFN) Alignment Detected** Indicates whether BFN alignment was detected.	0 No BFN alignment detected 1 BFN alignment detected
RX_HFN_STATE 2	0	**Receive HFN Alignment Detected** Indicates whether HFN alignment was detected.	0 No HFN alignment detected 1 HFN alignment detected
RX_STATE 1	0	**Receive State** Indicates the receive state. The state is sync if the receive state is ok and HFN and BFN states are ok (bIts RX_BFN_STATE and RX_HFN_STATE are set)	0 Global Receive State is not sync. 1 Global Receive State is sync.
RX_LOS 0	1	**Receive Loss of Signal (LOS)** Indicates either excessive 8b/10b violations (>15) or external indication of Loss of Signal from optical modules.	0 LOS not detected. 1 LOS detected.

18.4.1.2 CPRI Configuration (CPRIn_CONFIG)

address 0x8 (CPRIn_CONFIG)

Figure 18-36. CPRIn_CONFIG

Table 18-14. CPRIn_CONFIG Bit Descriptions

Name	Reset	Description	Setting
— 31–9	0	Reserved. Write to zero for future compatibility.	
RX_ENABLE 9	0	**Receive Enable** Enables or disables receive operations.	0 Disable receive operations 1 Enable receive operations.
— 8–6	0	Reserved. Write to zero for future compatibility.	

Table 18-14. CPRIn_CONFIG Bit Descriptions (Continued)

Name	Reset	Description	Setting
TX_ENABLE 5	0	**Transmit Enable** Enables or disables transmit operations.	0 Disable transmit operations. 1 Enable transmit operations.
— **4–**2	0	Reserved. Write to zero for future compatibility.	
SYNC_ MODE 1	0	End Point Slave Mode When this bit is cleared, the lane operates in Master Mode. As a master, it can generate a reset request to the Slave and receive a reset acknowledge. It uses the 10 ms pulse generated by the Timer for transmission. When the bit is set, the lane operates in Slave Mode, in which it can receive a reset request from the Master and generate a reset acknowledge. It uses the recovered 10 ms pulse for transmission.	0 Master Mode 1 Slave Mode
TX_CTRL_ INSERT_EN 0	0	**CPRI Control Word Insertion l Enable** Transmit Control Word insertion enable.	0 Transmit control word insertion disabled. 1 Transmit control word insertion enabled,.

18.4.1.3 CPRI Receive Line Coding Violation Counter (CPRIn_LCV)

address 0x1C (CPRIn_LCV)

Figure 18-40. CPRIn_HW_RESET

This register is used to control and monitor reset request or acknowledges mapped to bit 0 of Z.130.0 CPRI control word. The register is used to transmit reset request to RE nodes.

A reset request can be sent by setting RESET_GEN_EN and RESET_GEN_FORCE signals. The reset generation request will be hold as long as RESET_GEN_FORCE is asserted and until reset acknowledge have been received from the RE. However reset generation request can always be aborted by clearing the RESET_GEN_EN signal.

Table 18-18. CPRIn_HW_RESET Bit Descriptions

Name	Reset	Description	Setting
— 31–8	0	Reserved. Write to zero for future compatibility.	
RESET_GEN_DONE_HOLD 7	0	**Hold Reset Done** This bit holds the Reset Generation Done value. **Note:** This bit is sticky read-to-clear.	0 Reset generation not done. 1 Reset generation done.
RESET_GEN_DONE 6	0	**Reset Generation Done** Indicates whether the reset request or acknowledge is done. Set when CPRI completes sending 10 consecutive reset request or acknowledge indications	0 Reset request/ acknowledge is not done. 1 Reset request/ acknowledge is done.
RESET_DETECT_HOLD 5	0	**Hold Reset Detected** This bit holds the Reset Detected value. **Note:** This bit is sticky read-to-clear.	0 Reset request not detected. 1 Reset request detected.
RESET_DETECT 4	0	**Reset Detected** Indicates that a reset request/acknowledge was detected on the CPRI RX side.	0 Reset request/acknowledge not detected. 1 Reset request/acknowledge detected.
— 3	0	Reserved. Write to zero for future compatibility.	
RESET_OUT_EN 2	0	**Reset Indication Output Enable** Used to enable the reset output request.	0 Disable reset indication output 1 Enable reset indication output

Table 18-18. CPRIn_HW_RESET Bit Descriptions (Continued)

Name	Reset	Description	Setting
RESET_GEN_FORCE 1	0	**Forces Reset Request/Acknowledge** Setting this bit forces a reset request/acknowledge on the CPRI TX side.	0 Disable reset request/acknowledge. 1 Force reset request/acknowledge.
RESET_GEN_EN 0	0	**Reset Request/Acknowledge Generation Enable** Setting this bit enables generation of a reset request/acknowledge on the CPRI TX side via the dedicated control word (Z.130.0).	0 Generation of reset request/acknowledge disabled. 1 Generation of reset request/acknowledge enabled.

18.4.1.7 CPRI Control and Management Configuration (CPRIn_CM_CONFIG)

address 0x3C (CPRIn_CM_CONFIG)

Figure 18-100. CPRInRGCM

Table 18-77. CPRInRGCM Bit Descriptions

Name	Reset	Description	Setting
ROVS 31	0	**Receive Double Oversampling Mode** If this bit is set the received oversampling data is spread to two different buffers in the SOC memories. **Note**: In This mode the RSW field must be set to 0x2.(8-bit sample width.)	0b0 Normal Mode 0b1 Receive double oversampling mode

Table 18-77. CPRInRGCM Bit Descriptions (Continued)

Name	Reset	Description	Setting
RMUCM 30	0	**Receive Multi Unicast Mode** Determines if the CPRI works in multi unicast mode or not. In multi unicast mode the received data is send to two different destinations in the SOC memory.(First and Second destination). If this bit is set RMCM bit must be zero	0b0 Non multi cast mode 0b1 Receive multi unicast mode
29	0	Reserved. Write to zero for future compatibility.	
RMCM 28	0	**Receive MultiCast Mode** Determines if the CPRI works in multicast mode or not. In multicast mode the received data is sent to the SOC memory (as a first destination) and directly to the MAPLE (as a second destination). If this bit is set RMUCM bit must be zero.	0b0 Non multicast mode 0b1 Receive multicast mode
— 27–18	0	Reserved. Write to zero for future compatibility.	
RSW 17–16	0	**Receive Sample Width** Determines the receive sample width. Must be the equal to the TSW field in CPRInTGCM.	0x0 16 bit receive sample width 0x1 15 bit receive sample width 0x2 8 bit receive sample width
RTM 15	0	**Receive Transparent Mode** For details on transparent mode, refer to **Section 18.3.4.** Bits ROVS,RMUCM and RMCM should be zero.	0 Normal mode 1 Transparent mode
— 14–5	0	Reserved. Write to zero for future compatibility.	
RMAP_AC 4–0	0	**Receive Number of Antenna Carriers** This field describes the maximal number of the active AxCs. R	TNS															
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 18-102. CPRInTSCR

In WiMAX, even if only one CPRI operates, it may be desirable to synchronize the transmit to the 10 ms frame. In the case of n AxCs with oversampling m, TNS should be n*m*256*150 (n*m samples in a basic frame, 256 basic frame in a hyperframe, 150 hyperframes in a 10 ms frame)

Table 18-79. CPRInTSCR Bit Descriptions

Name	Reset	Description	Setting
TSA 31	0	**Transmit Synchronization Active** Determines whether synchronization is required. The synchronization is done to the 10ms frame. If this bit is set TNS field should be written.	0b0 Transmit synchronization is not required 0b1 Transmit synchronization is required
— 30–21	0	Reserved. Write to zero for future compatibility.	

Table 18-79. CPRInTSCR Bit Descriptions

Name	Reset	Description	Setting
TNS 20–0	0	**Transmit Number of Samples** Determines the number of transmit samples during a single Node B frame. The value of 0x0 is valid only if TSA is cleared. TNS can range from 0x 1 to 0x177000 (1 to 153600 samples in the Transmit Node B frame).	

18.4.2.27 Transmit CPRI Framer Buffer Size (CPRInTCFBS)

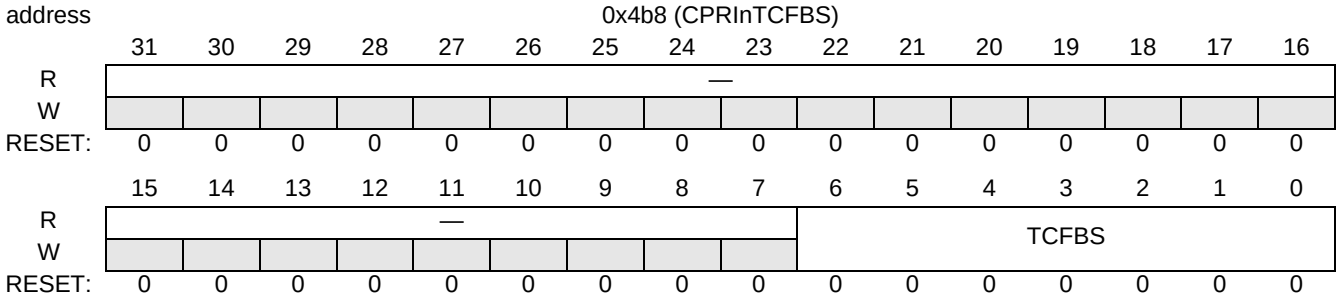

Figure 18-103. CPRInTCFBS

The buffer size actually determines the CPRI framer transmit latency. The CPRIn framer latency in chips time for the case of Sample Width 15 or 16 is TCFBS/(Oversampling Ratio)

The default value depends on the number of AXCs as defined by CPRInTGCM[TMAP_AC]. The default value can be overwritten by using TCFBS, but requires consideration of the following:

- A larger buffer means higher transmit latency. In the case of a few AxCs with no oversampling, the default buffer size is quite large and can be set to a smaller value to reduce latency.
- Using a buffer that is too small may cause data overrun.
- For higher sampling rates, the buffer size should be larger.

RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 18-109. CPRInRCR

CPRInRCR controls the activation/deactivation of the receive IQ, receive HDLC, receive Ethernet and Receive VSS. It also controls if the write access of the different CPRI modules to the system memory should be synchronized. After setting the RIQSYNC bit in the CPRI modules we want to synchronize and after all the relevant lanes are synchronized we set bit CPRIGRSR.GRIQS that will enable the write access of the different CPRI modules at the same time.

This register can be changed during normal operation. This register is reset due to auto negotiation reset.

Table 18-86. CPRInRCR Bit Descriptions

Name	Reset	Description	Setting
— 31–16	0	Reserved. Write to zero for future compatibility.	
RIQSYNC 15	0	**Receive IQ Synchronized** The bit determines if the received IQ data should be synchronized to the other CPRI. Setting this bit is the last step in the initialization.	0 The receive IQ DMA operation should not be synchronized to other CPRI modules. 1 The receive IQ DMA operation should be synchronized to other CPRI modules.
— 14–4	0	Reserved. Write to zero for future compatibility.	
RVSSE 3	0	**Receive VSS Enable** This bit determines if the VSS data is transferred to the system memory or not. Setting this bit is the last step in the initialization.	0 The received VSS data is not transferred to the VSS buffer in the system memory. 1 The received VSS data is transferred to the VSS buffer in the system memory.
RHDLCE 2	0	**Receive HDLC Enable** This bit determines if the HDLC data is transferred to the system memory or not. Setting this bit is the last step in the initialization.	0 The received HDLC data is not transferred to the HDLC buffers in the system memory. 1 The received HDLC data is transferred to the HDLC buffers in the system memory.
RETHE 1	0	**Receive Ethernet Enable** This bit determines if the Ethernet data is transferred to the system memory or not. Setting this bit is the last step in the initialization	0 The received Ethernet data is not transferred to the Ethernet buffers in the system memory. 1 The received Ethernet data is transferred to the Ethernet Buffers in the system memory.

Table 18-86. CPRInRCR Bit Descriptions

Name	Reset	Description	Setting
RIQE 0	0	**Receive IQ Enable** This bit determines if the IQ data is transferred to the system memory or not. Setting this bit is the last step in the initialization	0 The received IQ data is not transferred to the AxC buffers in the system memory. 1 The received IQ data is transferred to the AxC Buffers in the system memory.

18.4.3.2 Transmit Control Register (CPRInTCR)

address 0x504 (CPRInTCR)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	—															
W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

18.4.3.13 Receive IQ First Threshold (CPRInRIQFT)

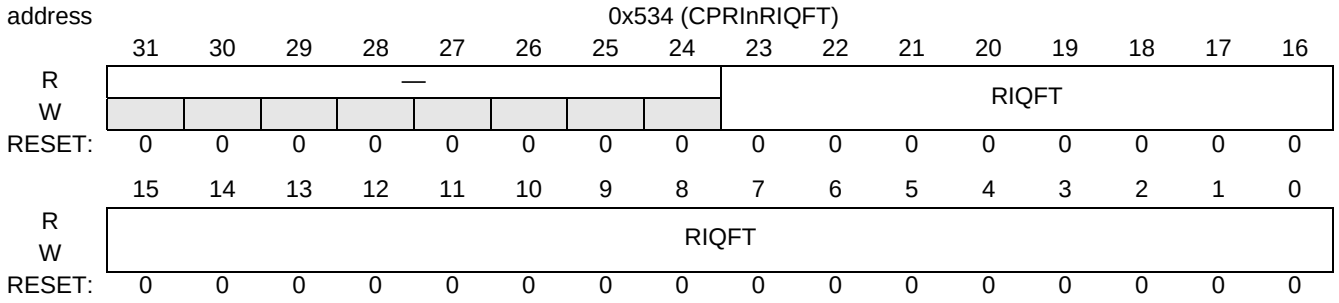

Figure 18-121. CPRInRIQFT

CPRInRIQFT determines the first threshold of the receive IQ buffers. When the receive buffers are filled up to the first threshold defined by this register, that is, the receive IQ buffer displacement register (CPRInRIQBDR) = (CPRInRIQFT) + (Receive IQ MBus Transaction Generation Size), the RIQFTE bit in the CPRInRER is set. If the associated enable bit in register CPRIICRy is also set, an interrupt is generated.

This register is reset due to auto negotiation reset.

Table 18-98. CPRInRIQFT Bit Descriptions

Name	Reset	Description	Setting
— 31–24	0	Reserved. Write to zero for future compatibility.	
RIQFT 23–0	0	**Receive IQ Data Buffer First Threshold** Determines the location of the first threshold in the AxC receive data buffers. The pointer should be integer multiple of the Receive IQ MBus Transaction Generation Size defined in register RIQMTS	0x000000 to (CPRInRIQBS–64)

18.4.3.14 Receive IQ Second Threshold (CPRInRIQST)

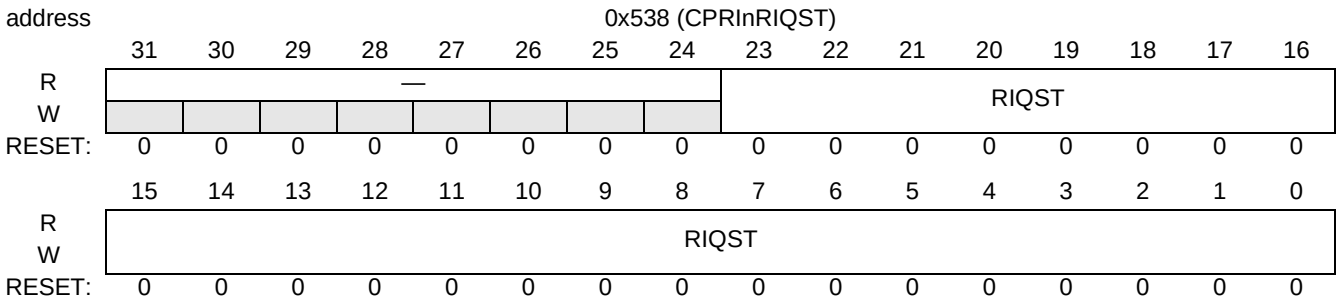

Figure 18-122. CPRInRIQST

CPRInRIQST determines the second threshold of the receive IQ buffers. When the receive buffers are filled up to the second threshold defined by this field, that is, the receive IQ buffer displacement register (CPRInRIQBDR) = (CPRInRIQST) + (Receive IQ MBus Transaction Generation Size), the RIQSTE bit in the CPRInRER is set. If the associated enable bit in register CPRIICRy is also set, an interrupt is generated.

This register is reset due to auto negotiation reset.

Table 18-99. CPRInRIQST Bit Descriptions

Name	Reset	Description	Setting
— 31–24	0	Reserved. Write to zero for future compatibility.	
RIQST 23–0	0	**Receive IQ Data Buffer Second Threshold** Determines the location of the second threshold in the AxC receive data buffers. The pointer should be integer multiple of the Receive IQ MBus Transaction Generation Size defined in register RIQMTS	0x000000 to (RIQBS–64)

18.4.3.15 Receive IQ Threshold (CPRInRIQT)

address 0x53c (CPRInRIQT)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RETHCT 7–0	0	**Receive Ethernet coalescing Threshold** Receive Ethernet event is issued after (RETHCT + 1) packets	0x00 Receive Ethernet event is issued after 1 packet 0x01 Receive Ethernet event is issued after 2 packets ... 0xFE Receive Ethernet event is issued after 255 packets. 0xFF Receive Ethernet event is issued after 256 packets

18.4.3.22 Transmit Ethernet Coalescing Threshold (CPRInTETHCT)

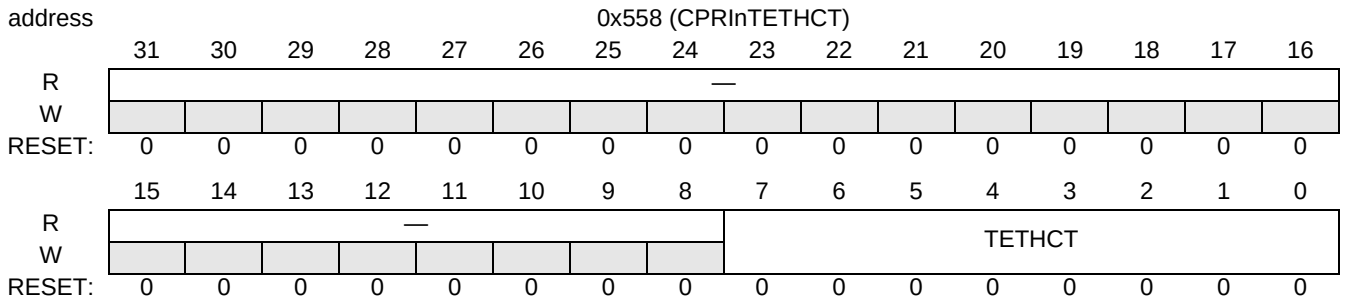

Figure 18-130. CPRInTETHC

The CPRInTETHCT register sets the transmit Ethernet packet interrupt threshold defined in number of packets transmitted. The CPRInTER[TETHE] bit is set if the transmit coalescing counter (indicated by the CPRInTETHCS register) is equal to transmit Ethernet coalescing threshold (TETHCT) value. If the associated enable bit in register CPRIICRy is also set, an interrupt is generated.

R W	MASKR															
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 18-142. CPRInMASKRy

CPRInMASKR registers determines the masking bits for auxiliary interface. Each bit refers to one bit in the frame to be transmitted. When a bit is set then the relevant bit of the frame to be transmitted is coming from the other CPRI unit in the pair through the auxiliary interface. When a bit is cleared then the relevant bit of the frame to be transmitted is coming from the system memory of this CPRI unit.

Table 18-119. CPRInMASKR<Y> Bit Descriptions

Name	Reset	Description	Setting
MASKR 31–0	0	**Mask Register** Determines the masking bits of the auxiliary interface. If the bit is set, then the auxiliary data for that bit is sent out. If this bit is cleared, then the transmit data for the bit is sent out.	0b0 Use transmit data for bit. 0b1 Use auxiliary data for bit.

18.4.3.35 CPRI Auxiliary Control Register (CPRInAUXCR)

address 0x7a0 (CPRInAUXCR)

Figure 18-147. CPRInRCCR

The receive chip counter register is active only in chip rate mode (sample width 8 bits, double oversampling). It counts the number of IQ data bytes and chips (basic frames) written to the AxC oversampling buffer in the device memory. The counter granularity is 2560 chips.

Table 18-124. CPRInRCCR Bit Descriptions

Name	Reset	Description	Setting
RIQBC 31–16	0	Receive IQ Byte count. This field determines the number of bytes written to the AxC buffers in the first destination location. The maximum value of this counter is (2560 transaction size) bytes if the transaction size is smaller than 1024 bytes If the transaction size is 1024 bytes, then the maximum value 0x2400 bytes. If the transaction size is 2048 bytes, then the maximum value of the counter is 0x4800 bytes	0x0 The number of bytes that has been written to the system memory is 0. 0x40 The number of bytes that has been written to the system memory is 64. 0x80 The number of bytes that has been written to the system memory is 128. : 0x4800 The number of bytes that has been written to the system memory is 4800 bytes.
— 15–5	0	Reserved. Write to zero for future compatibility.	

Table 18-124. CPRInRCCR Bit Descriptions

Name	Reset	Description	Setting	
RCCR 4–0	0	Receive Chip Counter Registers	0x0 0x1 : 0x1D	The number of chips that has been written to the buffers in the system memory is less than 2560 chips The number of chips that has been written to the buffers in the system memory is at least 2560 chips. The number of chips that has been written to the buffers in the system memory is at least 2560*29 chips.

TBFNT 7	0	**Transmit BFN Frame Timing**. This bit is set at the beginning of transmit BFN frame. The BFN frame timing is 10 ms.	0 New transmit BFN frame not started 1 New transmit BFN frame is started
THFNT 6	0	**Transmit Hyper Frame Timing**. This bit is set at the beginning of transmit hyper frame. The HFN frame timing is 66.67us.	0 New transmit hyper frame not started 1 New transmit hyper frame started
TETHE 5	0	**Transmit Ethernet Event** This field is set every time that transmit Ethernet coalescing event occurred. **Note:** This bit is set each time that the coalescing counter is equal to Transmit Ethernet Coalescing threshold.	0 No transmit Ethernet coalescing event occur 1 Transmit Ethernet coalescing event occur
THDLCE 4	0	**Transmit HDLC Event** This field is set each time that HDLC packet was transferred from system memory.	0 No transmit HDLC packet 1 Transmit HDLC packet

Table 18-136. CPRInTER Bit Descriptions

Name	Reset	Description	Setting
TVSSTE 3	0	**Transmit VSS Threshold Event** This field is set every time the number of TVSST bytes transferred from the VSS buffer in the main memory to CPRI DMA memory exceeds the threshold.The threshold is determined by the Transmit VSS Threshold (TVSST) register	0 No transmit VSS threshold event occurred. 1 A transmit VSS threshold event occurred.
TIQSTE 2	0	**Transmit IQ Second Threshold Event** This field is set when the number of bytes transmit bytes transferred from the transmit IQ buffer exceeds the second threshold. The second threshold pointer is determined by the CPRInTIQST register.	0 No transmit second threshold event occurred. 1 A transmit second threshold event occurred.
TIQFTE 1	0	**Transmit IQ First Threshold Event** This field is set when the number of bytes transmit bytes transferred from the transmit IQ buffer exceeds the first threshold The first threshold pointer is determined by the CPRInTIQFT register	0 No transmit first threshold event occurred. 1 A transmit first threshold event occurred.
TIQTE 1	0	**Transmit IQ Threshold Event** This field is set each time the number of transmit bytes transferred from the transmit IQ buffer exceeds the transmit IQ threshold. The transmit threshold value is determined by CPRInTIQT.	0 No transmit threshold event occurred. 1 A transmit threshold event occurred.

Figure 18-160. CPRInEER

This register contain the status of general error events. The register can be read in any time; the register bits are cleared by writing ones to them. Writing zeros has no effect

Table 18-137. CPRInEER Bit Description

Name	Reset	Description	Setting
— 31–23	0	Reserved. Write to zero for future compatibility.	
FA 23	0	**Frequency Alarm** This bit is set if the frequency of the CDR Clock is not synchronized to the Framer Clock	0 The CDR Clock is synchronized to the Framer Clock 1 The CDR Clock is not synchronized to the Framer Clock
22	0	Reserved. Write to zero for future compatibility.	
LLOF 21	0	**Local Loss of Frame** LLOF bit is set due to loss of received frame synchronization.	0 No local LOF detection 1 Local LOF detection.
LLOS 20	0	**Local Loss of Signal** LLOS bit is set due to 8b/10b line code errors (LCV)	0 No local LOS detection 1 Local LOS detection.
RSDI 19		**Remote SAP Defect Indication** The RSDI bit (z.130.0 b2) in the received CPRI frame is set.	0 No remote SDI detection 1 Remote SDI detect.
RRAI 18	0	**Remote Alarm Indication** The RAI bit (z.130.0 b1) in the received CPRI frame is set.	0 No remote RAI detection 1 Remote RAI detect.
RLOF 17	0	**Remote Loss of Frame** The LOF bit (z.130.0 b4) in the received CPRI frame is set.	0 No remote LOF detection 1 Remote LOF detect.
RLOS 16	0	**Remote Loss of Signal** The LOS bit (z.130.0 b3) in the received CPRI frame is set	0 No remote LOS detection 1 Remote LOS detect.
EXSSLOS 15	0	**External Sync Synchronization Lost** The external sync signal connected to the timer lost synchronization. This bit is set whenever the sync state machine of the timer returns to HUNT state from SYNC state.	0 Normal operation 1 External sync synchronization is lost
— 14–10	0	Reserved. Write to zero for future compatibility.	

Table 18-137. CPRInEER Bit Description (Continued)

Name	Reset	Description	Setting
TVSSUN 9	0	**Transmit VSS Underrun** Indicates whether a VSS underrun event has occurred. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the internal MBus bus and therefore it cannot read enough VSS data from the VSS buffers in the system memory.	0 No VSS underrun event occurred. 1 VSS underrun event occurred
RVSSOV 8	0	**Receive VSS Overrun** Indicates whether a VSS overrun event has occurred. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the MBus bus and therefore it can not write the VSS data to VSS buffer mapped on the system memory.	0 No VSS overrun event occurred 1: VSS overrun event occurred
RHBDUN 7	0	**Receive HDLC Buffer Descriptor Underrun** Indicates whether a new packet arrive and the buffer descriptor ring does not contain valid buffer descriptor. This error should not occur during normal operation. It indicates that the core program is not well defined or the CPRI does not receive enough bandwidth on the MBus.	0 No receive HDLC buffer descriptor underrun occurred 1 Receive HDLC buffer descriptor underrun occurred
THDLCUN 6	0	**Transmit HDLC Underrun** Indicates whether an underrun event has occurred. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the MBus and therefore it can not read the HDLC data from system memory	0 No transmit HDLC underrun occurred 1 Transmit HDLC underrun occurred
RHDLCOV 5	0	**Receive HDLC Overrun** Indicates whether an HDLC overrun event has occurred. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the MBus and therefore it can not write the HDLC data to system memory	0 No receive HDLC overrun occurred 1 Receive HDLC overrun occurred
REBDUN 4	0	**Receive Ethernet Buffer Descriptor Underrun** Indicates whether a new Ethernet packet arrived and the buffer descriptor ring did not contain valid buffer descriptor. This error should not occur during normal operation. It indicates that the core program is not defined well or the CPRI receive does not have enough bandwidth on the MBus.	0 No receive Ethernet buffer descriptor underrun occurred. 1 Receive Ethernet buffer descriptor underrun occurred
TETHUN 3	0	**Transmit Ethernet Underrun Occurred** Indicates whether an Ethernet underrun event has occurred. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the MBus and therefore it can not read the Ethernet data to system memory	0 No transmit Ethernet underrun occurred 1 Transmit Ethernet underrun occurred
RETHOV 2	0	**Receive Ethernet Overrun Occurred**. Indicates whether an Ethernet overrun event has occurred. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the MBus and therefore it can not write the Ethernet data to system memory	0 No receive Ethernet overrun occurred 1 Receive Ethernet overrun occurred

Table 18-137. CPRInEER Bit Description (Continued)

Name	Reset	Description	Setting
TIQUN 1	0	**Transmit IQ Underrun Occurred** Indicates whether an IQ underrun event has occurred. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the internal MBus and therefore it cannot read the data from the AxC buffers in the system memory.	0 No IQ underrun event occurred 1 IQ underrun event occurred
RIQOV 0	0	**Receive IQ Overrun Occurred** Indicates whether an IQ overrun event has occurred. This error should not occur during normal operation. It indicates that the CPRI has not received enough bandwidth on the MBus bus and therefore it can not write the IQ data to system memory.	0 No IQ overrun event occurred memory. 1 IQ Overrun event occurred

CPRIICR<y> determines the CPRI interrupt generation. The interrupts are asserted during normal operation. y can be any integer number in the range of 1 to 12. CPRIICR<y> register has 3 different field types: Field ERS selects the event register, field LEVEL the interrupt type (edge or level) and the LSBs the enabled interrupt having the same format as CPRInRER and CPRInTER registers.

Table 18-146. CPRIICRy Bit Descriptions

Name	Reset	Description	Setting
ERS 31–28	0	**Event Register Select** This field selects event registers.	0x0 CPRI1RER register is selected 0x1 CPRI1TER register is selected 0x2 CPRI2RER register is selected 0x3 CPRI2TER register is selected 0x4 CPRI3RER register is selected 0x5 CPRI3TER register is selected 0x6 CPRI4RER register is selected 0x7 CPRI4TER register is selected 0x8 CPRI5RER register is selected 0x9 CPRI5TER register is selected 0xA CPRI6RER register is selected 0xB CPRI6TER register is selected
— 27–17	0	Reserved. Write to zero for future compatibility.	
LEVEL 16	0	**LeveL interrupt** Selects whether the interrupt is edge or level triggered.	0 This interrupt is edge triggered 1 This interrupt is level triggered.
— 15–9	0	Reserved. Write to zero for future compatibility.	
EIQE 8	0	**Enable IQ event** Enable assertion of the CPRI_INTy interrupt when TIQRE bit is set if TER is selected. Enable assertion of the CPRI_INTy interrupt when RIQTSDT bit is set if RER is selected The event register is selected by the ERS field.	0 IQ event is masked 1 IQ event is enabled.
EBFNTE 7	0	**Enable BFN Frame Timing Event** Enable assertion of the CPRI_INTy interrupt when the R/TBFNT bit is set. The event register is selected by the ERS field.	0 BFN timing event is masked 1 BFN timing event is enabled.

Table 18-146. CPRIICRy Bit Descriptions

Name	Reset	Description	Setting
EHFNTE 6	0	**Enable Hyper Frame Timing Event** Enable assertion of the CPRI_INTy interrupt when the R/THFNT bit is set. The event register is selected by the ERS field.	0 HFN event is masked 1 HFN event is enabled.
EETHE 5	0	**Enable Ethernet Event** Enable assertion of the CPRI_INTy interrupt when the R/TETHE bit is set. The event register is selected by the ERS field.	0 Ethernet event is masked 1 Ethernet event is enabled.
EHDLCE 4	0	**Enable HDLC Event** Enable assertion of the CPRI_INTy interrupt when the R/THDLCE bit is set. The event register is selected by the ERS field.	0 HDLC event is masked 1 HDLC event is enabled.
EVSS 3	0	**Enable VSS Event** Enable assertion of the CPRI_INTy interrupt when the R/TVSSE bit is set. The event register is selected by the ERS field.	0 VSS event is masked 1 VSS event is enabled.
EIQSTE 2	0	**Enable IQ Second Threshold Event** Enable assertion of the CPRI_INTy interrupt when the R/TIQSTE bit is set. The event register is selected by the ERS field	0 IQ second threshold event is masked 1 IQ second threshold event is enabled.
EIQFTE 1	0	Enable IQ first Threshold Event Enable assertion of the CPRI_INTy interrupt when the R/TIQFTE bit is set. The event register is selected by the ERS field	0 IQ first threshold event is masked 1 IQ first threshold event is enabled.
EIQTE 0	0	Enable IQ Threshold Event Enable assertion of the CPRI_INTy interrupt when the R/TIQTE bit is set. The event register is selected by the ERS field	0 IQ threshold event is masked 1 IQ threshold event is enabled.

18.4.4.27 CPRI Receive CPU Control Interrupt Enable Register (CPRIRCCIER)

19 QUICC Engine Subsystem

The QUICC Engine subsystem is a versatile RISC-based communication processor that supports multiple external interfaces and protocols independently from the core processor(s) in an integrated processing device. This allows the cores to execute the data processing code and be relieved from the data transfer and handling overhead. This chapter provides an overview of the QUICC Engine subsystem components used in the MSC8157E, which include the following:

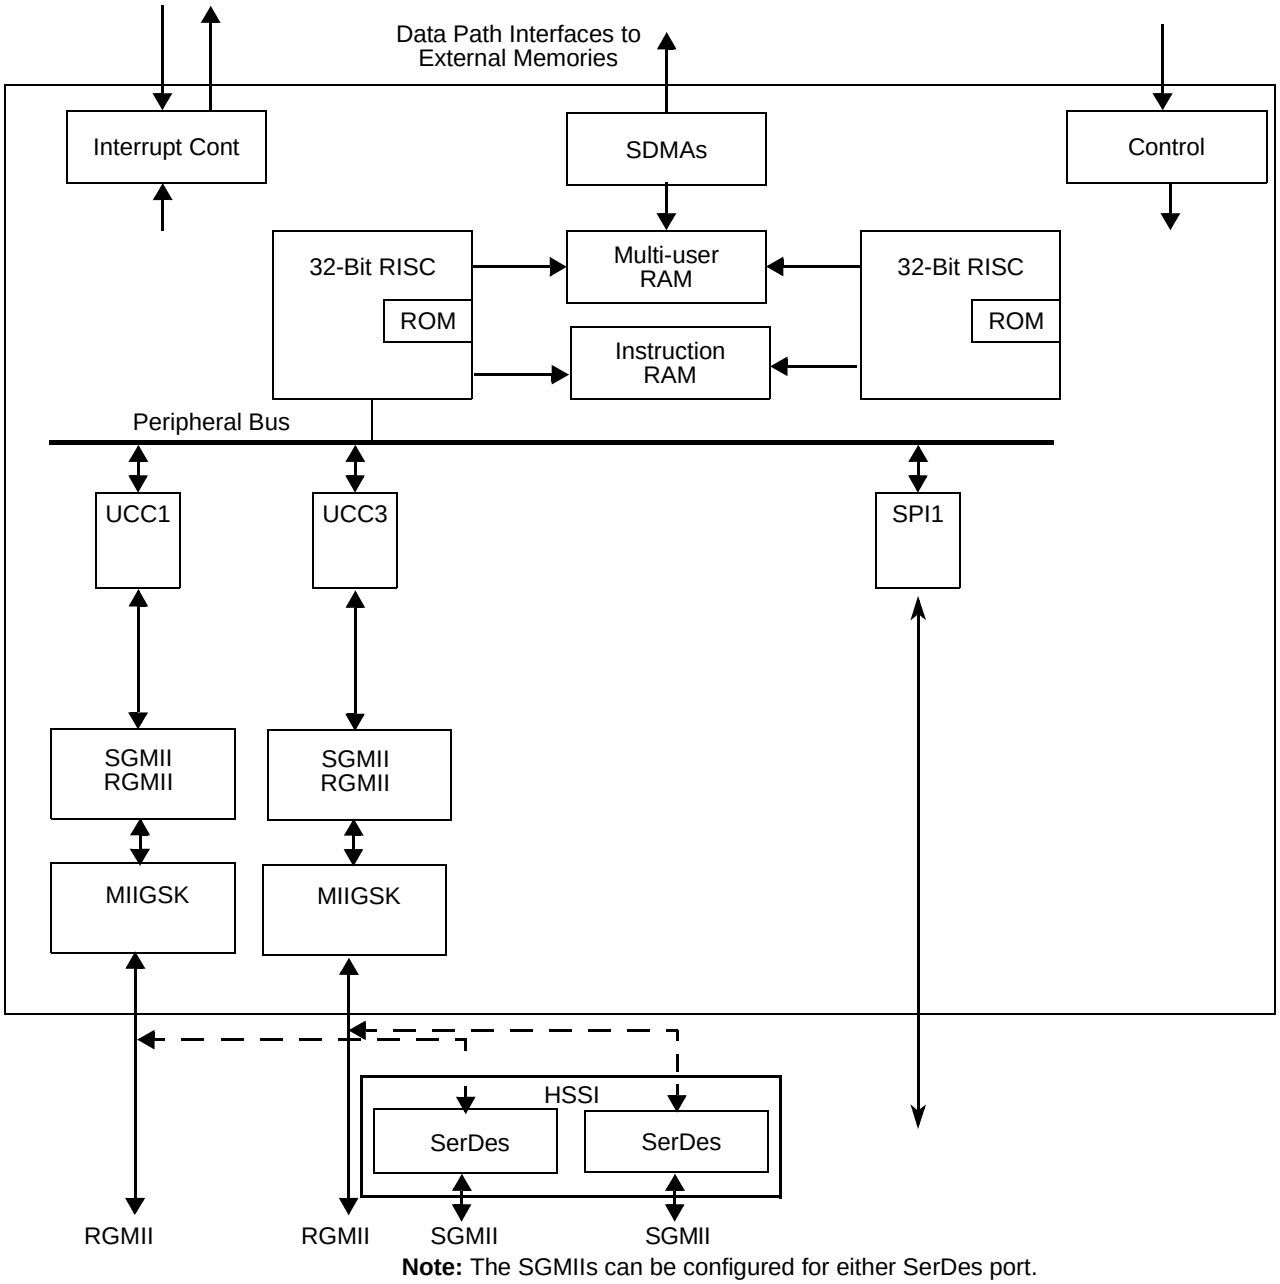
- Dual RISC engines with
  - Internal interfaces to the core and peripherals
  - Parameter RAM
  - Buffer descriptors
  - Multithreading operation
  - Serial numbers (SNUMs)
  - Instruction RAM (IRAM)
- Serial DMA controller
- Clocking
  - Signal multiplexing
  - Baud-rate generation
- Dedicated interrupt controller
- Two programmable Unified Communication Controllers (UCCs), each of which provides dedicated support for an Ethernet controller for RGMII/SGMII interfaces
- Serial peripheral interface (SPI)

Note: Detailed information about QUICC Engine functionality and programming is provided in the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM). Refer to that manual for all the functional and programming details

Note: If the QUICC Engine subsystem is not used for booting, the user must clear the QUICC Engine DRAM before using it to ensure correct operation.

19.1 Overview

Figure 19-1 shows an architectural diagram of the QUICC Engine subsystem. The UCCs group is controlled by a RISC engine. A common multi-user RAM is used to store parameters for RISC engines. Each RISC has a ROM associated with it that contains the code image. The instruction RAM is used to run RISC code from the RAM. The internal clocks (RCLK/TCLK) for each UCC can be programmed to use either an external or internal source. The rate of these clocks can be up to one-half of the QUICC Engine subsystem clock frequency. However, the ability of an interface to support a sustained bit stream depends on the protocol settings and other factors.



Note: The SGMIIs can be configured for either SerDes port.

Figure 19-1. QUICC Engine Subsystem Architectural Block Diagram

19.2 RISC Processors

The two 32-bit RISC processors reside on a bus separate from the SC3850 cores, and can, therefore, perform tasks independently from the DSP cores. The RISC processors handle lower-layer communications tasks and DMA control, freeing the DSP cores to handle higher-layer activities. The RISC processors work with the UCCs to implement user-programmable protocols and manage the serial DMA (SDMA) channels that transfer data between the I/O channels and memory. The RISC processor architecture and instruction set are optimized for data communications and data processing required by many wire-line and wireless communications standards. The SC3850 DSP cores issues commands to the RISC processors by writing to the QUICC Engine Command Register (CECR), which is described in **Section 19.9**. The RISC processors execute the commands to ensure synchronization with other tasks running on the QUICC Engine subsystem. The DSP core sets the CECR[FLG] bit when it issues a command, and the QUICC Engine subsystem clears the FLG after execution, indicating to the DSP core that it is ready for the next command. Subsequent commands to the CECR can be given only after FLG is clear. The software reset command may be issued by setting RST even if the FLG bit is set. The CECR rarely needs to be accessed. For example, to terminate the transmission of a frame without waiting until the end, a STOP TX command is issued through the CECR. The worst-case command execution latency is 200 clocks and the typical command execution latency is about 40 clocks. The RISC processors give SDMA commands to the SDMA. RISC processor features include:

- One QUICC Engine clock cycle per instruction
- 32-bit instruction object code
- Code execution from internal ROM or RAM
- 32-bit ALU data path
- 64-bit multi-port RAM access
- Optimized for communications processing
- DMA bursting of serial data to/from external memory

19.2.1 SC3850 Core Interface

The RISC processors communicate with the SC3850 cores in several ways:

- Many parameters are exchanged through the multi-port RAM.
- The RISC processors can execute special commands issued by the SC3850 cores. These commands should be issued only in special situations such as exceptions or error recovery.
- The RISC processor generates interrupts through the interrupt controller.
- The SC3850 cores can read the QUICC Engine subsystem status/event registers at any time.

19.2.2 Peripheral Interface

The RISC processors use the peripheral bus to communicate with all of its UCCs. Each controller has separate receive and transmit 192-byte FIFOs.

19.2.3 Parameter RAM

The QUICC Engine subsystem maintains a section in the multi-user RAM that contains the associated parameter values for the operation of the UCCs and SPI. Each peripheral has an associated page in the parameter RAM. The exact definition of the parameter RAM for each peripheral is in the protocol descriptions in the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM). The size of the parameter RAM page differs from protocol to protocol. The minimum size of the parameter RAM page assigned to any protocol is 64 bytes. The base address of the parameter RAM page must be aligned to 64 bytes.

Some parameter RAM values must be initialized before the UCC is enabled. The QUICC Engine subsystem initializes or writes other values. Once initialized, most parameter RAM values need not be accessed by user software, because most activity centers around the TxBDs and RxBDs rather than the parameter RAM. However, if the parameter RAM is accessed, note the following:

- You can read the parameter RAM at any time.
- You can write to the Tx parameter RAM only when the transmitter is disabled (that is, after a STOP TRANSMIT command or after the buffer/frame finishes transmitting after a GRACEFUL STOP TRANSMIT command and before a RESTART TRANSMIT command).
- You can write to the Rx parameter RAM only when the receiver is disabled. The CLOSE RX BD command does not stop reception, but it does allow the user to extract data from a partially full Rx buffer.

After reset, the QUICC Engine subsystem initializes the base addresses of the parameter RAM pages for all the UCCs to default values. You can override the default values by issuing the ASSIGN PAGE command to the QUICC Engine subsystem. The advantage of using the ASSIGN PAGE command is that you can arrange the parameter RAM area efficiently (with no unused areas) according to the specific peripherals/protocols used in your system.

Table 19-1 lists the default values of the parameter RAM pages base addresses assigned by the QUICC Engine subsystem to the different peripherals.

Table 19-1. Default Parameter RAM Base Addresses

Address Offset	Peripheral	Size (Bytes)
0x8400	UCC 1 (Rx and Tx)	256
0x8600	UCC 3 (Rx and Tx)	256
0x8900	SPI (Rx and Tx)	128

19.2.4 Buffer Descriptors (BDs)

If you are programming the UCCs, you need to know how the controllers use buffer descriptors to define buffer allocation. A buffer descriptor (BD) contains the essential information about each buffer in memory. Each buffer is referenced by a BD that can reside anywhere in system memory. These BDs are split between all UCCs.

Each 64-bit BD has the structure shown in **Figure 19-2**. This structure is common to all UCCs. A receive buffer descriptor (RxBD) table and a transmit buffer descriptor (TxBD) table are associated with each controller. Each table can have multiple BDs.

Offset	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x0	Status and Control															
0x2	Data Length															
0x4	High-Order Buffer Pointer															
0x6	Low-Order Buffer Pointer															

Figure 19-2. Buffer Descriptor Structure

In this discussion, the BD and field values use the following convention:

```
BD.field
```

Table 19-2 shows the possible BD and field naming conventions. Bit names in `RxBD.bd_cstat` and `TxBD.bd_cstat` use the following convention:

```
BD.bd_cstat.bit
```

Table 19-2. Buffer Descriptor Name Convention

BD	Field	Example
RxBD/TxBD	bd_cstat	`TxBD.bd_cstat`.R refers to the ready bit in the TxBD's status and control field.
	bd_length	`RxBD.bd_length` refers to RxBD data length field.
	bd_addr	`RxBD.bd_addr` refers to RxBD buffer pointer field.

The structural elements of a buffer descriptor are defined as follows:

- *Status and control*. The 16-bit value at `offset+0x0`, which contains status and control bits that control and report status information on the data transfer. The RISC processor updates the status bits after the buffer is sent or received. Only this field differs for each protocol. Refer to the relevant chapter in this manual for each protocol `RxBD.bd_cstat` and `TxBD.bd_cstat` bit description.
- *Data length*. The 16-bit value at `offset+0x2`, which contains the number of bytes sent or received.

- *RxBD data length*. The number of bytes the RISC processor writes into the RxBD buffer once the BD closes. The RISC processor updates this field after the received data is placed into the buffer and the buffer is closed. You do not need to initialize this field. In frame-based protocols, `RxBD.bd_length` contains the total frame length including CRC bytes. If a received frame length, including CRC, is an exact multiple of the parameter RAM maximum receive buffer length MRBLR, the last buffer holds no actual data but the associated BD contains the total frame length.
- *TxBD data length*. The number of data bytes the controller needs to transmit from its buffer. The RISC processor never modifies this field. This field needs to be initialized by the user.
- *Buffer pointer*. The 32-bit data at `offset+0x4`, which points to the beginning of the buffer in internal or external memory.
- *RxBD buffer pointer*. The buffer pointer value must be a multiple of four to be word-aligned.
- *TxBD buffer pointer*. The buffer pointer value can be even or odd.

19.2.5 Multithreading

The Ethernet Controllers are able to processes frames or cells at high bit rates (gigabit Ethernet and above OC-3 nominal rates). In order to achieve these bit rates the UCC receiver and the UCC transmitter are able to process multiple frames/cells simultaneously at any given time. This is implemented with the multithreading mechanism. Each thread processes a different frame/cell. The multithreading processing mechanism comprises three components: Distributor, Threads and in some cases Terminator. **Figure 19-3** shows a high-level diagram of the multithreading architecture.

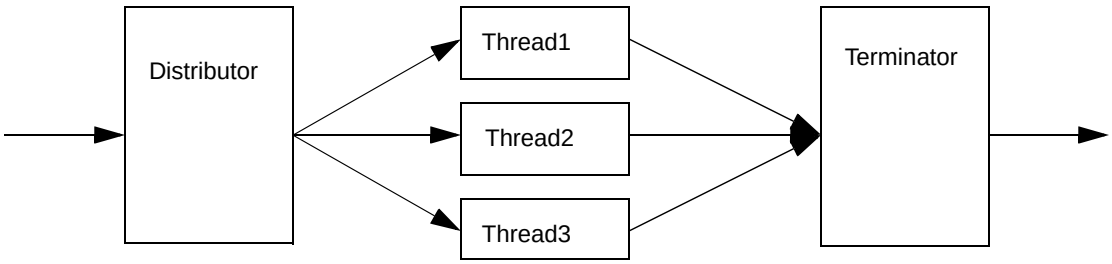


Figure 19-3. Multi-Threading Processing Mechanism

Each one of the components (distributor, threads and terminator) has an ID number associated with it, referred to as its Serial Number (SNUM). The distributor SNUM is always the SNUM of the UCC receiving or transmitting the data. Each one of the transmitter and receiver threads has its own parameter RAM located in the multi-port RAM. The user software initializes the values for the SNUM and the pointer of the parameter RAM base address at initialization time.

Note: See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM).for specific interface configuration details.

19.2.6 Serial Numbers (SNUMs)

Each peripheral has a unique serial number (SNUM) associated with it. Threads, which are used by the multithreading mechanisms described in **Section 19.2.5**, *Multithreading* also have a unique serial number. There are two cases for which you should specify the SNUM:

1. When issuing the ASSIGN PAGE command.
2. When initializing the multithreading mechanism.

Table 19-3 lists the Serial Numbers (SNUMs) used to program the multithreading options in the UCCs for the Ethernet controllers. The component column indicates the peripheral or thread name for each SNUM.

Table 19-3. SNUM Table

SNUM	Component	SNUM	Component	SNUM	Component	SNUM	Component
0x00	UCC1 TX	0x40	—	0x80		0xC0	Reserved
0x01	UCC1 RX	0x41	—	0x81		0xC1	Reserved

Note: See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for details on how to use the SNUM with the ASSIGN PAGE command.

19.2.7 IRAM

The QUICC Engine subsystem includes 48 KB of IRAM that can be used to store processing code for the RISC processors. The IRAM can be split into two 24-KB areas assigned individually to each of the two RISC processors, or it can be shared by both processors as one contiguous 48-KB memory space. Access is through the IRAM address register (IADDR) using the IRAM data register (IDR). See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for details.

19.3 Serial DMA Controller

The QUICC Engine subsystem has one physical serial DMA (SDMA) channel that interfaces with the internal MBus. The QUICC Engine subsystem implements two dedicated virtual SDMA channels for each peripheral, one for the receiver and one for the transmitter. Additional virtual channels are available for general purpose accesses.

19.3.1 Data Paths

Figure 19-4 is a simplified block diagram that shows the data paths in the MSC8157E. The MSC8157E may be implemented with one DDR bus (32 or 64 bit data).

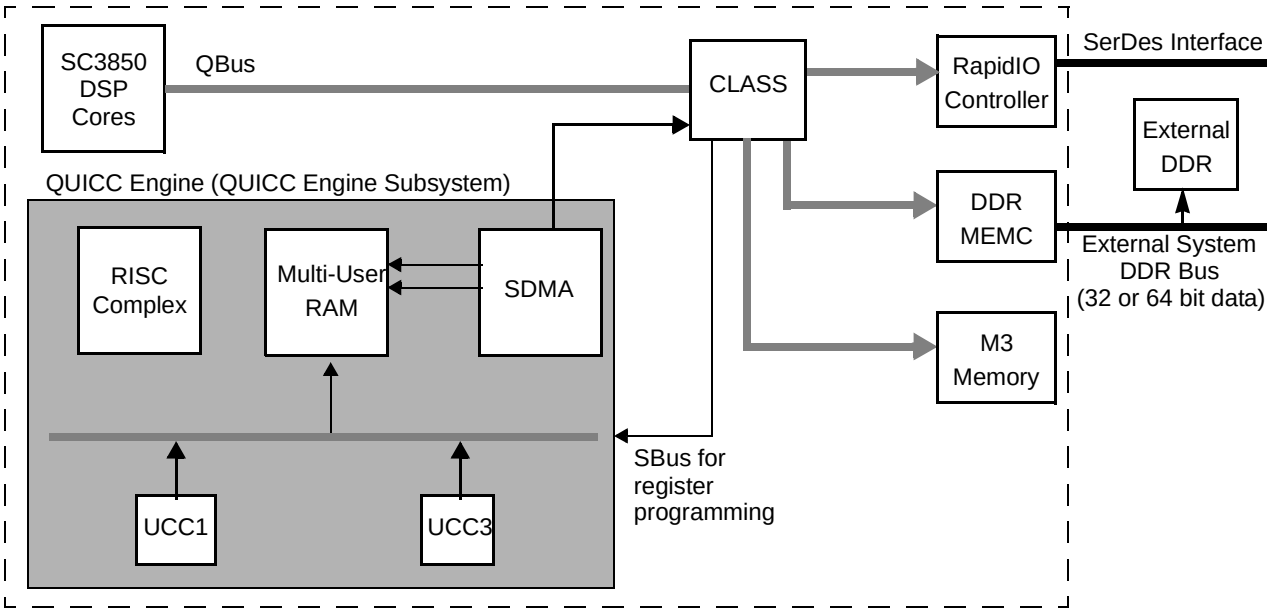

Figure 19-4. MSC8157E Data Paths

The CLASS is responsible for distribution of MBus transactions to the various possible targets (for example, RapidIO or DDR memory controller) based on the transaction address. See **Chapter 4**, *Chip-Level Arbitration and Switching System (CLASS)* for details.

19.3.2 SDMA and Bus Error

If a bus error occurs on an SDMA access from the QUICC Engine subsystem, the following occurs:

1. The QUICC Engine subsystem generates a unique maskable interrupt in the SDMA status register (SDSR),
2. The DSP core uses an interrupt service routine (ISR) to read the SDSR to determine which bus generated the error.
3. System recovery depends on how you configure the SDMR[SBER_1] bit. One of the following occurs:
   - The QUICC Engine subsystem disables the peripheral or thread associated with the bus error and continues to operate as usual on all other peripherals (default). The recovery sequence in this mode is based on re-initialization of the peripheral associated with the error, or
   - The QUICC Engine subsystem stops all activity, and must be reset through the reset command to the QUICC Engine Command Register (CECR).

In general, it should be noted that the DSP core, depending on how it is programmed, may read the SDMA address register (SDTA) to determine the address at which the bus error occurred, and the SDMA SNUM register (SDTM) to determine which peripheral or thread was being serviced by the SDMA virtual channel. See **Table 19-3** for the list of SNUMs.

The SDTA and the SDTM registers store information related to accesses to the MBus. These two registers are not updated with the address and SNUM of subsequent transactions as long as the event bit in the SDSR is set.

19.3.2.1 Simple Recovery from Bus Error

The simplest recovery from a bus error is a QUICC Engine subsystem reset followed by an overall QUICC Engine subsystem re-initialization procedure, regardless of the peripheral that has actually caused the error. The reasoning is that for some applications, stopping one peripheral leads to a chain reaction that ultimately disrupts the correct interworking operation of the QUICC Engine subsystem. For debug purposes, it is valuable to observe continued operation, but a selective recovery does not provide any added value. This non-distinctive procedure also reduces the complexity of the recovery flow.

19.3.2.2 Selective Peripheral Recovery Procedure

Selective recovery can be a complex procedure due to the following:

- The Ethernet controllers are multi-thread controllers and SNUM to peripheral/controller translation requires maintaining association tables.
- Status for multiple bus errors is not maintained, so in theory there might be additional non-reported bus errors and the recovery will not be complete.

For these reason, a full reset and re-initialization are recommended.

19.3.3 SDMA and Reset

When the QUICC Engine subsystem is reset through the CECR[RST] bit, the SDMA continues to process outstanding transactions in its FIFOs although the data related to these transactions may be corrupted. During system reset ($\overline{\text{SRESET}}$ or $\overline{\text{HRESET}}$), all SDMA FIFOs are flushed and all outstanding transactions are stopped.

19.3.4 MBus Access

The SDMA requests the bus from the CLASS at two possible priority levels. When the SDMA is in normal state, it requests the bus at priority level programmed by the user in the SDMR[EBPR] bit field. When the SDMA is in emergency state, it requests the bus at the highest priority level that the CLASS supports; the QUICC Engine subsystem is assigned an arbitration weight through a field in GCR11 (see **Section 8.2.26**, *General Interrupt Enable Register 5 (GIER5_x)*, on page 8-44 for details). SDTR and SDHY program the threshold and hysteresis values that affect the conditions for SDMA normal and emergency states. It is possible to mask the emergency state priority requests globally in SDMR[EBMSK] and enforce the priority set in SDMR[EBPR] regardless of the SDMA state.

The SDMA asserts the highest priority request (emergency state) for any one of the following reasons:

- When one of the FIFOs in the QUICC Engine subsystem reaches an emergency state (too full on Rx or too empty in the middle of a frame during Tx)
- When the internal SDMA data buffers are filled beyond a certain level (programmed in SDTR/SDHY registers).
- When the internal SDMA command queue is filled beyond a certain level (programmed in SDTR/SDHY registers).

A priority request to the multi-user RAM is also asserted by the SDMA, if needed, for the same reasons. It is possible to mask the high priority request globally in SDMR[ERMSK].

19.3.5 SDMA Internal Resource

The SDMA requires temporary buffering for some data in the multi-user RAM. The base address for the SDMA temporary buffer is programmed in the SDEBCR. The base address must be aligned to a 4-KB boundary. The size of the multi-user RAM needed for this buffering is programmable via the STBSZ bit field in the SDMR. The size the temporary buffer that must be allocated ranges from a minimum of 512 bytes to maximum of 3 KB in the multi-user RAM. See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for details.

19.4 Clocking

The QUICC Engine subsystem uses a programmable multiplexing system to route the various clocks used to transfer data through the external interfaces. Depending on the application and interface used, these signals can be supplied externally or taken from the internal programmable baud-rate generators. The following subsections describe the multiplexing unit and the internal baud-rate generators.

19.4.1 Multiplexer Logic

The QUICC Engine subsystem multiplexing logic routes clocks and connects the physical interfaces to the QUICC Engine subsystem peripherals, including the two UCCs. The multiplexer logic routes clocks to all the QUICC Engine subsystem peripherals from a bank of internal clocks (BRG[5–8]) and a bank of external clocks.

Physical signal connections are also configured using the clock route registers. However, because these signal lines are multiplexed with other functions at the I/O lines, you must make sure that the lines are also enabled through the GPIO registers and initial mode selection pins. **Figure 19-5** shows a block diagram of the QUICC Engine subsystem multiplexing logic.

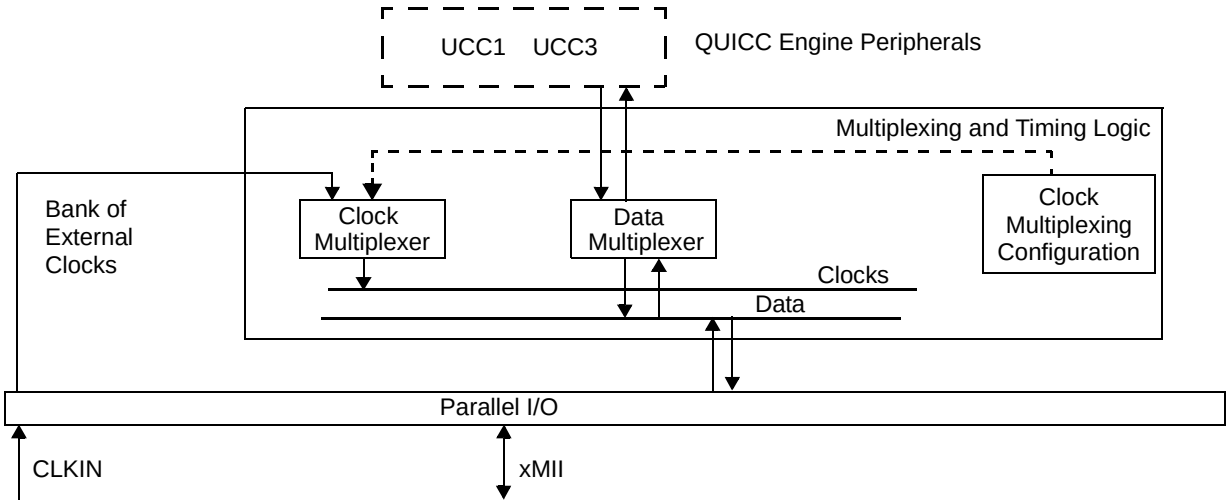

Figure 19-5. QUICC Engine Multiplexing Logic Block Diagram

The multiplexing logic is primarily used for clock assignment for UCC1 and UCC3. The clocks are derived from a bank of internal BRGs and external clock inputs as shown in **Figure 19-6**. The clock routing options are described in **Table 19-4** and **Table 19-5**. The bank of clocks selection logic applies an available clock to a peripheral that requires a clock. Because the peripheral is not directly connected to a specific clock source, peripherals can share the same clock. There are two main advantages to the bank-of-clocks approach. First, a peripheral is not forced to choose a serial device clock from a predefined input or BRG. Second, peripheral receivers and transmitters that need the same clock rate can share the same source. This configuration leaves additional signal lines for other functions and minimizes potential skew between multiple clock sources.

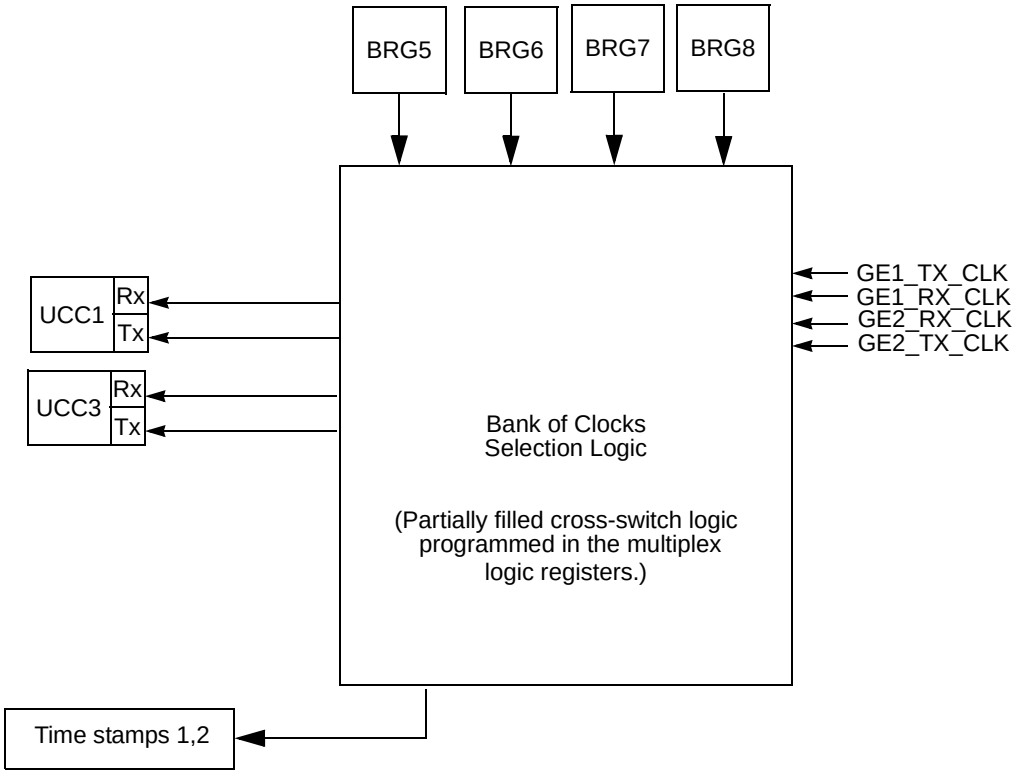

Figure 19-6. Bank of Clocks

Table 19-4. Clock Source Options Using External Clock Signals

Clock	External CLK			
	GE1_RX_CLK	GE1_TX_CLK	GE2_RX_CLK	GE2_TX_CLK
UCC1 Rx	V			
UCC1 Tx		V		
UCC3 Rx			V	
UCC3 Tx				V
Time Stamp 1			V	V
Time Stamp 2			V	V

Table 19-5. Clock Source Options - Internal Clock Generators

Clock	BRG Number			
	5	6	7	8
UCC1 Rx			V	
UCC1 Tx			V	
UCC3 Rx				V
UCC3 Tx				V

19.4.2 Baud-Rate Generators (BRGs)

The QUICC Engine subsystem contains four independent, identical baud-rate generators (BRGs) that can be used with the UCCs. The clocks produced by the BRGs are sent to the bank-of-clocks selection logic, where they can be routed to the controllers. Each BRG can be routed to one or more UCCs. **Figure 19-7** shows the block diagram for a BRG.

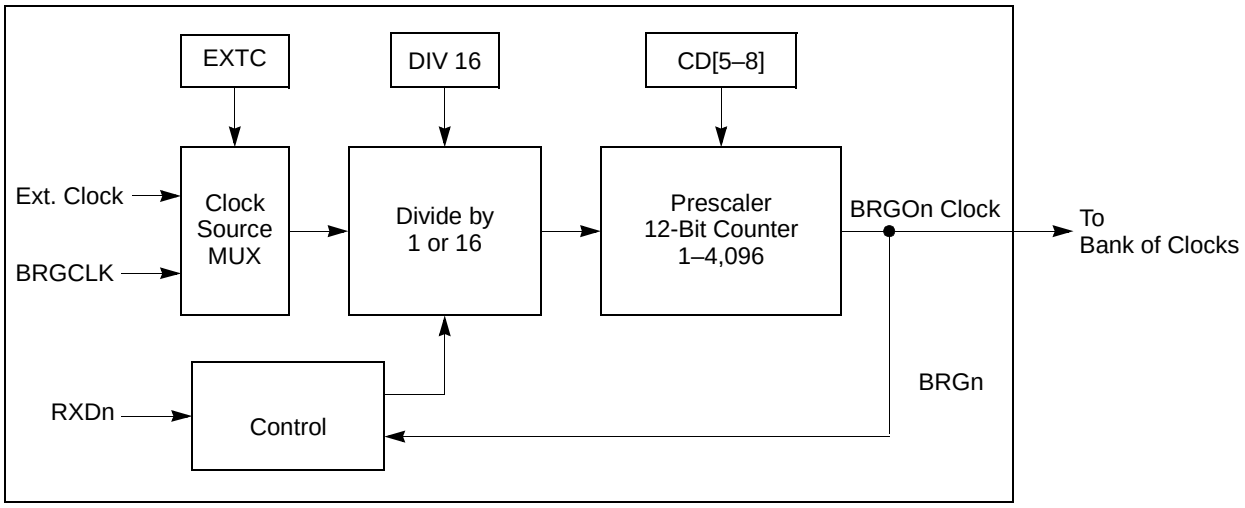

Figure 19-7. Baud-Rate Generator (BRG) Block Diagram

All BRGs can use BRGCLK as its source clock, or the external clock input selected by the value of BRGC*x*[EXTC]. The BRGCLK is an internal signal generated in the clock synthesizer. The external source option allows flexible baud-rate frequency generation, independent of the system frequency. Additionally, the external source option allows a single external frequency to be the source for more than one BRG. The external source signals are not synchronized internally before being used by the BRG. The BRG provides a divide-by-16 option (BRGC*x*[DIV16]) and a 12-bit prescaler (BRGC*x*[CD]) to divide the source clock frequency. The combined source-clock divide factor can be changed on-the-fly, except when changing to or from a CD value of 1, 2, or 3. For these values, disable the BRG and reset it before you program the new value. In addition, you should not make two changes within two source clock periods. If the BRG divides the clock by an even value, the transitions of BRGO*n* always occur on the rising edge of the source clock. If the divide factor is odd, the transitions alternate between the falling and rising edges of the source clock. The output of the BRG can be sent to the autobaud control block.

19.5 Interrupt Controller

The QUICC Engine subsystem interrupt controller sends general interrupts to the DSP cores in the MSC8157E device. The core must then initiate the correct interrupt service routine to handle the interrupt. Typically, this routine must read the interrupt status registers in the QUICC Engine subsystem to determine the appropriate action to take. For some specific interrupts, the MSC8157E uses a general configuration registers to expedite some interrupt responses:

- GIR1 includes two fields to specify whether an ECC error occurred for the QUICC Engine IRAM or DRAM (see **Section 8.2.21**, *General Interrupt Register 1 (GIR1)*, on page 8-35). These fields are maskable for each core individually using the corresponding fields in GIER1_x (see **Section 8.2.22**, *General Interrupt Enable Register 1 (GIER1_x)*, on page 8-37).

Note: See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for details about configuring the QUICC Engine interrupt system.

19.6 UCCs

The QUICC Engine subsystem UCCs implement the Ethernet protocols. This section provides a general overview of the UCCs. For a detailed description of the feature set and the protocol-specific programming model, refer to the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM). The key features of the UCCs include:

- Supports 1000 Mbps, full-duplex Ethernet/IEEE 802.3x/VLAN through RGMII/SGMII.
- UCC clock can be derived from a internal clock or an external signal.
- Uses bursts to improve bus usage.
- Multibuffer data structure for received and transmitted data.
- Buffers and buffer descriptors (BDs) may reside anywhere in system memory.
- Programmable size-virtual FIFO buffers.
- Echo and local loopback modes for testing.

19.6.1 UCC Functionality

The UCC block diagram is shown in **Figure 19-8**.

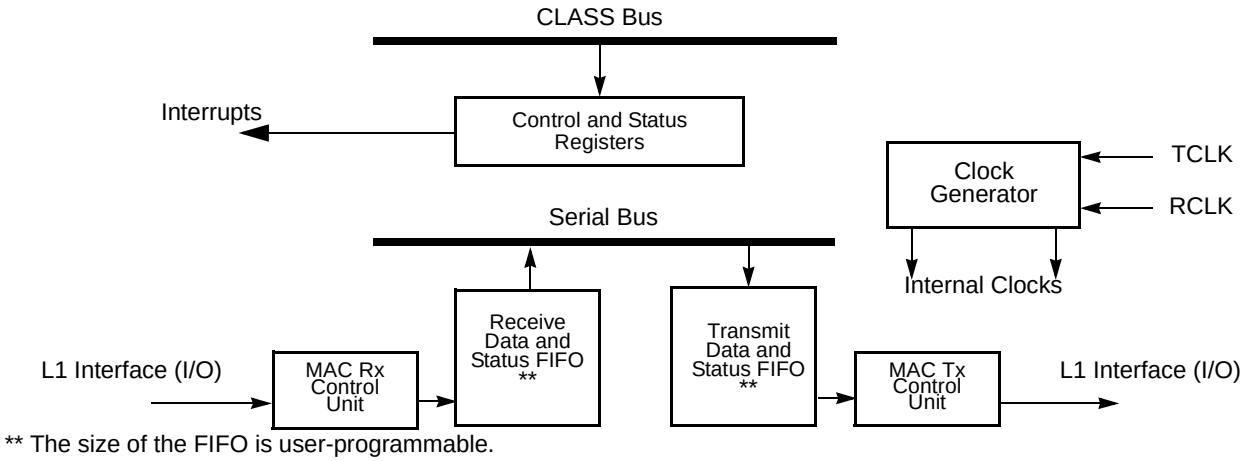

Figure 19-8. UCC Block Diagram

High-speed protocols require large FIFO depth. Sufficient FIFO size is important for increasing the QUICC Engine subsystem performance by eliminating overrun and underrun bottlenecks. Each protocol has an optimized FIFO size that depends not only on the bit rate, but also on other parameters such as packet or frame size. The UCC, when configured for high-speed protocols, extends the hardware FIFO into the QUICC Engine subsystem internal RAM. This extension is called virtual FIFO or VFIFO, because its size and location within the RAM are programmable according to the specific protocol. The FIFO as shown in **Figure 19-8** is constructed using a real hardware FIFO embedded in the UCC and its extension to a virtual FIFOs in the QUICC Engine subsystem RAM. This flexible FIFO structure enables the QUICC Engine subsystem to sustain wire speed frame or cell bursts by allocating larger FIFO memory when required. The size of the virtual FIFO is user-programmable. The actual size that is needed depends on a number of factors, especially the following:

- Maximum packet size
- Protocols running on the UCC
- Memory bus latency

19.6.2 UCC Programming Restrictions

The following sections describe programming restrictions for the UCCs.

19.6.2.1 Tx Virtual FIFO

Due to the structure of the Tx Virtual FIFO, it is possible for the Tx Virtual FIFO to contain part of a frame when there is no room for the remainder of the frame (that is, when the frame size is in the scale of magnitude of the Tx Virtual FIFO size). If the Tx Virtual FIFO contains a partial

frame, the transmission of the frame may start, even if there are fewer bytes of data than defined by the UCC Tx Virtual FIFO Threshold (UTFTT) value in the Tx Virtual FIFO. The only reason the frame might not begin to transmit is that it meets a specific sequence (which is rare, but possible) in which the UCC transmit-start condition is not met for the frame. The erroneous behavior is a result of incorrect recovery after the pausing data-retrieve phase from the BD buffer to the Tx Virtual FIFO in a certain internal stage. Reaching the UTFTT watermark in the Tx Virtual FIFO for each transmit frame prevents this sequence. UTFTT has an upper limit value that is less than the UCC Tx Virtual FIFO Size (UTFS) value. For each UTFS value, there is a maximum UTFTT value that corresponds to it. Configuring UTFTT higher than the suggested value can result in a UCC halt and Ethernet transmission stops.

Note: UTFTT refers to the payload of a single Ethernet frame. Transmission may start (this is the correct behavior) before surpassing the threshold if there is no space for additional data in the Tx Virtual FIFO

The UCC may stop transmitting when a large frame is partially stored in the Tx Virtual FIFO before the transmission of the frame starts. Note that the Tx BD ring buffer configuration (data allocation to the BD buffers) may adversely affect Tx Virtual FIFO usage, thus preventing the Tx Virtual FIFO from reaching the threshold for transmission in the Tx Virtual FIFO.

Use one of the following options to avoid this condition:

1. To prevent the failure, configure UTFS and UTFTT so that it is possible to store UTFTT data (payload) bytes in the Tx Virtual FIFO.

   For a single buffer per frame, the maximum allowable UTFTT values are:
   Ethernet Controller: Set UTFTT < [(0.9375 × UTFS) – 128]
   For example, for an Ethernet controller with UTFS = 1024, set UTFTT < 832.

   For multiple buffers per frame, the maximum allowable UTFTT values are:
   Ethernet Controller: Set UTFTT < [(UTFS × (M – 8)/M –128]
   For example, for an Ethernet controller with UTFS = 1024 and M = 64, set UTFFT < 768.

2. To recover from a possible failure, the application code should configure UTFTT to 0x40 and then restore it to its original value. The sequence triggers transmission from the point at which it stopped. Detection of such a UCC halt is done by monitoring Tx BD vacancy. A full Tx BD ring may indicate that the UCC has halted.

19.6.2.2 Multi-Threading Configuration

The Ethernet receiver might become stuck while in a multi-threaded configuration in case of heavy traffic. This condition is influenced by both the VFIFO size and the number of threads that are enabled.

Use at least one of the following measures to avoid the situation described above:

- Enable only one Rx thread.
- The Rx VFIFO size should be equal to 0.5 Kbytes.
- If the Rx VFIFO size is between 0.5 to 1.1 Kbytes, at least 4 threads must be enabled.
- If the Rx VFIFO size is between 1.1 to 1.6 Kbytes, at least 6 threads must be enabled.
- If the Rx VFIFO size is between 1.6 to 2.2 Kbytes, at least 8 threads must be enabled.
- If the Rx VFIFO size is between 2.2 to 4.5 Kbytes, the user must allocate 512 bytes (must be initialized to zero) in the Multiuser RAM. The base address for this area must be 512 bytes aligned. Immediately after the Ethernet Rx INIT command is ended (and before the UCC receiver is enabled), this address (24 bits) must be written to the Rx GPRAM in offsets 0x09–0x0b and 0x11–0x13. The user must write the value 0x3F to offsets 0x08 and 0x10. For example, if the base address for this new structure is 0x123400, the Rx GPRAM[0x08–0x0b and 0x10–0x13] will be equal to 0x3F123400. Note: In this case, there is no limitation to the number of threads that must be enabled.

19.7 Ethernet Controllers

The Ethernet interface is a widely-used local area network (LAN) that is based on the carrier-sense, multiple access, collision detect (CSMA/CD) approach. The **IEEE** 802.3 standard was developed to codify the requirements of such a system to insure interoperability between devices operating on the LAN. Because Ethernet and the **IEEE** protocols are similar and can coexist on the same LAN, this manual uses the generic term Ethernet unless otherwise noted. The MSC8157E uses two UCC Gigabit Ethernet Controllers (UECs) coordinated through the QUICC Engine subsystem. Each controller supports several standard MAC-PHY interfaces to connect to an external Ethernet transceiver. Supported interfaces include:

- 1000 Mbps RGMII interface
- 1000 Mbps SGMII interface.

The gigabit Ethernet modes were developed as individual company standards. As an alternative to the **IEEE** 802.3z (GMII) Ethernet standard that discuss general Ethernet interfacing, the RGMII Specification Reduced Pin-count Interface for Gigabit Ethernet Physical Layer Devices provides a method for Gigabit throughput while saving pins/board space. The RGMII Specification is managed by Broadcom, Marvell, and Hewlett-Packard, and is available on the Hewlett-Packard website at:

http://www.hp.com/rnd/pdfs/RGMIIv2_0_final_hp.pdf

To maintain Gigabit speed while reducing the data signals in half, the RGMI specification makes use of both the positive and negative edges of the clock. Because of this, meeting the RGMII specification requires careful attention to timing and delays.

A second protocol that uses an even lower pin count was developed by Cisco Systems. The Serial-GMH Specification defines a serial gigabit interface for Ethernet. The specification is available from the Cisco website at:

ftp://ftp-eng.cisco.com/smii/sgmii.pdf

The MSC8157E implements the SGMII through a SerDes interface managed by the HSSI (see **Chapter 15**, *High Speed Serial Interface (HSSI) Subsystem* for details.

Refer to the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for complete functional and programming details.

Figure 19-9 illustrates the block diagram of the UCC Ethernet controller.

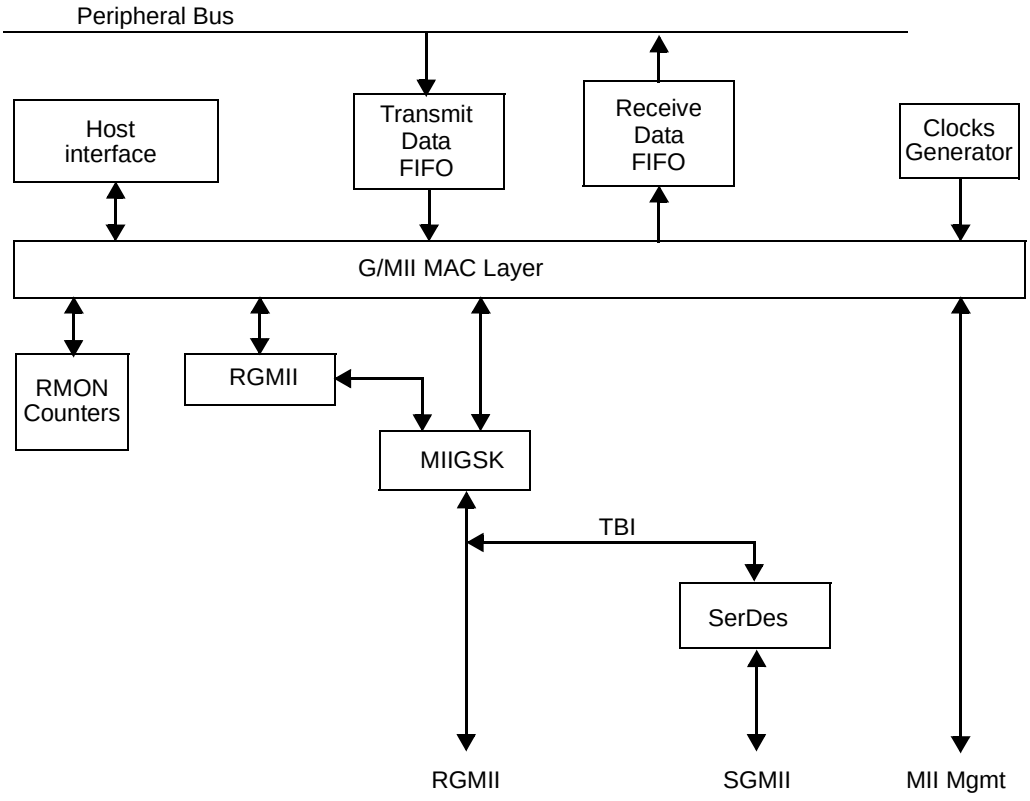

Figure 19-9. UCC Ethernet Controller Block Diagram

19.7.1 Operating Modes

Each Ethernet controller can be configured to use RGMII or SGMII mode. Two fields in the QUICC Engine Control Register allow programming of each controller independently (see **Section 8.2.8**, *QUICC Engine Control Register (QECR)*, on page 8-16 for details).

19.7.1.1 RGMII Mode

The RGMII is intended to be an alternative to the **IEEE** 802.3u MII, the **IEEE** 802.3z GMII, and TBI standards. The principle objective is to reduce the number of pins required to interconnect the MAC and the PHY from a maximum of 28 pins (TBI) to 12 pins in a cost effective and technology independent manner. In order to accomplish this objective, the data paths and all associated control signals are reduced and control signals are multiplexed together and both edges of the clock are used. For Gigabit operation, the clocks operate at 125 MHz.

19.7.1.2 SGMII Mode

The Serial Gigabit Media Independent Interface (SGMII) is designed to satisfy the following requirements:

- Convey network data and port speed between a 1000 PHY and a MAC with significantly less signal pins than required for GMII.
- Operate in full duplex.

In the MSC8157E, SGMII is implemented used the SerDes interface.

Note: The internal ten-bit interface (TBI) circuitry is used to serialize/deserialize the Ethernet frame data. The TBI must be configured to perform this function. See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for programming details.

19.7.2 Ethernet Physical Interfaces

You can program the physical interfaces by configuring the PSMR and MACCFG2 registers. See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for details.

Table 19-6 lists the external signal properties of the shared Management Data lines.**Chapter 3**, *External Signals* describes the assignment of the signals to the device pins.

Table 19-6. Management Data Signal Properties

Name	Function	I/O
MDC	**Management Data Clock for all Ethernet interfaces** The MDIO signal clock reference (2.5 MHz clock).	Output
MDIO	**Management Data Input/Output for all Ethernet interfaces** Transfers control signals between the PHY layer and the manger entity.	Input/ Output

The following subsections give details on the RGMII and SGMII signals.

19.7.2.1 Reduced Gigabit Media-Independent Interface (RGMII) Signals

The RGMII data paths and all associated control signals are reduced, control signals are multiplexed, and both edges of the clock are used. **Figure 19-10** shows the RGMII connections between the Ethernet controller and a PHY.

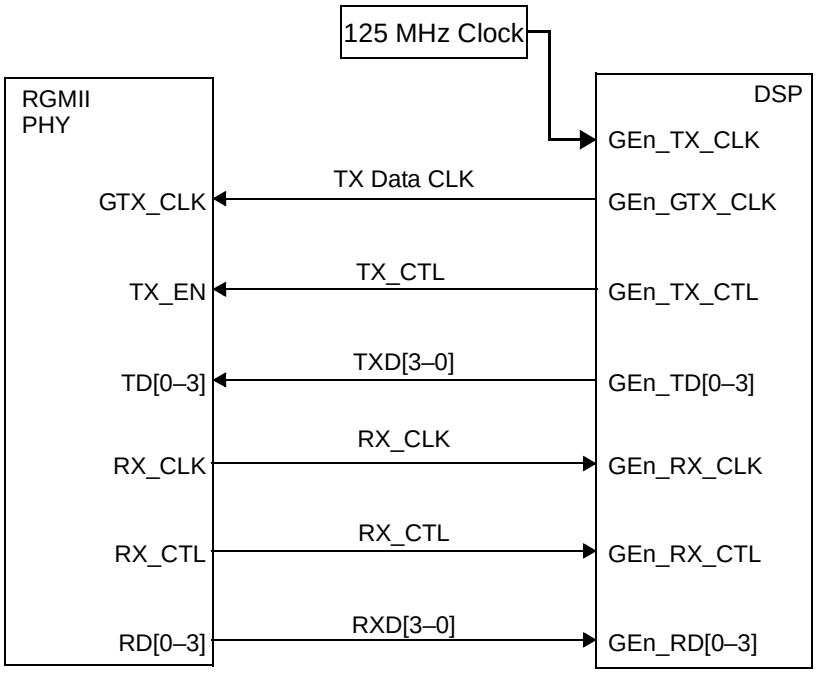

Figure 19-10. RGMII MAC-PHY Interface

19.7.2.1.1 RGMII Signals

Table 19-7 lists the RGMII signals.

Table 19-7. RGMII Signals

Consortium Name	I/O	Size	Function	Reference Clock
GTX_CLK	O	1	**Transmit Reference Clock** 125 MHz	—
TX_CLK	I	1	**Transmit Clock**	GTX_CLK
TX_CTL	O	1	**Transmit Control** TX_EN on clock positive edge. TX_ER on clock negative edge.	TXC

MDC	O	1	**Management Data Clock** The MDIO signal clock reference (2.5 MHz clock).	—
RX_CLK	I	1	**Continuous Receive Reference Clock** 125 MHz	—

19.7.2.1.2 RGMII Signal Configuration

The appropriate field in the QUICC Engine Control Register (ENET_SGMII_MODE1 for GE2 or ENET_SGMII_MODE0 for GE1) must be configured for RGMII (the field must be 0) (see **Section 8.2.8**, *QUICC Engine Control Register (QECR)*, on page 8-16 for details).

Note: The MSC8157E allows adjustment of the transmission delays for the RGMII signal lines using GCR4 (see **Section 8.2.12**, *General Control Register 4 (GCR4)*, on page 8-20 for register details). Recommended settings are listed in the MSC8157E data sheet. Guidelines for adjusting these numbers in individual designs is provided in *Using GCR4 to Adjust Ethernet Timing in MSC8157 DSPs* (AN4134).

19.7.2.2 Serial Gigabit Media-Independent Interface (SGMII) Signals

The SGMII is an alternative to the RGMII interface that further reduces the number of pins required to interconnect the MAC and PHY by using a SerDes 4 interface. It does not support auto-negotiation. The Ethernet controller SGMII interface uses the UEC ten-bit interface (TBI) connection internally, which connects to the SerDes block that serializes the transmitted data and deserializes the received data to/from the SGMII interface.

19.7.2.2.1 SGMII Signals

The SGMII physical interface transmits and receives data using two data signals and a clock signals to convey frame data and link rate information between a 1000 Mbps PHY and an Ethernet MAC. The data signals operate at 1.25 Gbaud. Due to the speed of operation, each of these signals (including the clock signal) is realized as a differential pair thus providing signal integrity while minimizing system noise. Therefore, each data and clock signal path uses two physical signal lines (the differential pair). **Table 19-8** lists the SGMII signals.

Table 19-8. SGMII Signals

Signal Name	I/O	Size	Function	Reference Clock
SRIO_REF_CLK SRIO_REF_CLK	I I	2	**Reference Clock** 125 MHz differential pair.	—
SG1_TX SG1_TX	O O	2	**Transmit Data 1** Differential pair for Ethernet 1 controller.	SRIO_REF_CLK SRIO_REF_CLK
SG2_TX SG2_TX	O O	2	**Transmit Data 2** Differential pair for Ethernet 2 controller.	SRIO_REF_CLK SRIO_REF_CLK
SG1_RX SG1_RX	I I	2	**Receive Data 1** Differential pair for Ethernet 1 controller.	SRIO_REF_CLK SRIO_REF_CLK
SG2_RX SG2_RX	I I	2	**Receive Data 2** Differential pair for Ethernet 2 controller.	SRIO_REF_CLK SRIO_REF_CLK
MDIO	I/O	1	**Management Data I/O** Transfers control signals between the PHY layer and the manager entity.	MDC
MDC	I	1	**Management Data Clock** The MDIO signal clock reference (25 MHz clock).	—

19.7.2.2.2 SGMII Signal Configuration

The SGMII signals are multiplexed with the serial RapidIO and PCI Express signals (see **Chapter 3**, *External Signals* and **Chapter 15**, *High Speed Serial Interface (HSSI) Subsystem*). Either signal can be routed through SerDes port 1 or 2, depending on the selected multiplex configuration. Selection is done at reset by the value of the S2P and S1P fields in the Reset Configuration Word Low (see **Section 5.3.1**, *Reset Configuration Word Low Register (RCWLR)*, on page 5-16 for details). The values of these fields determine which lanes of the SerDes ports are assigned to the SGMII signals. In addition, the appropriate field in the QUICC Engine Control Register (ENET_SGMII_MODE1 for GE2 or ENET_SGMII_MODE0 for GE1) must be configured for SGMII (the field must be 1) (see **Section 8.2.8**, *QUICC Engine Control Register (QECR)*, on page 8-16 for details).

19.7.3 Controlling PHY Links (Management Interface)

The support for MII Ethernet Management can be done by the SPI or by one UCC that can be selected using CMXGCR[SMI]. Control and status to and from the PHY is provided via the two-wire MII management interface described in the **IEEE** 802.3u standard. The MII management registers (MII management configuration, command, address, control, status, and indicator registers) exercise this interface between a host processor and one or more PHY devices.

The UEC MII registers support continuous read cycles (called a scan cycle); even through scan cycles are not explicitly defined in the standard. If requested (by setting MIIMCOM[scan cycle]),

the controller performs repetitive read cycles of the PHY status register, for example. This allows you to monitor link characteristics more efficiently. The different fields in the MII management indicator register (scan, not valid, and busy) indicate availability of each read of the scan cycle to the host via MIIMSTAT[PHY scan] bit field.

The length of the MII management interface preamble can also be modified through the MII registers. After establishing that a PHY supports preamble suppression, the host may configure the UEC to suppress the preamble. When enabled, the length of MII management frames are reduced from 64 to 32 clocks. This effectively doubles the efficiency of the interface.

19.7.4 Ethernet Controller Initialization

After the Ethernet Controller completes the reset sequence, software must initialize certain UEC registers and the required parameters in the parameter RAM. Based on system requirements, other optional registers and parameters can also be initialized at the same time.

Table 19-9 lists the minimum steps required for register and parameter initialization

Table 19-9. Minimum Register Initialization

Initialization Step	Registers
Configure the UCC to Fast protocols	URMODE,UTMODE
Set the Tx Global Parameter RAM	
Set the Rx Global Parameter RAM	
Set CMXUCR1	Select UCC1, UCC3 RxClk and TxClk
Initialize the MAC Station address	MACSTNADDR1 and MACSTNADDR2
Initialize the Media media access control configuration register and the UCC protocol specific mode register	This MACCFG2 together with UPSMR register adjust frame length and preamble length, specifies various CRC/pad combinations, specifies Full/Half Duplex and operating mode
Initialize the Fast Protocol Fifo Configuration registers	URFB, URFET, URFS, URFSET, UTFB, UTFS, UTFET, UTFTT, URTRY
UCC event register, Fast UCCE	Initialize interrupts to prepare for interrupt events
UCC mask register, Fast UCCM	Initialize the interrupt mask to prepare for interrupt events
Activate The Ethernet Controller	
Initialize the InitEnet parameter	CECDR
Initialize the Tx and Rx parameters of UCC1 ethernet.	CECR
Enable the Ethernet Controller MAC TX and RX	MACCFG1
Note: See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for register addressing, structure, and programming details.	

After initializing the registers, you must complete the following steps to bring the Ethernet Controller into a functional state:

1. To transmit Ethernet frames, build the TxBDs in memory, link them together as a ring, and point to the ring. A minimum of two TxBDs per ring is required.
2. To receive Ethernet frames, link the RxBDs together as a ring and point the corresponding registers to them. Both transmit and receive can be gracefully stopped after transmission and reception begins.

For SGMII mode, in addition to the minimum initialization steps, based on your system requirements, you must configure the QUICC Engine Control Register (QECR) to work in SGMII mode. See **Section 8.2.8, QUICC Engine Control Register (QECR)** on page 8-16 for details. You must also configure the TBI MII registers. See the *QUICC Engine Block Reference Manual with Protocol Interworking* (QEIWRM) for details.

19.7.5 Ethernet Programming Restrictions

The Ethernet implementation in the MSC8157E has the programming restrictions defined in the following sections.

19.7.5.1 RMON Statistics

Because there are a number of conditions that can cause the statistics to be inaccurate, do not use the TX CRC counter values for statistics.

19.7.5.2 Unreported Overrun

An Overrun status for a received frame is a notification that is was not fully received because the Ethernet controller is temporarily overloaded and that the frame should be discarded. In rare cases, such as when two sequential frames that cause an Overrun are received, the second frame is discarded but not reported as causing an overrun. The frame loss can be detected by a higher level protocol (such as TCP/IP). Make sure that the software requests a retransmission of the frame if the higher level protocol reports a frame loss.

19.7.5.3 Broadcast Status after an In-Band CRS Event

In RGMII mode, the Ethernet can erroneously indicate a Broadcast status for the previous frame (wrong RxBD[BC]) is generated after an in-band CRS event. To make sure a real broadcast event has occurred, program the application to ignore the RxBD[BC] bit and check the Broadcast address instead.

19.7.5.4 Pause Frame End

A pause frame is used to restrict flow control when the Ethernet controller is being overloaded. To end the pause, the application sends an XON receive pause frame with a Pause Time Value (PTV) = 0, which should cause the transmitter to exit the pause frame immediately. However, in the MSC8157E, the controller decrements that counter after clearing it before performing the compare to zero. As a result, the XON actually causes the transmitter to continue in the pause

state for 65535 pause quantas (3353920 bit-times). To prevent this occurrence, use a pause frame with a PTV = 1 to force an exit from a pause state.

Note: In the case of connecting to another QUICC Engine device, the programmer may not use the QUICC Engine Automatic Flow Control (AUFC) because in this mode, the Ethernet Controller generates Pause Commands with Pause Time Value = 0 in order to exit pause state. The programmer must configure the QUICC Engine block to use either of the following flow control modes:

— Lossless Flow Control: The Ethernet controller always uses the value of the UEMPR[PT] register when generating pause frames. It never automatically generates a pause frame with a pause time value of 0 when the receiver recovers from being above the RxFIFO threshold or below the free RxBDs threshold.

— Host Enabled Flow Control: Use the following guidelines for the specified QUICC Engine commands:

- START FLOW CONTROL. Sends pause frames with the Pause Time Value in the UEMPR[PT] field. The programmer may configure UEMPR[PT] for pause time and use the START FLOW CONTROL command for sending pause frames For exiting pause state, the programmer may configure UEMPR[PT] to 1 and use the START FLOW CONTROL command.
- STOP FLOW CONTROL. Sends a Pause Time Value of 0 and should be avoided.

19.7.5.5 Pause Frame Time

If a transmit is in progress, the pause time may be shorter than specified. When the Ethernet controller receives a pause frame with PTV not equal to 0 and MACCFG1[Rx Flow] = 1, it completes transmitting any current frame in progress; then it should pause for PTV $\times$ 512 bit-times. The MAC, however, does not take the full transmission time of the current frame into account when calculating the Tx pause time, and it may pause for 1–2 pause quanta (512–1024 bit-times) less than the PTV value. This can cause the Ethernet controller to pause transmission for up to 1024 bit-times less than the pause frame request value. If the PTV does not contain at least 2 pause quanta worth of margin, it may allow receive buffer overflows to occur in the link partner. Because the transmit pause does not take effect until after the current frame completes transmitting, the link partner pause frame generator must already include the maximum frame size as margin when calculating the pause time value to use to prevent overflow of the receiver buffers. To prevent this condition, always add 2 pause quanta to the pause time value when generating pause frames to prevent buffer overflow.

19.7.5.6 Transmit During Pause Frame

After receiving a PAUSE frame, the UCC Ethernet controller may transmit a frame although it has entered the PAUSE state. As a consequence, the pause duration is shortened by the length of the transmitted frame. The UCCS[BPR] and UCCE[CBPR] bits reflect the PAUSE state (A

PAUSE frame with Pause Time Value of zero ends the PAUSE state). A frame may be transmitted on the line during this PAUSE window. If this transmitted frame does not consume the entire PAUSE window, the following frame is suspended until the pause duration is over and only then it will be transmitted. If the short PAUSE frame can impact system performance, consider increasing the PAUSE frame time. The increased Pause frame should large enough so that the minimum pause requirement is always met. Make sure that by enlarging the PAUSE frame, all the PAUSEs are affected, not just the short ones.

19.7.5.7 Magic Packet Handling

The Ethernet MAC should recognize Magic Packet sequences by identifying an Ethernet frame containing a valid Ethernet header (Destination and Source Addresses) and valid FCS (CRC-32), and whose payload includes the specific Magic Packet byte sequence at any offset from the start of data payload. The specific byte sequence comprises an unbroken stream of 102 bytes, the first 6 bytes of which are 0xFFs, followed by 16 copies of the MACs unique IEEE station address in the normal byte order for Ethernet addresses.

The following are example partial sequences followed by the start of a complete sequence for station address 01_02_03_04_05_06:

- FF_FF_FF_FF_FF_FF_FF_01_02_03_04_05_06_01...
  Seventh byte of 0xFF does not match next expected byte of Magic Packet sequence (01). Pattern search restarts looking for 6 bytes of FF at byte 01.
- FF_FF_FF_FF_FF_FF_01_FF_FF_FF_FF_FF_FF_01_02_03_04_05_06_01...
  First FF byte following 01 does not match Magic Packet sequence. Pattern search restarts looking for 6 bytes of FF at second byte of FF following 01.

The following is an example partial sequence followed by the start of a complete sequence which is erroneously not recognized for station address 01_02_03_04_FF_06:

- FF_FF_FF_FF_FF_FF_01_02_03_04_FF_FF_FF_FF_FF_FF_01_<complete sequence>
  11th byte (0xFF) is seen as the 11 byte of the partial pattern and is not recognized as the start of a complete sequence. Pattern search restarts looking for 6 bytes of 0xFF at 12th byte, but sees only 5.

19.7.5.7.1 Failure to Exit Magic Packet Mode

If a complete Magic Packet sequence (including 6 byes of 0xFF) immediately follows a partial Magic Packet sequence, however, the complete sequence is not recognized and the MAC does not exit Magic Packet mode.

To prevent this occurrence, place one byte of data that is not 0xFF and does not match any bytes of Destination Address before the start of the Magic Packet sequence in the frame. Because the Magic Packet sequence pattern search starts at the 3rd byte after Destination Address, the Magic

Packet sequence can be placed at the start of the data payload as long as the second byte of the length/type field follows the placement rule.

19.7.5.7.2 Malformed Magic Packet Mode Triggers Exit

The following describes these scenarios:

1. Any Ethernet frame containing a valid Ethernet header (Destination and Source Addresses) and valid FCS (CRC-32), and whose payload includes the specific Magic Packet byte sequence at any offset from the start of data payload. The specific byte sequence comprises an unbroken stream of 102 bytes, the first 6 bytes of which are 0xFFs, followed by 16 copies of the MACs unique IEEE station address in the normal byte order for Ethernet addresses.
2. Once the Ethernet MAC has recognized a valid Destination Address for one frame, it continues searching for valid 102-byte Magic Packet sequences through multiple frames without checking for a valid Destination Address on each frame. The only events that cause the MAC to go back to check for valid Destination Address before checking for a Magic Packet sequence on new frames are:
   - A frame containing a recognized full Magic Packet sequence (with valid or invalid FCS)
   - Software disable of Magic packet mode (MACCFG2[MPE] = 0)
   - Perform soft reset via MACCFG1[Rx_EN] and MACCFG1[Tx_EN].
3. The Ethernet controller may exit Magic Packet mode if it receives a frame with Destination Address not matching station address, or invalid unicast or broadcast address in a valid Magic Packet sequence for the device.

If an erroneous recognition of a Magic Packet can affect system functionality, avoid the use of Magic Packets.

19.7.5.8 Ethernet Transmit Scheduler

If the data in the buffer is all 00s (bmax) or FFs (bmin), it results in an incorrect offset/address result, causing the Ethernet scheduler to select an arbitrary queue. To avoid incorrect behavior of the Ethernet Tx scheduler (including a possible stuck condition), always us all even values for the Weight Factor in the scheduling parameters.

19.7.5.9 Initialization of SGMII Mode

A key function of the TBI block in the 1 Gbps MAC is link initialization. The link initialization function does not always properly detect when the link is synchronized. As a result, in some instances, the link initialization may not complete (Link Status remains 0).

Note: The MSC8157E does not support auto negotiation (AN) in SGMII mode.

Use the following sequence prior to the clearing of IEVENT to ensure correct link initialization (this assumes that the SerDes PLL has already completed its reset sequence and the SerDes clocks are running):

1. Perform an MII Mgmt write cycle to TBI Control Register.

   MIIMCON[0000_0000_0000_0000_0001_0000_0000_0000]

   Set AN enable. A change in value of AN enable performs a reset of the AN function of the TBI. Although the MSC8157E does not support AN functionality, the AN bit is used to reset the initialization state machine internally.

2. Check to see if MII Mgmt write is complete.

   Read MII Mgmt Indicator register and check for Busy = 0,
   MIIMIND ---> [0000_0000_0000_0000_0000_0000_0000_0000]

   This indicates that the write cycle was completed.

3. Perform an MII Mgmt read cycle of Control Register.

   Clear MIIMCOM[Read Cycle]

   Set MIIMCOM[Read Cycle]

4. Check to see if MII Mgmt read is complete.

   Read MII Mgmt Indicator register and check for Busy = 0,
   MIIMIND ---> [0000_0000_0000_0000_0000_0000_0000_0000]

   This indicates that the read cycle was completed.

5. Wait for 100 µs

6. Perform an MII Mgmt write cycle to TBI Control Register.

   Clear MIIMCOM[Read Cycle]

   MIIMCON[0000_0000_0000_0000_0000_0001_0100_0000]

   This tells the TBI to restart link initialization and start operating with auto-negotiation disabled.

7. Check to see if MII Mgmt write is complete.

   Read MII Mgmt Indicator register and check for Busy = 0,
   MIIMIND ---> [0000_0000_0000_0000_0000_0000_0000_0000]

   This indicates that the write cycle was completed.

8. Perform an MII Mgmt read cycle of Control Register.

   Clear MIIMCOM[Read Cycle]

   Set MIIMCOM[Read Cycle]

9. Check to see if MII Mgmt read is complete.

Read MII Mgmt Indicator register and check for Busy = 0,
MIIMIND ---> [0000_0000_0000_0000_0000_0000_0000_0000]

This indicates that the read cycle was completed.

10. Continue with the remainder of the SGMII initialization sequence.

19.8 Serial Peripheral Interface (SPI)

The serial peripheral interface (SPI) allows the exchange of data with other devices containing an SPI. The SPI also communicates with peripheral devices such as EEPROMs, real-time clocks, A/D converters, and ISDN devices. The SPI is a full-duplex, synchronous, character-oriented channel that supports a four-wire interface (receive, transmit, clock, and slave select). The SPI block consists of transmitter and receiver sections, an independent baud-rate generator, and a control unit. The transmitter and receiver sections use the same clock, which is derived from the SPI baud rate generator in master mode and generated externally in slave mode. During an SPI transfer, data is sent and received simultaneously. The SPI receiver and transmitter are double-buffered, as shown in **Figure 19-11**, giving an effective FIFO size (latency) of 2 characters. When the SPI is disabled in the SPI mode register (SPMODE[EN] = 0), it consumes little power.

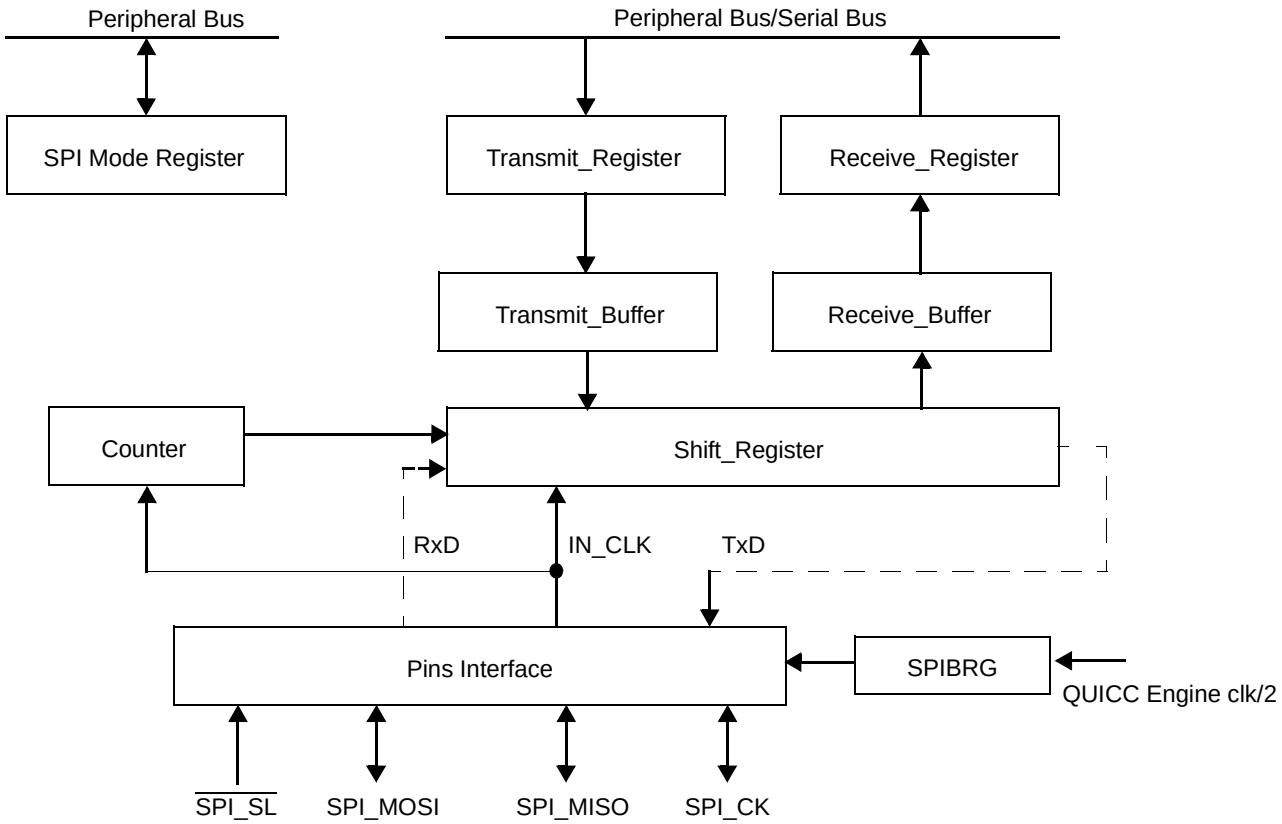

Figure 19-11. SPI Block Diagram

19.8.1 SPI Operating Modes

The SPI can be programmed to work in a single- or multiple-master environment. This section describes the SPI master and slave operation in a single-master configuration and then discusses the multi-master environment. The following sections present a summary of the main modes of operation which the SPI supports.

19.8.1.1 SPI as a Master Device

In master mode, the SPI sends a message to the slave peripheral, which sends back a simultaneous reply. A single-master device with multiple slaves can use general-purpose parallel I/O signals to selectively enable slaves, as shown in **Figure 19-12**. To eliminate the multi-master error in a single-master environment, the master $\overline{\text{SPI\_SL}}$ input can be forced inactive by selecting $\overline{\text{SPI\_SL}}$ for general-purpose I/O.

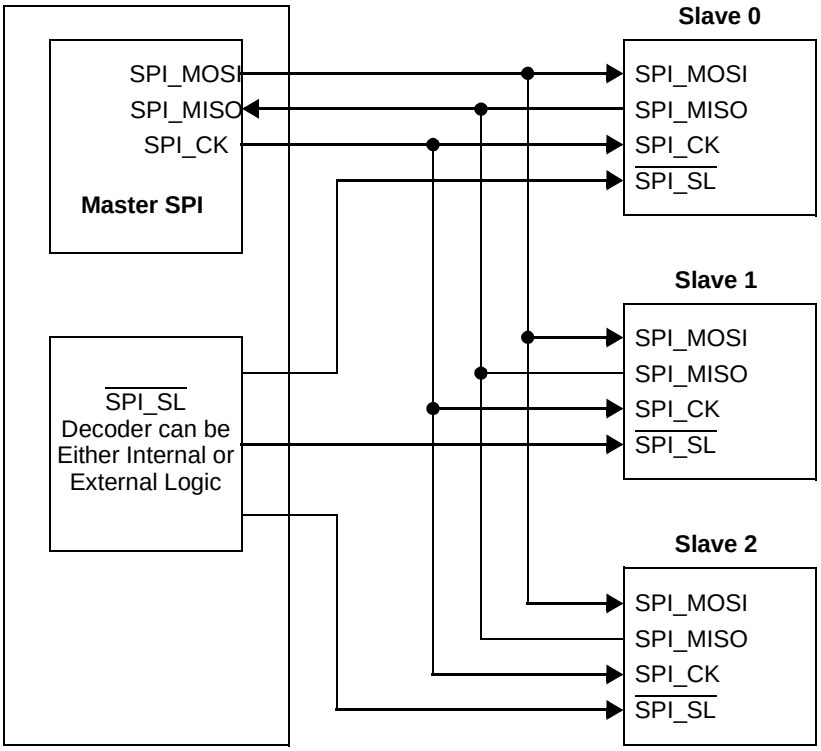

Figure 19-12. Single-Master/Multi-Slave Configuration

To start exchanging data, the QUICC Engine subsystem writes the data to be sent into a buffer, configures a TxBD with TxBD[R] set, and configures one or more RxBDs. The QUICC Engine subsystem then sets SPCOM[STR] in the SPI command register to start sending data, which starts once the SDMA channel loads the Tx FIFO with data.

The SPI then generates programmable clock pulses on SPI_CK for each character and simultaneously shifts Tx data out on SPI_MOSI and Rx data in on SPI_MISO. Received data is

written into a Rx buffer using the next available RxBD. The SPI keeps sending and receiving characters until the whole buffer is sent or an error occurs. The QUICC Engine subsystem then clears TxBD[R] and RxBD[E] and issues a maskable interrupt to the interrupt controller.

When multiple TxBDs are ready, TxBD[L] determines whether the SPI keeps transmitting without SPCOM[STR] being set again. If the current TxBD[L] is cleared, the next TxBD is processed after data from the current buffer is sent. Typically, there is no delay on SPI_MOSI between buffers. If the current TxBD[L] is set, sending stops after the current buffer is sent. In addition, the RxBD is closed after transmission stops, even if the Rx buffer is not full; therefore, Rx buffers need not be the same length as Tx buffers.

19.8.1.2 SPI as a Slave Device

In slave mode, the SPI receives messages from an SPI master and sends a simultaneous reply. The slave's $\overline{\text{SPI\_SL}}$ must be asserted before Rx clocks are recognized; once $\overline{\text{SPI\_SL}}$ is asserted, SPI_CK becomes an input from the master to the slave. SPI_CK can be any frequency from DC to QUICC Engine clk/4.

To prepare for data transfers, the slave's core processor writes data to be sent into a buffer, configures a TxBD with TxBD[R] set, and configures one or more RxBDs. The core processor then sets SPCOM[STR] to activate the SPI. Once $\overline{\text{SPI\_SL}}$ is asserted, the slave shifts data out from SPI_MISO and in through SPI_MOSI. A maskable interrupt is issued when a full buffer finishes receiving and sending or after an error. The SPI uses successive RxBDs in the table to continue reception until it runs out of Rx buffers or $\overline{\text{SPI\_SL}}$ is deasserted.

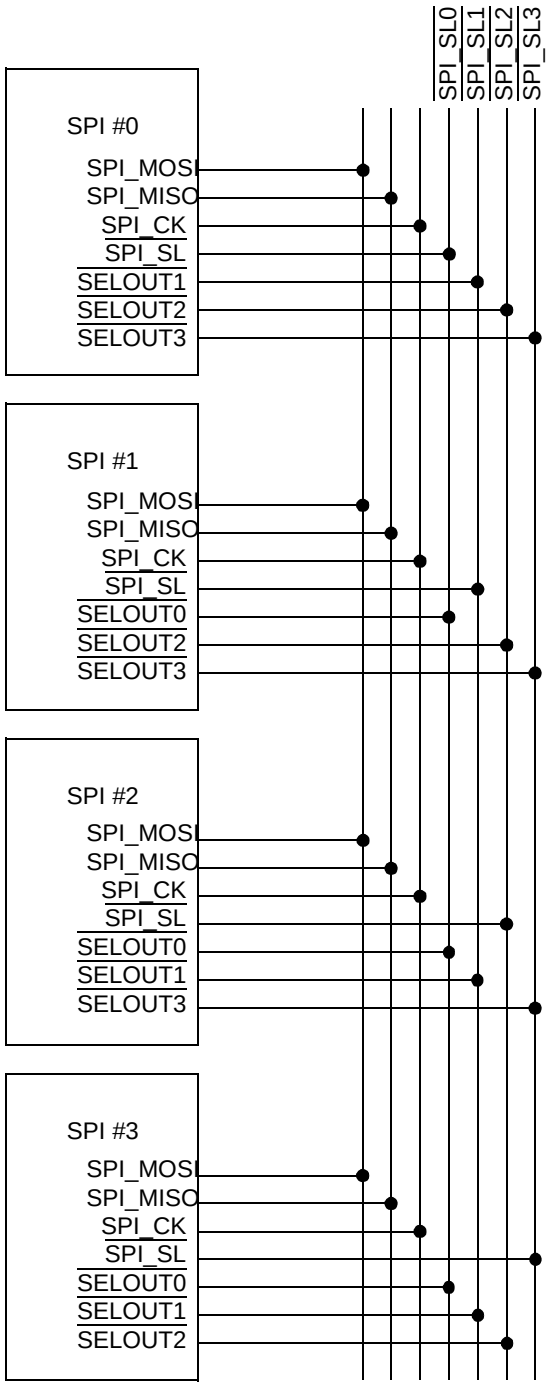
Transmission continues until no more data is available or $\overline{\text{SPI\_SL}}$ is deasserted. If it is deasserted before all data is sent, it stops but the TxBD stays open. Transmission continues once $\overline{\text{SPI\_SL}}$ is reasserted and SPI_CK begins toggling. After the characters in the buffer are sent, the SPI sends ones as long as $\overline{\text{SPI\_SL}}$ remains asserted.

Note: When enabling the SPI or changing parameters in SPI Mode Register (like CP,CI), $\overline{\text{SPI\_SL}}$ must remain deasserted for at least 2 QUICC Engine clk/2 clocks afterwards. Also if $\overline{\text{SPI\_SL}}$ is deasserted between transfers, its deassertion time should be at least 2 QUICC Engine clk/2 clocks.

19.8.2 SPI in Multi-Master Operation

The SPI can operate in a multi-master environment in which SPI devices are connected to the same bus. In this configuration, the SPI_MOSI, SPI_MISO, and SPI_CK signals of all SPIs are shared; the $\overline{\text{SPI\_SL}}$ inputs are connected separately, as shown in **Figure 19-13**. Only one SPI device at a time can act as a master—all others must be slaves. When an SPI is configured as a master and its $\overline{\text{SPI\_SL}}$ input is asserted, a multi master error occurs because more than one SPI device is a bus master. The SPI sets SPIE[MME] in the SPI event register and a maskable interrupt is issued to the QUICC Engine subsystem. It also disables SPI operation and the output drivers of SPI signals. The core processor must clear SPMODE[EN] before the SPI is used again. After correcting the problems, clear SPIE[MME] and re-enable the SPI.

The maximum sustained data rate that the SPI supports is QUICC Engine clk/50. However, the SPI can transfer a single character at much higher rates—QUICC Engine clk/8 in master mode and QUICC Engine clk/4 in slave mode. Gaps should be inserted between multiple characters to keep from exceeding the maximum sustained data rate.



Notes:
- All signals are open-drain
- For a multi-master QUICC Engine subsystem with more than two masters, SPI_SL and SPIE[MME] will not detect all possible conflicts.
- It is the responsibility of the software to arbitrate for the SPI bus (with token passing, for example).
- SPI_SLx signals are implemented in the software with general-purpose I/O signals.

Figure 19-13. Multimaster Configuration

19.8.3 External Signal Configuration

The SPI supports a four-wire interface—transmit, receive, clock, and slave select. See **Table 3-1** for detailed signal descriptions. After reset, the signals are assigned as GPIO17 to GPIO20. They must be configured as SPI signals by writing the correct values to the GPIO configuration registers. Refer to **Table 3-10** *SPI Signals* on page 3-18 and **Chapter 22**, *GPIO* for programming information.

The SPI can be configured as a slave or as a master in single- or multiple-master environments. The master SPI generates the transfer clock SPI_CK, using the SPI baud rate generator (BRG). The SPI BRG input is QUICC Engine clk /2. The selection as slave or master determines the signal direction (input or output) to select when configuring the signals using the GPIO configuration registers.

SPI_CK is a gated clock, active only during data transfers. Four combinations of SPI_CK phase and polarity can be configured by using SPMODE[CI, CP]. SPI signals can also be configured as open-drain to support a multimaster configuration in which a shared SPI signal is driven by the processor or an external SPI device.

The SPI master-in slave-out SPI_MISO signal acts as an input for master devices and as an output for slave devices. Conversely, the master-out slave-in SPI_MOSI signal is an output for master devices. The dual functionality of these signals allows the SPIs in a multimaster environment to communicate with one another using a common hardware configuration.

- When the SPI is a master, SPI_CK is the clock output signal that shifts received data in from SPI_MISO and transmitted data out to SPI_MOSI. SPI masters must output a slave select signal to enable SPI slave devices by using a separate general-purpose I/O signal. Assertion of $\overline{\text{SPI\_SL}}$ while it is a master causes an error.
- When the SPI is a slave, SPI_CK is the clock input that shifts received data in from SPI_MOSI and transmitted data out through SPI_MISO. $\overline{\text{SPI\_SL}}$ is the input enable to the SPI slave. In a multi-master environment, $\overline{\text{SPI\_SL}}$ (always an input) is also used to detect an error when more than one master is operating.

19.8.4 SPI Transmission and Reception Process

Because the SPI is a character-oriented communication unit, the core processor must pack and unpack the receive/transmit frames. A frame consists of all of the characters transmitted or received during a completed SPI transmission session, from the first character written to the internal SPI transmit data register (SPITD) to the last character transmitted following the setting of the LST bit in the SPI command (SPCOM) register.

The core processor receives data by reading the SPI receive data register (SPIRD) when the SPI event register (SPIE) not-empty bit (SPIE[NE]) is set. The core processor transmits data by writing it into the SPITD. When the next character to transmit is the final one in the current

frame, the core processor sets the last (SPCOM[LST]) bit and then writes the final character to SPITD. The SPI sets the not-full (SPIE[NF]) bit whenever its transmit FIFO is not full. It clears the bit when the last character is written to SPITD and resets it after sending the last data.

The SPI-core processor handshake protocol can use a polling or interrupt mechanism. When using polling, the core processor reads the SPIE at a predefined frequency and acts according to the value of the SPIE bits. The polling frequency depends on the SPI serial channel frequency. When using the interrupt mechanism, setting either SPIE[NF] or SPIE[NE] causes an interrupt to the core processor. The core processor then reads the SPIE and acts accordingly. There are three basic modes of operation for transmitting and receiving: master, slave, and multimaster.

19.9 Programming Model

This section provides a summary list of the MSC8157E QUICC Engine subsystem, Ethernet controller, and SPI registers with their offsets.

Note: The QUICC Engine registers use a base address of 0xFEE00000.

Table 19-10. MSC8157E QUICC Engine Register Summary

Register Name	Acronym	Offset
IRAM Registers		
IRAM Address Register	IADD	0x0000
IRAM Data Register	IDATA.	0x0004
Interrupt Controller Registers

20 UART

The UART, also known as the serial communication interface (SCI), is a full-duplex port for serial communications with other devices. This interface uses two dedicated signals: transmit data (UART_TXD) and receive data (UART_RXD) (see **Figure 20-1**). The external connections shared by these signals with GPIO[28–29] are available as general-purpose I/O (GPIO) signals when they are not configured for UART operation (see **Chapter 21**, *GPIO* for details).

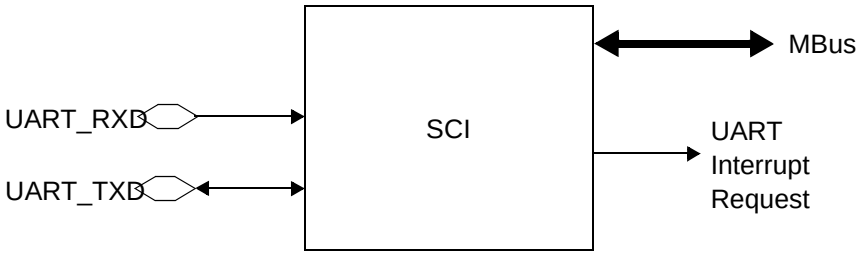

Figure 20-1. UART Interface

The UART is accessible, via the MBus, to an external host or to each of the SC3850 cores. The UART generates one interrupt signal that connects to each SC3850 core so that each SC3850 core can service UART interrupts. For details on UART interrupt signal connectivity, refer to **Chapter 13**, *Interrupt Handling*. When accepting an interrupt request, an SC3850 core or external host should read the UART status register (SCISR) to identify the interrupt source and service it accordingly. During reception, the UART generates an interrupt request when a new character is available to the UART data register, SCI Data Register (SCIDR). An SC3850 core or external host then reads the character from the data register. During transmission, the UART generates an interrupt request when its data register can be written with new character. An SC3850 core or external host then writes the character to the data register.

As **Figure 20-2** shows, the UART allows full duplex, asynchronous, non-return-to-zero (NRZ) serial communication between the MSC8157E and remote devices, including other MSC8157E devices. The UART transmitter and receiver operate independently, although they use the same baud-rate generator and same character length. An SC3850 core monitors the status of the UART, writes the data to be transmitted, and processes received data.

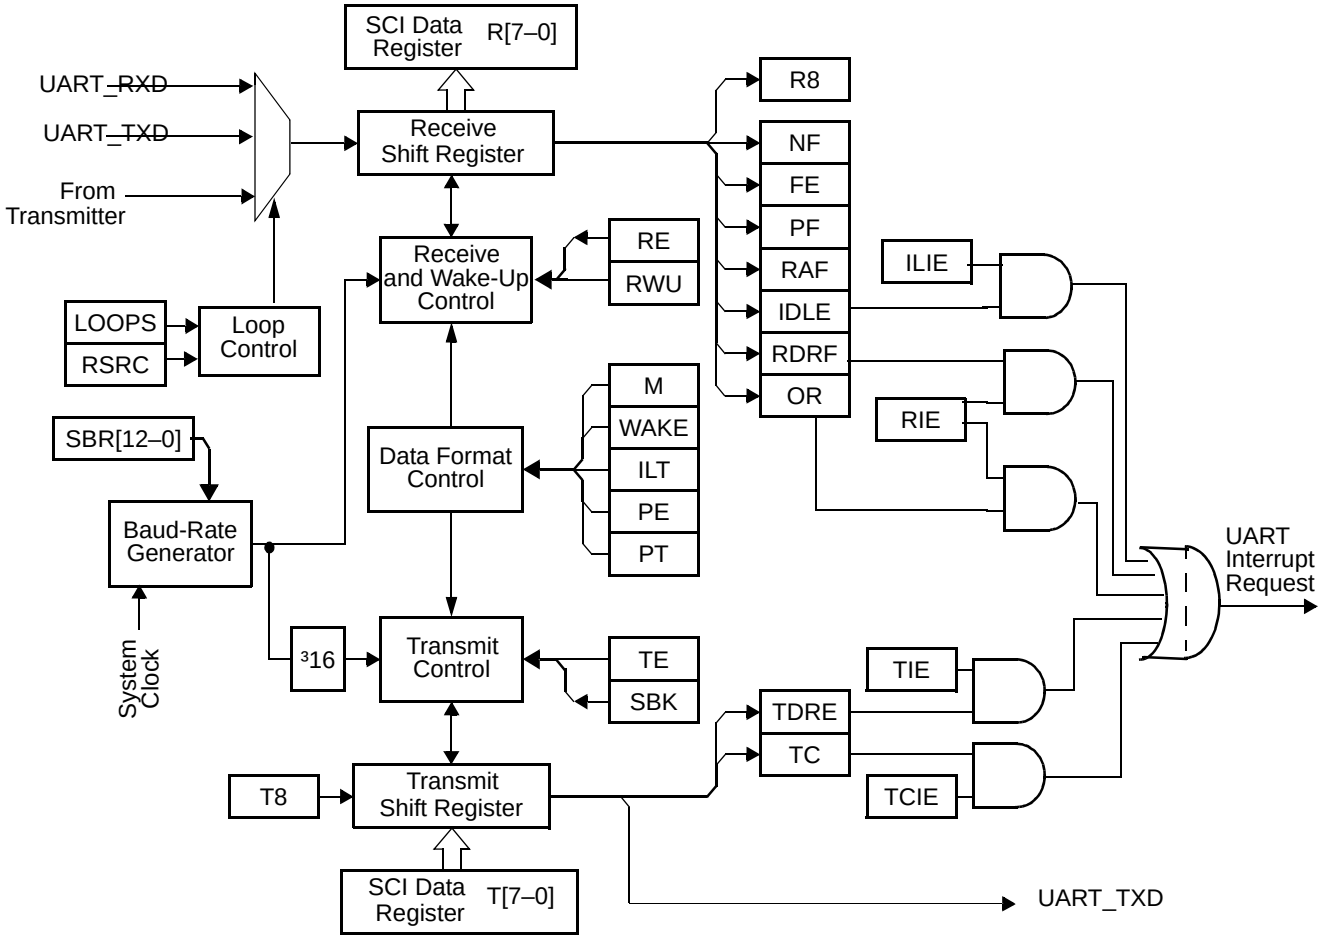

Figure 20-2. UART Block Diagram

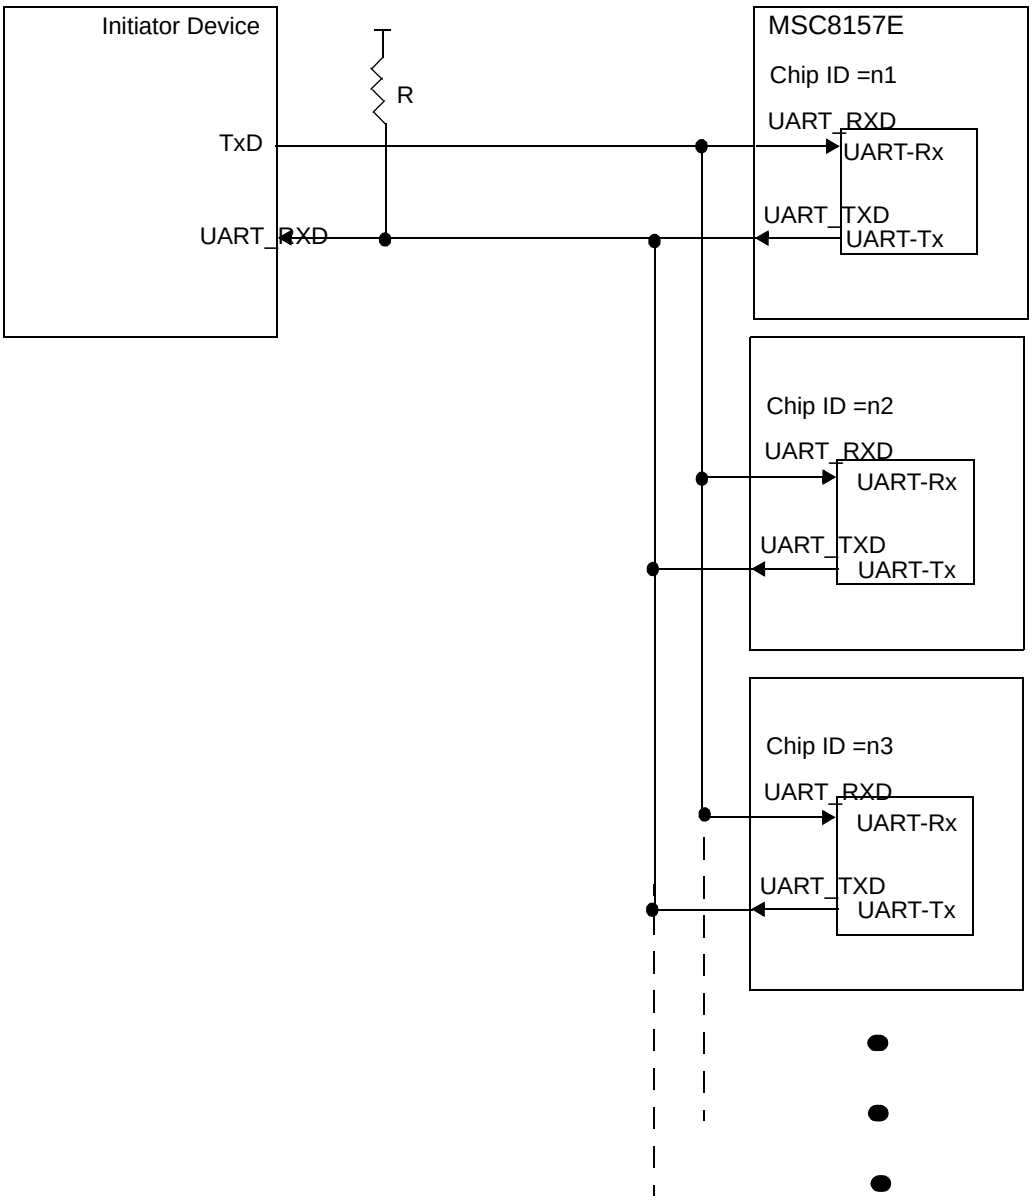
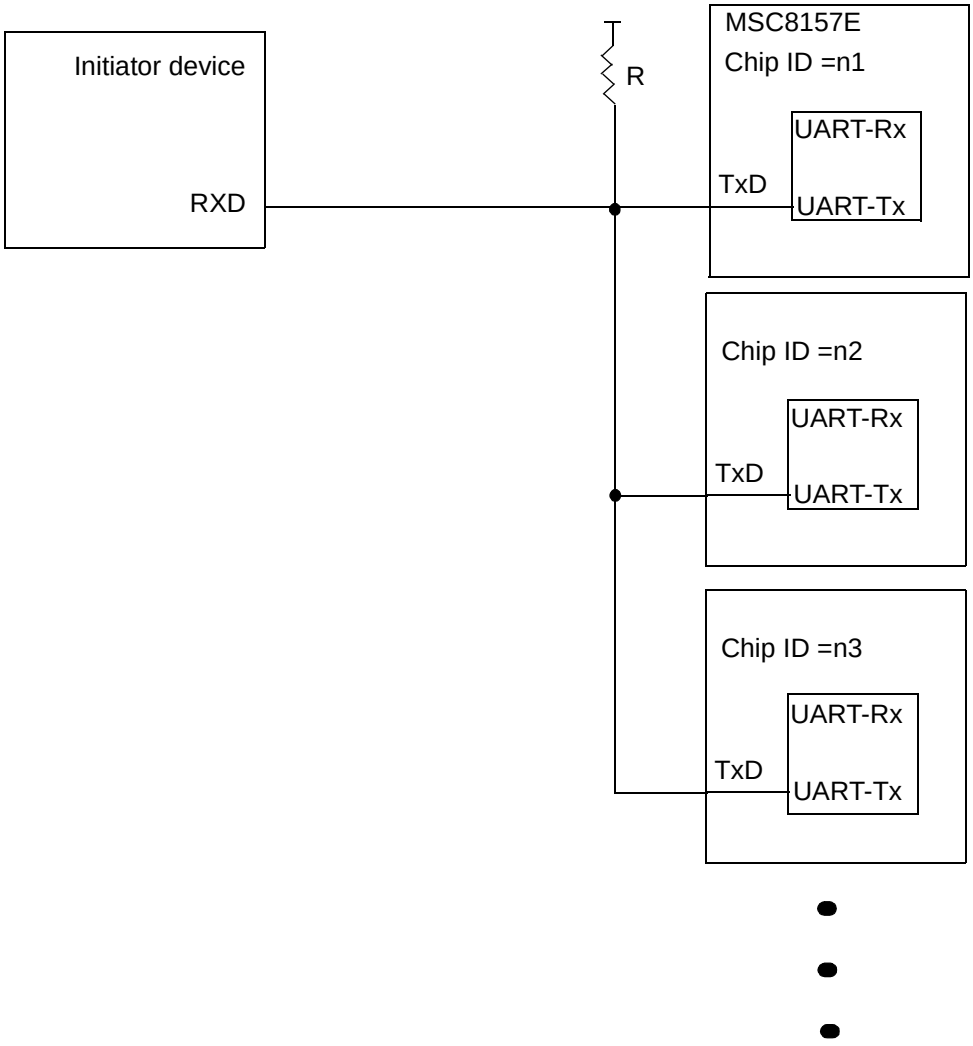
Figure 20-3 shows the full duplex UART system in which the MSC8157E UART transmits and receives simultaneously. A higher-level protocol should handle the full duplex communication to guarantee that no more than one target UART transmits to the UART_RXD signal of the initiator at a given time. Receiver wake-up can obtain such a protocol (see **Section 21.2.7**, *Receiver Wake-Up*). The UART UART_TXD signal can be configured with full CMOS drive or with open-drain drive (see **Chapter 21**, *GPIO*). In both cases, the external pull-up resistor is needed to avoid floating input at the UART_RXD of the initiator.



Note: The RC value on the MultiPoint TxD may limit system baud rate.

Figure 20-3. Full Duplex Multiple UART System

Figure 20-4 shows the UART on a single-wire connection of a half duplex system. The UART_TXD signal must be configured with open-drain drive (see **Chapter 21**, *GPIO*) and an external pull-up resistor. For details on single-wire, see **Section 21.4.2**, *Single-Wire Operation*.



Note: The RC value on the MultiPoint UART_TXD might limit system baud rate.

Figure 20-4. Single-Wire Connection

The UART uses the standard NRZ mark/space data format illustrated in **Figure 20-5**.

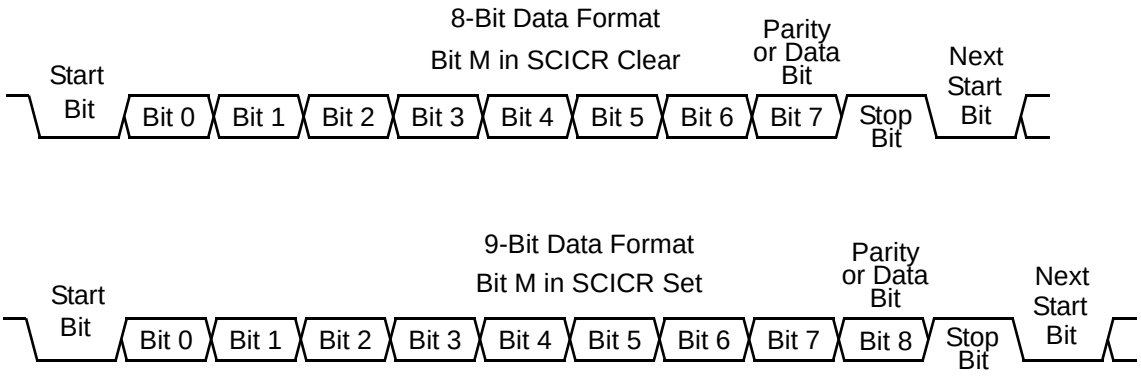


Figure 20-5. UART Data Formats

Each data character is contained in a frame that includes a start bit, eight or nine data bits, and a stop bit. Clearing the M bit in SCI Control Register 1 (SCICR) configures the SCI for 8-bit data characters. A frame with eight data bits has a total of 10 bits, including a start bit and a stop bit.

Table 20-1. Examples of 8-Bit Data Format

Start Bit	Data Bits	Address Bits	Parity Bits	Stop Bit
1	8	0	0	1
1	7	0	1	1
1	7	1	0	1

Note: The address bit identifies the frame as an address character. The address bit is bit 7 (M = 0) or bit 8 (M = 1) See **Section 21.2.7**, *Receiver Wake-Up*.

Setting the M bit configures the UART for nine-bit data characters. When the UART is configured for 9-bit data characters, the ninth data bit is the T8 or R8 bit in the SCIDR. T8 remains unchanged after transmission and can be used repeatedly without rewriting it. A frame with nine data bits has a total of 11 bits, including a start bit and a stop bit.

Table 20-2. Example of 9-Bit Data Format

Start Bit	Data Bits	Address Bits	Parity Bits	Stop Bit
1	9	0	0	1
1	8	0	1	1
1	8	1	0	1

Note: The address bit identifies the frame as an address character. The address bit is bit 7 (M = 0) or bit 8 (M = 1). See **Section 21.2.7**, *Receiver Wake-Up*.

A 13-bit modulus counter in the baud-rate generator derives the baud rate for both the receiver and the transmitter. A value ranging from 1 to 8191 is written to the SBR[12–0] bits to determine the System Peripherals clock/2 clock divisor. Writing a 0 to SBR[12–0] disables the baud-rate generator. The SBR bits are in the SCI Baud-Rate Register (SCIBR). The baud-rate clock is synchronized with the bus clock and drives the receiver. The baud-rate clock divided by 16 drives the transmitter. The receiver has an acquisition rate of 16 samples per bit time. Baud-rate generation is subject to two sources of error:

- Integer division of the System Peripherals clock/2 may not give the exact target frequency.
- Synchronization with the bus clock can cause phase shift.

Refer to **Section 21.2.2**, *Data Sampling*, for details on adjusting to the received baud rate at the receiver.

Table 20-3 lists some examples of achieving target baud rates with a System Peripherals clock/2 frequency of 250 MHz, using the following formula:

$$UART\ baud\ rate = System\ clock / (16 \times SCIBR[12–0])$$

Table 20-3. Baud Rates (System Peripherals clock/2 = 250 MHz)

Bits SBR	Receiver Clock (Hz)	Transmitter Clock (Hz)	Target Baud Rate	Error (Percentage)
34	7,352,941	459,559	460,000	0.096
68	3,676,471	229,779	230,000	0.096
136	1,838,235	114,890	115,000	0.096
244	1,024,590	64,037	64,000	0.058
407	614,251	38,391	38,400	0.024
814	307,125	19,195	19,200	0.024
1628	153,563	9598	9600	0.024
3255	76,805	4800	4800	0.006
6510	38,402	2400	2400	0.006
Not supported			1200	—

Note: The error relates only to the first source error. These numbers are based on a CLASS frequency of 500 MHz, but the frequency can be configured as indicated in the Clock Modes **Table 7-1** in the Clocks chapter. The divider values must be recomputed for a different CLASS frequency.

20.1 Transmitter

The UART transmitter accommodates either 8-bit or 9-bit data characters. The state of the M bit in the SCI Control Register (SCICR) determines the length of the data characters. When 9-bit data is transmitted, bit T8 in the SCIDR is the ninth bit (bit 8).

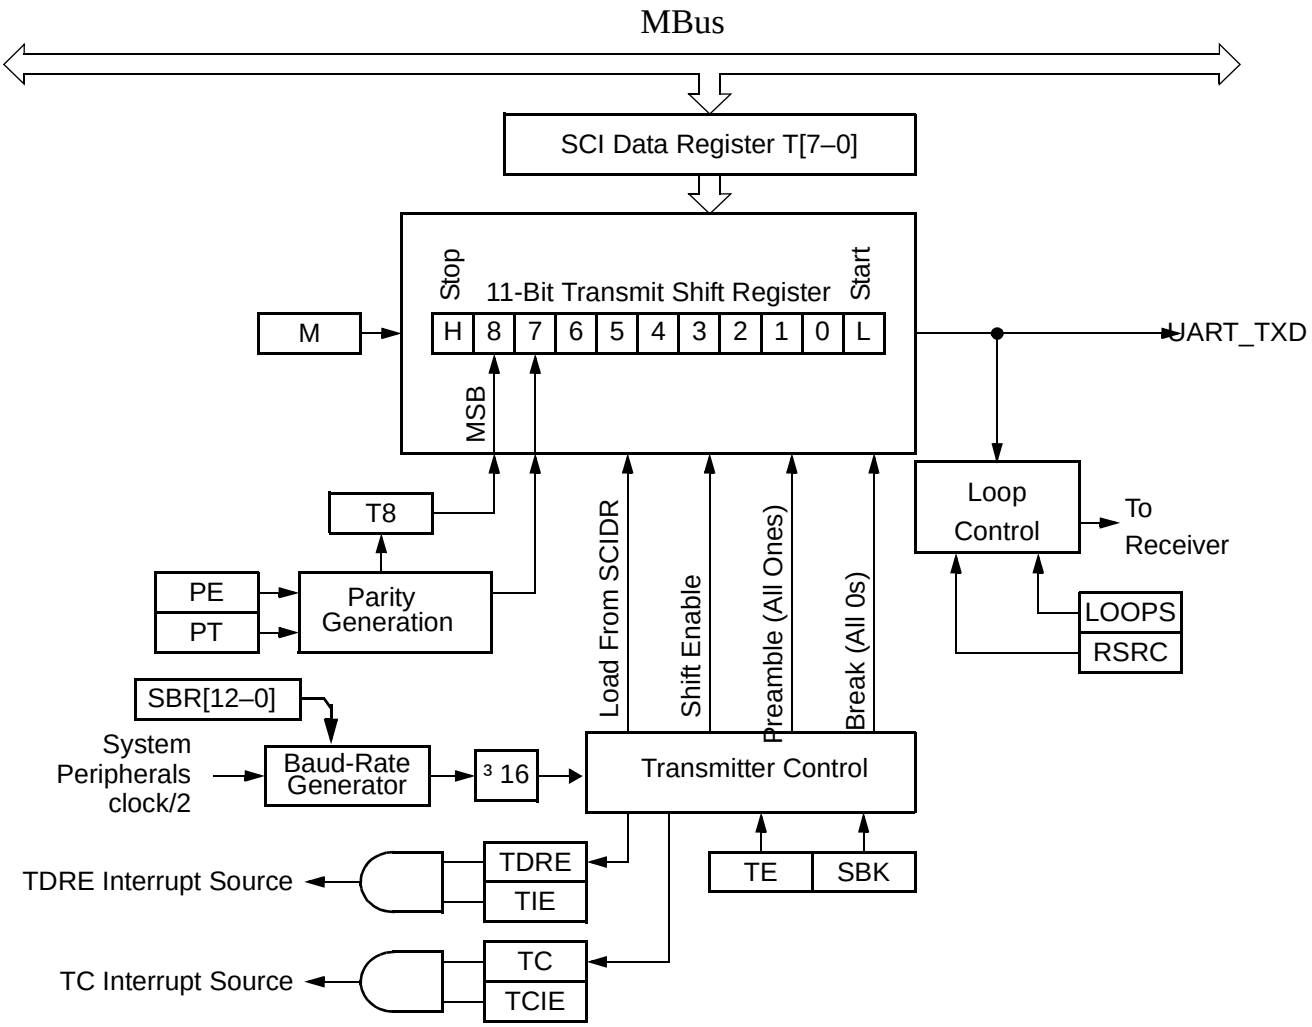

Figure 20-6. Transmitter Block Diagram

20.1.1 Character Transmission

To transmit data, one of the SC3850 cores or an external host writes the data character to the SCI Data Register (SCIDR), which is then transferred to the transmitter shift register. The transmitter shift register then shifts out the data bits on the UART_TXD signal, after it prefaces them with a start bit and appends them with a stop bit. The SCI data register is the write-only buffer between the MBus and the transmit shift register.

The UART also sets a flag, the transmit data register empty flag (TDRE), every time it transfers data from the buffer (SCIDR) to the transmitter shift register. If the Transmit Interrupt Enable (TIE) bit in the SCICR is set, the TDRE flag asserts a UART interrupt request. The transmit interrupt service routine responds to this flag by writing another character to the transmitter buffer (SCIDR), while the shift register is still shifting out the first character. If the TDRE flag is set and no new data or break character transferred to the shift register, the UART sets a flag, transmit complete (TC) and UART_TXD becomes idle.

Begin a UART transmission as follows:

1. Configure the UART:
   a. Select a baud rate. Write the appropriate value to the SCIBR to start the baud-rate generator. Note that the baud-rate generator is disabled when the baud rate is zero. Writing to the 5 MSB (SBR[12–8]) bits of the SCIBR has no effect without also writing to the 8 LSB of SCIBR (SBR[7–0]).
   b. Configure GPIO29 for UART UART_TXD (see **Chapter 21**, *GPIO*):
      - Select the UART transmit signal for the GPIO29 external connection via the GPIO29 configuration registers.
      - Set the direction bit for the GPIO29 port to select output.
   c. Write to the SCICR to configure data length, parity, and other configuration bits (LOOPS, RSRC, M, WAKE, ILT, PE, PT) and enable the transmit and receive interrupts as required (TIE, TCIE, RIE, ILIE, TE, RE, RWU, and SBK). A preamble character is now shifted out of the transmitter shift register.
2. Perform the transmit procedure for each character:
   d. Poll the TDRE flag by reading the SCISR or responding to the UART interrupt. Keep in mind that the TDRE reset value is one.
   e. If the TDRE flag is set, write the data to be transmitted to SCIDR, where the ninth bit is written to the T8 bit in SCIDR if the UART is in 9-bit data format. Reading TDRE bit in the SCISR and then writing new data to T[7–0] in the SCIDR clears the TDRE flag. Otherwise, the last data transmitted and then UART_TXD goes to idle condition, that is, a logic 1 (high).
3. Repeat step 2 for each subsequent transmission.

Note: The TDRE flag is set when the shift register is loaded with the next data to be transmitted from SCIDR, which occurs 9/16ths of a bit time *after* the start of the stop bit of the previous frame.

Note: When the shift register is empty (the TC and TDRE flags are set), transmission starts no more than one bit time after the data register is written. If only the TC interrupt source is enabled (SCICR[TCIE] = 1, SCICR[TIE] = 0), then you must ensure at least one bit time interval between successive writes to the SCIDR to enable the transmitter software to write twice to the SCIDR per interrupt.

Setting the Transmitter Enable (SCICR[TE]) bit to 1 automatically loads the transmit shift register with a preamble of 10 logic 1s (if M = 0) or 11 logic 1s (if M = 1). After the preamble shifts out, control logic transfers the data from the SCIDR into the transmit shift register. A logic 0 start bit automatically goes into the least significant bit position of the transmit shift register. A logic 1 stop bit goes into the most significant bit position.

Hardware supports odd or even parity. When parity is enabled, the most significant bit (msb) of the data character is the parity bit.

When the transmit shift register is not transmitting a character, UART_TXD goes to the idle condition, logic 1. When software clears the SCICR[TE] bit, the transmitter relinquishes control of UART_TXD.

Note: If SCIDDR[DDRTX] is set, UART_TXD is driven by a logic 0 (pulled down). Otherwise, if SCIDDR[DDRTX] is cleared, the UART_TXD signal is not driven. See **Chapter 21**, *GPIO* for details about configuring this signal.

If software clears SCICR[TE] while a transmission is in progress (TC = 0), the frame in the transmit shift register continues to shift out. Then the transmitter relinquishes control of UART_TXD even if there is data pending in the SCI data register. To avoid accidentally cutting off the last frame in a message, always wait for TDRE to go high after the last frame before clearing SCICR[TE].

To separate messages with preambles with minimum idle line time, use the following sequence between messages (see also **Figure 20-7**, *Queuing an Idle Character*):

1. Write the last character of the first message to the SCIDR.
2. Wait for the TDRE flag to go high, indicating the transfer of the last frame to the transmit shift register.
3. Insert a preamble by clearing and then setting the SCICR[TE] bit.
4. Write the first character of the second message to the SCIDR.

Another way to separate messages with idle line is to wait until the TC flag is set after writing the last character of the first message to SCIDR, indicating this character has already been transmitted. When TC is set, UART_TXD goes idle. Then, after some idle line time, write the first character of the second message to SCIDR.

20.1.2 Break Characters

Setting the send break bit (SCICR[SBK]) to a value of 1 loads the transmit shift register with a break character. A break character contains all logic 0s and has no start, stop, or parity bit. Break character is ten logic 0s (if M = 0) or eleven logic 0s (if M = 1). As long as SCICR[SBK] is at logic 1, transmitter logic continuously loads break characters into the transmit shift register. After software clears the SBK bit, the shift register finishes transmitting the last break character and then transmits at least one logic 1. The automatic logic 1 at the end of a break character guarantees the recognition of the start bit of the next frame.

20.1.3 Idle Characters

An idle character contains all logic 1s and has no start, stop, or parity bit. The length of idle characters depends on the M bit in SCICR. The preamble is a synchronizing idle character that begins the first transmission initiated after the SCICR[TE] bit is written from 0 to 1. Clearing and then setting the SCICR[TE] bit during a transmission queues an idle character to be sent after the frame currently being transmitted.

Note: When queuing an idle character, return the SCICR[TE] bit to logic 1 before the stop bit of the current frame shifts out to UART_TXD. Setting SCICR[TE] after the stop bit appears on UART_TXD discards data previously written to the SCI data register. Toggle the SCICR[TE] bit for a queued idle character while the TDRE flag is set and immediately before writing the next character to the SCI data register. See **Figure 20-7**, *Queuing an Idle Character*.

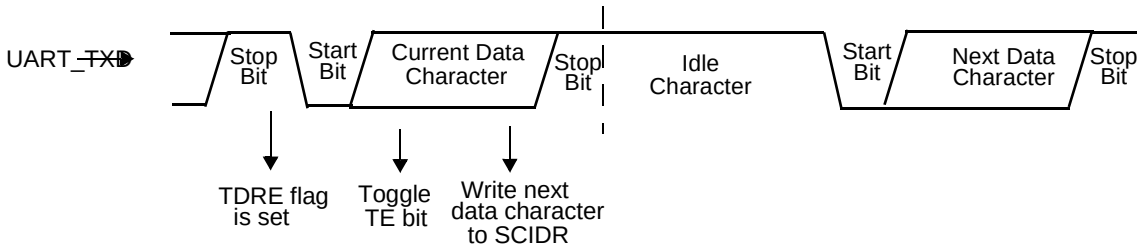

Figure 20-7. Queuing an Idle Character

20.1.4 Parity Bit Generation

The UART can be configured to enable parity bit generation by the parity enable bit (SCICR[PE]). The parity type bit (SCICR[PT]) determines whether to place even or odd parity at T8 (if M = 1) or at T7 (if M = 0) bits of SCIDR.

20.2 Receiver

The SCI receiver can accommodate either 8-bit or 9-bit data characters. The state of the SCICR[M] bit determines the length of data characters. When receiving 9-bit data, bit R8 in the SCIDR is the ninth bit (bit 8).

20.2.1 Character Reception

During a UART reception, the receive shift register shifts a frame in through UART_RXD. The SCI data register is the read-only buffer between the MBus and the receive shift register. After a complete frame shifts into the receive shift register, the data portion of the frame (the character) is transferred to the SCI data register. The receive data register full flag, RDRF, in SCISR is set, indicating that the received character can be read.

The overrun flag, OR, is set when software fails to read the SCIDR before the receive shift register receives the next character. If the receive interrupt enable bit (SCICR[RIE]) is also set, the Receive Data Register Full (RDRF) or the OR flags generate an interrupt request.

Begin an SCI reception as follows:

1. Configure the SCI:
   f. Select the target baud rate and write the appropriate value to the SCI Baud Rate Register (SCIBR). Note that the baud-rate generator is disabled when the baud rate is zero. Writing to 5 MSB bits of SCIBR (SBR[12–8]) has no effect without also writing to 7 LSB of SCIBR (SBR[7–0]).
   g. Configure GPIO28 for UART UART_RXD (see **Chapter 21**, *GPIO*):
   — Select the UART UART_RXD signal as the external connection via the GPIO port 20 configuration registers.
   — Clear the direction bit for GPIO28 in the direction register to select input.
   h. Write to the SCICR to configure data length, parity, and other configuration bits (LOOPS, RSRC, M, WAKE, ILT, PE, PT) and enable the transmitter, interrupts, receive, and wake up as required (TIE, TCIE, RIE, ILIE, TE, RE, RWU, and SBK).If the SBK bit is set, the receiver wakes up if there are particular conditions on the UART_RXD signal according to the WAKE control bit. Refer to **Section 21.2.7**, *Receiver Wake-Up*.
2. Perform the reception procedure for each character:
   i. Poll the RDRF flag by reading the SCISR or responding to the UART interrupt.
   j. If the RDRF flag is set, read the data to be received from SCIDR, where the ninth bit is read from R8 bit in SCIDR if the SCI is in 9-bit data format. Reading RDRF bit at SCISR and then reading new data from SCIDR clears RDRF flag.
3. Repeat step 2 for each subsequent reception.

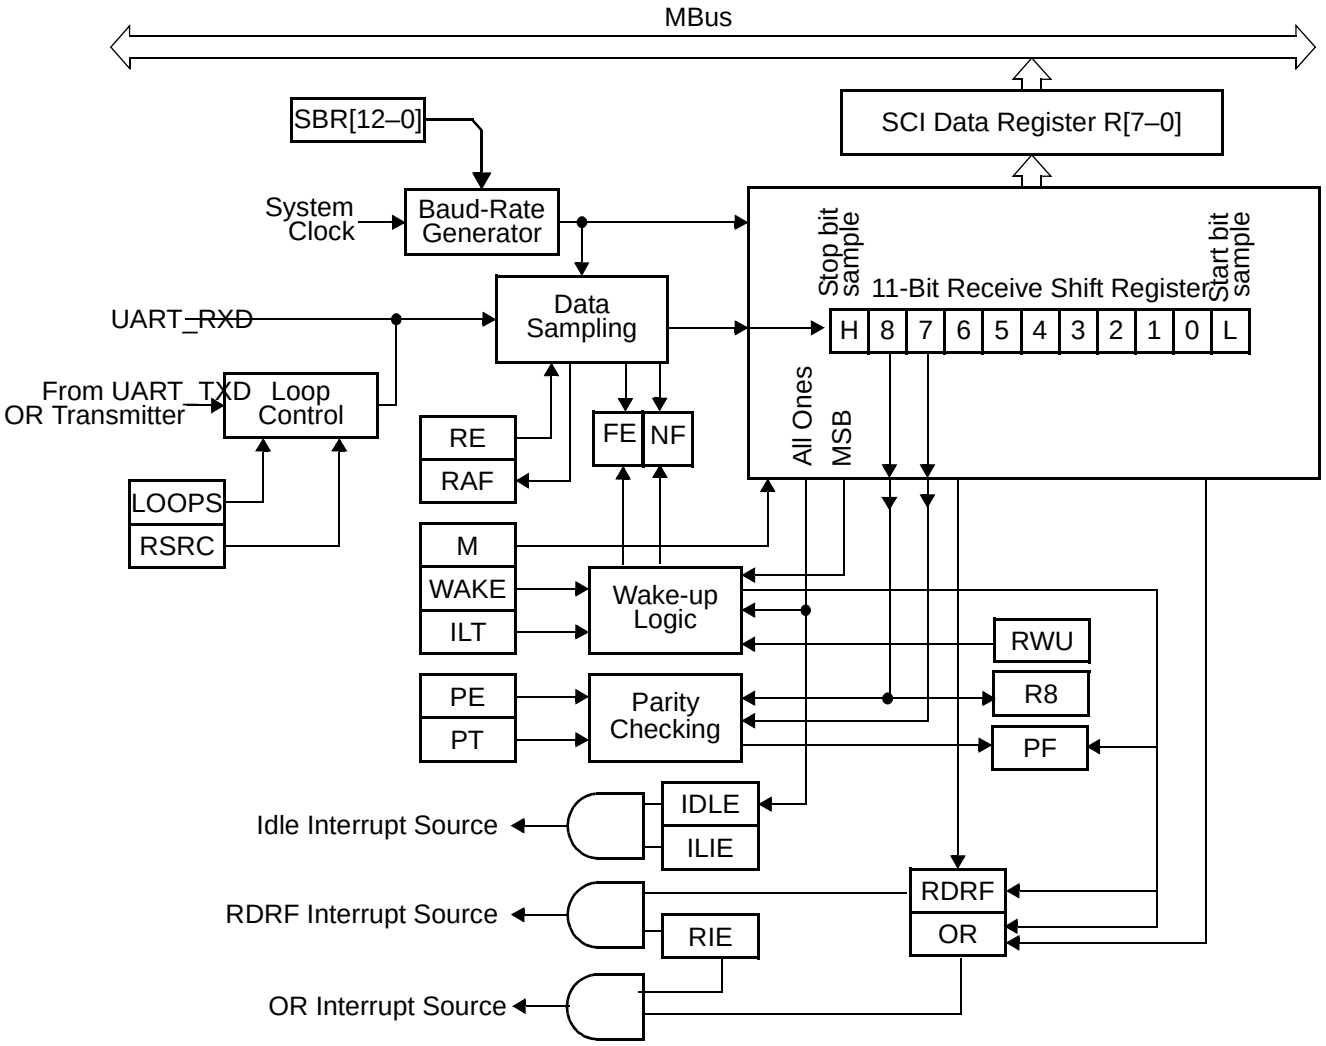

Figure 20-8. UART Receiver Block Diagram

20.2.2 Data Sampling

The receiver samples UART_RXD at the RT clock rate. The RT clock is an internal signal with a frequency 16 times the baud rate. To adjust for baud rate mismatch between the baud rate generated by RT clock and the target baud rate, the RT clock (see **Figure 20-9**) is re-synchronized:

- After every start bit.
- After the receiver detects a data bit change from logic 1 to logic 0 (after the majority of data bit samples at RT8, RT9, and RT10 returns a valid logic 1 and the majority of the next RT8, RT9, and RT10 samples returns a valid logic 0).

To locate the start bit, data sampling logic searches for a logic 0 preceded by three logic 1s. When the falling edge of a possible start bit occurs, the RT clock logic begins to count to 16.

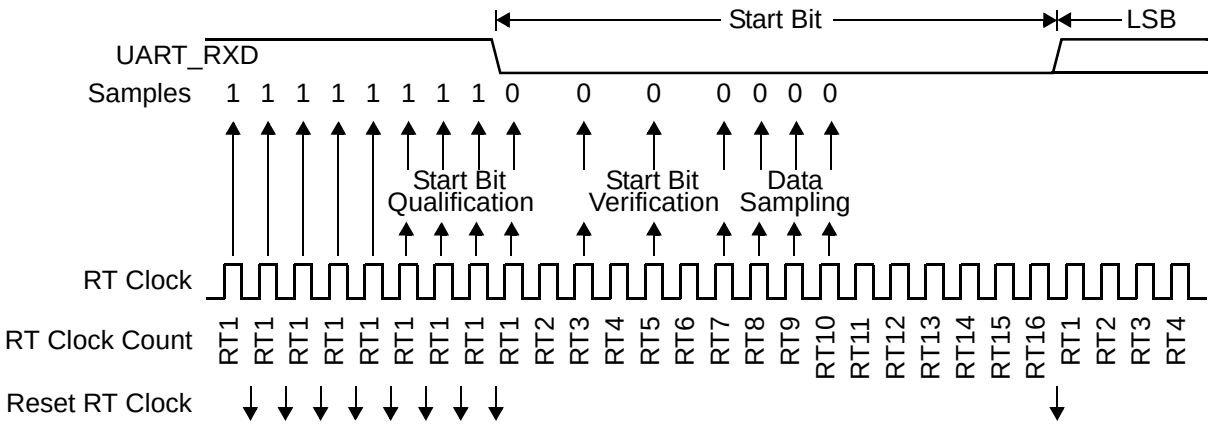

Figure 20-9. Receiver Data Sampling

To verify the start bit and to detect noise, data sampling logic takes samples at RT3 and RT5. If both samples are logic 1 the RT counter is reset and a new search for a start bit begins, else also RT7 sample is taken. If at least two samples (from RT3, RT5, and RT7) are logic 0 then the start bit is perceived. The noise flag, NF, is set if two samples are logic 0 and one is logic 1. **Table 20-4** summarizes the results of the start bit verification samples.

Table 20-4. Start Bit Verification

RT3, RT5, and RT7 Samples	Start Bit Verification	Noise Flag
000	Yes	0
001	Yes	1
010	Yes	1
011	No	0
100	Yes	1
101	No	0
11 (RT7 sample is not taken)	No	0

If start bit verification is not successful, the RT counter is reset and a new search for a start bit begins. To determine the value of a data bit and to detect noise, sample logic takes samples at RT8, RT9, and RT10. The data bit value is determined by the majority of the samples. The noise flag, NF, is set if not all samples have the same logical value. **Table 20-5** summarizes the results of the data bit samples.

Table 20-5. Data Bit Recovery

RT8, RT9, and RT10 Samples	Data Bit Determination	Noise Flag
000	0	0
001	0	1
010	0	1
011	1	1
100	0	1
101	1	1
110	1	1
111	1	0

Note: The RT8, RT9, and RT10 samples do not affect start bit verification. If any or all of the RT8, RT9, and RT10 start bit samples are logic 1s following a successful start bit verification, the noise flag (NF) is set and the receiver assumes that the bit is a start bit (logic 0).

To verify a stop bit and to detect noise, sample logic takes samples at RT8, RT9, and RT10. The noise flag, NF, is set if not all samples have the same logical value (the same as for data bit sampling). If the majority of the samples are logic 0 framing error flag, FE, is set. **Table 20-6** summarizes the results of the stop bit samples.

Table 20-6. Stop Bit Recovery

RT8, RT9, and RT10 Samples	Framing Error Flag	Noise Flag
000	1	0
001	1	1
010	1	1
011	0	1
100	1	1
101	0	1
110	0	1
111	0	0

In **Figure 20-10** the start bit verification samples RT3 and RT5 determine that the first logic 0 detected is noise and not the beginning of a start bit. The RT counter is reset and the start bit search resumes. The noise flag is not set because the noise occurred before the start bit was found.

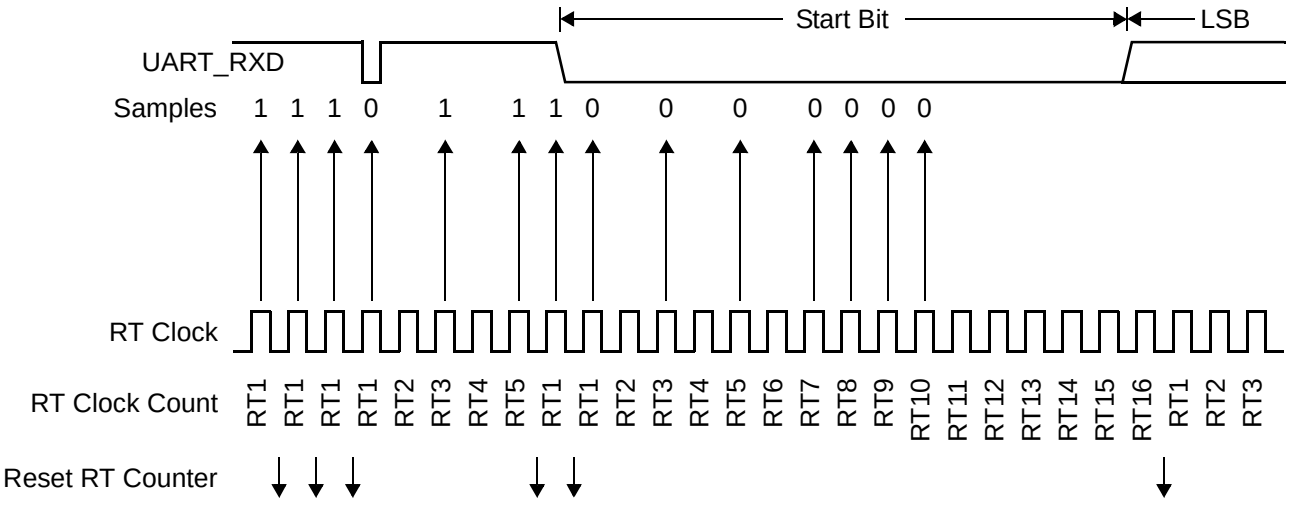

Figure 20-10. Start Bit Search Example 1

In **Figure 20-11**, the verification sample at RT3 is high. The RT3 sample sets the noise flag. Although the perceived bit time is misaligned, the data samples RT8, RT9, and RT10 of the next bit are within the bit time and data recovery is successful.

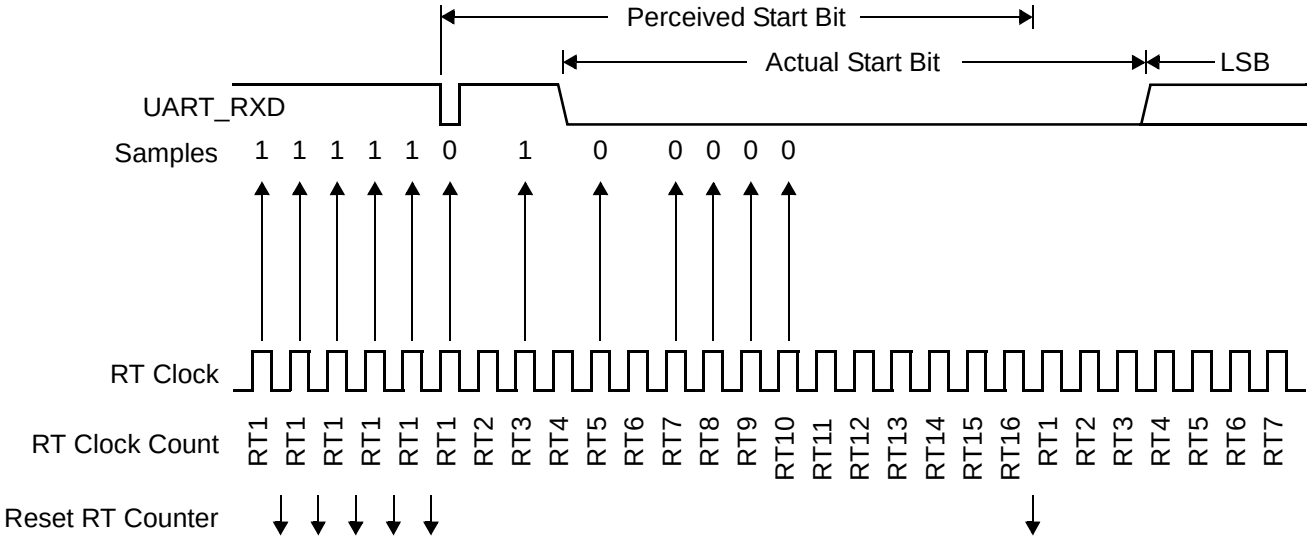

Figure 20-11. Start Bit Search Example 2

In **Figure 20-12** the first start bit verification is a case similar to that in **Figure 20-10**, *Start Bit Search Example 1*, but this time the first logic 0 detected is the real beginning of start bit. The noise is at samples R3 and R5 which causes the RT counter to reset and the start bit search begins again. Although the perceived bit time is misaligned, the data samples RT8, RT9, and RT10 of the next bit are within the bit time and data recovery is successful. For this case the noise and framing error flags are not set.

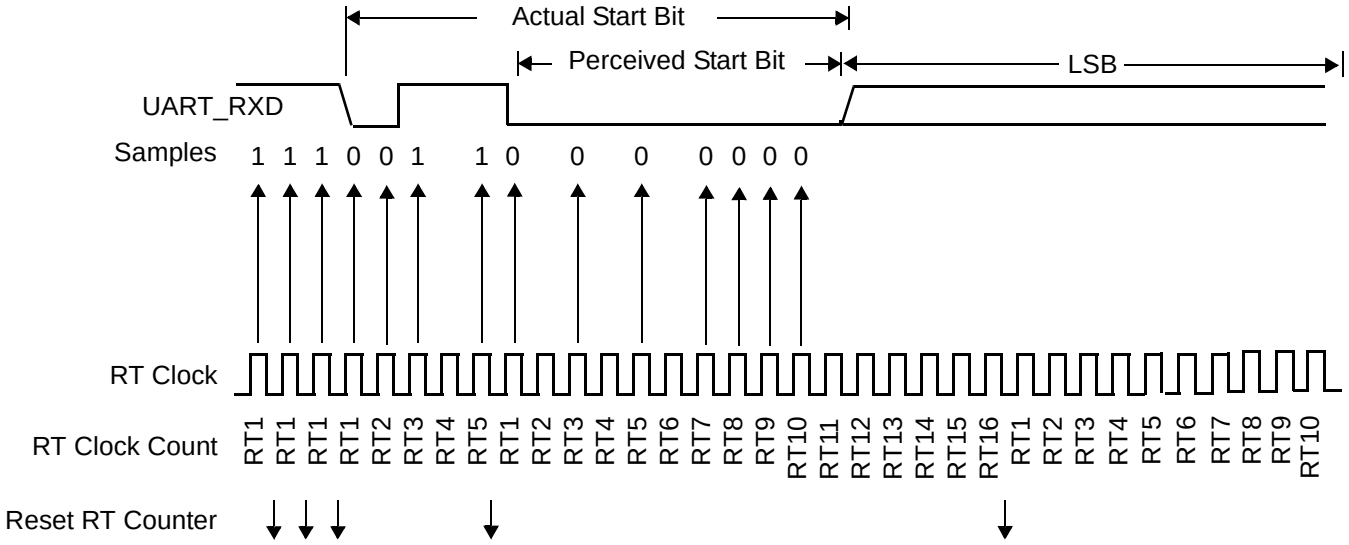

Figure 20-12. Start Bit Search Example 3

In **Figure 20-13**, a large burst of noise is perceived as the beginning of a start bit, although the test sample at RT5 is high. The RT5 sample sets the noise flag. Although this is a worst-case misalignment of perceived bit time, the RT8, RT9, and RT10 data samples of the next bit are within the bit time, and data recovery is successful.

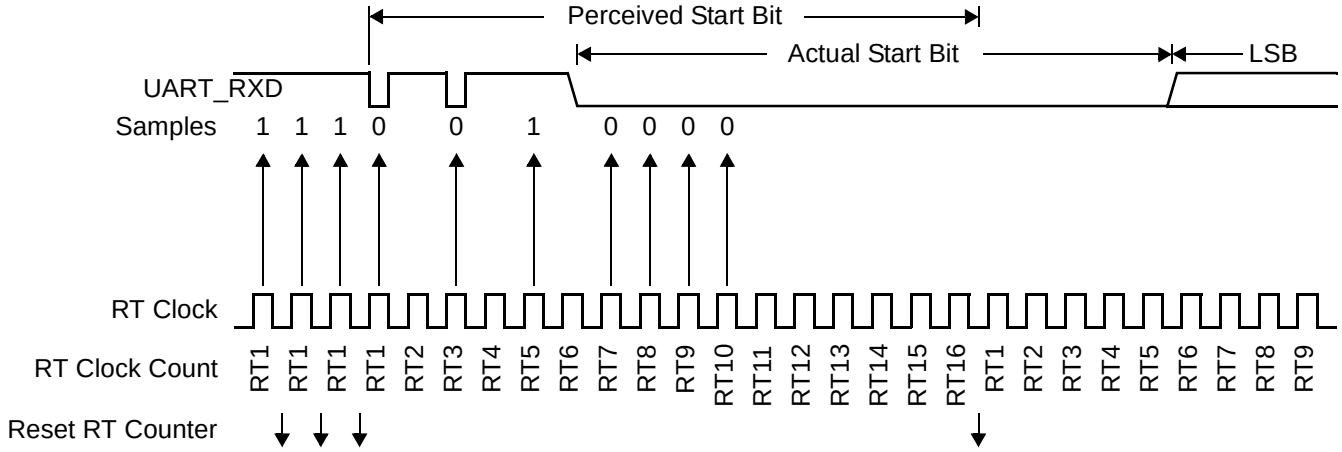

Figure 20-13. Start Bit Search Example 4

Figure 20-14 shows the effect of noise early in the start bit time. Although this noise does not affect proper synchronization with the start bit time, it does set the noise flag.

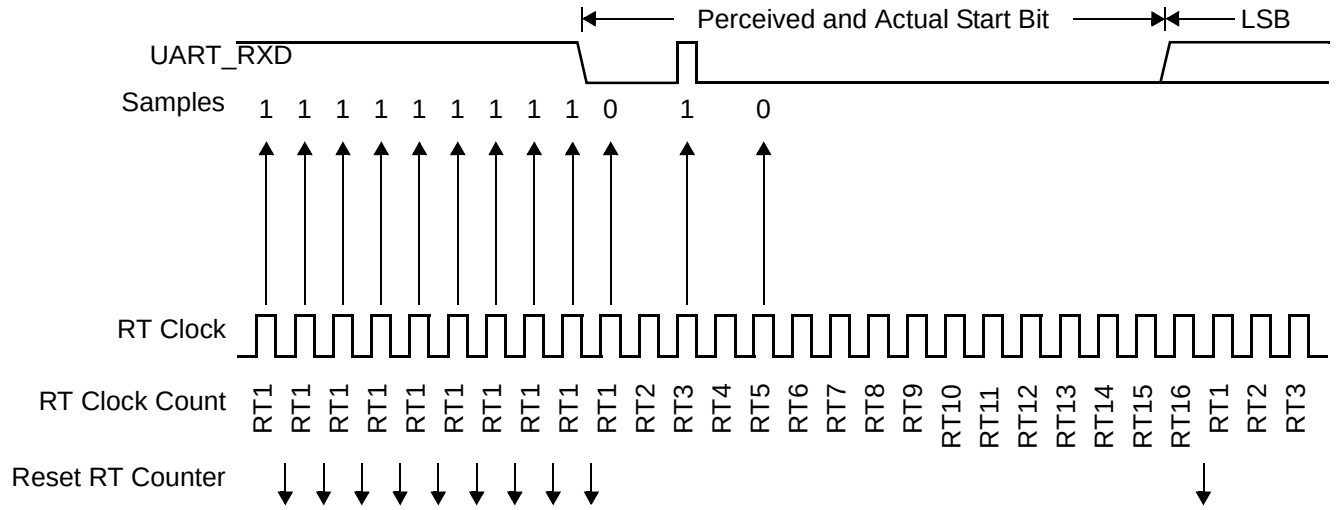

Figure 20-14. Start Bit Search Example 5

Figure 20-15 shows a burst of noise near the beginning of the start bit that causes the start bit not to be found and resets the RT counter. The sample after the reset is low but is not preceded by three high samples that would qualify as a falling edge. Depending on the timing of the start bit search and on the data, the frame may be missed entirely or it may set the framing error flag.

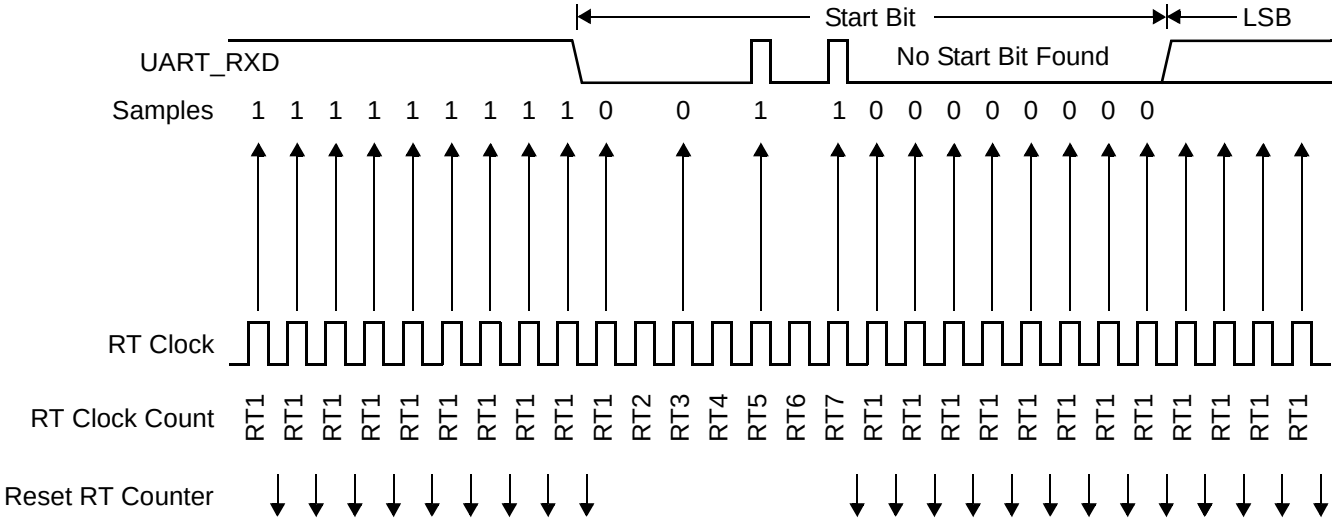

Figure 20-15. Start Bit Search Example 6

In **Figure 20-16**, a noise burst makes the majority of data samples RT8, RT9, and RT10 high. This sets the noise flag but does not reset the RT counter. In the start bits only, the RT8, RT9, and RT10 data samples are not used for determining bit value.

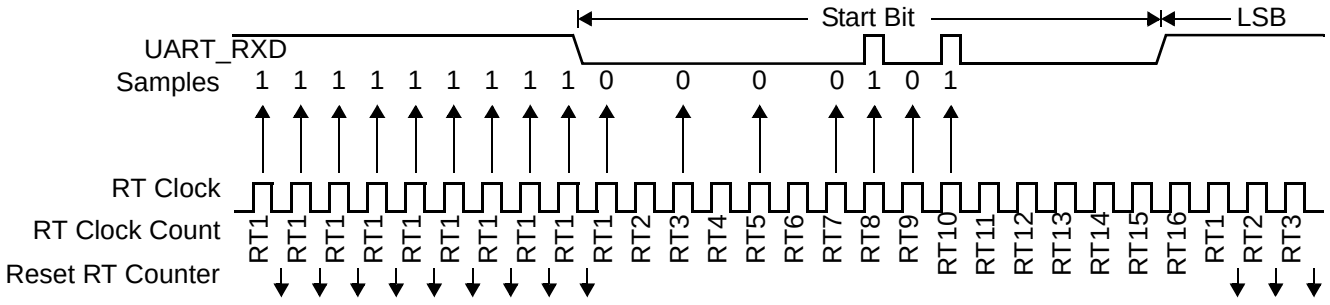

Figure 20-16. Start Bit Search Example 7

20.2.3 Framing Error

If the data sampling logic does not detect a logic 1 where the stop bit should be in an incoming frame, it sets the framing error flag, SCISR[FE]. A break character also sets the FE flag because a break character has no stop bit. The FE flag is set at the same time that the RDRF flag is set. FE inhibits further data reception until it is cleared. Clear SCISR[FE] by reading SCISR and then reading the SCIDR.

20.2.4 Parity Error

The UART can be configured to enable parity check via the Parity Enable (PE) bit in the SCICR. The parity type (SCICR[PT]) determines whether to check for even or odd parity. The Parity Error Flag, SCISR[PF], is set when the parity enable bit is set and the parity of the received character does not match the PT bit. Clear SCISR[PF] by reading the SCISR and then reading SCIDR.

20.2.5 Break Characters

The UART recognizes a break character as a start bit followed by 8 or 9logic 0 data bits and a logic 0 stop bit. Receiving a break character has the following effects on UART registers:

1. The framing error flag (SCISR[FE]) is set.
2. The receive data register full flag (SCISR[RDRF]) is set.

Note: Once the RDRF flag is cleared after being set by a break character, a valid frame must set the RDRF flag again before another break character can set it again.

3. The SCIDR is cleared.
4. The overrun flag (OR), noise flag (NF), parity error flag (PF), or the receiver active flag (RAF) is set (see the discussion in **Section 20.6**).

20.2.6 Baud-Rate Tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples (RT8, RT9, and RT10) to fall outside the actual stop bit. A noise error occurs if the RT8, RT9, and RT10 samples are not all the same logical values. A framing error occurs if the receiver clock is misaligned so that the majority of the RT8, RT9, and RT10 stop bit samples are a logic zero. In most applications, the baud-rate tolerance is much more than the degree of misalignment that is likely to occur.

As the receiver samples an incoming frame, it resynchronizes the RT clock on any valid falling edge within the frame. Resynchronization within frames corrects a misalignment between transmitter bit times and receiver bit times.

20.2.6.1 Slow Data Tolerance

Figure 20-17 shows how much a slow received frame can be misaligned without causing a noise error or a framing error. The slow stop bit begins at RT8 instead of RT1 but arrives in time for the stop bit data samples at RT8, RT9, and RT10.

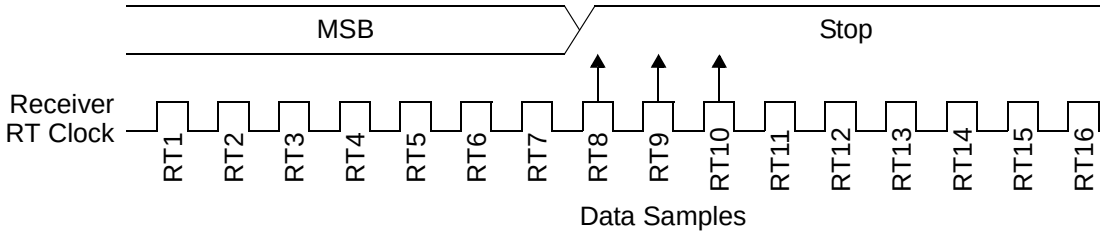

Figure 20-17. Slow Data

For an 8-bit data character, data sampling of the stop bit takes the receiver 9 bit × 16 RT cycles +10 RT cycles =154 RT cycles. With the misaligned character shown in **Figure 20-17**, the receiver counts 154 RT cycles at the point when the count of the transmitting device is 9 bit × 16 RT cycles + 3 RT cycles = 147 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a slow 8-bit data character with no errors is:

$$((154 - 147) / 154) \times 100 = 4.54\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 10 bit × 16 RT cycles + 10 RT cycles = 170 RT cycles. With the misaligned character, the receiver counts 170 RT cycles at the point when the count of the transmitting device is 10 bit × 16 RT cycles + 3 RT cycles = 163 RT cycles. The maximum percent difference between the receiver count and the transmitter count of a slow 9-bit character with no errors is:

$$((170 - 163) / 170) \times 100 = 4.12\%$$

20.2.6.2 Fast Data Tolerance

Figure 20-18 shows how much a fast received frame can be misaligned without causing a noise error or a framing error. The fast stop bit ends at RT10 instead of RT16, but it is still sampled at RT8, RT9, and RT10.

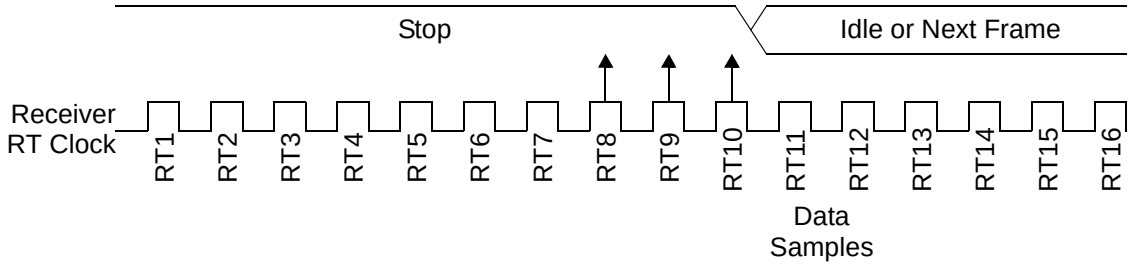

Figure 20-18. Fast Data

For an 8-bit data character, data sampling of the stop bit takes the receiver 9 bit times × 16 RT cycles + 10 RT cycles = 154 RT cycles. With the misaligned character shown in Figure 20-18, the receiver counts 154 RT cycles at the point when the count of the transmitting device is 10 bit times × 16 RT cycles = 160 RT cycles.

The maximum percent difference between the receiver count and the transmitter count of a fast 8-bit character with no errors is:

$$((154 - 160) / 154) \times 100 = 3.90\%$$

For a 9-bit data character, data sampling of the stop bit takes the receiver 10 bit × 16 RT cycles + 10 RT cycles = 170 RT cycles. With the misaligned character, the receiver counts 170 RT cycles at the point when the count of the transmitting device is 11 bit × 16 RT cycles = 176 RT cycles. The maximum percent difference between the receiver count and the transmitter count of a fast 9-bit character with no errors is:

$$((170 - 176) / 170) \times 100 = 3.53\%$$

20.2.7 Receiver Wake-Up

The receiver can be put into a standby state, so that the UART (SCI) can ignore transmissions intended only for other receivers in multiple-receiver systems. This is sometimes called putting the receiver to sleep. Setting the receiver wake-up (RWU) bit in the SCICR puts the receiver into a standby state during which receiver interrupts are disabled. The SCI still loads the receive data into the SCIDR, but it does not set the SCISR[RDRF] flag or any other flag. The transmitting device can address messages to selected receivers by including addressing information in the initial frame or frames of each message. Once the receiver is asleep, there must be a wake-up procedure to allow it to respond to messages addressed to it. The SCICR[WAKE] bit determines how the SCI is brought out of the standby state to process an incoming message. This wake bit enables either idle line wake-up or address mark wake-up.

20.2.7.1 Idle Input Line Wake-Up (WAKE = 0)

In idle input line wake-up, an idle condition on UART_RXD (all logic 1s) clears the SCICR[RWU] bit and wakes up the SCI. The initial frame or frames of every message contain addressing information. All receiver software evaluate the addressing information, and receivers for which the message is addressed process the frames that follow. Any receiver for which a message is not addressed can set its SCICR[RWU] bit and return to the standby state. The RWU bit remains set and the receiver remains on standby until another idle character appears on UART_RXD.

Idle line wake-up requires that messages be separated by at least one idle character and that no message contain idle characters. The idle character that wakes a receiver does not set the receiver idle bit, IDLE, or the receive data register full flag, SCISR[RDRF]. The idle line type bit, SCICR[ILT], determines whether the receiver begins counting logic 1s as idle character bits after the start bit or after the stop bit.

Note: With the WAKE bit clear, setting the SCICR[RWU] bit after UART_RXD has been idle can cause the receiver to wake up immediately.

20.2.7.2 Address Mark Wake-Up (WAKE = 1)

In address mark wake-up, a logic 1 in the MSB position of a frame clears the SCICR[RWU] bit and wakes up the SCI. This frame is considered to contain an address character. Hence, all data characters should have their MSB at zero. Each receiver software evaluates the addressing information when awakened and compares it to its own address. If the addresses match, the receiver(s) process the frames that follow. If the addresses do not match, the receiver software puts the receiver to sleep by setting the SCICR[RWU] bit. The RWU bit remains set and the receiver remains on standby until another address frame appears on UART_RXD.

The logic 1 in the MSB of an address character clears the receiver RWU bit before the stop bit is received and sets the SCISR[RDRF] interrupt flag. Address mark wake-up allows messages to contain idle characters but requires that the MSB be reserved for use in address frames.

20.3 Reset Initialization

After reset the UART transmitter and receiver are disabled and UART_TXD and UART_RXD are not driven. For information on initializing the transmitter, refer to **Section 20.1.1**. For information on initializing the receiver, refer to **Section 20.2.1**.

20.4 Modes of Operation

The following sections summarize the UART modes of operation.

20.4.1 Run Mode

Run mode is the normal mode of operation.

20.4.2 Single-Wire Operation

Normally, the UART (SCI) uses two signals for transmitting and receiving data. In single-wire operation, UART_RXD is disconnected from the UART and is available as a GPIO signal (see **Chapter 21**, *GPIO*). The UART uses UART_TXD for both receiving and transmitting data. Setting the data direction bit for UART_TXD, SCIDDR[DDRTX], configures UART_TXD as the output for transmitted data. Clearing the data direction bit, SCIDDR[DDRTX], disables the transmitter to drive UART_TXD.

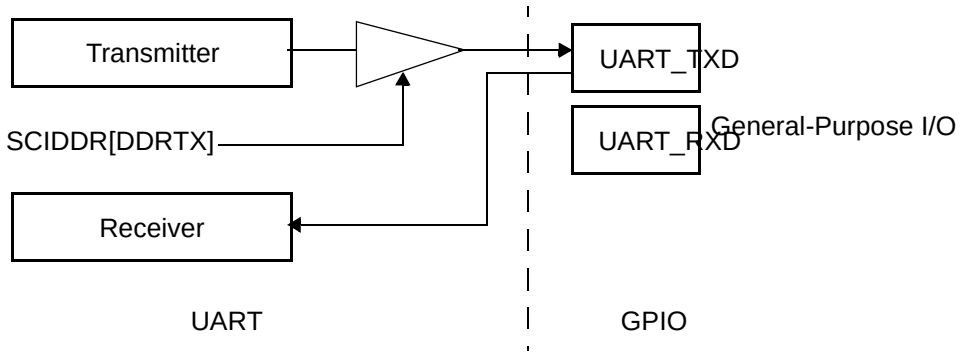

Figure 20-19. Single-Wire Operation (LOOPS = 1, RSRC = 1)

Enable single-wire operation by setting the SCICR[LOOPS] bit and the receiver source bit, SCICR[RSRC]. Setting the SCICR[LOOPS] bit disables the path from UART_RXD to the receiver. Setting the SCICR[RSRC] bit connects the receiver input to the output of UART_TXD. Both the transmitter and receiver must be enabled (SCICR[TE] = 1 and SCICR[RE] = 1). You can configure UART_TXD (see **Chapter 21**, *GPIO*) for full CMOS drive or for open-drain drive. The configuration bit controls UART_TXD in both normal operation and single-wire operation. The configuration bit also allows the UART_TXD outputs to be tied together in a multiple-transmitter system, which allows the UART_TXD signals of nonactive transmitters to follow the logic level of an active one. External pull-up resistors are necessary when using open-drain outputs.

20.4.3 Loop Operation

To help isolate system problems, the Loop mode is sometimes used to check software without changing the physical connections in the external system. In Loop mode, the transmitter output is connected to the receiver input internally. The UART_RXD signal is disconnected from the external connection which then becomes available for use as a GPIO signal. Clearing the data direction bit of UART_TXD disconnects the transmitter output from the external connection.

To enable loop operation, set the SCICR[LOOPS] bit and clear SCICR[RSRC]. Setting the SCICR[LOOPS] bit disables the path from UART_RXD to the external output connection. Clearing the SCICR[RSRC] bit connects the transmitter output to the receiver input. Both the transmitter and receiver must be enabled (SCICR[TE] = 1 and SCICR[RE] = 1) for loop operation.

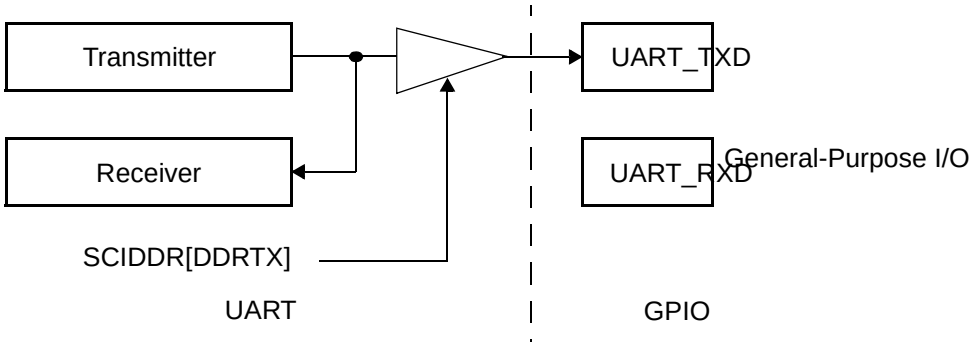

Figure 20-20. Loop Operation (LOOPS = 1, RSRC = 0)

20.4.4 Stop Mode

The UART stops its clock to provide reduced power consumption when the GCR1[UART_STC] bit is set (see **Section 8.2.1**, *General Configuration Register 1 (GCR1)*, on page 8-3). When the UART enters Stop mode, the states of the UART registers are unaffected. The UART registers cannot be accessed during Stop mode. When the UART_STC bit is cleared, UART operation resumes. Entering Stop mode during a transmission or reception results in invalid data. Therefore, disable the receiver and transmitter (SCICR[TE] = 0, SCICR[RE] = 0) before entering Stop mode.

20.4.5 Receiver Standby Mode

Refer to **Section 21.2.7**, *Receiver Wake-Up*.

20.5 Interrupt Operation

Table 20-7 lists the five interrupts generated by the UART to communicate with an SC3850 core or external host.The UART outputs only one signal, which can be activated by each of the five interrupt sources (refer to **Figure 20-1**, *UART Interface*, on page 20-1). Receiver interrupts are disabled when the receiver is in standby state (RWU is set).

Table 20-7. UART Interrupt Sources

Source	Transmitter/ Receiver	Interrupt Enable Bit	Flag at Status Register	Description
TDRE	T	TIE:SCICR[7]	TDRE:SCISR[15]	Indicates that a character was transferred from SCIDR to the transmit shift register.
TC	T	TCIE:SCICR[6]	TC:SCISR[14]	Indicates that a transmit is complete.
RDRF	R	RIE:SCICR[5]	RDRF:SCISR[13]	Indicates that received data is available in SCIDR.
OR	R	RIE:SCICR[5]	OR:SCISR[11]	Indicates an overrun condition.
IDLE	R	ILIE:SCICR[4]	IDLE:SCISR[12]	Indicates that receiver input has become idle.
Note: For details, refer to SCI Status Register (SCISR), on **page 20-29**				

The UART (SCI) only originates interrupt requests. An interrupt source flag (see **Table 20-7**) generates interrupt request if its associated interrupt enable bit is set. The interrupt vector offset and interrupt number are chip dependent.

20.6 UART Programming Model

All UART registers are mapped into the MBus address space. This section describes the UART (SCI) module registers, which are listed as follows:

- SCI Baud-Rate Register (SCIBR), on **page 20-25**.
- SCI Control Register (SCICR), on **page 20-26**.
- SCI Status Register (SCISR), on **page 20-29**.
- SCI Data Register (SCIDR), on **page 20-31**.
- SCI Data Direction Register (SCIDDR), on **page 20-32**.

Note: The UART register use a base address of: 0xFFF26C00.

20.6.1 SCI Baud-Rate Register (SCIBR)

SCIBR SCI Baud-Rate Register Offset 0x00

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—			SBR12	SBR11	SBR10	SBR9	SBR8	SBR7	SBR6	SBR5	SBR4	SBR3	SBR2	SBR1	SBR0
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

SCIBR determines the SCI baud rate. A write to SCIBR[12–8] has no effect without a write to SCIBR[7–0], since writing to SCIBR[12–8] puts the data in a temporary location until SCIBR[7–0] is written.

Note: The formula for calculating the baud rate is: SCI baud rate = (System Peripherals clock/2)/(16 × BR).

Note: The baud-rate generator is disabled until the SCICR[TE] bit or the SCICR[RE] bit is set for the first time after reset. The baud-rate generator is disabled when BR = 0.

Table 20-8. SCIBR Bit Descriptions

Name	Reset	Description	Settings
— 31-13	0	Reserved. Write to zero for future compatibility.	
SBR[12–0] 12-0	4	**SCI Baud Rate** The baud-rate register used by the counter to determine the baud rate of the SCI.	Can contain a value from 1 to 8191.

20.6.2 SCI Control Register (SCICR)

SCICR SCI Control Register Offset 0x08

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LOOPS	—	RSRC	M	WAKE	ILT	PE	PT	TIE	TCIE	RIE	ILIE	TE	RE	RWU	SBK
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 20-9. SCICR Bit Descriptions

Name	Reset	Description	Settings
— 31–16	0	Reserved. Write to zero for future compatibility.	
LOOPS 16	0	**Loop Select Bit** Disables the path from UART_RXD to the receiver input for loop (RSRC = 0) or single-wire mode (RSRC =1). See **Table 20-10**. The transmitter and the receiver must be enabled to use the loop functions. The receiver input is determined by the RSRC bit. The transmitter output is controlled by SCIDDR[DDRTX] bit. If the data direction bit (SCIDDR[DDRTX]) for UART_TXD is set and LOOPS = 1, the transmitter output drives UART_TXD. If the data direction bit is clear and LOOPS =1, the SCI transmitter does not drive UART_TXD.	1 Loop operation enabled. 0 Normal operation enabled.
— 14	0	Reserved. Write to zero for future compatibility.	
RSRC 13	0	**Receiver Source Bit** When LOOPS = 1, determines the internal feedback path for the receiver.	1 Receiver input connects to UART_TXD. 0 Receiver input internally connected to transmitter output.
M 12	0	**Data Format Mode Bit** Determines whether data characters are eight or nine bits long.	1 One start bit, nine data bits, one stop bit. 0 One start bit, eight data bits, one stop bit.
WAKE 11	0	**Wake** Determines which condition wakes up the SCI: a logic 1 (address mark) in the most significant bit position of a received data character or an idle condition on UART_RXD (10 consecutive logic 1s if M = 0 or 11 consecutive logic 1s if M=1).	1 Address mark wake-up. 0 Idle line wake-up.

Table 20-9. SCICR Bit Descriptions (Continued)

Name	Reset	Description	Settings
ILT 10	0	**Idle Line Type Bit** Determines when the receiver starts counting logic 1s as idle character bits. The counting begins either after the start bit or after the stop bit. If the count begins after the start bit, then a string of logic 1s preceding the stop bit may cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions.	1 Idle character bit count begins after stop bit. 0 Idle character bit count begins after start bit.
PE 9	0	**Parity Enable Bit** Enables the parity function. When enabled, the parity function inserts (when transmitter enabled) and checks (when receiver enabled) a parity bit at the most significant bit position.	1 Parity function enabled. 0 Parity function disabled.
PT 8	0	**Parity Type Bit** Determines whether the SCI generates and checks for even parity or odd parity. With even parity, an even number of 1s clears the parity bit and an odd number of 1s sets the parity bit. With odd parity, an odd number of 1s clears the parity bit and an even number of 1s sets the parity bit.	1 Odd parity. 0 Even parity.
TIE 7	0	**Transmitter Interrupt Enable** Enables the transmit data register empty flag, TDRE, to generate interrupt requests. **Note:** Since SCISR[TDRE] reset value is 1, setting TIE immediately after reset results in a UART interrupt request, regardless of SCICR[TE].	1 TDRE interrupt source enabled. 0 TDRE interrupt source disabled.
TCIE 6	0	**Transmission Complete Interrupt Enable** Enables the transmission complete flag, TC, to generate interrupt requests. **Note:** Since the SCISR[TC] reset value is 1, setting TCIE immediately after reset results in a UART interrupt request, regardless of SCICR[TE].	1 TC interrupt source enabled. 0 TC interrupt source disabled.
RIE 5	0	**Receiver Full Interrupt Enable** Enables the receive data register full flag, RDRF, and the overrun flag, OR, to generate interrupt requests.	1 RDRF and OR interrupt sources enabled. 0 RDRF and OR interrupt sources disabled.
ILIE 4	0	**Idle Line Interrupt Enable** Enables the idle line flag, IDLE, to generate interrupt requests.	1 IDLE interrupt source enabled. 0 IDLE interrupt source disabled.
TE 3	0	**Transmitter Enable** Enables the SCI transmitter. The TE bit can be used to queue an idle preamble.	1 Transmitter enabled. 0 Transmitter disabled.
RE 2	0	**Receiver Enable** Enables the SCI receiver.	1 Receiver enabled. 0 Receiver disabled.

Table 20-9. SCICR Bit Descriptions (Continued)

Name	Reset	Description	Settings
RWU 1	0	**Receiver Wake-Up** Enables the wake-up function and inhibits further receiver interrupt requests. Normally, hardware wakes the receiver by automatically clearing RWU.	1 RWU, Standby state. 0 Normal operation.
SBK 0	0	**Send Break** Toggling this bit sends one break character (10 or 11 logic 0s). Toggling implies clearing the SBK bit before the break character has finished transmitting. As long as SBK is set, the transmitter continues to send break characters.	1 Transmit break characters. 0 No break characters.

Table 20-10. Loop Functions

LOOPS	RSRC	SCIDDR[DDRTX]	Function
0	x	x	Normal operation
1	0	0	Loop mode, UART_TXD is not driven by the SCI transmitter
1	0	1	Loop mode, UART_TXD is driven by the SCI transmitter
1	1	0	Single-wire mode UART_TXD acting as an input for the received data. The external connection that UART_RXD shares can be configured as a GPIO.
1	1	1	Single-wire mode with UART_TXD acting as an output for the transmitted data. The transmitted data is also internally connected to the receiver input. The external connection that UART_RXD shares can be configured as a GPIO.
Note: See **Chapter 21**, *GPIO* for details on configuring the signal multiplexing.			

20.6.3 SCI Status Register (SCISR)

SCISR SCI Status Register Offset 0x10

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TDRE	TC	RDRF	IDLE	OR	NF	FE	PF	—							RAF
Type	R								R/W							R
Reset	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SCISR can be read any time. A write has no meaning or effect.

Table 20-11. SCISR Bit Descriptions

Name	Reset	Description	Settings
— 31–16	0	Reserved. Write to zero for future compatibility.	
TDRE 15	1	**Transmit Data Register Empty Flag** Set when the transmit shift register receives a character from the SCI data register. When TDRE is 1, the transmit data register (SCIDR) is empty and can receive a new value to transmit. This flag can generate an interrupt request (refer to **Section 20.5**). Clear TDRE by reading TDRE and then writing to T[7–0] in the SCIDR.	1 Character transferred to transmit shift register; transmit data register empty. 0 No character transferred to transmit shift register.
TC 14	1	**Transmit Complete Flag** Set low when there is a transmission in progress or when a preamble or break character is loaded. TC is set high when the TDRE flag is set and no data, preamble, or break character is being transmitted. When TC is set, UART_TXD becomes idle (logic 1). This flag can generate an interrupt request (refer to **Section 20.5**). Clear TC by reading TC and then writing to T[7–0] in the SCIDR. TC is cleared automatically when data, preamble, or break is queued and ready to be sent. Also, TC is cleared in the event of a simultaneous set and clear of the TC flag (transmission not complete).	1 No transmission in progress. 0 Transmission in progress.
RDRF 13	0	**Receive Data Register Full Flag** Set when the data in the receive shift register transfers to the SCI data register. This flag can generate an interrupt request (refer to **Section 20.5**). Clear RDRF by reading RDRF bit at SCISR and then reading R[7–0] in the SCIDR. **Note:** Once the RDRF flag is cleared, after it is set by a break or idle character, a valid frame must set the RDRF flag before another break or idle character can set it again.	1 Received data available in SCI data register. 0 Data not available in SCI data register.

Table 20-11. SCISR Bit Descriptions (Continued)

Name	Reset	Description	Settings
IDLE 12	0	**Idle Line Flag** Set when 10 consecutive logic 1s (if M = 0) or 11 consecutive logic 1s (if M = 1) appear on the receiver input. Once the IDLE flag is cleared, a valid frame must again set the RDRF flag before an idle condition can set the IDLE flag.This flag can generate an interrupt request (refer to **Section 20.5**). Clear IDLE by reading IDLE and then reading R[7–0] in the SCIDR. **Note:** When the receiver wake-up bit (RWU) is set, an idle line condition does not set the IDLE flag.	1 Receiver input has become idle. 0 Receiver input is either active now or has never become active since the IDLE flag was last cleared.
OR 11	0	**Overrun Flag** Set when software fails to read the SCI data register before the receive shift register receives the next frame. The OR bit is set immediately after the stop bit has been completely received for the second frame. The data in the shift register is lost, but the data already in the SCI data registers is not affected. This flag can generate an interrupt request (refer to **Section 20.5**). Clear OR by reading OR then reading R[7–0] in the SCIDR.	1 Overrun. 0 No overrun.
NF 10	0	**Noise Flag** Set when the SCI detects noise on the receiver input. NF is set during the same cycle as the RDRF flag but is not set for an overrun. Clear NF by reading NF and then reading R[7–0] in the SCIDR.	1 Noise. 0 No noise.
FE 9	0	**Framing Error Flag** Set when a logic 0 is accepted as the stop bit. FE is set during the same cycle as the RDRF flag but is not set for an overrun. FE inhibits further data reception until it is cleared. Clear FE by reading FE and then reading R[7–0] in the SCIDR.	1 Framing error. 0 No framing error.
PF 8	0	**Parity Error Flag** Set when the parity enable bit, PE, is set and the parity of the received data does not match its parity bit. Clear PF by reading PF and then reading R[7–0] in the SCIDR.	1 Parity error. 0 No parity error.
— 7–1	0	Reserved. Write to zero for future compatibility.	
RAF 0	0	**Receiver Active Flag** Set when the receiver detects a logic 0 during the RT1 time period of the start bit search. RAF is cleared when the receiver detects an idle character.	1 Reception in progress. 0 No reception in progress.

20.6.4 SCI Data Register (SCIDR)

SCIDR SCI Data Register Offset 0x18

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	R8	T8	—						R7/T7	R6/T6	R5/T5	R4/T4	R3/T3	R2/T2	R1/T1	R0/T0
Type	R	R/W	R/W						R[7–0] is R T[7–0] is W							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: In the SCIDR, writing affects only T[8–0]; writing to R[8–0] has no effect.

Table 20-12. SCIDR Bit Descriptions

Name		Reset	Description	Settings
— 31–16		0	Reserved. Write to zero for future compatibility.	
R8 15		0	**Received Bit 8** The ninth data bit received when the SCI is configured for 9-bit data format (M = 1).	
T8 14		0	**Transmit Bit 8** The ninth data bit transmitted when the SCI is configured for 9-bit data format (M = 1).	
— 13–8		0	Reserved. Write to zero for future compatibility.	
7–0	**R[7–0]**	0	**Received Bits 7–0** Received bits seven through zero for 9-bit or 8-bit data formats.	
	T[7–0]		**Transmit Bits 7–0** Transmit bits seven through zero for 9-bit or 8-bit formats.	

Notes:
1. If the value of T8 is the same as in the previous transmission, T8 does not have to be rewritten. The same value is transmitted until T8 is rewritten.
2. In 8-bit data format, only SCIDR[7–9] need to be accessed.
3. When transmitting in 9-bit data format, write to SCIDR[15–0] (one access). Otherwise, write first to T8 and then to the low byte (SCIDR[7–0]).

20.6.5 SCI Data Direction Register (SCIDDR)

SCIDDR SCI Data Direction Register Offset 0x28

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—						DDRTX	—								
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

When LOOPS is cleared and TE is set, UART_TXD is an output regardless of the state of SCIDDR[DDRTX].

Table 20-13. SCIDDR Bit Descriptions

Name	Reset	Description	Settings
— 31–10	0	Reserved. Write to zero for future compatibility.	
DDRTX 9	0	**Data Direction Bit TX** Controls the TX signal direction in single-wire mode (refer to **Section 20.4.2**).	1 If TE=1, TX is driven by the transmitter. Otherwise, if TE=0, UART_TXD is driven by logic 0. 0 UART_TXD is not driven when the transmitter is disabled (TE=0) or when LOOPS=1.
— 8–0	0	Reserved. Write to zero for future compatibility.	
Note: The setting descriptions assume that the UART_TXD signal is configured for UART operation.			

21 Timers

The MSC8157E device includes 3 types of timers:

- *Device-level timers*. Each MSC8157E device contains sixteen 16-bit and eight 32-bit device timers. Each can be used by any of the DSP cores within MSC8157E as well as by an external host. See **Section 21.1** for details.
- *SC3850 DSP core subsystem timers*. Each of the SC3850 DSP core subsystems contain two timers used by the specific DSP core for any required operating system purpose. For details, see the *SC3850 DSP Core Subsystem Reference Manual* available with a signed non-disclosure agreement. Contact your Freescale representative or distributor for details.
- *Software watchdog timers.* The MSC8157E device includes 8 software watchdog timers. Each of the software watchdog timers can be used by any of the cores within MSC8157E as well as by an external host. For details, see **Section 21.3**.

21.1 Device-Level Timers

There are four identical 16-bit quad timer modules and two identical 32-bit quad timers in the MSC8157E device. Each quad timer module contains four identical timer groups (16-bit or 32-bit, respectively) that serve as frequency dividers, clock generators, and event counters. Each 16-bit timer or 32-bit timer group contains a prescaler, a counter, a load register, a hold register, a capture register, two compare registers, and two status and control registers. The timers interface with the MSC8157E inputs/outputs as listed in **Table 21-1** and **Table 21-2**. This document uses the term *timer* to refer to the four internal timers in each module and quad timer to refer to each of the timer modules. The term channel is used in register naming for clarity.

Table 21-1. Device-Level 16-bit Timers Connectivity

Timer Module	Timer Channel	Input Signal Type	Input Signal	Output Type	Output
0	0	External	TMR0	—	—
	1	External	TMR1	External	TMR0
	2	External	CLKIN	—	—
	3	—	—	External	TMR1
1	0	External	TMR0	—	—
	1	External	TMR2	—	—
	2	External	CLKIN	—	—
	3	—	—	External	TMR2

Table 21-1. Device-Level 16-bit Timers Connectivity (Continued)

Timer Module	Timer Channel	Input Signal Type	Input Signal	Output Type	Output
2	0	External	TMR0	—	—
	1	External	TMR3	—	—
	2	External	CLKIN	—	—
	3	—	—	External	TMR3
3	0	External	TMR0	—	—
	1	External	TMR4	—	—
	2	External	CLKIN	—	—
	3	—	—	External	TMR4

Notes:
1. The external inputs list the external signal line connected to the specified timer input. The external outputs connect to the specified timer output. Most of the timer outputs do not connect to an external signal line. Even for cases in which a connection is indicated, the output is not valid unless the output is enabled by the TMRnSCTL[OEN] bit for the timer (see **Section 21.4.1.2**). Inputs and outputs for the TMRn signal lines are multiplexed.
2. Inputs and outputs for the TMRn signal lines are multiplexed. See **Table 3-12*Timer Signals,*** on page 3-24 .
3. Device-level 16-bit timer IP Bus Clock is either the peripherals clock (250 MHz) or the SerDes PLL2 reference clock. See **Section 15.10.53**, *SRDS Bank 1–2 PLL Control Register 0 (SRDSB[1–2]PLLCR0)*, on page 15-96. GCR8[TIMERS_CLKMUX_SEL] determines the IP Bus Clock for all 16-bit device level timers (see **Section 8.2.19**, *General Control Register 8 (GCR8)*, on page 8-33.
4. The inputs chosen for each channel should not run at a frequency that is more than half of the frequency of the Timers internal clock.

Table 21-2. Device-Level 32-bit Timers Connectivity

Timer Module	Timer Channel	Input Signal Type	Input Signal	Output Type	Output
0	0	MUX	mux0	—	—
	1	MUX	mux1	—	—
	2	MUX	mux2	—	—
	3	MUX	mux3	External	TMR5
1	0	MUX	mux4	—	—
	1	MUX	mux5	—	—
	2	MUX	mux6	—	—
	3	MUX	mux7	External	TMR6

Notes:
1. The external inputs list the external signal line connected to the specified timer input. The external outputs connect to the specified timer output. Most of the timer outputs do not connect to an external signal line. Even for cases in which a connection is indicated, the output is not valid unless the output is enabled by the TMR32bnSCR[OEN] bit for the timer (see **Section 21.4.1.2**).
2. Inputs and outputs for the TMRn signal lines are multiplexed. See **Table 3-12*Timer Signals,*** on page 3-24 .
3. Device-level 32-bit timers IP Bus Clock is either the Peripherals Clock (250 MHz) or the SerDes PLL2 reference clock. See **Section 15.10.53**, *SRDS Bank 1–2 PLL Control Register 0 (SRDSB[1–2]PLLCR0)*, on page 15-96. GCR8[TIMERS_32B_CLKMUX_SEL] determines the IP Bus Clock for all 32-bit device level timers (see **Section 8.2.19**, *General Control Register 8 (GCR8)*, on page 8-33.
4. Input multiplexers (mux0 to mux7) are independent multiplexers determining the input per each timer. Each multiplexer has the same input options as can be seen in **Table 8-18*GCR7 Bit Descriptions,*** on page 8-30 . The 32-bit Timer0 inputs are determined by GCR7[TIMER_32B_0_MUX0_SEL to TIMER_32B_0_MUX3_SEL].
5. The inputs chosen for each channel should not run at a frequency that is more than half of the frequency of the Timers internal clock.

21.1.1 Features

Features of the timers include:

- Counters support the following operations:
  - Cascade.
  - Preloading.
  - Count once or continuously.
  - Share input pins.
  - Do capture and compare.
  - Count up or down.
- Count modulo is programmable.
- Maximum count rate is the Timers clock rate when the timer input signals are not used.
- Maximum count rate is half the Timers clock when the timer input signals are used.
- Each counter has a separate prescaler.

21.1.2 Timer Module Architecture

Each quad timer module contains four timers. The block diagram of one 16-bit timer within a quad timer module is shown in **Figure 21-1**. The 32-bit timer block is similar. As the figure shows, the primary clock selector contains a prescaler, primary clock multiplex, and an optional invert. It selects and optionally inverts a clock source for the primary clock. The primary clock can be selected from any of the following:

- Normal clocking:
  - Timers clock
  - Timers clock divided by the prescaler: /1, /2, /4,..., /128.
- Clocking from external events through a timer input signal.
- Clocking in Cascaded mode using an output from another timer in the same quad timer module.

Before a timer is enabled to count events, initialize the timer output signal by writing the desired initialization value to TMRxSCTL[VAL] (page 21-24) and then set the TMRxSCTL[FORC] bit (page 21-24).

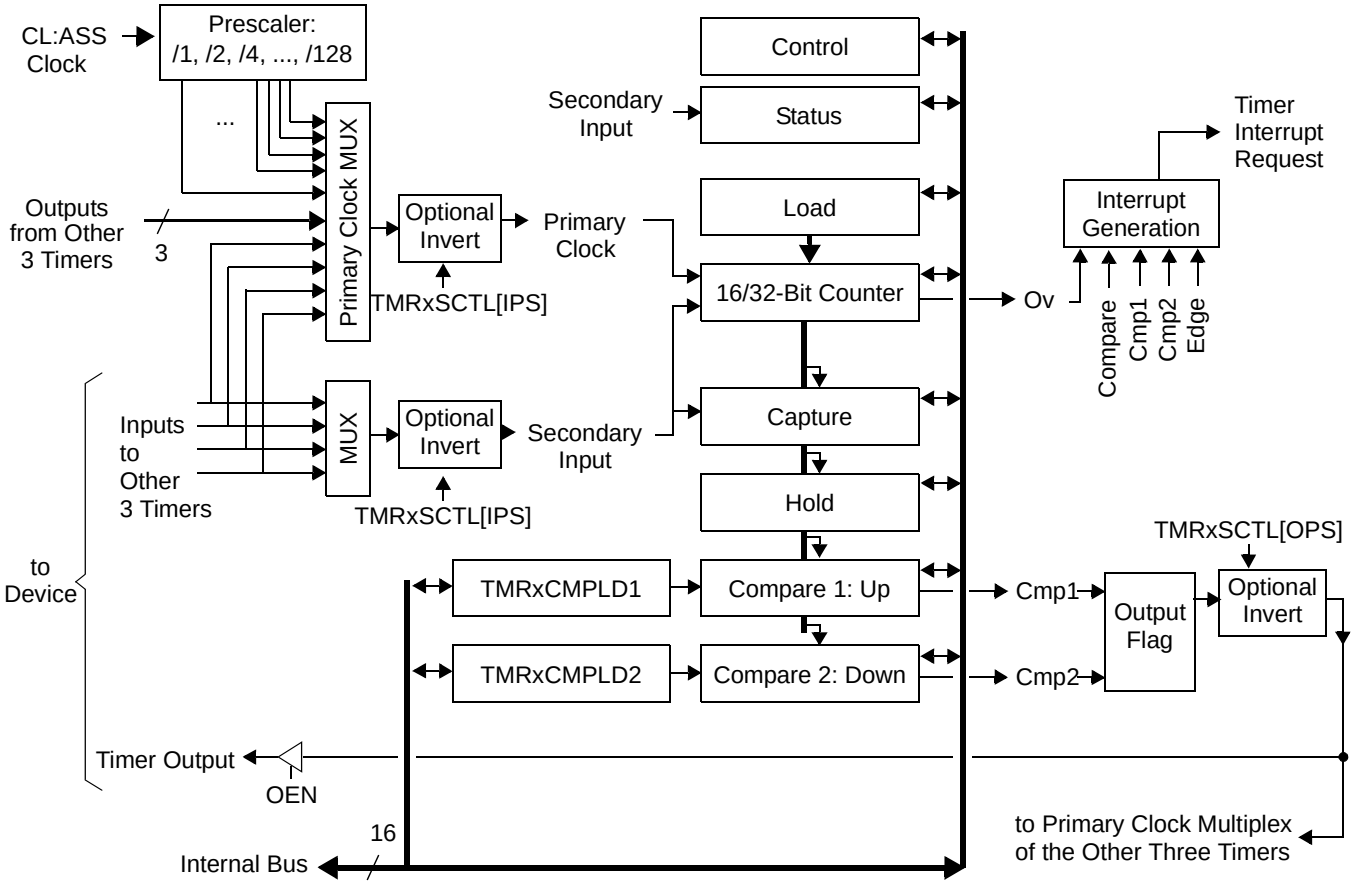

Figure 21-1. 16-Bit Timer Module Block Diagram — One of Four Timers

21.1.3 Setting Up Counters for Cascaded Operation

To create a counter larger than 16 bits, the first timer is programmed for the desired configuration and count mode (it is *not* programmed in Cascade mode). This first timer also programs the TMRxCTL[PCS] field to select the desired primary clock. All other timers in the cascade are simply programmed with their count mode set to Cascade mode (TMRxCTL[CM] = 111). They also program the TMRxCTL[PCS] field using the appropriate timer N output so that each can receive their clocks from the previous timer in the chain. The first timer in the chain must never be programmed in cascade mode. Also, the first timer in the chain must not choose one of the outputs from the timers for its primary clock. All timers in the cascade follow the counting mode of the first timer in the chain. In Cascade mode, a special high-speed signal path is used, bypassing the timer output flag logic to ensure that the cascaded channels operate as a single synchronous counter. You can connect timers using the other (non-cascade) timer modes and selecting the outputs of other timers as a clock source. In this case, the timers operate in a *ripple* mode, in which higher-order counters transition a clock later than in a purely synchronous design.

This is *not* the typical use for cascaded counters.

21.1.3.1 Operation of the Cascaded Timer

If the first timer in a cascaded chain is counting up and it encounters a compare event, the timer connected to it is incremented. If the first timer in the chain is counting down and it encounters a compare event, the timer is decremented. You can correctly read all 16-bit portions of a cascaded timer as follows using the TMRxHOLD registers:

1. Read any 16-bit portion of the cascaded timer from its TMRxCNTR register. You can do this at any time.
2. When any TMRxCNTR register in the module is read, all other timers simultaneously load their values into their hold registers.
3. Read the 16-bit portions of all other timers in the cascade from their TMRxHOLD registers.

21.1.3.2 Cascading Restrictions

To ensure that there are no feedback loops in a cascade, there are restrictions on which timers can be cascaded. The timer with the lowest number must always be the first in the cascade, the timer with the second lowest number must be second, and so on. The timer with the highest number must always be last in the cascade. **Table 21-3** summarizes the cascading restrictions.

Table 21-3. Restrictions On Cascading Timers

Timer Number	Valid Cascade Inputs	Legal Values for Cascading using TMRxCTL[PCS]	Description
Timer 0	None	None	Timer 0 can only be the first timer in a cascaded timer. It cannot receive another timer's output for cascaded operation. Timer 0 must always be the first timer in the cascade.
Timer 1	Timer 0 output	0100: Timer 0	Timer 1 can be cascaded with Timer 0, with Timer 0 as the first timer in the chain.
Timer 2	Timer 0 output Timer 1 output	0100: Timer 0 0101: Timer 1	Timer 2 can be cascaded with Timer 0 or Timer 1 when Timer 2 is not the first timer in the cascade.
Timer 3	Timer 0 output Timer 1 output Timer 2 output	0100: Timer 0 0101: Timer 1 0110: Timer 2	Timer 3 can be cascaded with Timer 0, Timer 1, or Timer 3. Timer 3 must always be the last timer in a cascade.

21.1.4 Timer Operating Modes

The timer operates in two modes:

- Count the Timers clock or external events via the timer input using the primary clock.

- Count the Timers clock or external events via the timer input using the primary clock while a second input signal, the secondary clock, is asserted, thus timing the width of the secondary clock signal.

Each timer can be configured in the following ways:

- to count the rising, falling, or both edges of the selected input pin.
- to decode and count quadrature encoded input signals.
- to count up and down using dual inputs in a count with direction format.
- program the timer terminal count value (modulo).
- program the value loaded into the timer after it reaches its terminal count.
- program the timer to count repeatedly or to stop after completing one count cycle.
- program the timer to count to a programmed value (using the compare functionality) and then immediately reinitialize or to count through the compare value until the count rolls over to zero.

The counting modes define the different modes for clocking the timers. The count mode is selected in the TMRxCTL[CM] field (page 21-22). If a timer is programmed to count to a specific value and then stop, the TMRCTL[CM] bit is cleared when the count terminates. **Table 21-4** summarizes the counting modes.

Table 21-4. Summary of Timer Counting Modes

Counting Mode	CM Bits	Description	Primary Clock	Secondary Clock
Disabled	000	Timer not active.	—	—
Count	001	Counts the rising edges of the selected clock source (falling edges if TMRxSCTL[IPS] is set). This mode is useful for generating periodic interrupts for timing purposes or for counting external events.	Clock*	—
Dual-Edge Count	010	Counts both edges of a timer Input signal. This mode is useful for counting the changes in the external environment. When this mode is selected, TMRxCTL[PCS] must not be set to any value between 1000 and 1111; that is, it must not set to the input clock or any scaled version of the input clock.	Clock	—
Gated Count	011	Counts primary clock edges while the secondary input is high (low if TMRxSCTL[IPS] is set). This mode is used to time the duration of external events when the primary clock is set to the input clock and the secondary input is set to use one of the timer input signals. It can also be used to count the number of external events that occur on one of the timer input signals, set as the primary clock, while a second timer input signal, connected to the secondary Input signal, is asserted.	Clock	Gate*

Table 21-4. Summary of Timer Counting Modes

Counting Mode	CM Bits	Description	Primary Clock	Secondary Clock
Quadrature Count	100	Counts using quadrature encoded signals. The quadrature signals are square waves, 90 degrees out of phase. The decoding of quadrature signal provides both count and direction information. A timing diagram illustrating the basic operation of a quadrature incremental position encoder is provided in **Figure 21-2.**	Quadrature signal	Quadrature signal
Signed Count	101	Counts the primary clock source while a secondary input provides the count direction (up or down) for each recognized count.	Clock to count	Count direction
Triggered Count	110	Counts the primary clock source only after a rising edge is detected on the secondary input (falling edge if TMRxSCTL[IPS] is set). The counting continues until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count is reached, counting stops. Subsequent odd-numbered edges of the secondary input restart the counting, and even numbered edges stop counting. This process continues until a compare event occurs.	Clock to count	Enable/disable timer*
Cascade Count	111	Cascades multiple timers. Cascade mode is used for creating timers larger than 16-bits. Up to four timers may be cascaded together to create a 64-bit wide timer. The Cascaded Timer mode is synchronous. See **Section 21.1.4.2**.	Clock to count	Triggers timer
Note: * This input can be inverted by the TMRxSCTL[IPS] bit.				

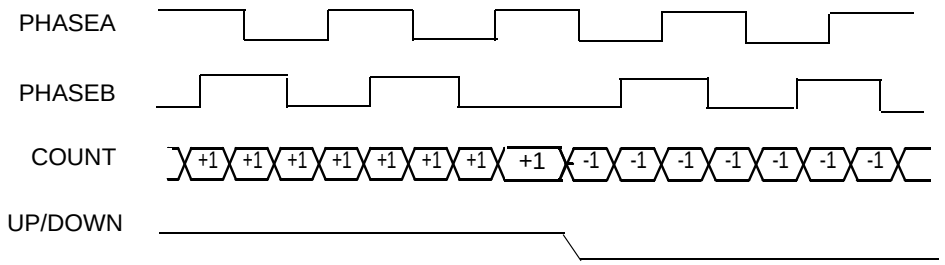

Figure 21-2. Quadrature Incremental Position Encoder

Other count modes derived as special cases of the modes described in **Table 21-4** are described in the remainder of this section.

21.1.4.1 One-Shot Mode

One-Shot mode is a variation on Triggered Count mode if the timer is set up as follows:

- TMRxCTL[CM] = 110 to count the rising and falling edges of the primary source (see **Table 21-6**).

- The Count Length bit, TMRxCTL[LEN] = 1.
- Output Flag mode, TMRxCTL[OFLM] = 101 to select set on compare, cleared on secondary input signal edge.
- The Count Once bit, TMRxCTL[ONCE] = 1 to count till a compare and then stop.

An external event causes the timer to count. When terminal count is reached, the timer output flag is asserted. This delayed output assertion can be used to provide timing delays.

21.1.4.2 Pulse Output Mode

In Pulse Output mode, a variation on Count mode, the timer outputs a stream of pulses with the same frequency as the selected clock source (cannot be the Timers clock/1) if the timer is set up as follows:

- TMRxCTL[CM] = 001 to count the rising edges of the primary source.
  (see **Table 21-6*TMR[0–3]SCTL[0–3] Bit Descriptions,*** on page 21-24).
- The Output Flag Mode, TMRxCTL[OFLM], = 111 to enable gated clock output while the timer is active.
- The Count Once bit, TMRxCTL[ONCE], = 1 to count till a compare and then stop.

The number of output pulses is equal to the compare value minus the initial value. The primary count source must be set to one of the timer outputs for gated clock output mode.

21.1.4.3 Fixed Frequency PWM Mode

Fixed Frequency Pulse Width Modulated (PWM) mode is a subset of Count mode. The timer is set up as follows:

- TMRxCTL[CM] = 001 to count the rising edges of the primary source.
- The Count Length bit, TMRxCTL[LEN], = 0 so that the timer continues counting past the compare value (binary roll-over).
- The Count Once bit, TMRxCTL[ONCE], = 0 to count repeatedly.
- The Output Flag Mode, TMRxCTL[OFLM], = 110 so that the output flag is set when a compare occurs.

The timer output yields a PWM signal with:

- a frequency equal to the count clock frequency divided by 65,536.
- a pulse width duty cycle equal to the compare value divided by 65,536.

21.1.4.4 Variable Frequency PWM Mode

The timer output yields a PWM signal with a frequency and pulse width determined by the values programmed into the TMRxCMP1 and TMRxCMP2 registers and the input clock frequency if the timer is set up as follows:

- TMRxCTL[CM] = 001 TMRxCTL[CM] = 001 to count the rising edges of the primary source (see **Table 21-6**).
- The Count Length bit, TMRxCTL[LEN], = 1 so that the timer counts to the compare value and then reinitializes.
- The Count Once bit, TMRxCTL[ONCE], = 0 to count repeatedly.
- The Output Flag Mode, TMRxCTL[OFLM], = 100 to toggle the timer output flag using alternating compare registers.

This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. The TMRxCMPLD1 and TMRxCMPLD2 registers are especially useful for this mode because they give you time to calculate values for the next PWM cycle during the PWM current cycle.

To set up the timer to run in Variable Frequency PWM mode with compare preload, use the set up described here for the desired timer. During set-up, update the TMRxCTL register last because the timer starts counting if the count mode changes to any value other than 000. Set up the Timer Control (TMRxCTL) register bits as follows:

- Count Mode (CM) = 001 to count the rising edges of the primary source.
- Primary Count Source (PCS) = 1000 to specify the best granularity for waveform timing; prescaler [Timers clock (250 MHz)]/1.
- Secondary Count Source (SCS) = Any value because the bits are ignored in this mode.
- Count Once (ONCE) = 0 to count repeatedly.
- Count Length (LEN) = 1 so that the timer counts till it reaches a compare and then reinitializes the timer register.
- Direction (DIR) = Count up (0) or count down (1). The compare register values must be chosen carefully to account for roll-under and so on.
- External Initialization (EIN) = 0 so that another timer cannot force a reinitialization of this timer. However, you can set this bit if you need the functionality.
- Output Mode (OFLM) = 100 to toggle the timer output flag using alternating compare registers.

Set up the Timer Status and Control Register (TMRxSCTL) bits as follows:

- Output Polarity Select (OPS) = Your choice, true (0) or inverted (1).
- Output Enable (OEN) = 1 to enable the timer output to be put on an external pin. Set this bit as needed.

- Ensure that the rest of the TMRxSCTL bits are cleared. Interrupts are enabled in the Timer Comparator Status and Control Register (TMRxCOMSC) instead of in this register.

Set up the Timer Comparator Status and Control Register (TMRxCOMSC) bits as follows:

- Timer Compare 2 Interrupt Enable (TCF2EN) = 1 to allow an interrupt to be issued when TCF2 is set).
- Timer Compare1 Interrupt Enable (TCF1EN) = 0 so that an interrupt cannot be issued when TCF1 is set.
- Timer Compare 1 Interrupt Source (TCF1) = 0 to clear the timer compare 1 interrupt source flag. This bit is set when a successful comparison of the timer and the TMRxCMP1 register occurs.
- Timer Compare 2 Interrupt Source (TCF2) = 0 to clear the timer compare 2 interrupt source flag. This bit is set when a successful comparison of the timer and the TMRxCMP2 register occurs.
- Compare Load Control 1 (CL1) = 10 to load the compare register when TCF2 is set.
- Compare Load Control 2 (CL2) = 01 to load the compare register when TCF1 is set.

To service the TCF2 interrupts generated by the Timer, the interrupt controller must be configured to enable the interrupts for the timer being used. Additionally, you must write an interrupt service routine to do at least the following:

- Clear the TCF2 and TCF1 flags.
- Calculate and write new values for TMRxCMPLD1[15–0] and TMRxCMPLD2[15–0].

Figure 21-3 shows the timing for the compare preload cycle, which begins when a compare event on TMRxCMP2 causes TCF2 to be set. TMRxCMP1 is loaded with the value in the TMRxCMPLD1 one internal bus clock later. In addition, the timer asserts an interrupt, and the interrupt service routine executes while both comparator load registers are updated with new values. When TCF1 is set, TMRxCMP2 is loaded with the value of the CLV2 bits in TMRxCMPLD2. During the subsequent TCF2 event, TMRxCMP1 is loaded with the value of the TMRxCMPLD1[CLV1] bits. The cycle starts over again as an interrupt is asserted and the interrupt service routine clears TCF1 and TCF2 and calculates new values for TMRxCMPLD1 and TMRxCMPLD2.

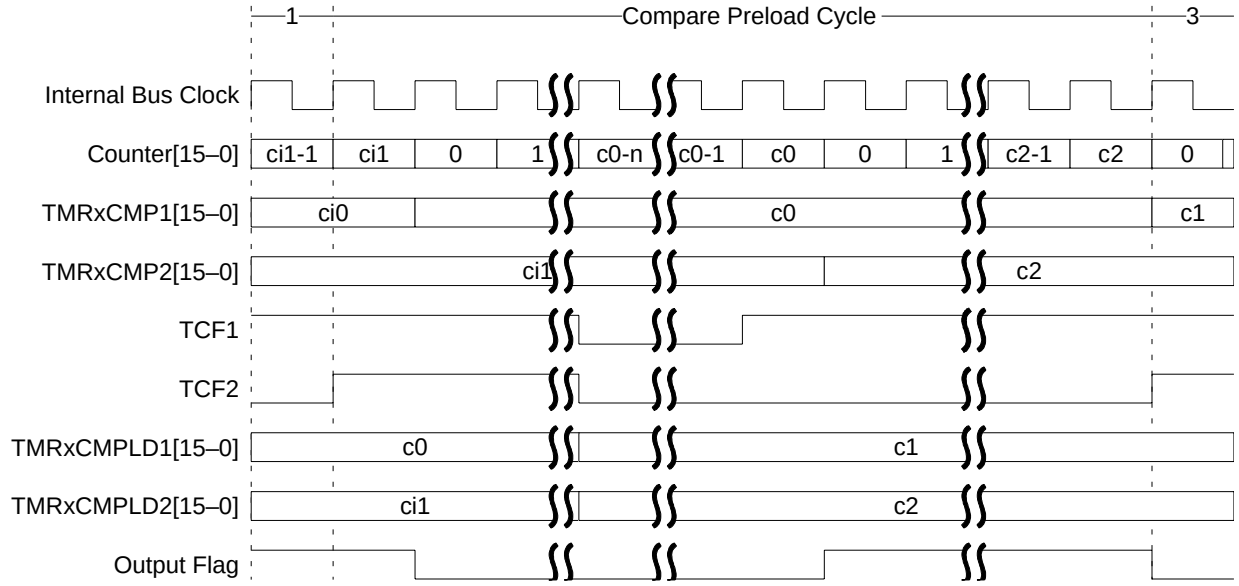

Figure 21-3. Compare Preload Timing

21.1.5 Timer Compare Functionality

The compare registers (TMRxCMP1 and TMRxCMP2) provide a bidirectional modulo count capability. TMRxCMP1 is used when the timer is counting *up*. Program it with the desired maximum count value or to 0xFFFF to indicate the maximum un signed value prior to roll-over. TMRxCMP2 is used when the timer is counting *down*. Program it with the maximum negative count value or to 0x0000 to indicate the minimum unsigned value prior to roll-under. The only exception occurs when the timer is operating with alternating compare registers.

Count until compare and then reinitialize is controlled by CTRL[LENGTH] bit. If set, the counter counts until the value stored at compare register (CMP1 or CMP2, depending on count direction) and at the next trigger the counter will reinitialize.

For counting until a variable value is required, use the following method:

1. Clear CTRL[LENGTH] bit.
2. Set COMSCR[CL1] to 0b01.
3. Set CMP1 to the first compare value (X).
4. Add to CMPLD1 the second compare value (Y), i.e. set CMPLD1 to X+Y.
5. At every compare event, the service routine should add to CMPLD1 the next compare value.
6. Overflow is supported by the counter, that is, when the counter value is 0xFFFF_FFFF the next trigger causes it to rollover to 0x0000_0000.

Note: This method is described is for count-up mode. For count-down mode, instead of COMSCR[CL1], CMP1 and CMPLD1, use COMSCR[CL2], CMP2 and CMPLD2.

When TMRxCTL[OFLM] = 100, alternating values of TMRxCMP1 and TMRxCMP2 are used to generate successful compares, and the output flag toggles while using alternating compare registers. For example, when TMRxCTL[OFLM] = 100, the timer is programmed to count upwards. It counts until the TMRxCMP1 value is reached, reinitializes, then counts until the TMRxCMP2 value is reached, reinitializes, then counts until the TMRxCMP1 value is reached, and so on. In this Variable Frequency PWM mode, the TMRxCMP2 value defines the desired pulse width of the *on-time*, and the TMRxCMP1 register defines the *off-time*. The Variable Frequency PWM mode is defined for positive counting only. See **Section 21.1.4.4**, *Variable Frequency PWM Mode*, on page 21-9.

Use caution when changing TMRxCMP1 and TMRxCMP2 while the timer is active. If the timer has already passed the new value, it counts to 0xFFFF or 0x0000, rolls over/under, and then begins counting toward the new value. The check is for Count = TMRxCMPx, not Count > = TMRxCMP1 or Count < = TMRxCMP2). Use of the preload registers addresses this problem.

21.1.5.1 Compare Preload Registers

The TMRxCMPLD1, TMRxCMPLD2 and TMRxCOMSC registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. The feature is used for updating the CMP1 and CMP2 registers from CMPLD1 and CMPLD2 by hardware whenever a successful compare occurs. To ensure correct functionality, use the loading method described in this section.

Note: When using the Compare Preload feature, never use the Count to Compare and then Reinitialize feature.

The compare preload feature speeds updating of the compare registers. The compare preload feature allows you to calculate new compare values and store them into the comparator preload registers. When a compare event occurs, the new compare values in the comparator preload registers are directly written to the compare registers, eliminating the use of software to do this.

The compare preload feature is used in variable frequency PWM mode. See **Section 21.1.4.4**, *Variable Frequency PWM Mode*, on page 21-9. The TMRxCMP1 register determines the pulse width for the logic low part of the timer output, and TMRxCMP2 determines the pulse width for the logic high part of the timer output. The period of the waveform is determined by the TMRxCMP1 and TMRxCMP2 values and the frequency of the primary clock source.
See **Figure 21-4**.

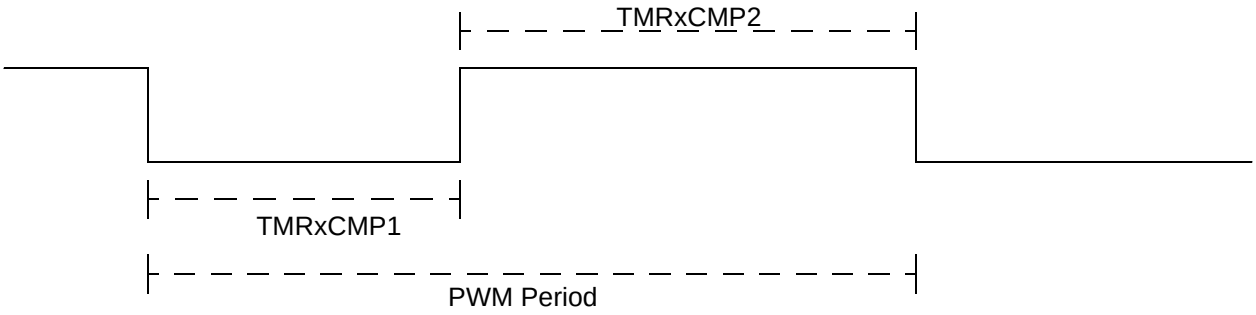

Figure 21-4. Variable PWM Waveform

To update the duty cycle or period of the waveform, update the TMRxCMP1 and TMRxCMP2 values using the compare preload feature.

21.1.5.2 Capture Register Use

The capture register, TMRxCAP (page 21-28), stores a copy of the timer value when an input edge (positive, negative, or both) on the secondary input signal is detected. The capture mode, programmable via TMRxSCTL[CM] (page 21-24), is one of the following:

- CM = 00. Disabled.
- CM = 01. Load the capture register on the *rising* edge of the signal.
- CM = 10. Load the capture register on the *falling* edge of the signal.
- CM = 11. Load the capture register on *either* edge of the signal.

When a capture event occurs, there are no further updates of TMRxCAP until the input edge flag (IEF) is cleared by writing a value of 0 to the TMRxSCTL[IEF] bit (page 21-24).

21.1.5.3 Broadcast from an Initiator Timer

Any timer can be assigned as an initiator. An initiator compares signal can be broadcast to the other timers within the module. The other timers can be configured as follows to reinitialize their timers and/or force their output to predetermined values when an initiator timer compare event occurs:

- Select one timer as the initiator timer by setting the TMRxSCTL[MSTR] bit.
- Program the other timers to perform an action when a compare event occurs on the initiator timer as follows:
  - The other timer is reinitialized if its TMRxCTL[EIN] bit is set.
  - The other timer forces its output flag signal if its TMRxSCTL[EEOF] bit is set.

21.1.6 System Global Timer Register (32b timers only)

The System Global Timer and the System Global Timer Control Registers allow the user to read needed information from the four timer hold registers in one 32-bit read from the System Global

Timer Register. The System Global Timer Control Register permits a highly flexible selection of relevant sections from the four hold registers. The result is a 32-bit register that reflects user-configuration selections from the LSBs of timers 0 to 3. shows a functional diagram of the registers. See **Section 21.4.1.23**, *Timer_32b Global System Timer Register (TMR_32b_n_GLB)*, on page 21-39 and **Section 21.4.1.24**, *Timer_32b Global System Timer Control Register (TMR_32b_n_GLBCTL)*, on page 21-40 for programming details.

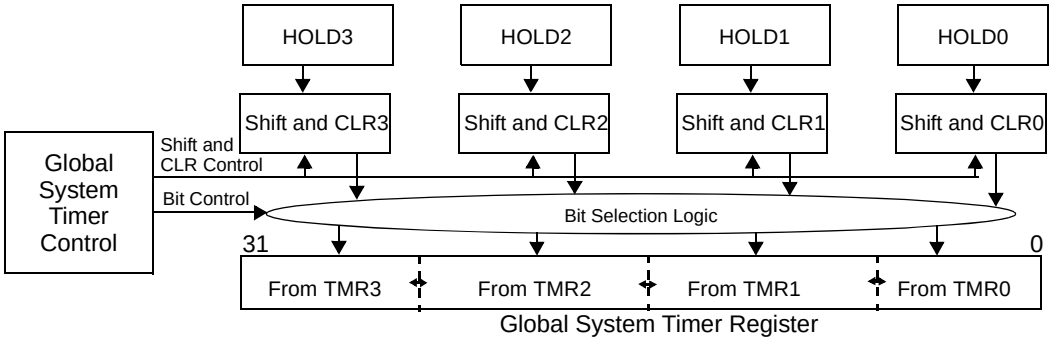

Figure 21-5. Global System Timer Diagram

21.1.7 Resets and Interrupts

The timers reset conditions are shown in **Chapter 5**, *Reset*. This reset forces all registers to their reset state and clears the output flag signal if it is asserted. The timer is turned off until the settings in the control register are changed. Each timer in a quad timer module can be programmed for interrupts. The available types of interrupts are as follows:

- Timer compare
- Timer compare 1
- Timer compare 2
- Timer overflow
- Timer input edge

Each of these different types is ORed together within each timer to generate a single interrupt request signal to the interrupt controller.

21.1.7.1 Timer Compare Interrupts

Interrupt requests are generated when a successful compare occurs between a timer and its compare registers while the Timer Compare Flag Interrupt Enable bit, TMRxSCTL[TCFIE], is set. These interrupt requests are cleared by writing a zero to the appropriate TMRxSCTL[TCF] bit. When a timer compare interrupt is set in the TMRxSCTL and the compare preload registers are available, one of the following two interrupts is also asserted:

- Timer compare 1 interrupt

- Timer compare 2 interrupt

Timer compare 1 interrupts are generated when a successful compare occurs between a timer and its TMRxCMP1 register while the Timer Compare 1 Interrupt Enable (TCF1EN) is set in the TMRxCOMSC register. These interrupts are cleared by writing a zero to the TMRxCOMSC[TCF1] bit. Timer compare 2 interrupts are generated when a successful compare occurs between a timer and its TMRxCMP2 register while the Timer Compare 2 Interrupt Enable (TCF2EN) bit is set in the TMRxCOMSC register. These interrupts are cleared by writing a zero to the TCF2 bit in the TMRxCOMSC.

21.1.7.2 Timer Overflow Interrupts

Timer overflow interrupts are generated when a timer rolls over its maximum value while the TCFIE bit is set in the TMRxSCTL register. These interrupts are cleared by writing a zero to the Timer Overflow Flag (TOF) bit of the appropriate TMRxSCTL.

21.1.7.3 Timer Input Edge Interrupts

Timer input edge interrupts are generated by a transition of the input signal (either positive or negative, depending on TMRxSCTL[IPS] setting) while the Input Edge Flag Interrupt Enable (IEFIE) bit is set in the TMRxSCTL. These interrupts are cleared by writing a zero to the appropriate TMRxSCTL[IEF] bit.

21.1.8 Special CPRI Support

Both the 16-bit and 32-bit timers can be configured to support synchronous CPRI operation using a 122.88 MHz clock multiplexing option as a reference clock. Use the following steps to enable this special mode:

1. Configure the reference clock frequency by writing a “1” to the SRDSB2PLLCR0[RFCK_EN] field. See **Section 15.10.53**, *SRDS Bank 2 Reset Control Register (SRDSB2RSTCTL)*, on page 15-96.
2. For 16-bit timers, select the reference clock by writing a “1” to the GCR8[TIMERS_CLKMUX_SEL] field. See **Section 8.2.19**, *General Control Register 8 (GCR8)*, on page 8-33. To use them, the timers must be enabled by writing a 1 to the TMRnSCTL[OEN] bit (see **Section 21.4.1.2**, *Timer Channel Status and Control Registers (TMRnSCTLx)*, on page 21-24).
3. For 32-bit timers, select the reference clock by writing a “1” to the GCR8[TIMERS_32B_CLKMUX_SEL] field. See **Section 8.2.19**, *General Control Register 8 (GCR8)*, on page 8-33.

Note: See **Table 21-1*Device-Level 16-bit Timers Connectivity,*** on page 21-1 and **Table 21-2*Device-Level 32-bit Timers Connectivity,*** on page 21-2 for configuration details.

21.2 SC3850 DSP Core Subsystem Timers

For a detailed description of the core subsystem timers, see the *SC3850 DSP Core Subsystem Reference Manual.*

21.3 Software Watchdog Timers

There are total of eight identical software watchdog timers (WDTs). Typically, one is used per core and the remainder are used for external hosts. However, you can allocate the WDTs in any manner to meet your system requirements.

The WDT is responsible for asserting a hardware reset or machine-check interrupt (MCP) if the software fails to service the software watchdog timer for a certain period of time (for example, because software is lost or trapped in a loop with no controlled exit). Each WDT is a free-running down-counter that generates a reset or a non-maskable interrupt on underflow. To prevent a reset, software must periodically restart the countdown. Watchdog timer operations are configured in the system watchdog control register (SWCRR). See **Section 21.4.3.1** for details.

Note: If any of the watchdog timers generate a reset, it resets all of the SC3850 core subsystems in the MSC8157E device.

The software watchdog timer is enabled after reset to cause a hard reset or non-maskable interrupt (MCP) if it times out. If the software WDT is not needed, you must clear SWCRR[SWEN] to disable it. If it is used, the software WDT requires a special service sequence that executes periodically. Without this periodic servicing, the software watchdog timer times out and issues a reset or a nonmaskable interrupt, as programmed in SWCRR[SWRI]. Once software writes SWRI, the state of SWEN cannot be changed. **Figure 21-1** shows the high level WDT block diagram.

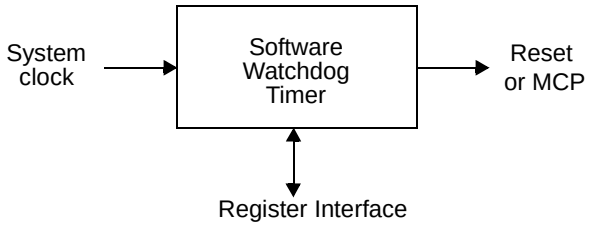

Figure 21-1. Software Watchdog Timer High Level Block Diagram

21.3.1 Features

The key features of the WDT include the following:

- Based on 16-bit prescaler and 16-bit down-counter.
- Provide a selectable range for the time-out period.
- Provide ~8.59 s maximum software time-out delay for 500 MHz input clock.

21.3.2 Modes of Operation

The WDT unit can operate in the following modes:

- WDT enable/disable mode:

  If the software watchdog timer is not needed, user can disable it. SWCRR[SWEN] bit enables the watchdog timer. It should be cleared by software after a system reset to disable the software watchdog timer. When the watchdog timer is disabled, the watchdog counter and prescaler counter are held in a stopped state.

  — WDT enable mode (SWCRR[SWEN] = 1)
  This is the default value after soft reset.

  — WDT disable mode (SWCRR[SWEN] = 0)
  If the software watchdog timer is not needed, the user must clear SWCRR[SWEN] to disable it.

- WDT reset/interrupt output mode

  Without software periodic servicing, the software watchdog timer times out and issues a reset or a nonmaskable interrupt (MCP), programmed in SWCRR[SWRI].

  According to SWCRR[SWRI] programming, WDT timer causes a hard reset or machine check interrupt to the core.

  — Reset mode (SWCRR[SWRI] = 1)
  Software watchdog timer causes a hard reset (this is the default value after soft reset).

  — Interrupt mode (SWCRR[SWRI] = 0)
  Software watchdog timer causes a machine check interrupt to the core.

- WDT prescaled/non-prescaled clock mode

  The WDT counter clock can be prescaled by programming CRR[SWPR] bit that controls the divide-by-65536 of WDT counter.

  — Prescale mode (CRR[SWPR] = 1)
  The WDT clock is prescaled.

  — Non-prescale mode (CRR[SWPR] = 0)
  The WDT clock is not prescaled.

21.3.3 Software WDT Servicing

The software watchdog timer service sequence consists of the following two steps:

- Write 0x556C to the System Watchdog Service Register (SWSRR)
- Write 0xAA39 to SWSRR

The service sequence reloads the watchdog timer and the timing process begins again. If a value other than 0x556C or 0xAA39 is written to the SWSRR, the entire sequence must start over. Although the writes must occur in the correct order before a time-out, any number of instructions

can be executed between the writes. This allows interrupts and exceptions to occur between the two writes when necessary. **Figure 21-6** shows a state diagram for the watchdog timer.

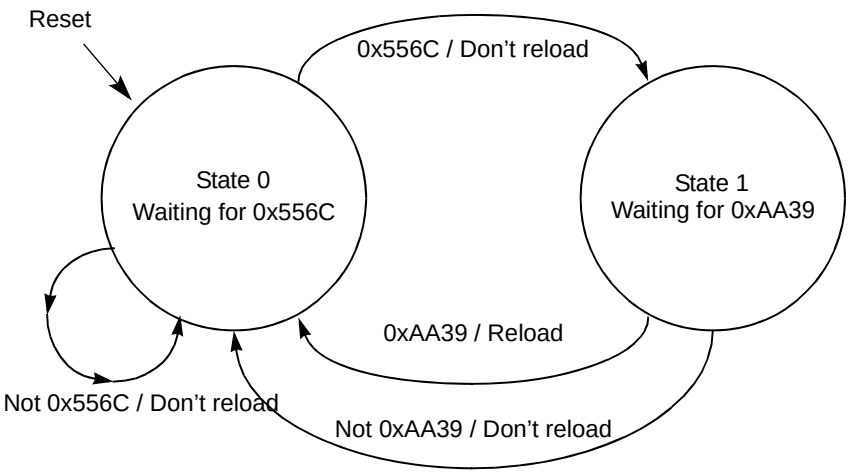

Figure 21-6. Software Watchdog Timer Service State Diagram

Although most software disciplines permit or even encourage the watchdog concept, some systems require a selection of time-out periods. For this reason, the software watchdog timer must provide a selectable range for the time-out period. **Figure 21-7** shows how to handle this need.

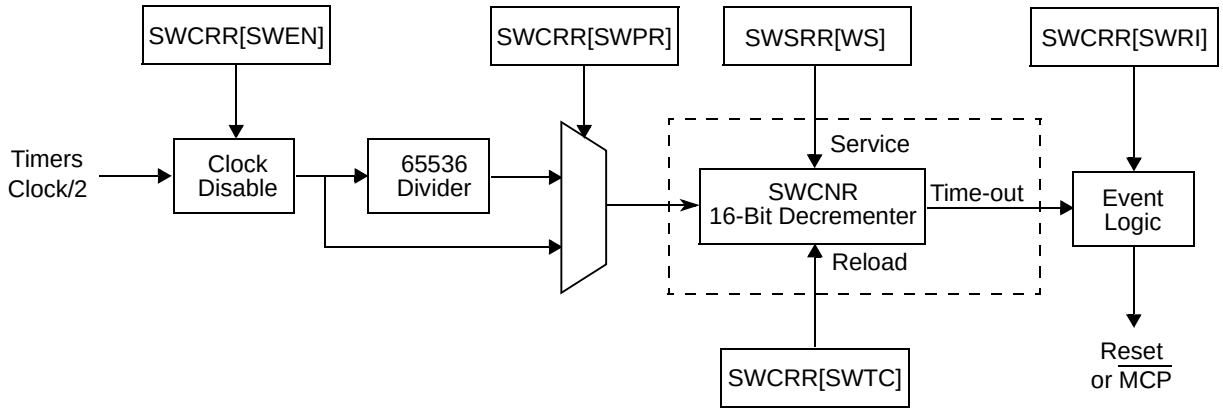

Figure 21-7. Software Watchdog Timer Functional Block Diagram

In **Figure 21-7**, the range is determined by SWCRR[SWTC]. The value in SWTC is then loaded into a 16-bit decrementer clocked by the Timers clock. An additional divide-by-65536 prescaler value is used when needed.

The decrementer begins counting when loaded with a value from SWTC. After the timer reaches 0x0, a software watchdog expiration request is issued to the reset or MCP (machine check

processor) control logic. Upon reset, SWTC is set to the maximum value and is again loaded into the System Watchdog Service Register (SWSRR), starting the process over. When a new value is loaded into SWTC, the software watchdog timer is not updated until the servicing sequence is written to the SWSRR. If SWCRR[SWEN] is loaded with 0, the modulus counter does not count.

21.4 Timers Programming Model

Because they are programmed differently, the device-level, SC3850 DSP core platform level, and software watchdog timers are described in separate subsections.

21.4.1 Device-Level Timers

This section describes the device-level timers. For a complete listing of all registers in all modules with their memory locations, see **Chapter 9**, *Memory Map*. The 16-bit device-level timer registers are listed as follows, along with the pages on which the registers are discussed:

- Timer Channel Control Registers (TMR[0–3]CTL[0–3], page 21-22.
- Timer Channel Status and Control Registers (TMR[0–3]SCTL[0–3]), page 21-24.
- Timer Channel Compare Register 1 (TMR[0–3]CMP1[0–3]), page 21-26.
- Timer Channel Compare Register 2 (TMR[0–3]CMP2[0–3]), page 21-26.
- Timer Channel Compare Load Register 1 (TMR[0–3]CMPLD1[0–3]), page 21-26.
- Timer Channel Compare Load Register 2 (TMR[0–3]CMPLD2[0–3]), page 21-26.
- Timer Channel Comparator Status and Control Registers (TMR[0–3]COMSC[0–3]), page 21-27.
- Timer Channel Capture Register (TMR[0–3]CAP[0–3]), page 21-27.
- Timer Channel Load Register (TMR[0–3]LOAD[0–3]), page 21-28.
- Timer Channel Hold Registers (TMR[0–3]HOLD[0–3]), page 21-28.
- Timer Channel Counter Register (TMR[0–3]CNTR[0–3]), page 21-28.

Note: The base addresses for the device level timer modules are as follows:

- Timer 0 = 0xFFF26000
- Timer 1 = 0xFFF26100
- Timer 2 = 0xFFF26200
- Timer 3 =- 0xFFF26300

The 32-bit device-level timer registers are listed as follows, along with the pages on which the registers are discussed:

- Timer_32b Channel Compare Register 1 (TMR_32b_[0–1]_CMP1[0–3]), page 21-29.
- Timer_32b Channel Compare Register 2 (TMR_32b_[0–1]_CMP2[0–3]), page 21-29.
- Timer_32b Channel Capture Register (TMR_32b_[0–1]_CAP[0–3]), page 21-30.
- Timer_32b Channel Load Register (TMR_32b_[0–1]_LOAD[0–3]), page 21-30.
- Timer_32b Channel Hold Registers (TMR_32b_[0–1]_HOLD[0–3]), page 21-31.
- Timer_32b Channel Counter Register (TMR_32b_[0–1]_CNTR[0–3]), page 21-31.
- Timer_32b Channel Control Registers (TMR_32b_[0–1]_CTL[0–3], page 21-32.
- Timer_32b Channel Status and Control Registers (TMR_32b_[0–1]_SCR[0–3]), page 21-35.
- Timer_32b Channel Compare Load Register 1 (TMR_32b_[0–1]_CMPLD1[0–3]), page 21-37.
- Timer_32b Channel Compare Load Register 2 (TMR_32b_[0–1]_CMPLD2[0–3]), page 21-37.
- Timer_32b Channel Comparator Status and Control Registers (TMR_32b_[0–1]_COMSC[0–3]), page 21-38.
- Timer_32b Global System Timer Register (TMR_32b_[0–1]_GLB), page 21-39
- Timer_32b Global System Timer Control Register (TMR_32b_GLBCTL), page 21-40
- Timer_32b Timer Set and Forget Timer (TMR_32b_[0–1]_SAF), page 21-42
- Timer_32b Timer Clear Lock Register (TMR_32b_[0–1]_CLRL), page 21-43

Note: The base addresses for the device level timer modules are as follows:

- Timer_32b_0 = 0xFFF26400
- Timer_32b_1 = 0xFFF26600

21.4.1.1 Timer Channel Control Registers (TMRnCTLx)

TMR[0–3]CTL[0–3] Timer Control Registers Offset 0x18 + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CM			PCS				SC		ONCE	LEN	DIR	EIN	OFLM		
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21-5. TMR[0–3]CTL[0–3] Bit Descriptions

Name	Reset	Description	Settings
CM 15–13	0	**Count Mode** Control the basic counting behavior of the counter. Rising edges are counted only when TMRxSCTL[IPS] = 0. Falling edges are counted only when TMRxSCTL[IPS] = 1. When count mode 010 is selected, the PCS bits must not be set to 1000–1111. When count mode 111 is selected, the PCS bits must be set to one of the “Timer N output” selections.	000 No operation. Disabled. 001 Count rising edges of the primary source. 010 Count rising and falling edges of the primary source. 011 Count rising edges of the primary source while the secondary input is high active. 100 Quadrature count mode, uses primary clock and secondary input. 101 Count rising edges of the primary clock; secondary input specifies direction (1 = minus). 110 Edge of the secondary input triggers primary count until a compare occurs. 111 Cascaded timer mode (up/down).
PCS 12–9	0	**Primary Count Source** Select the primary count source. A timer selecting its own output for input is not a legal choice. The result is no counting.	0000 Timer 0 input signal. 0001 Timer 1 input signal. 0010 Timer 2 input signal. 0011 Timer 3 input signal. 0100 Timer 0 output for cascaded timer operation. 0101 Timer 1 output for cascaded timer operation. 0110 Timer 2 output for cascaded timer operation. 0111 Timer 3 output for cascaded timer operation. 1000 Prescaler (Timers clock/1). 1001 Prescaler (Timers clock/2). 1010 Prescaler (Timers clock/4). 1011 Prescaler (Timers clock/ 8). 1100 Prescaler (Timers clock/16). 1101 Prescaler (Timers clock/32). 1110 Prescaler (Timers clock/64). 1111 Prescaler (Timers clock/128).

Table 21-5. TMR[0–3]CTL[0–3] Bit Descriptions (Continued)

Name	Reset	Description	Settings
SC 8–7	0	**Secondary Count Source** Provides additional information, such as direction, used for counting. These bits also define the source used by both the Capture mode bits and the input Edge Flag in the Timer Channel Status and Control register. The Timer n input signals are inputs of the timers in the quad timer module.	00 Timer 0 input signal. 01 Timer 1 input signal. 10 Timer 2 input signal. 11 Timer 3 input signal.
ONCE 6	0	**Count Once** Selects continuous or one-shot counting. If counting up, a successful compare occurs when the timer reaches TMRxCMP1 value. If counting down, a successful compare occurs when a timer reaches TMRxCMP2 value.	0 Count repeatedly. 1 Count to the compare value and then stop.
LEN 5	0	**Count Length** Determines whether the timer counts to the compare value and then reinitializes itself, or the timer continues counting past the compare value (binary roll-over). If counting up, a successful compare occurs when the timer reaches the TMRxCMP1 value. If counting down, a successful compare occurs when the timer reaches the TMRxCMP2 value.	0 Roll-over. 1 Count to the compare value and then reinitialize.
DIR 4	0	**Count Direction** Selects either the normal count up direction, or the reverse down direction.	0 Count up. 1 Count down.
EIN 3	0	**External Initialization** Enables another timer within the same module to force the reinitialization of this timer when the other timer has an active compare event. Details on Broadcast mode are presented in **Section 21.1.5.3**, *Broadcast from an Initiator Timer,* on page 21-13.	0 External timers can not force a reinitialization of this timer. 1 External timers may force a reinitialization of this timer.
OFLM 2–0	0	**Output Mode** Determine the mode of operation for the timer output signal. For all of these modes except 000 and 111, the output flag is not toggled when the timer reaches the compare value but instead when the timer advances one value beyond. For example, for a compare value of 7, it toggles on the transition from 7 to 8, not 6 to 7. Unexpected results may occur if the Output mode field is set to use alternating compare registers (mode 100) and the ONCE bit is set.	000 Asserted while timer is active. 001 Clear timer output on successful compare. 010 Set timer output on a successful compare. 011 Toggle the timer output flag when a successful compare occurs. 100 Toggle the timer output flag using alternating compare registers. 101 Set on compare, cleared on secondary input signal's edge. 110 Set on compare, cleared on timer rollover. 111 Enable gated clock output while the timer is active.

21.4.1.2 Timer Channel Status and Control Registers (TMRnSCTLx)

TMR[0–3]SCTL[0–3] Timer Channel Status and Control Register Offset 0x1C + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	TCF	TCFIE	TOF	TOFIE	IEF	IEFIE	IPS	INPUT	CM		MSTR	EEOF	VAL	FORC	OPS	OEN
Type	R/W							R	R/W					W	R/W	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 21-6. TMR[0–3]SCTL[0–3] Bit Descriptions

Name	Reset	Description	Settings
TCF 15	0	**Timer Compare Flag** Set when a successful compare occurs. Clear the bit by writing 0 to it.	0 No successful compare. 1 Successful compare.
TCFIE 14	0	**Timer Compare Flag Interrupt Enable** Enables interrupts when the TCF bit is set.	0 No interrupt. 1 Interrupt.
TOF 13	0	**Timer Overflow Flag** Set when the timer rolls over its maximum value 0xFFFF or 0x0000, depending on count direction. Clear the bit by writing 0 to it.	0 No overflow. 1 Overflow. The timer has reached its maximum or minimum value.
TOFIE 12	0	**Timer Overflow Flag Interrupt Enable** Enables interrupts when the TOF bit is set.	0 No interrupt. 1 Interrupt.
IEF 11	0	**Input Edge Flag** Set when a positive input transition occurs while the timer is enabled. Clear the bit by writing a 0 to it. Setting the input polarity select (TMRxSCTL[IPS]) bit enables the detection of negative input edge transitions. Also, the control register secondary count source determines which external input pin is monitored by the detection circuitry.	0 No action. 1 Positive input transition while timer enabled.
IEFIE 10	0	**Input Edge Flag Interrupt Enable** Enables interrupts when the IEF bit is set.	0 No action. 1 Interrupts enabled.
IPS 9	0	**Input Polarity Select** Inverts the input signal polarity.	0 No action. 1 Invert signal polarity.
INPUT 8	0	**Secondary Input Signal** This bit reflects the current state of the external input pin selected via the secondary count source after application of the IPS bit. This bit is read-only.	0 Low. 1 High.

Table 21-6. TMR[0–3]SCTL[0–3] Bit Descriptions (Continued)

Name	Reset	Description	Settings
CM 7–6	0	**Input Capture Mode** Specifies the operation of the capture register as well as the operation of the input edge flag.	00 Capture function is disabled. 01 Load capture register on the rising edge of the secondary count source input. 10 Load capture register on the falling edge of the secondary count source input. 11 Load capture register on any edge of the secondary count source input.
MSTR 5	0	**Initiator Mode** Enables the compare function output to broadcast to the other timers in the module. This identifies a timer as the initiator timer in Broadcast mode. This signal is used to reinitialize the other timers and/or force their outputs. For details on Broadcast mode, see **Section 21.1.5.3**, *Broadcast from an Initiator Timer,* on page 21-13.	0 No action. 1 Broadcast mode.
EEOF 4	0	**Enable External Output Force** Enables the compare from another timer configured as the initiator to force the state of this timer output signal. For details on Broadcast mode, see **Section 21.1.5.3**, *Broadcast from an Initiator Timer,* on page 21-13.	o No action. 1 Other timer can force this timer's output flag signal.
VAL 3	0	**Forced Output Flag Value** Determines the value of the timer output flag signal when a software-triggered FORCE command occurs.	
FORC 2	0	**Force Output** Forces the current value of the VAL bit to be written to the timer output. Always read this bit as a 0. The VAL and FORCE bits can be written simultaneously in a single write operation. Write to the FORCE bit only if the timer is disabled. Setting this bit while the timer is enabled may yield unpredictable results.	0 No action. 1 Forces the current value of the VAL bit to be written to timer output.
OPS 1	0	**Output Polarity Select** Determines the polarity of the output signal.	0 True polarity. 1 Inverted polarity.
OEN 0	0	**Output Enable** Enables the timer output. The OPS bit determines the polarity of the output.	0 Timer output not enabled. 1 Timer output enabled.

21.4.1.3 Timer Channel Compare 1 Registers (TMRnCMP1x)

TMR[0–3]CMP1[0–3] Timer Channel Compare 1 Registers Offset x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CV															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TMR[0–3]CMP1[0–3] store the comparison value (CV) for comparison with the timer value.

21.4.1.4 Timer Channel Compare 2 Registers (TMRnCMP2x)

TMR[0–3]CMP2[0–3] Timer Channel Compare 2 Registers Offset 0x04 + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CV															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TMR[0–3]CMP2[0–3] store the comparison value (CV) for comparison with the timer value.

21.4.1.5 Timer Channel Compare Load 1 Registers (TMRnCMPLD1x)

TMR[0–3]CMPLD1[0–3] Timer Channel Compare Load 1 Registers Offset 0x20 + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLV1															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TMR[0–3]CMPLD1[0–3] store the preload value for the TMR[0–3]CMP1[0–3].

21.4.1.6 Timer Channel Compare Load 2 Registers (TMRnCMPLD2x)

TMR[0–3]CMPLD2[0–3] Timer Channel Compare Load 2 Registers Offset 0x24 + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CLV2															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TMR[0–3]CMPLD2[0–3] store the preload value for the TMR[0–3]CMP2[0–3].

21.4.1.7 Timer Channel Comparator Status and Control Registers (TMRnCOMSCx)

TMR[0–3]COMSC[0–3] Timer Channel Comparator Status and Control Registers — Offset 0x28 + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—								TCF2EN	TCF1EN	TCF2	TCF1	CL2		CL1	
Type	R								R/W

TMR[0–3]COMSC[0–3] store the preload values used for the TMR[0–3]CMP2[0–3] registers.

Table 21-7. TMR[0–3]COMSC[0–3] Bit Descriptions

Name	Reset	Description	Settings
— 15–8	0	Reserved. Write to 0 for future compatibility.	
TCF2EN 7	0	**Timer Compare 2 Interrupt Enable** Enables the compare 2 interrupt. An interrupt is issued when both this bit and the TCF2 bit are set.	0 No action. 1 Enable compare 2 interrupt.
TCF1EN 6	0	**Timer Compare 1 Interrupt Enable** Enables the compare 1 interrupt. An interrupt is issued when both this bit and the TCF1 bit are set.	0 No action. 1 Enable compare 1 interrupt.
TCF2 5	0	**Timer Compare 2 Interrupt Source** Indicates a successful comparison of the timer and the TMRxCMP2. This bit is sticky and remains set until it is explicitly cleared by writing a zero to this bit location.	0 Normal operation. 1 Successful compare 2.
TCF1 4	0	**Timer Compare 1 Interrupt Source** Indicates a successful comparison of the timer and the TMRxCMP1. This bit is sticky and remains set until it is explicitly cleared by writing a zero to this bit location.	0 Normal operation. 1 Successful compare 1.
CL2 3–2	0	**Compare Load Control 2** Control when TMRxCMP2 is preloaded with the value from TMRxCMPLD2.	00 Never preload. 01 Load upon successful compare with the value in TMRxCMP1. 10 Load upon successful compare with the value in TMRxCMP2. 11 Reserved.
CL1 1–0	0	**Compare Load Control 1** Control when TMRxCMP1 is preloaded with the value from TMRxCMPLD1.	00 Never preload. 01 Load upon successful compare with the value in TMRxCMP1. 10 Load upon successful compare with the value in TMRxCMP2. 11 Reserved.

21.4.1.8 Timer Channel Capture Registers (TMRnCAPx)

TMR[0–3]CAP[0–3] Timer Channel Capture Registers Offset 0x08 + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	CAPV															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TMR[0–3]CAP[0–3] store the values captured from the timers.

21.4.1.9 Timer Channel Load Registers (TMRnLOADx)

TMR[0–3]LOAD[0–3] Timer Channel Load Registers Offset 0x0C + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	LDV															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TMR[0–3]LOAD[0–3] store the value used to load the timer.

21.4.1.10 Timer Channel Hold Registers (TMRnHOLDx)

TMR[0–3]HOLD[0–3] Timer Channel Hold Registers Offset 0x10 + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	HDV															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TMR[0–3]HOLD[0–3] store the value whenever any timer is read.

21.4.1.11 Timer Channel Counter Registers (TMRnCNTRx)

TMR[0–3]CNTR[0–3] Timer Channel Counter Registers Offset 0x14 + x*0x40

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	COUNTER															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

TMR[0–3]CNTR[0–3] are counters.

21.4.1.12 Timer_32b Channel x Compare 1 Registers (TMR_32b_n_CMP1_x)

TMR_32b_[0–1]_CMP1_[0–3] Timer_32b Channel Compare 1 Registers — Offset x*0x40

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 21-8. TMR_32b_[0–1]_CTL[0–3] Bit Descriptions

Name	Reset	Description	Settings
— 31–16	0	Reserved. Write to zero for future compatibility.	
CM 15–13	0	**Count Mode** Control the basic counting behavior of the counter. Rising edges are counted only when TMR_32b_SCR[IPS] = 0. Falling edges are counted only when TMR_32b_SCR[IPS] = 1. When count mode 010 is selected, the PCS bits must not be set to 1000–1111. When count mode 111 is selected, the PCS bits must be set to one of the “Timer N output” selections.	000 No operation. Disabled. 001 Count rising edges of the primary source. 010 Count rising and falling edges of the primary source. 011 Count rising edges of the primary source while the secondary input is high active. 100 Quad count mode, uses primary and secondary sources. 101 Count rising edges of the primary clock; secondary input specifies direction (1 = minus). 110 Edge of the secondary input triggers primary count until a compare occurs. 111 Cascaded timer mode (up/down).

Table 21-8. TMR_32b_[0–1]_CTL[0–3] Bit Descriptions (Continued)

Name	Reset	Description	Settings
PCS 12–9	0	**Primary Count Source** Select the primary count source. A timer selecting its own output for input is not a legal choice. The result is no counting.	0000 Timer 0 input signal. 0001 Timer 1 input signal. 0010 Timer 2 input signal. 0011 Timer 3 input signal. 0100 Timer 0 output. 0101 Timer 1 output. 0110 Timer 2 output. 0111 Timer 3 output. 1000 Prescaler (Timers clock/1). 1001 Prescaler (Timers clock/2). 1010 Prescaler (Timers clock/4). 1011 Prescaler (Timers clock/ 8). 1100 Prescaler (Timers clock/16). 1101 Prescaler (Timers clock/32). 1110 Prescaler (Timers clock/64). 1111 Prescaler (Timers clock/128).
SC 8–7	0	**Secondary Count Source** Provides additional information, such as direction, used for counting. These bits also define the source used by both the Capture mode bits and the input Edge Flag in the Timer Channel Status and Control register. The Timer n input signals are inputs of the timers in the quad timer module.	00 Timer 0 input signal. 01 Timer 1 input signal. 10 Timer 2 input signal. 11 Timer 3 input signal.
ONCE 6	0	**Count Once** Selects continuous or one-shot counting. If counting up, a successful compare occurs when the timer reaches TMR_32b_x_CMP1 value. If counting down, a successful compare occurs when a timer reaches TMR_32b_x_-CMP2 value.	0 Count repeatedly. 1 Count to the compare value and then stop.
LEN 5	0	**Count Length** Determines whether the timer counts to the compare value and then reinitializes itself, or the timer continues counting past the compare value (binary roll-over). If counting up, a successful compare occurs when the timer reaches the TMR_32b_x_CMP1 value. If counting down, a successful compare occurs when the timer reaches the TMR_32b_x_CMP2 value.	0 Roll-over. 1 Count to the compare value and then reinitialize.
DIR 4	0	**Count Direction** Selects either the normal count up direction, or the reverse down direction.	0 Count up. 1 Count down.
COINIT 3	0	**Co-channel Initialization** Enables another timer within the same module to force the reinitialization of this timer when the other timer has an active compare event.	0 Co-channel timers can not force a reinitialization of this timer. 1 Co-channel timers may force a reinitialization of this timer.

Table 21-8. TMR_32b_[0–1]_CTL[0–3] Bit Descriptions (Continued)

Name	Reset	Description	Settings
OM 2–0	0	**Output Mode** Determine the mode of operation for the OFLAG output signal. For all of these modes except 000 and 111, the output flag is not toggled when the timer reaches the compare value but instead when the timer advances one value beyond. For example, for a compare value of 7, it toggles on the transition from 7 to 8, not 6 to 7. Unexpected results may occur if the Output mode field is set to use alternating compare registers (mode 100) and the ONCE bit is set.	000 Asserted while timer is active. 001 Clear OFLAG output on successful compare. 010 Set OFLAG output on a successful compare. 011 Toggle OFLAG output flag when a successful compare occurs. 100 Toggle OFLAG output flag using alternating compare registers. 101 Set on compare, cleared on secondary input signal's edge. 110 Set on compare, cleared on timer rollover. 111 Enable gated clock output while the timer is active.

Note: The base addresses for the 32-bit device level timer modules are as follows:

- Timer_32b_0 = 0xFFF26400
- Timer_32b_1 = 0xFFF26600

21.4.1.19 Timer_32b Channel Status and Control Registers (TMR_32b_n_SCRx)

TMR_32b_[0–1]_SCR[0–3] Timer_32b Channel Status and Control Register — Offset 0x1C + x*0x40

Table 21-9. TMR_32b_[0–1]SCR[0–3] Bit Descriptions

Name	Reset	Description	Settings	
— 31–16	0	Reserved. Write to zero for future compatibility.		
TCF 15	0	**Timer Compare Flag** Set when a successful compare occurs. Clear the bit by writing 0 to it.	0 1	No successful compare. Successful compare.
TCFIE 14	0	**Timer Compare Flag Interrupt Enable** Enables interrupts when the TCF bit is set.	0 1	No interrupt. Interrupt.
TOF 13	0	**Timer Overflow Flag** Set when the timer rolls over its maximum value 0xFFFFFFFF or 0x00000000, depending on count direction. Clear the bit by writing 0 to it.	0 1	No overflow. Overflow. The timer has reached its maximum or minimum value.
TOFIE 12	0	**Timer Overflow Flag Interrupt Enable** Enables interrupts when the TOF bit is set.	0 1	No interrupt. Interrupt.
IEF 11	0	**Input Edge Flag** Set when a positive input transition occurs while the timer is enabled. Clear the bit by writing a 0 to it. Setting the input polarity select (TMR_32b_SCR[IPS]) bit enables the detection of negative input edge transitions. Also, the control register secondary count source determines which external input pin is monitored by the detection circuitry.	0 1	No action. Positive input transition while timer enabled.
IEFIE 10	0	**Input Edge Flag Interrupt Enable** Enables interrupts when the IEF bit is set.	0 1	No action. Interrupts enabled.
IPS 9	0	**Input Polarity Select** Inverts the input signal polarity.	0 1	No action. Invert signal polarity.

Table 21-9. TMR_32b_[0–1]SCR[0–3] Bit Descriptions (Continued)

Name	Reset	Description	Settings
INPUT 8	0	**Secondary Input Signal** Reflects the current state of the secondary Input signal.	00 Capture function disabled. 01 Load capture register on rising edge of the secondary count source input. 10 Load capture register on falling edge of the secondary count source input. 11 Load capture register on any edge of the secondary count source input.
CM 7–6	0	**Input Capture Mode** Specifies the operation of the capture register as well as the operation of the input edge flag.	00 Capture function is disabled. 01 Load capture register on the rising edge of the secondary count source input. 10 Load capture register on the falling edge of the secondary count source input. 11 Load capture register on any edge of the secondary count source input.
MSTR 5	0	**Initiator Mode** Enables the compare function output to broadcast to the other timers in the module. This identifies a timer as the initiator timer in Broadcast mode. This signal is used to reinitialize the other timers and/or force their outputs. For details on Broadcast mode, see **Section 21.1.5.3**, *Broadcast from an Initiator Timer,* on page 21-13.	0 No action. 1 Broadcast mode.
EEOF 4	0	**Enable External Output Force** Enables the compare from another timer configured as the initiator to force the state of this timer output signal. For details on Broadcast mode, see **Section 21.1.5.3**, *Broadcast from an Initiator Timer,* on page 21-13.	o No action. 1 Other timer can force this timer's output flag signal.
VAL 3	0	**Forced Output Flag Value** Determines the value of the timer output flag signal when a software-triggered FORCE command occurs.	
FORC 2	0	**Force Output** Forces the current value of the VAL bit to be written to the timer output. Always read this bit as a 0. The VAL and FORCE bits can be written simultaneously in a single write operation. Write to the FORCE bit only if the timer is disabled. Setting this bit while the timer is enabled may yield unpredictable results.	0 No action. 1 Forces the current value of the VAL bit to be written to timer output.
OPS 1	0	**Output Polarity Select** Determines the polarity of the output signal.	0 True polarity. 1 Inverted polarity.
OEN 0	0	**Output Enable** Enables the timer output. The OPS bit determines the polarity of the output.	0 Timer output not enabled. 1 Timer output enabled.

Note: The base addresses for the 32-bit device level timer modules are as follows:

- Timer_32b_0 = 0xFFF26400

- Timer_32b_1 = 0xFFF26600

Table 21-11. TMR_32b_[0–1]_GSDWCTRL Bit Descriptions

Name	Reset	Description	Settings
DHR3 31	1	**Disable Timer 3 Hold Reflection** Enable/disable Timer 3 hold reflection	0 Enable Timer 3 hold reflection. 1 Disable Timer 3 hold reflection
DHR2 30	1	**Disable Timer 2 Hold Reflection** Enable/disable Timer 2 hold reflection	0 Enable Timer 2 hold reflection. 1 Disable Timer 2 hold reflection
DHR1 29	1	**Disable Timer 1 Hold Reflection** Enable/disable Timer 1 hold reflection	0 Enable Timer 1 hold reflection. 1 Disable Timer 1 hold reflection
DHR0 28	1	**Disable Timer 0 Hold Reflection** Enable/disable Timer 0 hold reflection	0 Enable Timer 0 hold reflection. 1 Disable Timer 0 hold reflection
— 27–21	0	Reserved. Write to zero for future compatibility.	
HR2 20–16	0	**Timer 2 Hold Reflection** This field chooses which bits in the Timer 2 HOLD register to reflect in the TMR_32b_GLB. The number entered in this field is reduced by the number of bits selected by HR0 and HR1 and the result indicates how many Timer 2 HOLD low bits to display in the TMR_32b_GLB.	
— 15–13	0	Reserved. Write to zero for future compatibility.	
HR1 12–8	0	**Timer 1 Hold Reflection** This field chooses which bits in the Timer 1 HOLD register to reflect in the TMR_32b_GLB register. The number entered in this field is reduced by the number specified by HR0 and the result indicates how many Timer 1 HOLD low bits to display in TMR_32b_GLB.	
— 7–5	0	Reserved. Write to zero for future compatibility.	
HR0 4–0	0	**Timer 0 Hold Reflection** This field chooses which bits in the Timer 0 HOLD register to reflect in the TMR_32b_GLB register. The number entered in this field chooses the highest bit to reflect in TMR_32b_GLB, which displays this bit down to the least significant bit in the Timer 0 HOLD register.	

Note: The base addresses for the 32-bit device level timer modules are as follows:

- Timer_32b_0 = 0xFFF26400

- Timer_32b_1 = 0xFFF26600

This register controls which bit from the 4 timer/counters in the timer module are reflected in the TMR_32b_GLB. HR0 takes precedent. If it is configured as 31, then no other timer can have bits displayed. HR1 is next and if it is larger thank HR0, the difference specifies the number of low bits from the Timer 1 HOLD register to display. HR2 is next and if it is larger than HR1, the difference specifies the number of Timer 2 HOLD register low bits to display. Any remaining bits are reflected from the Timer 3 HOLD register low bits. **Figure 21-8** shows an example configuration and its effects on the display in the TMR_32b_GLB.

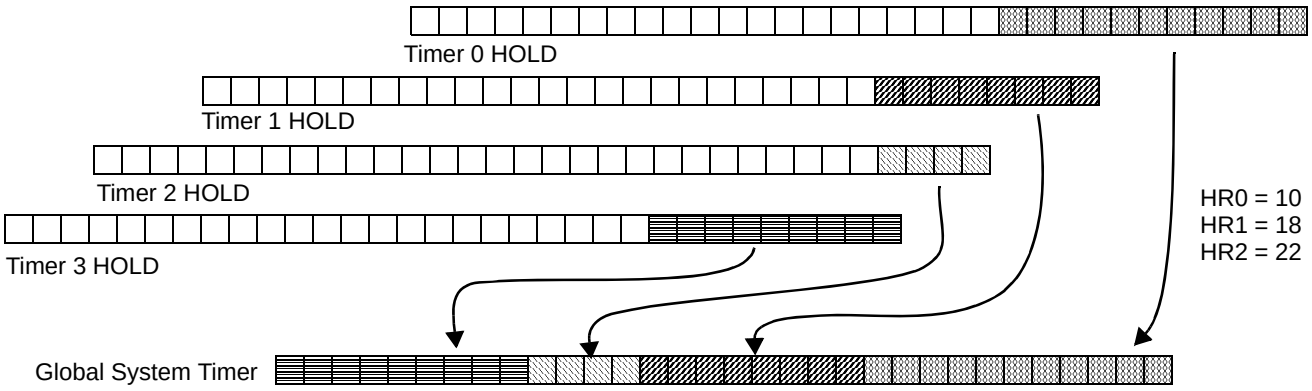

Figure 21-8. Hold Reflection Example Showing SWR Content

21.4.1.25 Timer_32b Timer Set and Forget Register (TMR_32b_n_SAF)

TMR_32b_[0–1]_SAF Timer_32b Set and Forget Register Offset 0x108

— 31–4	0	Reserved. Write to zero for future compatibility.	
CL3 3	0	**Clear Lock for Timer Input 3** When set (1), the timer input 3 lock is released. This bit automatically clears after the lock release cycle.	0 No action. 1 Clear lock for timer input 3.
CL2 2	0	**Clear Lock for Timer Input 2** When set (1), the timer input 2 lock is released. This bit automatically clears after the lock release cycle.	0 No action. 1 Clear lock for timer input 2.
CL1 1	0	**Clear Lock for Timer Input 1** When set (1), the timer input 1 lock is released. This bit automatically clears after the lock release cycle.	0 No action. 1 Clear lock for timer input 1.
CL0 0	0	**Clear Lock for Timer Input 0** When set (1), the timer input 0 lock is released. This bit automatically clears after the lock release cycle.	0 No action. 1 Clear lock for timer input 0.

Note: The base addresses for the 32-bit device level timer modules are as follows:

- Timer_32b_0 = 0xFFF26400
- Timer_32b_1 = 0xFFF26600

21.4.2 SC3850 DSP Core Subsystem Timers

For a detailed information about programming the core subsystem timers, see the *SC3850 DSP Core Subsystem Reference Manual.*

21.4.3 Software Watchdog Timers

This section describes the software WDT registers, which include:

- System Watchdog Control Register 0–7 (SWCRR[0–7]), see page 21-45.
- System Watchdog Count Register 0–7 (SWCNR[0–7]), see page 21-46.
- System Watchdog Service Register 0–7 (SWSRR[0–7]), see page 21-46.

Note: The watchdog timers use the following base addresses:

- System Watchdog Timer 0 = 0xFFF25000
- System Watchdog Timer 1 = 0xFFF25100
- System Watchdog Timer 2 = 0xFFF25200
- System Watchdog Timer 3 = 0xFFF25300
- System Watchdog Timer 4 = 0xFFF25400
- System Watchdog Timer 5 = 0xFFF25500
- System Watchdog Timer 6 = 0xFFF25600
- System Watchdog Timer 7 = 0xFFF25700

21.4.3.1 System Watchdog Control Register 0–7 (SWCRR[0–7])

SWCRR[0–7] System Watchdog Control Register 0–7 Offset 0x04

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	SWTC															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SWTC															
	—													SWEN	SWRI	SWPR
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SWCRR[0–7] control the software watchdog timer period and configure WDT operation. SWCRR can be read at any time but can be written only once after system reset. **Table 21-14** defines the SWCRR[0–7] bit fields.

Table 21-14. SWCRR[0–7] Bit Descriptions

Name	Reset	Description	Settings
SWTC 31–16	0xFFFF	**Software Watchdog Time Count** The SWTC field contains the modulus that is reloaded into the watchdog counter by a service sequence. When a new value is loaded into SWCRR[SWTC], the software watchdog timer is not updated until the servicing sequence is written to the SWSRR. If SWCRR[SWEN] is loaded with 0, the modulus counter does not count. The new value is also used at the next and all subsequent reloads. Reading the SWCRR register returns the value in the System Watchdog Control Register. Reset initializes the SWCRR[SWTC] field to $FFFF. **Note:** The prescaler counter is reset anytime a new value is loaded into the watchdog counter and also during reset.	
— 15–3	0	Reserved. Write to zero for future compatibility.	
SWEN 2	0	**Watchdog Enable** SWCRR[SWEN] bit enables the watchdog timer. It should be cleared by software after a system reset to disable the software watchdog timer. When the watchdog timer is disabled, the watchdog counter and prescaler counter are held in a stopped state.	0 Watchdog timer disabled. 1 Watchdog timer enabled.
SWRI 1	0	**Software Watchdog Reset/Interrupt Select** Depending on the SWCRR[SWRI] programming, WDT timer causes a hard reset or machine check interrupt to the core.	0 Software watchdog timer causes a machine check interrupt to the core. 1 Software watchdog timer causes a hard reset (this is the default value after soft reset).
SWPR 0	0	**Software Watchdog Counter Prescale** Controls the divide-by-65536 WDT counter prescaler.	0 The WDT counter is not prescaled. 1 The WDT counter clock is prescaled.

21.4.3.2 System Watchdog Count Register 0–7 (SWCNR[0–7])

SWCNR[0–7] System Watchdog Count Register 0–7 Offset 0x08

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	—															
Type	R															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	SWCN															
Type	R															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SWCNR[0–7] provide visibility to the WDT counter values. Writes to SWCNR have no effect and terminate without transfer error exception.

Table 21-15. SWCNR[0–7] Bit Descriptions

Name	Reset	Description
— 31–16	0	Reserved. Write to zero for future compatibility.
SWCN 15–0	0xFFFF	**Software Watchdog Count Field** The read-only SWCNR[SWCN] field reflects the current value in the watchdog counter. Writing to the SWCNR register has no effect, and write cycles are terminated normally. Reset initializes the SWCNR[SWCN] field to $FFFF. Reading the 16 LS bits of 32-bit SWCNR register with two 8-bit reads is not guaranteed to return a coherent value.

21.4.3.3 System Watchdog Service Register 0–7 (SWSRR[0–7])

SWSRR[0–7] System Watchdog Service Register 0–7 Offset 0x0E

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	WS															
Type	W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

When the WDT is enabled, writing 0x556C followed by 0xAA39 to the SWSRR register before the WDT times out prevents a reset. If SWSRR is not serviced before the time-out, the watchdog timer sends a signal to the reset or interrupt controller module. Both writes must occur before the time-out in the order listed, but any number of instructions can be executed between the two writes. Reset initializes the SWSRR[WS] field to 0x0000. SWSRR can be written at any time, but returns all zeros when read. **Table 21-16** defines the bit fields of SWSRR.

Table 21-16. SWSRR[0–7] Bit Descriptions

Name	Reset	Description
WS 15–0	0	**Software Watchdog Service Field** Write 0x556C followed by 0xAA39 to this register to prevent software watchdog timer time-out. SWSRR[WS] can be written at any time, but returns all zeros when read. Writing any other value resets the servicing sequence.

22 GPIO

The MSC8157E device has 32 general-purpose I/O (GPIO) ports, 16 of which can be configured as external maskable interrupt inputs, and 25 can be configured as dedicated peripheral interface ports. As GPIOs, each port is configured as an input or output. The dedicated peripheral functions multiplexed with the GPIO ports are grouped to maximize the usefulness of the ports in the greatest number of applications.

Configuration as an input or output port is done using a register for data outputs that is read or written at any time. If configured as output, the GPIO ports can also be configured as open-drain (that is, configured in an active low wired-OR configuration on the board). In this mode, an output drives a zero voltage but goes to tri-state when driving a high voltage.

GPIO ports have configurable internal pull-up resistors. These resistors are enabled by default. They can be disabled by programming the GPIO Pull-Up Enable Register (GPUER); see the **Chapter 8**, *General Configuration Registers* for details.

Note: To understand the port assignment capability described in this chapter, you must also understand the operation of the CPRI, SPI, timers, UART, I^2C, and DMA peripherals.

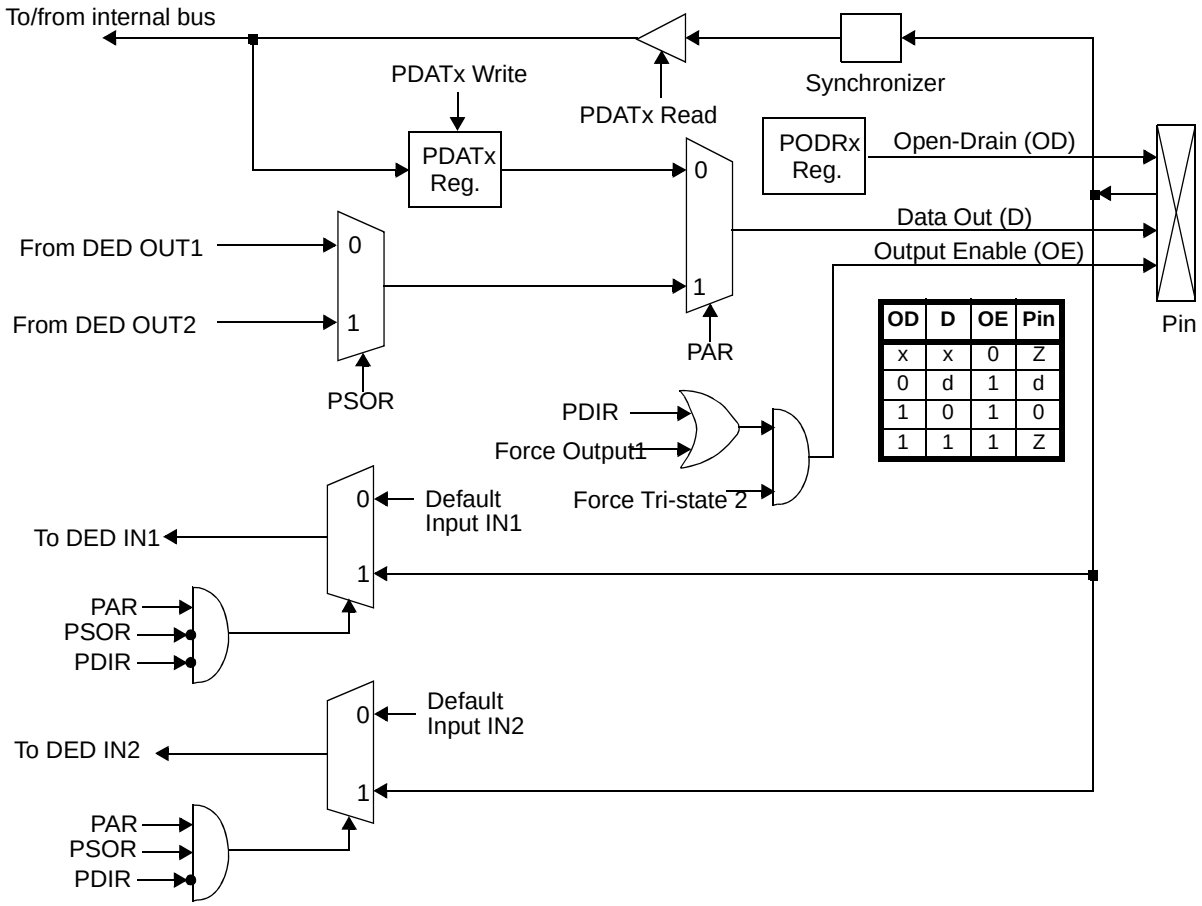
22.1 Features

Following are the key features of the GPIO ports:

- 32 GPIO ports.
- All ports are bidirectional.
- Seventeen ports have alternate on-device peripheral functions.
- At system reset, all 32 port inputs and outputs are disabled and the pull-up resistors are enabled.
- All port values can be read while the port is connected to an internal peripheral.
- All ports have open-drain output capability.
- Sixteen of the GPIOs can function as interrupt inputs.
- Four of the GPIOs can function as SPI signals.
- Seven of the GPIOs can function as timer signals.
- Two of the GPIOs can function as a UART port.
- Two of the GPIOs can function as an I^2C interface.
- Four of the GPIOs can function as external DMA control signals.
- Twelve of the GPIOs can be configured as CPRI signals (two per controller).

22.2 GPIO Block Diagram

Figure 22-1 shows a GPIO functional block diagram.



Notes: 1. Force Output may be asserted high by dedicated peripheral 2 direction control, only when PAR = 1 and PSOR = 1 (selects this peripheral) and PDIR = 0 (input). It is used for bidirectional operation allowing the peripheral to dynamically control the port direction.
2. Force Tri-state may be asserted low by dedicated peripheral 1 output enable, only when PAR = 1 and PSOR = 0 (selects this peripheral) and PDIR = 1 (output). It is used for tri-state output operation, allowing the peripheral to control the port drive dynamically.

Port Control Register Bits

Register Name	0	1	Description
PARx	General-purpose	Dedicated	Port Assignment Registers
PSORx	Dedicated 1	Dedicated 2	Port Special Options Registers
PDIRx	Input	Output	Port Data Direction Registers
PODRx	Regular	Open drain	Port Open-Drain Registers
PDATx	0 (data)	1 (data)	Port Data Registers
Note: In addition to these registers, you must set each the ports as inputs using the General Input Enable (GIER) register. See **8.2.10**, *GPIO Input Enable Register (GIER)* for details.			

Figure 22-1. Port Functional Operation

22.3 GPIO Connection Functions

This section describes the GPIO port when it has GPIO or dedicated functionality, which depends on the settings in the Pin Assignment Register (PAR), as follows:

- Each port is independently configured as a GPIO if the corresponding PAR bit is cleared. A port is configured as an input if the corresponding control bit in the Pin Data Direction Register (PDIR) is cleared; it is configured as an output if the corresponding PDIR bit is set.
- Each port is configured as a dedicated on-device peripheral port if the corresponding PAR bit is set.

All PAR and PDIR bits are cleared on total system reset, which disables the output direction of the GPIO ports.

Data transfer is done through the Pin Data Register (PDAT). Data written to the PDAT is stored in an output register. If a GPIO is configured as an output, the output register data is gated onto the GPIO port. If a GPIO is configured as an input and the port is enabled by the appropriate bit in the GIER, a read of PDAT*x* is actually a read of the GPIO port itself. Data written to PDAT when the GPIO is configured as an input is still stored in the output register, but it is prevented from reaching the external port.

When a multiplexed GPIO port is not configured as a GPIO, it has a dedicated functionality, as described in **Table 22-1**. If an input to a peripheral is not supplied externally, a default value is supplied to the internal peripheral as listed in the right-most column.

Table 22-1 describes the functionality of the GPIO ports according to the configuration of the port registers (PAR, PSOR, and PDIR). Each port can be configured as a GPIO (input, regular output, or open-drain output), one of two dedicated outputs, or one of two dedicated inputs. A route of one GPIO-dedicated output to another GPIO-dedicated input gives even more flexibility. The implemented routing is described in **Table 22-1** as primary and secondary input.

Table 22-1. GPIO Dedicated Assignment (PARx = 1)

GPIO	Port Function					
	PSORx = 0			PSORx = 1		
	PDIRx = 1 (Output, Unless Tri-State Option is Specified)	PDIRx = 0 (Input)	Default Input	PDIRx = 1 (Output)	PDIRx = 0 (Input, Unless Inout Option is Specified)	Default Input

30	—	—	0	I2C_SCL	I2C_SCL	1
31	—	—	0	I2C_SDA	I2C_SDA	1

Note: You must enable the port to use it as an input. See **Section 8.2.10**, *GPIO Input Enable Register (GIER)* for details.

22.4 GPIO Programming Model

The GPIO registers reside on a 256 KB address space. The GPIO block has five memory-mapped, read/write, 32-bit control registers. This section describes these registers in detail. Following is a list of the GPIO registers:

- Pin Open-Drain Register (PODR), **page 22-6**
- Pin Data Register (PDAT), **page 22-7**
- Pin Data Direction Registers (PDIR), **page 22-8**
- Pin Assignment Register (PAR), **page 22-9**
- Pin Special Options Registers (PSOR), **page 22-10**

Note: The GPIO registers use a base address of: 0xFFF27200.

If the corresponding PAR[DD*x*] bit is 1 (configured as a dedicated peripheral function port) before a PSOR or PDIR bit is programmed, an external connection may function for a short period as an unwanted dedicated function and cause unpredictable behavior. Thus, it is recommended that you program the GPIO in the following sequence: PSOR, PODR, PDIR, PAR.

In addition to the GPIO registers, there are two registers in the set of General Configuration Registers (GCRs) that control GPIO operation. These are as follows:

- GPIO Pull-Up Enable Register (GPUER), see **Section 8.2.9**, *GPIO Pull-Up Enable Register (GPUER)*, on page 8-17.
- GPIO Input Enable Register (GIER), see **Section 8.2.10**, *GPIO Input Enable Register (GIER)*, on page 8-18. To be used as an input line, a port must be enabled by this register.

Note: The base address for the general configuration registers is: 0xFFF28000.

22.4.1 Pin Open-Drain Register (PODR)

PODR Pin Open-Drain Register Offset 0x00

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	OD31	OD30	OD29	OD28	OD27	OD26	OD25	OD24	OD23	OD22	OD21	OD20	OD19	OD18	OD17	OD16
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	OD15	OD14	OD13	OD12	OD11	OD10	OD9	OD8	OD7	OD6	OD5	OD4	OD3	OD2	OD1	OD0
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PODR indicates a normal or active low open drain mode for wired-OR configuration of the outputs.

Table 22-2. PODR Bit Descriptions

Name	Reset	Description	Settings
OD[31–0] 31–0	0	**Open-Drain Configuration** Determines whether the corresponding port is actively driven as an output or is an open-drain driver. As an open-drain driver, the port is driven active-low. Otherwise, it is tri-stated (high impedance).	0 The I/O port is actively driven as an output. 1 The I/O port is an open-drain driver.

Note: The GPIO registers use a base address of: 0xFFF27200.

22.4.2 Pin Data Register (PDAT)

PDAT Pin Data Register Offset 0x08

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	D31	D30	D29	D28	D27	D26	D25	D24	D23	D22	D21	D20	D19	D18	D17	D16
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

A read of a PDAT register returns the data at the pin if the input line is enabled by the correct bit in the GIER, independently of whether the port is defined as an input or output. Thus, output conflicts at the pin can be detected by comparing the written data with the data on the pin. A write to the PDAT*x* is sampled in a register bit, and if the equivalent PDIR bit is configured as an output, the value sampled for that bit is driven onto its respective pin. PDAT can be read or written at any time.

If a pin is selected as GPIO, it is accessed through the PDAT. Data written to the PDAT register is stored in an output register. If a port is configured as an output, the output register data is gated onto the pin. When PDAT is read, the GPIO pin itself is read. If a GPIO port is configured as an input and enabled by the correct bit in the GIER, data written to the PDAT register is still stored in the output register, but it is prevented from reaching the actual pin. When the PDAT register is read and enabled as an input, the state of the actual pin is read.

Note: The GPIO registers use a base address of: 0xFFF27200.

22.4.3 Pin Data Direction Register (PDIR)

PDIR Pin Data Direction Register Offset 0x10

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	DR31	DR30	DR29	DR28	DR27	DR26	DR25	DR24	DR23	DR22	DR21	DR20	DR19	DR18	DR17	DR16

SO[31–0] 31–0	0	**Special-Option** Determines whether an external connection configured for a dedicated function (PAR[DD] = 1) uses option 1 or option 2. See **Table 22-1**.	0 Dedicated peripheral function. Option 1. 1 Dedicated peripheral function. Option 2.

Note: The GPIO registers use a base address of: 0xFFF27200.

23 Hardware Semaphores

The MSC8157E hardware semaphores (HS) hold eight coded hardware semaphores. A coded hardware semaphore provides a simple way to achieve a “lock” operation via a single write access, eliminating the need for such sophisticated read-modify-write mechanisms as the reservation. Using the hardware semaphores, external hosts and on-device bus initiators can protect internal and external shared resources and ensure coherency in any sequence of operations on these resources. Each coded hardware semaphore is an eight-bit register with a selective write mechanism, as follows (see **Figure 23-1**):

- The semaphore is *free* if its value is zero.
- The semaphore is *locked* if its value is non-zero and its value is the *lock code*. Each processor/task that needs the lock capability of the semaphore must have a unique non-zero eight-bit code for locking the semaphore for correct protocol operation.
- A write of a non-zero value (lock code) is successful only if the current value of the semaphore is zero (free). This write is defined as a successful *lock* operation, and the written value is the *lock code*.
- A write of a non-zero value (lock code) is ignored if the current value of the semaphore is non-zero (locked). This write is defined as a failed *lock* operation, since the coded semaphore is considered locked with the non-zero code it holds.
- To maintain the protocol coherency, only the initiator that successfully locked the semaphore is allowed (and obligated) to free it. A write of zero is always successful and is defined as a *free* operation.

When a processor/task must lock an unlocked semaphore to its unique code, it writes its unique lock code to the semaphore register. It then reads back the semaphore value, and if it matches its lock code, the lock operation is successful. A value mismatch (a different non-zero code or zero) indicates to the initiator that the lock operation failed and must be retried. After a successful lock operation, the initiator can do any coherent operation associated with this semaphore and then it must free the semaphore (write zero).

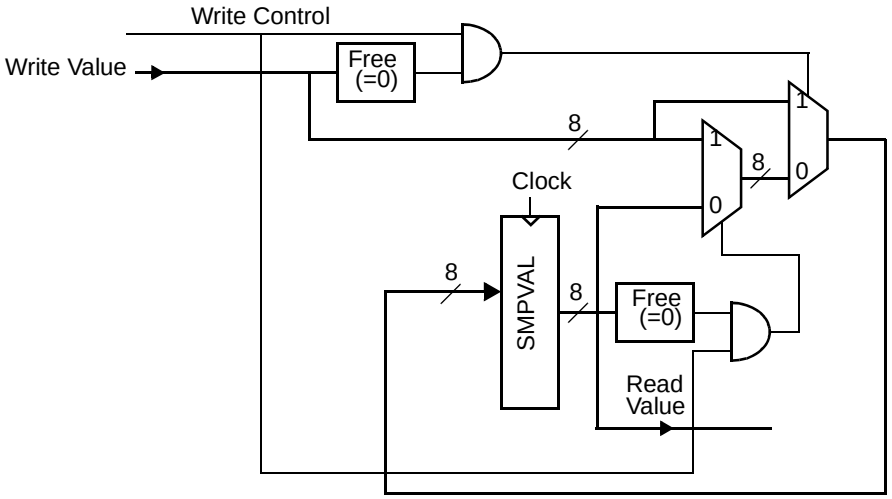

Figure 23-1. Hardware Semaphore Block Diagram

The hardware semaphore registers reside in the CCSR address space and have a constant offset. They are accessed through the MBus. The addresses of the hardware semaphore registers are presented in **Chapter 9**, *Memory Map*. The registers use a base address of 0xFFF27100.

It is writable to any value. ≠ 0 Semaphore is locked with lock code indicated by its current value. It is writable only to zero.

24 I²C

The inter-integrated circuit (IIC or I²C) bus is a two-wire—serial data (I2C_SDA) and serial clock (I2C_SCL)— bidirectional serial bus that provides a simple efficient method of data exchange between the system and other devices, such as microcontrollers, EEPROMs, real-time clock devices, A/D converters, and LCDs. The two-wire bus minimizes the interconnections between devices. The synchronous, multi-initiator I²C bus allows the connection of additional devices to the bus for expansion and system development. The bus includes collision detection and arbitration that prevent data corruption if two or more initiators attempt to control the bus simultaneously. In the MSC8157E device, the maximum I2C_SCL frequency is 400 kHz. **Figure 24-1** is a block diagram of the I²C block.

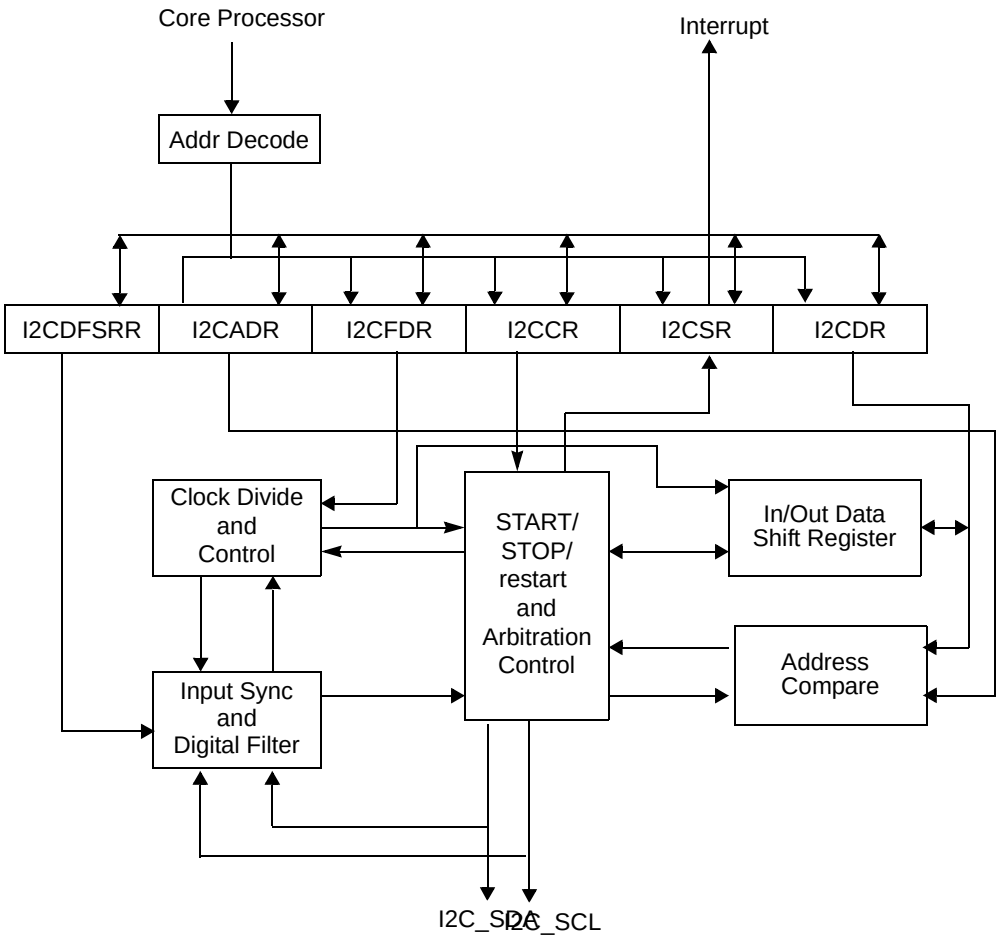

Figure 24-1. I²C Controller Block Diagram

24.1 Features

The I^2C interface includes the following features:

- Two-wire interface
- Multi-initiator operation
- Arbitration lost interrupt with automatic mode switching from initiator to target
- Calling address identification interrupt
- START and STOP signal generation/detection
- Acknowledge bit generation/detection
- Bus busy detection
- Software-programmable clock frequency
- Software-selectable acknowledge bit
- On-chip filtering for spikes on the bus

24.2 Modes of Operation

The following modes of operation are supported by the I^2C controller:

- Initiator mode. The I^2C is the driver of the I2C_ line. It cannot use its own target address as a calling address. The I^2C cannot be an initiator and a target simultaneously. The initiator device initiates the data transfer by generating a START condition.
- The module must be enabled before a START condition from a I^2C initiator is detected.
- START condition. This condition denotes the beginning of a new data transfer (each data transfer contains several bytes of data) and awakens all targets. This mode is I^2C-specific.
- Repeated START condition. A START condition that is generated without a STOP condition to terminate the previous transfer. This mode is I^2C-specific.
- STOP condition. The initiator can terminate the transfer by generating a STOP condition to free the bus. This mode is I^2C-specific.
- Interrupt-driven byte-to-byte data transfer. When successful target addressing is achieved (and I2C_SCL returns to zero), the data transfer can proceed on a byte-to-byte basis in the direction specified by the R/W bit sent by the calling initiator. Each byte of data must be followed by an acknowledge bit, which is signalled from the receiving device. Several bytes can be transferred during a data transfer session.
- Boot sequencer mode. Used only for loading the reset configuration word (RCW) only. See **Chapter 5**, *Reset*.

24.3 I2C Module Functional Blocks

The I2C module includes the following blocks:

- Clock control
- Input synchronization
- Digital input filter
- Transaction monitoring
- Arbitration control
- Transfer control
- In/out data shift register
- Address compare

24.3.1 Clock Control

The clock control block handles requests from clock for transferring and controlling data for multiple tasks. A 9-cycle data transfer (8-bit data plus the ACK bit) clock is requested for the following conditions:

- Initiator mode
  - transmit target address after START condition
  - transmit target address after restart condition
  - transmit data
  - receive data
- Target mode
  - transmit data
  - receive data
  - receive target address after START or restart condition

24.3.2 Input Synchronization

The input synchronization block synchronizes the input I2C_SCL and I2C_SDA signals to the [I2C Input Clock] and detects transitions of these signals.

24.3.3 Digital Input Filter

The I2C_SCL and I2C_SDA signal inputs are filtered to eliminate noise. Three consecutive signal samples are compared using a pre-determined sampling rate. If they are all high, the filter output is high. If they are all low, the output is low. For any high/low combination, the filter output is the value of the previous clock cycle. The sampling rate is the binary value stored in the frequency register. The sampling cycle duration is controlled by a down counter that sets a signal at the end of the count. This allows software to write to the frequency register to control the

filtered sampling rate. The value written to the I2CDFSRR should be defined by the system noise and the I2CFDR value. I2CDFSRR must be less than six times the division factor defined by I2CFDR. Note that the division factor stands for a I2CDFSRR value of 1.

24.3.4 Transaction Monitoring

The different conditions of the I^2C data transfers are monitored as follows:

- START conditions are detected when an I2C_SDA fall occurs while I2C_SCL is high.
- STOP conditions are detected when and I2C_SDA rise occurs while I2C_SCL is high.
- Data transfers in progress are canceled when a STOP condition is detected or if there is a target address mismatch. Cancellation of data transactions resets the clock module
- The bus state is busy beginning with the detection of a START condition, and idle when a STOP condition is detected.

24.3.5 Arbitration Control

The arbitration control block controls the arbitration procedure of the initiator mode. A loss of arbitration occurs whenever the initiator detects a 0 on the external I2C_SDA line while attempting to drive a 1, tries to generate a START or restart at an inappropriate time, or detects an unexpected STOP request on the line. Arbitration by the initiator in initiator mode is lost under the following conditions:

- Low detected when high expected (transmit)
- Ack bit, low detected when high expected (receive)
- A START condition is attempted when the bus is busy
- A START condition is attempted when the bus is nearly busy (the I^2C controller does not yet recognize the bus as busy, but the bus is set to Initiator mode and I2C_SDA samples low).
- A start condition is attempted when the requesting device is not the bus owner
- Unexpected STOP condition detected

24.3.6 Transfer Control

The I^2C contains logic that controls the output to the serial data (I2C_SDA) and serial clock (I2C_SCL) lines of the I^2C. The I2C_SCL output is pulled low as determined by the internal clock generated in the clock module. The I2C_SDA output can only change at the midpoint of a low cycle of the I2C_SCL, unless performing a START, STOP, or restart condition. Otherwise, the I2C_SDA output is held constant. The I2C_SDA signal is pulled low when one or more of the following conditions are true in either initiator or target mode:

- Initiator mode
  - data bit (transmit)

- ack bit (receive)
- START condition
- STOP condition
- Restart condition

- Target mode
  - acknowledging address match
  - data bit (transmit)
  - ack bit (receive)

The I2C_SCL signal corresponds to the internal I2C_SCL signal when one or more of the following conditions are true in either initiator or target mode:

- Initiator mode
  - bus owner
  - lost arbitration
  - START condition
  - STOP condition
  - Restart condition begin
  - Restart condition end
- Target mode
  - address cycle
  - transmit cycle
  - ack cycle

24.3.7 In/Out Data Shift Register

This block controls the interface between the serial data line and the data register, both transmitting data to and receiving data from the I^2C. In transmit mode, a write to I2CCR[MTX] sets the direction to transmit. The contents of the parallel register are loaded into a shift register, which are then shifted on the I2C_SDA line.

24.3.8 Address Compare

The address compare block determines whether a target has been properly addressed and whether a specific action is required. The four performed address comparisons are described as follows:

- The address sent by the current initiator matches the general broadcast address (addresses all targets)
- The address matches the target address
- A broadcast message to update the I2CSR was received
- A message was addressed via the target address to update the I2CSR and to generate an interrupt

24.4 Functional Description

The reset state of the I^2C is the boot sequencer mode. After the boot sequencer has completed, the I^2C interface performs as a target receiver. The I^2C unit always performs as a target receiver as a default, unless explicitly programmed to be an initiator or target transmitter address.

A standard I^2C transfer consists of the following:

- START condition
- Target target address transmission (7-bit calling address plus the read/write bit)
- Data transfer
- STOP condition

Figure 24-2 shows the interaction of these four parts with the calling address, data byte, and new calling address components of the I^2C protocol. The details of the protocol are described in the following subsections.

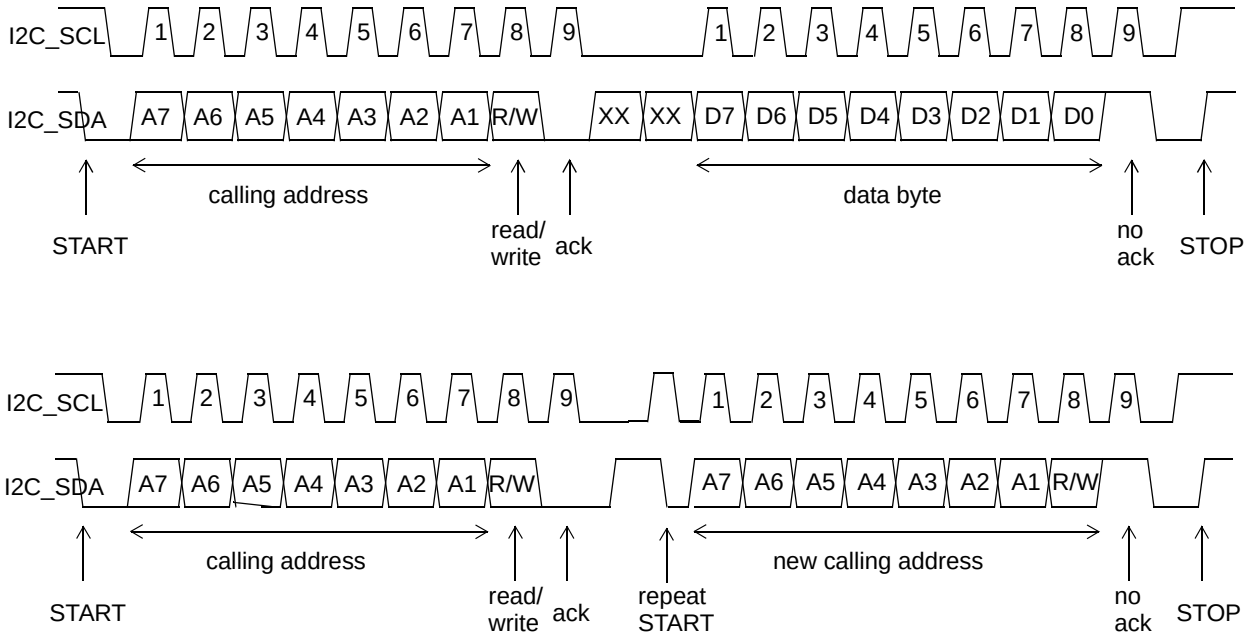

Figure 24-2. I^2C Interface Transaction Protocol

24.4.1 START Condition

When the I^2C bus is not engaged (both I2C_SDA and I2C_SCL lines are at logic high), an initiator can initiate a transfer by sending a START condition. As shown in **Figure 24-2**, a START condition is defined as a high-to-low transition of I2C_SDA while I2C_SCL is high. This condition denotes the beginning of a new data transfer. Each data transfer can contain several bytes and awakens all targets. The START condition is initiated by a software write that sets the I2CCR[MSTA].

24.4.2 Target Address Transmission

The first byte of data is transferred by the initiator immediately after the START condition is the target address. This is a seven-bit calling address followed by a R/W bit, which indicates the direction of the data being transferred to the target. Each target in the system has a unique address. In addition, when the I^2C module is operating as an initiator, it must not transmit an address that is the same as its target address. An I^2C device cannot be initiator and target at the same time. Only the target with a calling address that matches the one transmitted by the initiator responds by returning an acknowledge bit (pulling the I2C_SDA signal low at the 9th clock) as shown in **Figure 24-2**. If no target acknowledges the address, the initiator should generate a STOP condition or a repeated START condition. When target addressing is successful (and I2C_SCL returns to zero), the data transfer can proceed on a byte-to-byte basis in the direction specified by the R/W bit sent by the calling initiator.

The I^2C module responds to a general call (broadcast) command when I2CCR[BCST] is set. See the Philips I^2C specification for details. A broadcast address is always zero, however the I^2C module does not check the R/W bit. The second byte of the broadcast message is the initiator device ID. Because the second byte is automatically acknowledged by hardware, the receiver device software must verify that the broadcast message is intended for itself by reading the second byte of the message. If the device ID is for another receiver device and the third byte is a write command, then software can ignore the third byte during the broadcast. If the device ID is for another receiver device and the third byte is a read command, software must write 0xFF to I2CDR with I2CCR[TXAK] = 1, so that it does not interfere with the data written from the addressed device. Each data byte is 8 bits long. Data bits can be changed only while I2C_SCL is low and must be held stable while I2C_SCL is high, as shown in **Figure 24-2**. There is one clock pulse on I2C_SCL for each data bit, and the most significant bit (msb) is transmitted first. Each byte of data must be followed by an acknowledge bit, which is signalled from the receiving device by pulling the I2C_SDA line low at the ninth clock. Therefore, one complete data byte transfer takes nine clock pulses. Several bytes can be transferred during a data transfer session. If the target receiver does not acknowledge the initiator, the I2C_SDA line must be left high by the target. The initiator can then generate a stop condition to abort the data transfer or a START condition (repeated START) to begin a new calling. If the initiator receiver does not acknowledge the target transmitter after a byte of transmission, the target interprets that the end-of-data has been reached. Then the target releases the I2C_SDA line for the initiator to generate a STOP or a START condition.

24.4.3 Repeated START Condition

Figure 24-2 shows a repeated START condition, which is generated without a STOP condition that can terminate the previous transfer. The initiator uses this method to communicate with another target or with the same target in a different mode (transmit/receive mode) without releasing the bus.

24.4.4 STOP Condition

The initiator can terminate the transfer by generating a STOP condition to free the bus. A STOP condition is defined as a low-to-high transition of the I2C_SDA signal while I2C_SCL is high. For more information, see **Figure 24-2**. Note that an initiator can generate a STOP even if the target has transmitted an acknowledge bit, at which point the target must release the bus. The STOP condition is initiated by a software write that clears I2CCR[MSTA]. As described in **Section 24.4.3**, the initiator can generate a START condition followed by a calling address without generating a STOP condition for the previous transfer. This is called a repeated START condition.

24.4.5 Arbitration Procedure

The I^2C interface is a true multiple initiator bus that allows more than one initiator device to be connected on it. If two or more initiators simultaneously try to control the bus, each initiator's (including the I^2C module) clock synchronization procedure determines the bus clock—the low period is equal to the longest clock low period and the high is equal to the shortest one among the initiators. A bus initiator loses arbitration if it transmits a logic 1 on I2C_SDA while another initiator transmits a logic 0. The losing initiators immediately switch to target-receive mode and stop driving the I2C_SDA line. In this case, the transition from initiator to target mode does not generate a STOP condition. Meanwhile, the I^2C unit sets the I2CSR[MAL] status bit to indicate the loss of arbitration and, as a target, services the transaction if it is directed to itself.

Arbitration is lost (and I2CSR[MAL] is set) in the following circumstances:

- I2C_SDA sampled as low when the initiator drives a high during address or data-transmit cycle.
- I2C_SDA sampled as low when the initiator drives a high during the acknowledge bit of a data-receive cycle.
- A START condition is attempted when the bus is busy.
- A repeated START condition is requested in target mode.

The I^2C module does not automatically retry a failed transfer attempt. If the I^2C module is enabled in the middle of an ongoing byte transfer, the interface behaves as follows:

- Target mode—the I^2C module ignores the current transfer on the bus and starts operating whenever a subsequent START condition is detected. If ICCR[MEN] is set and ICCR[RX] is cleared while the I2C_SDA signal is low and I2C_SCL is high, a false start condition is detected. If in this case, the data bits match the I^2C target address, then I2CSR[MAAS] is set. The application must correct the condition to release the I2C_SCL bus.

- Initiator mode—the I^2C module cannot tell whether the bus is busy; therefore, if a START condition is initiated, the current bus cycle can be corrupted. This ultimately results in the current bus initiator of the I^2C interface losing arbitration, after which bus operations return to normal.

24.4.6 Clock Synchronization

Due to the wire AND logic on the I2C_SCL line, a high-to-low transition on the I2C_SCL line affects all devices connected on the bus. The devices begin counting their low period when the initiator drives the I2C_SCL line low. After a device has driven I2C_SCL low, it holds the I2C_SCL line low until the clock high state is reached. However, the change of low-to-high in a device clock may not change the state of the I2C_SCL line if another device is still within its low period. Therefore, synchronized clock I2C_SCL is held low by the device with the longest low period. Devices with shorter low periods enter a high wait state during this time. When all devices concerned have counted off their low period, the synchronized I2C_SCL line is released and pulled high. Then there is no difference between the device clocks and the state of the I2C_SCL line, and all the devices begin counting their high periods. The first device to complete its high period pulls the I2C_SCL line low again.

24.4.7 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfer. Target devices can hold the I2C_SCL low after completion of a 1-byte transfer (9 bits). In such cases, it halts the bus clock and forces the initiator clock into wait states until the target releases the I2C_SCL line.

24.4.8 Clock Stretching

Targets can use the clock synchronization mechanism to slow down the transfer bit rate. After the initiator has driven the I2C_SCL line low, the target can drive I2C_SCL low for the required period and then release it. If the target I2C_SCL low period is greater than the initiator I2C_SCL low period, then the resulting I2C_SCL bus signal low period is stretched.

24.5 Initialization/Application Information

This section describes some programming guidelines recommended for the I^2C interface. It also includes **Figure 24-3**, a recommended flowchart for the I^2C interrupt service routines. The I^2C registers in this chapter are shown in big-endian format. If the system is in little-endian mode, software must swap the bytes appropriately. The I^2C controller does not guarantee its recovery from all illegal I^2C bus activity. In addition, a malfunctioning device may hold the bus captive. A good programming practice is for software to rely on a watchdog timer to help recover from I^2C bus hangs. The recovery routine should also handle the case when the status bits returned after an interrupt are not consistent with what was expected due to illegal I^2C bus protocol behavior.

24.5.1 Initialization Sequence

A hard reset initializes all the I^2C registers to their default states. The following initialization sequence initializes the I^2C unit:

- All I^2C registers must be located in a cache-inhibited page, that is the register locations must be defined as non-cacheable by the memory management units (MMUs).
- The GPIO registers must be configured to select the I^2C signal multiplexing options. See **Chapter 21**, *GPIO* for details.
- Update I2CFDR[FDR] and select the required division ratio to obtain the I2C_SCL frequency from the [I^2C Input Clock] clock.
- Update I2CADR to define the target address for this device.
- Modify I2CCR to select initiator/target mode, transmit/receive mode, and interrupt-enable or disable.
- Set the I2CCR[MEN] to enable the I^2C interface.

24.5.2 Generation of START

After initialization, the following sequence can be used to generate START:

- If the device is connected to a multiinitiator I^2C system, test the state of I2CSR[MBB] to check whether the serial bus is free (I2CSR[MBB] = 0) before switching to initiator mode.
- Select initiator mode (set I2CCR[MSTA]) to transmit serial data and select transmit mode (set I2CCR[MTX]) for the address cycle.
- Write the target address being called into the data register (I2CDR). The data written to I2CDR[7–1] comprises the target calling address. I2CCR[MTX] indicates the direction of transfer (transmit/receive) required from the target.

The scenario above assumes that the I^2C interrupt bit (I2CSR[MIF]) is cleared. If I2CSR[MIF] = 1 at any time, the I^2C interrupt handler should immediately handle the interrupt.

24.5.3 Post-Transfer Software Response

Transmission or reception of a byte automatically sets the data transferring bit (I2CSR[MCF]), which indicates that one byte has been transferred. The I^2C interrupt bit (I2CSR[MIF]) is also set; an interrupt is generated to the processor if the interrupt function is enabled during the initialization sequence (I2CCR[MIEN] = 1). In the interrupt handler, software must do the following:

- Clear I2CSR[MIF]
- Read the contents of the I^2C data register (I2CDR) in receive mode or write to I2CDR in transmit mode. Note that this causes I2CSR[MCF] to be cleared. See **Section 24.5.10** for details.

When an interrupt occurs at the end of the address cycle, the initiator remains in transmit mode. If initiator receive mode is required, I2CCR[MTX] should be toggled at this stage. See Section 24.5.10, “Interrupt Service Routine Flowchart.” If the interrupt function is disabled, software can service the I2CDR in the main program by monitoring I2CSR[MIF]. In this case, I2CSR[MIF] should be polled rather than I2CSR[MCF] because MCF behaves differently when arbitration is lost. Note that interrupt or other bus conditions may be detected before the I^2C signals have time to settle. Thus, when polling I2CSR[MIF] (or any other I2CSR bits), software delays may be needed (in order to give the I^2C signals sufficient time to settle). During target-mode address cycles (I2CSR[MAAS] = 1), I2CSR[SRW] should be read to determine the direction of the subsequent transfer and I2CCR[MTX] should be programmed accordingly. For target-mode data cycles (I2CSR[MAAS] = 0), I2CSR[SRW] is not valid and I2CCR[MTX] should be read to determine the direction of the current transfer. See **Section 24.5.10** for details.

24.5.4 Generation of STOP

A data transfer ends with a STOP condition generated by the initiator device. An initiator transmitter can generate a STOP condition after all the data has been transmitted. If an initiator receiver wants to terminate a data transfer, it must inform the target transmitter by not acknowledging the last byte of data, which is done by setting the transmit acknowledge (I2CCR[TXAK]) bit before reading the next-to-last byte of data At this time, the next-to-last byte of data has already been transferred on the I^2C interface, so the last byte will not receive the data acknowledge when I2CCR[TXAK] is set. For 1-byte transfers, a dummy read should be performed by the interrupt service routine. (See Section 24.5.10, “Interrupt Service Routine Flowchart.”) Before the interrupt service routine reads the last byte of data, a STOP condition must first be generated. Eventually, I2CCR[TXAK] must be cleared again for subsequent I^2C transactions. This can be accomplished when setting up the I2CCR for the next transfer.

24.5.5 Generation of Repeated START

At the end of a data transfer, if the initiator still wants to communicate on the bus, it can generate another START condition followed by another target address without first generating a STOP condition by setting I2CCR[RSTA].

24.5.6 Generation of I2C_SCL When I2C_SDA Low

In some cases it is necessary to force the I^2C module to become the I^2C bus initiator out of reset and drive the I2C_SCL signal (even though I2C_SDA may already be driven, which indicates that the bus is busy). This can occur when a system reset does not cause all I^2C devices to be reset. Thus, the I2C_SDA signal can be driven low by another I^2C device while the I^2C module is coming out of reset and will stay low indefinitely. The following procedure can be used to force the I^2C module to generate I2C_SCL so that the device driving I2C_SDA can finish its transaction:

- Disable the I^2C and set the initiator bit by setting I2CCR to 0x20.
- Enable the I^2C by setting I2CCR to 0xA0.
- Read the I2CDR.
- Return the I^2C module to target mode by setting I2CCR to 0x80.

24.5.7 Target Mode Interrupt Service Routine

In the target interrupt service routine, the module addressed as a target should be tested to check if a calling of its own address has been received. If I2CSR[MAAS] = 1, software should set the transmit/receive mode select bit (I2CCR[MTX]) according to the R/$\overline{W}$ command bit (I2CSR[SRW]). Writing to I2CCR clears I2CSR[MAAS] automatically. The only time I2CSR[MAAS] is read as set is from the interrupt handler at the end of that address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have I2CSR[MAAS] = 0. A data transfer can then be initiated by writing to I2CDR for target transmits or dummy reading from I2CDR in target-receive mode. The target drives I2C_SCL low between byte transfers. I2C_SCL is released when the I2CDR is accessed in the required mode.

24.5.8 Target Transmitter and Received Acknowledge

In the target transmitter routine, the received acknowledge bit (I2CSR[RXAK]) must be tested before sending the next byte of data. The initiator signals an end-of-data by not acknowledging the data transfer from the target. When no acknowledge is received (I2CSR[RXAK] = 1), the target transmitter interrupt routine must clear I2CCR[MTX] to switch the target from transmitter to receiver mode. A dummy read of I2CDR then releases I2C_SCL so that the initiator can generate a STOP condition. See Section 24.5.10, “Interrupt Service Routine Flowchart.”

24.5.9 Loss of Arbitration and Forcing of Target Mode

When an initiator loses arbitration the following conditions all occur—

- I2CSR[MAL] is set
- I2CCR[MSTA] is cleared (changing the initiator to target mode)
- An interrupt occurs (if enabled) at the falling edge of the 9th clock of this transfer.

Thus, the target interrupt service routine should test I2CSR[MAL] first, and the software should clear I2CSR[MAL] if it is set. See **Section 24.3.5**, for details.

24.5.10 Interrupt Service Routine Flowchart

Figure 24-3 shows an example algorithm for an I^2C interrupt service routine. Deviation from the flowchart may result in unpredictable I^2C bus behavior. However, in the target receive mode (not shown in the flowchart), the interrupt service routine may need to set I2CCR[TXAK] when the

next-to-last byte is to be accepted. It is recommended that a sync instruction follow each I^{2}C register read or write to guarantee in-order instruction execution.

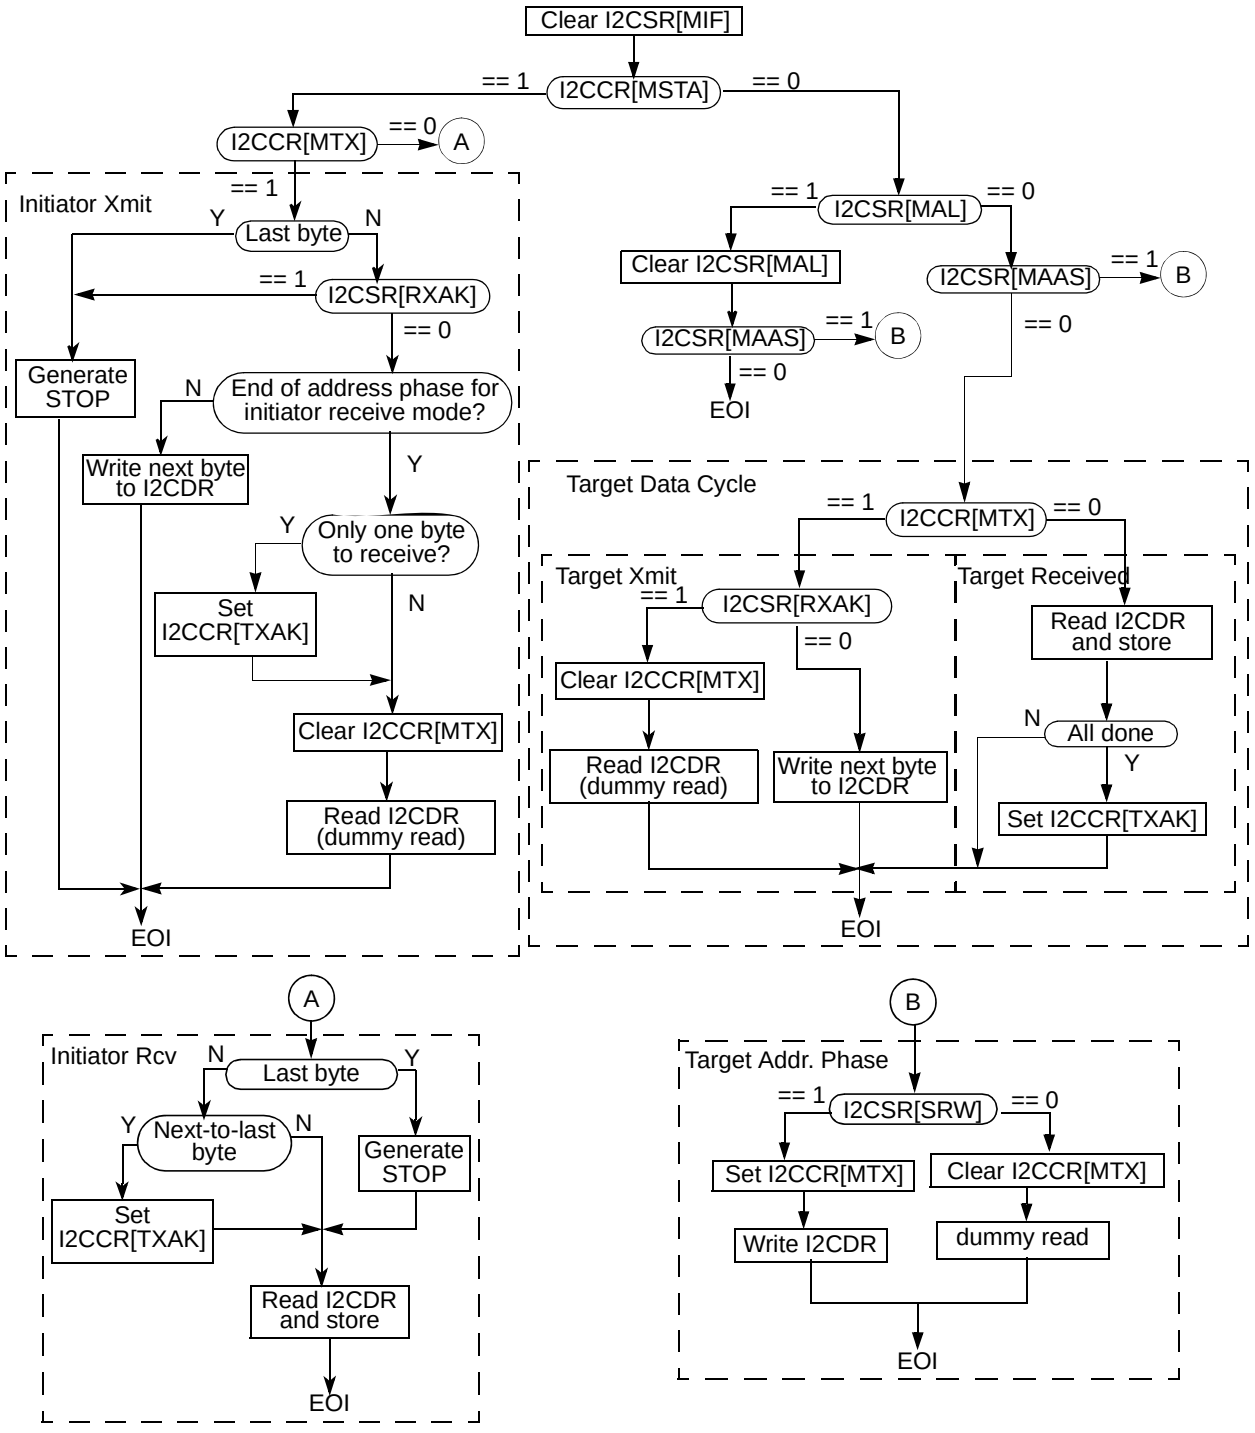

Figure 24-3. Example I^{2}C Interrupt Service Routine Flowchart

24.6 Programming Model

The registers covered in this section are as follows:

- I^{2}C Address Register (I2CADR), page 24-14
- I^{2}C Frequency Divider Register (I2CFDR), page 24-15
- I^{2}C Control Register (I2CCR), page 24-16
- I^{2}C Status Register (I2CSR), page 24-17
- I^{2}C Data Register (I2CDR), page 24-19
- Digital Filter Sampling Rate Register (I2CDFSRR), page 24-19

Note: Reserved bits should always be written with the value they returned when read. In other words, the register should be programmed by reading the value, modifying the appropriate fields, and writing back the value. The return value of the reserved fields should not be assumed, even though the reserved fields return zero. This note does not apply to the I^{2}C data register (I2CDR).

Note: The I^{2}C registers use a base address of: 0xFFF24C00. Accesses to the I^{2}C registers should be 1 byte in size and to addresses using the specified register offset.

24.6.1 I^{2}C Address Register (I2CADR)

I2CADR I^{2}C Address Register Offset 0x00

Bit	7	6	5	4	3	2	1	0
	ADDR							—
Type	R/W							
Reset	0	0	0	0	0	0	0	0

I2CADR contains the address to which the I^{2}C interface responds when addressed as a target. This is not the address sent on the bus during the address-calling cycle when the I^{2}C module is in initiator mode. **Table 24-1** describes the I2CADR fields.

Table 24-1. I2CADR Bit Descriptions

Name	Reset	Description
ADDR 7–1	0	**Target Address** Contains the specific target address used by the I^{2}C interface. The default mode of the I^{2}C interface is target mode for an address match.
— 0	0	Reserved. Write to zero for future compatibility.

24.6.2 I²C Frequency Divider Register (I2CFDR)

I2CFDR I2C Frequency Divider Register Offset 0x04

Bit	7	6	5	4	3	2	1	0
	—		FDR					
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Table 24-2 describes the I2CFDR fields. It also maps the I2CFDR[FDR] field to the clock divider values.

Table 24-2. I2CFDR Bit Descriptions

Name	Reset	Description	Settings			
— 7–6	0	Reserved. Write to zero for future compatibility.				
FDR 5–0	0	**Frequency Divider Ratio** Used to prescale the clock for bit rate selection. The serial bit clock frequency of I2C_SCL is equal to the [I²C Input Clock] clock divided by the divider. The frequency divider value can be changed at any point in a program.	**FDR**	**Divider (Decimal)**	**FDR**	**Divider (Decimal)**

24.6.3 I²C Control Register (I2CCR)

I2CCR — I²C Control Register — Offset 0x08

Bit	7	6	5	4	3	2	1	0
	MEN	MIEN	MSTA	MTX	TXAK	RSTA	—	BCST
Type	R/W	R/W	W	R/W	R/W	W	R/W	R/W
Reset	0	0	0	0	0	0	0	0

Table 24-3 describes the I2CCR fields.

Table 24-3. I2CCR Bit Descriptions

Name	Reset	Description	Settings
MEN 7	0	**Module Enable** This bit controls the software reset of the I²C module. When cleared, the interface is held in reset but the registers can still be accessed. This bit must be set before any other control register bits have any effect. All I²C registers for target receive or initiator START can be initialized before setting this bit.	0 The module is reset and disabled. 1 The I²C module is enabled.
MIEN 6	0	**Module Interrupt Enable** Enables/disables interrupts from the I²C module. Clearing the bit does not clear any pending interrupts. When set, the interrupt occurs only if I2CSR[MIF] is also set.	0 Interrupts are disabled. 1 Interrupts are enabled.
MSTA 5	0	**Initiator/Target Mode START** Issues a STOP and changes to Target mode or a START and changes to Initiator mode. It the initiator loses arbitration, the bit is cleared without generating a STOP condition on the bus.	0 Issues a STOP condition and changes mode from initiator to target. 1 Issues a START condition and initiator mode is selected.
MTX 4	0	**Transmit/Receive Mode Select** This bit selects the direction of the initiator and target transfers. When configured as a target, this bit should be set by software according to I2CSR[SRW]. In initiator mode, the bit should be set according to the type of transfer required. Therefore, for address cycles, this bit will always be high. The MTX bit is cleared when the initiator loses arbitration.	0 Receive mode. 1 Transmit mode.
TXAK 3	0	**Transfer Acknowledge** This bit specifies the value driven onto the I2C_SDA line during acknowledge cycles for both initiator and target receivers. The value of this bit only applies when the I²C module is configured as a receiver, not a transmitter. It also does not apply to address cycles; when the core is addressed as a target, an acknowledge is always sent.	0 An acknowledge signal (I2C_SDA low) is sent to the bus on the 9th clock after receiving one byte of data. 1 No acknowledge signal response is sent (I2C_SDA high).
RSTA 2	0	**Repeat START** Setting this bit always generates a repeated START condition on the bus and provides the core with the current bus initiator. Attempting a repeated START at the wrong time (or if the bus is owned by another initiator), results in loss of arbitration.	0 No START condition generated. 1 Generates repeat START condition.

Table 24-3. I2CCR Bit Descriptions (Continued)

Name	Reset	Description	Settings
— 1	0	Reserved. Write to zero for future compatibility.	
BCST 0	0	**Broadcast** Enables/disables the I^{2}C module to accept broadcast messages at address zero.	0 Broadcast disabled. 1 Broadcast enabled.

24.6.4 I^{2}C Status Register (I2CSR)

I2CSR I^{2}C Status Register Offset 0x0C

Bit	7	6	5	4	3	2	1	0
	MCF	MAAS	MBB	MAL	BCSTM	SRW	MIF	RXAK
Type	R	R	R	R/W	R	R	R/W	R
Reset	1	0	0	0	0	0	0	1

Table 24-4 describes the I2CSR fields.

Table 24-4. I2CSR Bit Descriptions

Name	Reset	Description	Settings
MCF 7	1	**Module Data Transfer Complete** When one byte of data is being transferred, the bit is cleared. It is set by the falling edge of the 9th clock of the byte transfer.	0 Byte transfer in progress. MCF is cleared under either of the following conditions: a. When I2CSR is read in receive mode or written in transmit mode, or b. after a START sequence is recognized by the I^{2}C controller in target mode. 1 Byte transfer is completed.
MAAS 6	0	**Module Address as Target** When the value in I2CDR matches the calling address, or the calling address matches the broadcast address (if broadcast mode is enabled), this bit is set. The processor is interrupted if I2CCR[MIEN] is set. Next, the processor must check the SRW bit and set I2CCR[MTX] accordingly. Writing to the I2CCR automatically clears this bit.	0 Not addressed as target. 1 Addressed as target.
MBB 5	0	**Module Bus Busy** Indicates the status of the bus. When a START condition is detected, MBB is set. If a STOP condition is detected, it is cleared.	0 I^{2}C bus is idle. 1 I^{2}C bus is busy.
MAL 4	0	**Module Arbitration Lost** Automatically set when the arbitration procedure is lost. The core does not automatically retry a failed transfer attempt. This bit can only be cleared by software.	0 Arbitration is not lost. 1 Arbitration is lost.

Table 24-4. I2CSR Bit Descriptions (Continued)

Name	Reset	Description	Settings
BCSTM 3	0	**Broadcast Match** Writing to the I2CCR automatically clears this bit.	0 No broadcast match. 1 Calling address matches the broadcast address instead of the programmed target address, or the I^2C initiator drove an address of all 0s.
SRW 2	0	**Target Read/Write** When MAAS is set, SRW indicates the value of the R/W command bit of the calling address, which is sent from the initiator. This bit is valid only when both of the following conditions are true: • A complete transfer occurred and no other transfers have been initiated. • The I^2C interface is configured as a target and has an address match. By checking this bit, the processor can select target transmit/receive mode according to the command of the initiator.	0 Target receive, initiator writing to target. 1 Target transmit, initiator reading from target.
MIF 1	0	**Module Interrupt** The MIF bit is set when an interrupt is pending, causing a processor interrupt request if I2CCR[MIEN] is set. MIF is set when one of the following events occurs: • One byte of data is transferred (set at the falling edge of the 9th clock). • The value in I2CADR matches with the calling address in target-receive mode. • Arbitration is lost. The bit can only be cleared by software.	0 No interrupt pending. 1 Interrupt pending.
RXAK 0	1	**Received Acknowledge** The value of I2C_SDA during the reception of acknowledge bit of a bus cycle.	0 Acknowledge received after completion of 8-bit transmission on the bus. 1 No acknowledge detected on the ninth clock.

24.6.5 I²C Data Register (I2CDR)

I2CDR I²C Data Register Offset 0x10

Bit	7	6	5	4	3	2	1	0
	DATA							
Type	R/W							
Reset	0	0	0	0	0	0	0	0

Table 24-5 describes the I2CDR fields.

Table 24-5. I2CDR Bit Descriptions

Name	Reset	Description
DATA 7–0	0	**Data** Transmission starts when an address and the R/W bit are written to the data register and the I²C interface performs as the initiator. A data transfer is initiated when data is written to the I2CDR. The most significant bit is sent first in both cases. In the initiator receive mode, reading the data register allows the read to occur, but also allows the I²C module to receive the next byte of data on the I²C interface. In target mode, the same function is available after it is addressed.

24.6.6 Digital Filter Sampling Rate Register (I2CDFSRR)

I2CDFSRR Digital Filter Sampling Rate Register Offset 0x14

Bit	7	6	5	4	3	2	1	0
	—		DFSR					
Type	R/W							
Reset	0	0	0	1	0	0	0	0

Table 24-6 describes the I2CDFSRR fields.

Table 24-6. I2CDFSRR Bit Descriptions

Name	Reset	Description
— 7–6	0	Reserved. Write to zero for future compatibility.
DFSR 5–0	010000	**Digital Filter Sampling Rate** To assist in filtering out signal noise, the sample rate is programmed. This field is used to prescale the frequency at which the digital filter takes samples from the I²C bus. The resulting sampling rate is calculated by dividing the system frequency by the non-zero value of DFSR. If I2CDFSRR is set to zero, the I²C bus sample points default to the reset divisor 0x10. The value of DFSR should be defined by the system noise and the I2CFDR[FDR] value. DFSR must be less than six times the division factor defined by I2CFDR[FDR].

25 Debugging, Profiling, and Performance Monitoring

The MSC8157E device includes a number of mechanisms to evaluate and debug system operation. These features include:

- JTAG test access port (TAP) and boundary scan architecture
- On-chip emulator (OCE) module in each core
- Special debug and profiling elements in the device that permit:
  - Event counting
  - Entering debug mode after detection of a predefined state
  - Special trace modes in the QUICC Engine module and DSP core subsystems
  - Special debug errors
  - Host reads and writes of all registers in debug mode
- Performance monitoring of events occurring within internal modules including the DMA controller and RapidIO controller.

25.1 TAP, Boundary Scan, and OCE

The dedicated user-accessible test access port (TAP) is designed to be compatible with the **IEEE** Std. 1149.6 test access port and boundary scan architecture. Problems associated with testing high-density circuit boards led to development of this standard under the sponsorship of the test technology committee of **IEEE** and the joint test action group (JTAG). The MSC8157E supports circuit-board test strategies based on this standard. This section covers aspects of JTAG that are specific to the MSC8157E. It includes the items that the standard requires to be defined, with additional information specific to the MSC8157E device. For details on the standard, refer to the **IEEE** Std. 1149.6 documentation.

The JTAG port also provides access to the on-chip emulator (OCE) module, a dedicated block for debugging applications. Therefore, this section includes information on registers and functionality of the OCE module that are specific to the MSC8157E. For details on the OCE module functionality, see the *SC3850 DSP Core Subsystem Reference Manual*.

The SC3850 core OCE module interfaces with the SC3850 core and its peripherals non-intrusively so that you can examine registers, memory, or on-device peripherals, thus facilitating hardware and software development on the SC3850 core-based devices. Special

circuits and dedicated signals on the SC3850 core avoid sacrificing user-accessible internal resource. As the DSP applications grow in both size and complexity, the OCE module provides many features of the breakpoints, conditional breakpoints, breakpoints on data-bus values, and event detection that offer the user non-destructive access to peripherals, variety in profiling, a program tracing buffer, and real-time access to memory.

Note: There are some restrictions about using data breakpoints with some multi-variable move instructions. Multi-variable move instructions utilize the wide memory data bus to move several data elements in one access. For example, MOVE.2W transfers two 16-bit items as one 32-bit access. When the OCE data event detection channel (EDCD) is configured to detect a byte, word, or long reference data value and the core performs a multi-variable move, the reference value is searched in the positions on the bus where the variable could appear. In the MOVE.2W example, an EDCD search for a 16-bit value should be performed on bits 15–0 and 31–16 of the bus concurrently. However, for some SC3850 multi-variable byte move instructions, the EDCD does not check for the reference value in all optional positions of a byte. Therefore, it is possible that the EDCD byte breakpoints can be missed in these cases. The affected instructions include: MOVE2.2B, MOVE2.4B, MOVE2.8B, MOVEU2.2B, MOVEU2.4B, and MOVEU.8B.

25.1.1 Overview

The MSC8157E TAP consists of five dedicated signal lines, a 16-state TAP controller, and three test data registers. A Boundary Scan Register (BSR) links most of the device signal connections into a single shift register. The test logic, which uses static logic design, is independent of the device system logic. The MSC8157E JTAG can do the following:

- Perform boundary scan operations to check circuit-board electrical continuity.
- Bypass the MSC8157E for a given circuit-board test by effectively reducing the Boundary Scan Register (BSR) to a single cell.
- Sample the MSC8157E system connections during operation and transparently shift out the result in the BSR. Preload values to outputs prior to circuit board testing.
- Disable the drive to outputs during circuit board testing.
- Access the OCE controller and circuits to control a target system.
- Give entry to Debug mode.
- Query identification information (manufacturer, part number and version) from an MSC8157E-based device.
- Force test data onto the outputs of an MSC8157E-based device while replacing its BSR in the serial data path with a single-bit register.

Note: Precautions must be taken to ensure that the **IEEE** Std. 1149.6-like test logic does not interfere with non-test operation.

To access the JTAG registers, shift the appropriate command into the JTAG instruction register and then shift the required value into the register. See **Section 25.1.3** for a discussion of the JTAG instructions. **Figure 25-1** shows the MSC8157E JTAG 5-bit instruction register and the following test registers:

- Boundary Scan Register (BSR). Regarding the length of the BSR, The boundary scan bit definitions vary according to the specific chip implementation of the MSC8157E and are described by the BSDL file on the product website
- 1-bit Bypass Register
- 32-bit Identification Register (ID)
- 32 × 32-bit General-Purpose Register Bank (GSBI)
- Test port access register

Table 25-1 lists the test access port (TAP) signals.

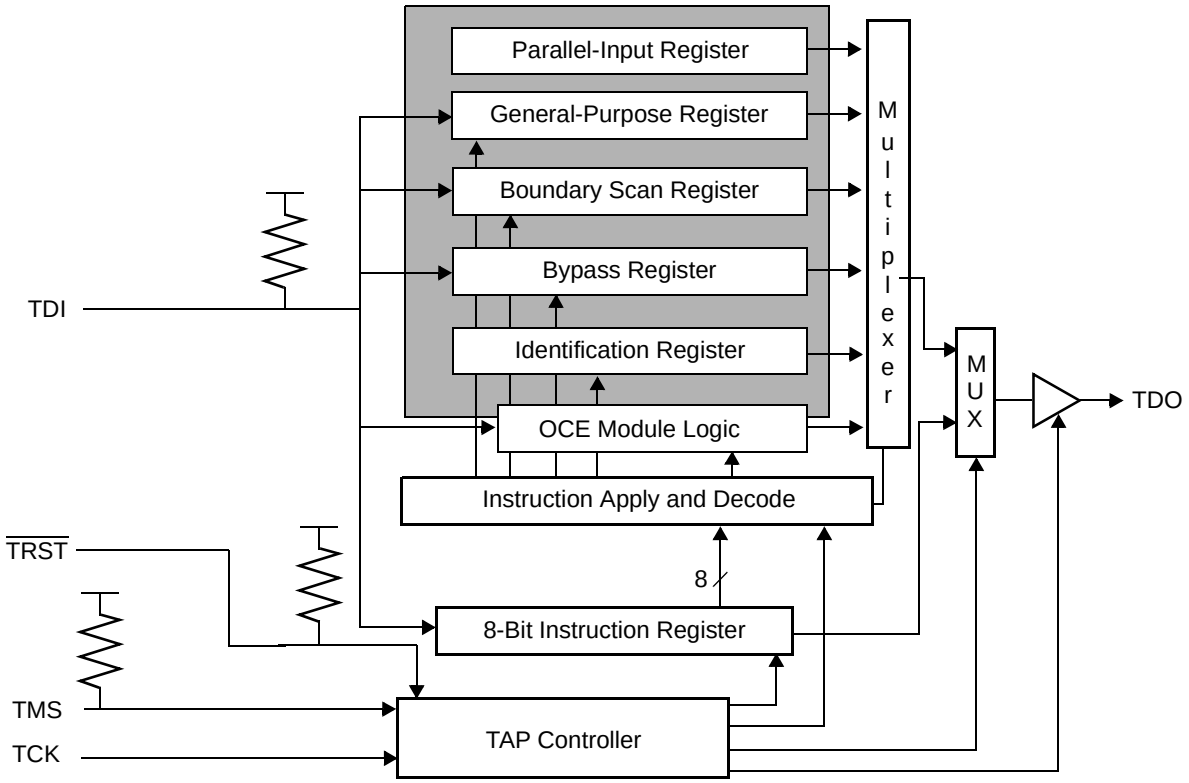

Figure 25-1. Test Logic Block Diagram

Table 25-1. TAP Signals

Signal	Description
TCK	A test clock input to synchronize the test logic.
TMS	A test mode select input (with an internal pull-up resistor) that is sampled on the rising edge of TCK to sequence the TAP controller state machine.
TDI	A test data input (with an internal pull-up resistor) that is sampled on the rising edge of TCK.

Table 25-1. TAP Signals (Continued)

Signal	Description
TDO	A data output that can be tri-stated and actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO changes on the falling edge of TCK.
$\overline{\text{TRST}}$	An asynchronous reset (with an internal pull-up resistor) that provides initialization of the TAP controller and other logic required by the standard.

25.1.2 TAP Controller

The TAP controller interprets the sequence of logical values on the TMS signal. This synchronous state machine controls the operation of the JTAG logic. The value adjacent to each arc in **Figure 25-2** represents the value of the TMS signal sampled on the rising edge of the TCK signal. For a description of the TAP controller states, refer to the **IEEE** Std. 1149.6 documentation.

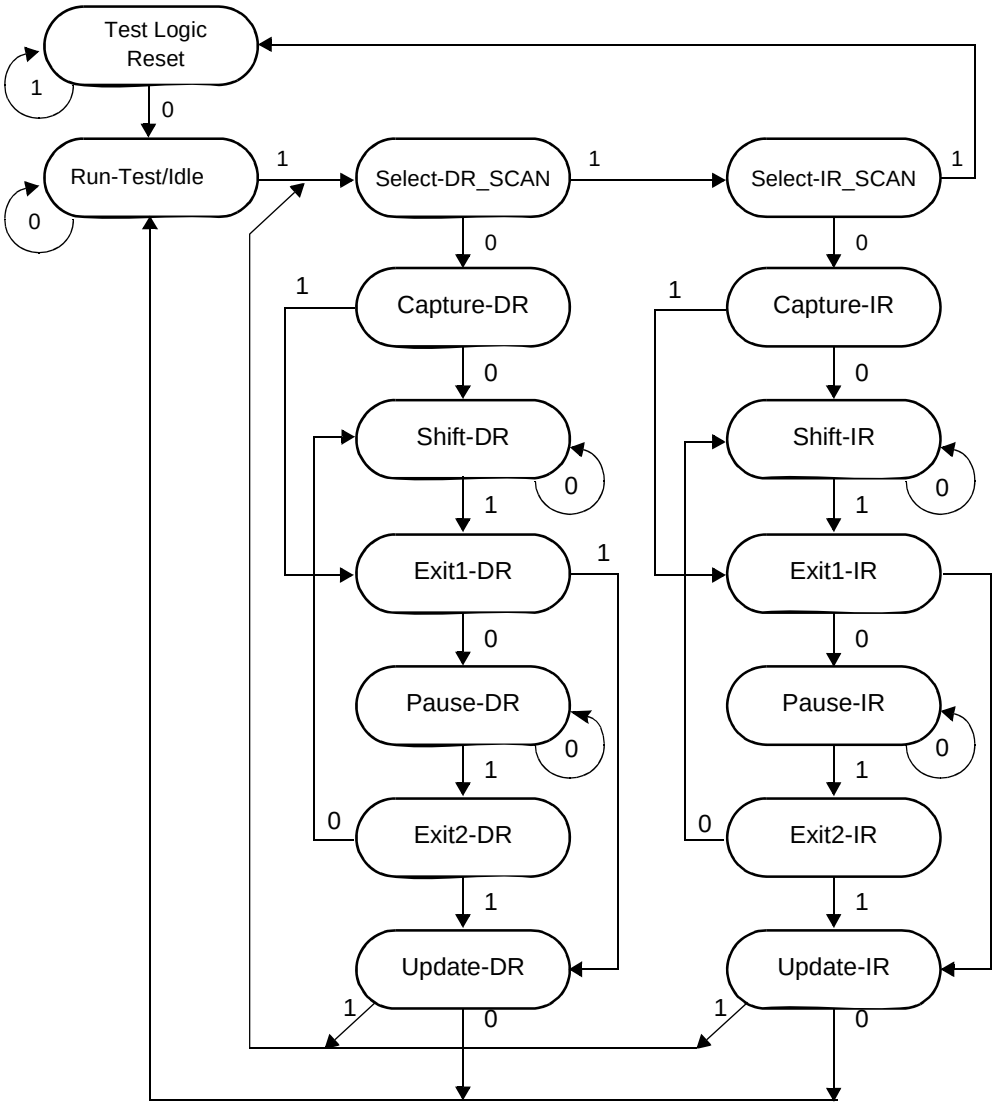

Figure 25-2. TAP Controller State Machine

25.1.3 Instruction Decoding

The MSC8157E includes the three mandatory public instructions EXTEST, SAMPLE/PRELOAD, and BYPASS and also supports the optional CLAMP and HIGHZ instructions defined by **IEEE Std.** 1149.6. The following public instructions perform key functions:

- READ_STATUS enables the JTAG port to query the status of the OCE circuitry.
- ENABLE_ONCE enables the JTAG port to communicate with the OCE circuitry.
- DEBUG_REQUEST enables the JTAG port to force the MSC8157E into Debug mode.
- CHOOSE_ONCE allows the operation of multiple OCE devices. This instruction should always execute before the first ENABLE_ONCE instruction and should shift a 1 to the SC3850 OCE module choose cells for each module that you want to enable. Since there are six internal OCE modules, you must shift 6 bits to the choose cells. For details, see **Section 25.1.4**.

The MSC8157E includes an 8-bit instruction register without parity, consisting of a shift register with eight parallel outputs. Data is transferred from the shift register to the parallel outputs during the UPDATE-IR controller state. The eight bits decode to the unique instructions listed in **Table 25-3**. All other encoding, with the exception of the manufacturer private instructions, is reserved for future enhancements and is decoded as BYPASS.

The parallel output of the Instruction Register is reset to 0xF3 in the test-logic-reset controller state, which is equivalent to the IDCODE instruction. During the CAPTURE-IR controller state, the parallel inputs to the instruction shift register are loaded with the code 01 in the least significant bits, as required by the standard. Two bits of the GPR are configured to select an SC3850 core, whose status is output from the multiplexer. Therefore, the status of all SC3850 cores can be viewed serially by updating the GPR between each SC3850 core status reading. Alternatively, all six SC3850 cores can be viewed simultaneously from the PIREG. For details on core states, refer to the *SC3850 StarCore DSP Reference Manual*.

Table 25-2. Instruction Register Capture and SC3850 Core Status Values

Name/bits	Description	Settings
FBiST_Done 7	**FBIST Done** Field built-in self test completed.	0 FBIST not complete. 1 FBIST completed
MBIST_Failed 6	**MBIST Failed** Indicates an MBIST failure.	0 No MBIST failure. 1 MBIST failed
MBIST_Done 5	**MBIST Done** Indicates that the MBIST is completed.	0 Either an activated MBIST is still running or no MBIST was initiated by the last HRESET 1 All active MBISTs are complete
— 4–3	Reserved. Always 0.	

Table 25-2. Instruction Register Capture and SC3850 Core Status Values

Name/bits	Description	Settings
clock_end_ count 2	**Clock End Count** Indicates that the counter in the clock block completed its count.	0 Clock block done signal not asserted 1 Clock block done signal asserted
— 1–0	Contains value (01) required by the JTAG standard	Read-only

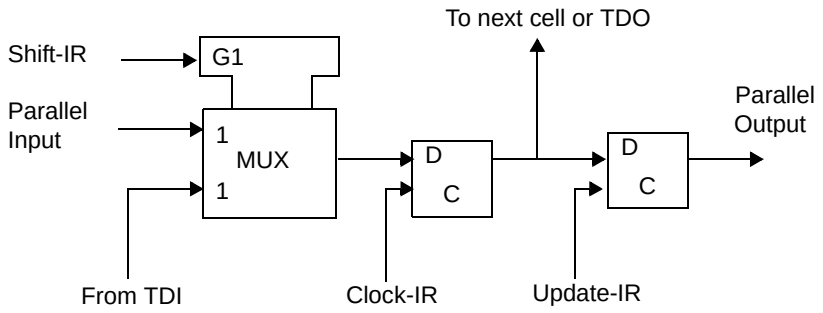

Figure 25-3. Instruction Register (IR) Configuration

Table 25-3 describes the 8-bit instructions coded in the Instruction Register.

Table 25-3. Instruction Decoding

Opcode	Instruction	Updates IR	Description
Standard Instructions			
0x00	EXTEST	Yes	Selects the Boundary Scan Register (BSR). EXTEST also asserts internal reset for the MSC8157E system logic to force a predictable internal state while external boundary scan operations are performed. By using the TAP, the register can: • Scan user-defined values into the output buffers • Capture values presented to inputs • Control the direction of bidirectional signals • Control the output drive of tri-statable outputs For details on the function and use of EXTEST, refer to the **IEEE** Std. 1149.6 documentation. Although the latest specification recommends not using all zeroes, it was mandated by earlier versions of the specification and is retained for backward compatibility.
0xF0	SAMPLE	Yes	SAMPLE provides a means to obtain a snapshot of system data and control signals.
0xF0	PRELOAD	Yes	Initializes the BSR output cells prior to the selection of EXTEST. This initialization ensures that known data appears on the outputs when an EXTEST instruction is entered.

Table 25-3. Instruction Decoding (Continued)

Opcode	Instruction	Updates IR	Description
0xF1	CLAMP	Yes	Optional in the **IEEE** Std. 1149.6. This public instruction selects the one-bit Bypass Register as the serial path between TDI and TDO, while allowing signals driven from the component to be determined from the Boundary Scan Register. During testing of ICs on PCBs, it may be necessary to place static guarding values on signals that control logic operations not involved in the test. The EXTEST instruction can be used for this purpose, but since it selects the BSR, the required guarding signals would be loaded as part of the complete serial data stream shifted in, both at the start of the test and each time a new test pattern is entered. Since the CLAMP instruction allows guarding values to be applied using the BSR of the appropriate ICs while selecting their Bypass Registers, it allows much faster testing than EXTEST. Data in the boundary scan cell remains unchanged until a new instruction is shifted in. **Note:** The CLAMP instruction also asserts internal reset for the MSC8157E system logic to force a predictable internal state while external boundary scan operations are performed.
0xF2	HIGHZ	Yes	Optional in the **IEEE** Std. 1149.6. It is a manufacturer's public instruction to prevent back-drive of the outputs during circuit-board testing. When HIGHZ is invoked, all output drivers, including the two-state drivers, are turned off (that is, high impedance). The HIGHZ instruction selects the Bypass Register. It also asserts internal reset for the MSC8157E system logic to force a predictable internal state while external boundary scan operations are performed.
0xF3	IDCODE	Yes	Selects the ID Register. This instruction is a public instruction to allow the manufacturer, part number and version of a component to be determined through the TAP. The ID Register configuration is as follows: • Bits 31–28: Version Information • Bits 27–12: Customer Part Number • Bits 11–1: Manufacturer Identity One application of the ID Register is to distinguish the manufacturer(s) of components on a board when multiple sourcing is used. included in the design. As required by the **IEEE** Std. 1149.6, the operation of the test logic has no effect on the operation of the internal system logic when the IDCODE instruction is selected. The value for the MSC8157E is 0x0189501D.
0xFE	STATUS	Yes	Private instruction that allows the user to scan out STATUS from the Instruction Register without changing the Instruction Update Register.
0xFF	BYPASS	Yes	Selects the single-bit Bypass Register. This creates a shift-register path from TDI to the Bypass Register and, finally, to TDO, circumventing the 573-bit BSR register. This instruction enhances test efficiency when a component other than the MSC8157E-based device is the device under test. When the current instruction selects the Bypass Register, the shift-register stage is set to a logic zero on the rising edge of TCK in the CAPTURE-DR controller state. Therefore, the first bit to be shifted out after the Bypass Register is selected is always a logic zero.
Clocking Control			
0x05	FREEZE	Yes	Private instruction that stops the clocks. The instructions causes all device clocks to stop. Resuming execution from this stopped state is not possible.

Table 25-3. Instruction Decoding (Continued)

Opcode	Instruction	Updates IR	Description
TLM			
0x03	TLM_SELECT	Yes	Private instruction that provides access to the TAP Linking Module.
0x04	TLM_HOLD	No	Private instruction that provides access to a TAP Linking Module. The most recent instruction that updated the Instruction Register is not overwritten by this instruction. Both the TLM Update Register and whatever else is selected by the instruction in the IR receive the TDI, but only the TLM Shift Register sends data to TDO.
OCE Instructions			
0xA0	ENABLE_ONCE	Yes	Not included in the **IEEE** Std. 1149.6. This public instruction allows you to perform system debug functions. When the ENABLE_ONCE instruction is decoded, TDI and TDO connect directly to the OCE registers. The OCE controller selects the specific OCE register connected between TDI and TDO, depending on the OCE instruction being executed. All communication with the OCE controller is through the SELECT-DR-SCAN path of the JTAG TAP Controller. Before the ENABLE_ONCE instruction is selected, the CHOOSE_ONCE instruction should be executed to define which OCE is to be activated. **Note:** This instruction is valid only if the core processor is running.
0xA1	DEBUG_REQUEST	Yes	Not included in the **IEEE** Std. 1149.6. This public instruction allows you to generate a debug request signal to the MSC8157E. When the DEBUG_REQUEST instruction is decoded, TDI and TDO connect to the OCE registers. In addition, ENABLE_ONCE is active and forced to request Debug mode from the MSC8157E to perform system debug functions. Before the DEBUG_REQUEST instruction is selected, the CHOOSE_ONCE instruction should be executed to define which OCE module is to be selected for DEBUG_REQUEST. **Note:** Issuing this instruction does not ensure that the SC3850 core enters the debug state. Monitor the core status to make sure that it has stopped.
0xA2	CHOOSE_ONCE	Yes	Not included in the **IEEE** Std. 1149.6. This instruction enables selected SC3850 OCE modules. All instructions executed after this one target only the selected OCE set. Therefore, this instruction always executes, regardless of the selected OCE set.
0xA3	RD_STATUS	Yes	The status of the OCE can be read from a dedicated status register inside the OCE by the JTAG instruction, RD_STATUS.

25.1.4 Multi-Core JTAG and OCE Module Concept

The MSC8157E uses JTAG TAP for standard defined testing compatibilities and for multi-core OCE module control and OCE module interconnection control. The MSC8157E has an internal OCE module per SC3850 core. The OCE modules interconnect in a chain and are configured and directed by the JTAG TAP controller. Each of the MSC8157E OCE modules has an interface to a JTAG port. The interface is active even when a reset signal to the SC3850 core is asserted. However, system reset must be deasserted to allow a proper interface with the cores. This interface is synchronized with the internal clocks derived from the JTAG TCK clock. Each OCE module includes an OCE controller, an event counter, an event detector unit, a synchronizer, an event selector, and a trace unit.

Note: For details on the OCE module features, consult the *SC3850 DSP Core Subsystem Reference Manual*.

The JTAG port performs the following tasks via the JTAG-OCE module interface:

- Chooses one or more OCE module blocks (CHOOSE_ONCE)
- Issues a debug request to the OCE module (DEBUG_REQUEST)
- Writes an OCE command to the OCE Command Register (DEBUG_REQUEST or ENABLE_ONCE)
- Reads and writes to internal OCE registers (DEBUG_REQUEST or ENABLE_ONCE)
- Queries the status of the OCE block (RD_STATUS)

25.1.5 Enabling the OCE Module

The CHOOSE_ONCE mechanism integrates multiple cores and thus multiple OCE modules on the same device. Using the CHOOSE_ONCE instruction, you can selectively activate one or more of the OCE modules on the MSC8157E. The OCE modules selected by the CHOOSE_ONCE instruction are cascaded as shown in **Figure 25-4**. Only selected OCE modules

respond to ENABLE_ONCE and DEBUG_REQUEST instructions from the JTAG. All OCE modules are deselected after reset.

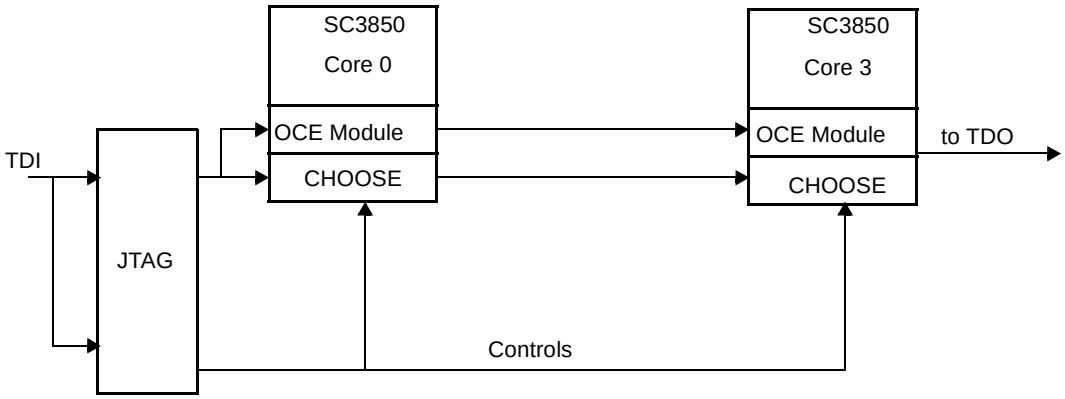

Figure 25-4. Cascading Multiple OCE Modules

Since all the OCE modules are cascaded, the selection procedure is performed serially. The sequence is:

1. Select the CHOOSE_ONCE instruction.
2. Enter at Shift_DR state the serial stream that specifies the modules to be selected (1 = selected, 0 = not selected).

The number of bits in this stream, that is, the number of clocks in this state, is equal to the number of selected SC3850 cores in the cascade, which is *six*. This state is indicated by the CHOOSE_CLOCK_DR signal. For example, for the six SC3850 cores on the MSC8157E, to activate the sixth core in the cascade, which is the closest to TDO and the farthest from TDI, the data is 1,0,0,0,0,0 (first a one, then five zeros). If the data is 0,0,1,0,1,0, then both the second and the fourth cells are selected.

Only the OCE command register (ECR) should be accessed in cascaded mode. To do this, first enter the CHOOSE_ONCE instruction and set ENABLE_ONCE to 1 for all cores. Then shift in the cascaded value for all ECRs in series. When the shift is ended and the controller issues a SHIFT_UPDATE, all registers are updated in parallel. However, it is not guaranteed that this occurs in the same SC3850 clock cycle for all cores.

25.1.6 DEBUG_REQUEST and ENABLE_ONCE Commands

After completing the CHOOSE_ONCE instruction, you can execute DEBUG_REQUEST and ENABLE_ONCE instructions. More than one such instruction can execute, and other instructions can be placed between them, as well as between them and the CHOOSE_ONCE instruction. The OCE modules selected in the CHOOSE_ONCE instruction remain selected until the next CHOOSE_ONCE instruction. The DEBUG_REQUEST or ENABLE_ONCE instruction is shifted in during the SHIFT-IR state, as are all JTAG instructions.

25.1.7 RD_STATUS Command

In the OCE, the status bits are no longer shifted out when shifting in any JTAG instruction. Instead, there is a special instruction which will return the status of selected core(s). **Figure 25-5** shows an example of CORE_CMD and RD_STATUS instructions.

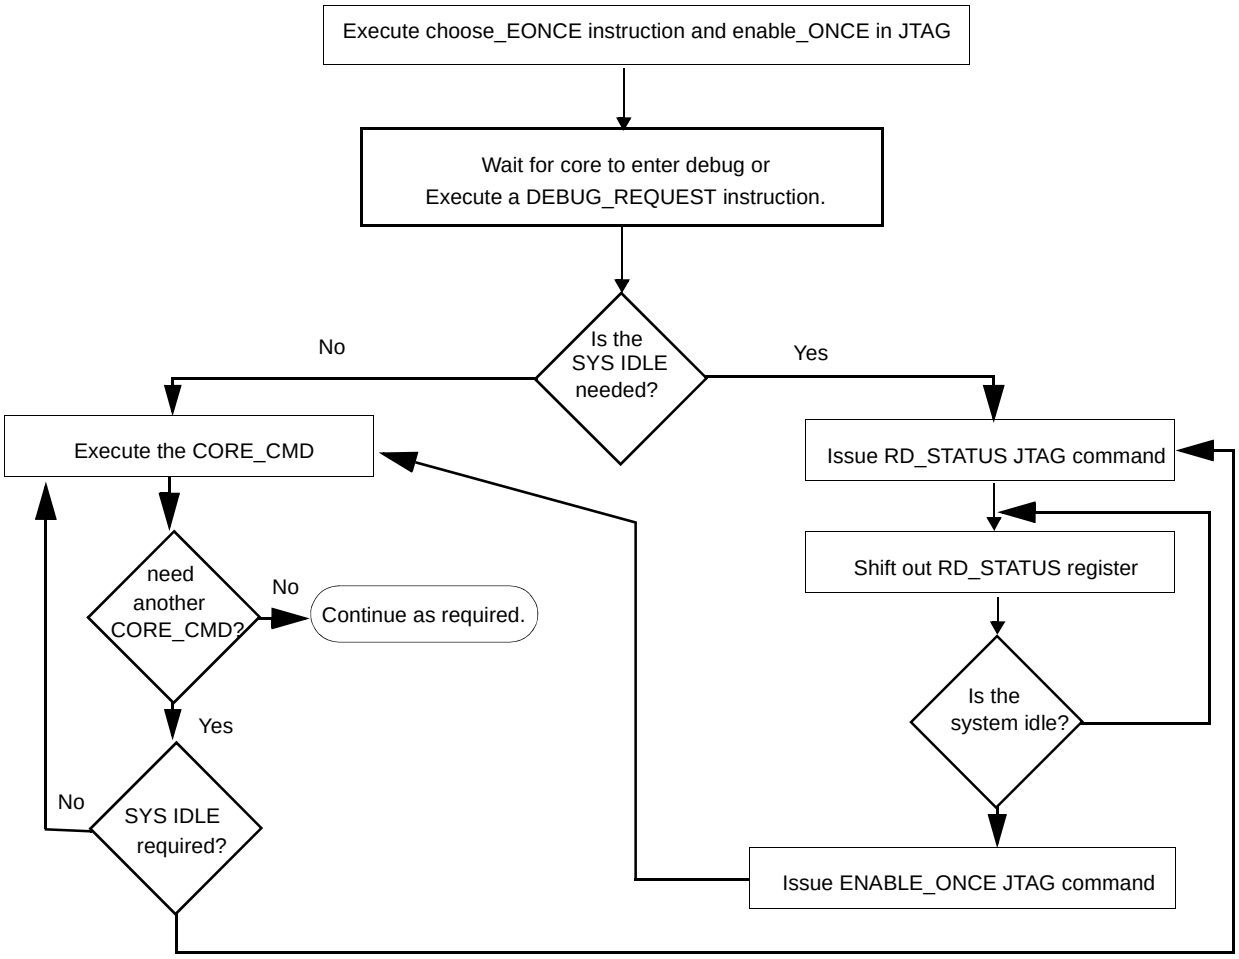

Figure 25-5. CORE_CMD and RD_STATUS Flow

25.1.8 Reading/Writing OCE Registers Through JTAG

An external host can read or write almost every OCE register through the JTAG interface by performing the following steps:

1. Execute the CHOOSE_ONCE command in the JTAG.
2. Send the data showing which OCE module is chosen. This command enables the JTAG to manage multiple OCE modules in a device.
3. Execute the ENABLE_ONCE command in the JTAG.

4. Write the OCE command into the ECR; that is, enter the JTAG TAP state machine into the SHIFT-DR state and then give the required command on the TDI input signal.

After the command is shifted in, the JTAG TAP state machine must enter the UPDATE-DR state. The data shifted via the TDI is sampled into the ECR. If, for example, the command written into the ECR is *Write EDCA0_CTRL*, then the host must again enter the JTAG into SHIFT-DR and shift the required data, which is to be written into the EDCA0_CTRL, via TDI. If the command is *read some register*, then the DR chain must be passed again and the contents of the register are shifted out through the TDO output signal. When JTAG shifts data to the OCE module, the lsb of the data is shifted first. See **Figure 25-6**.

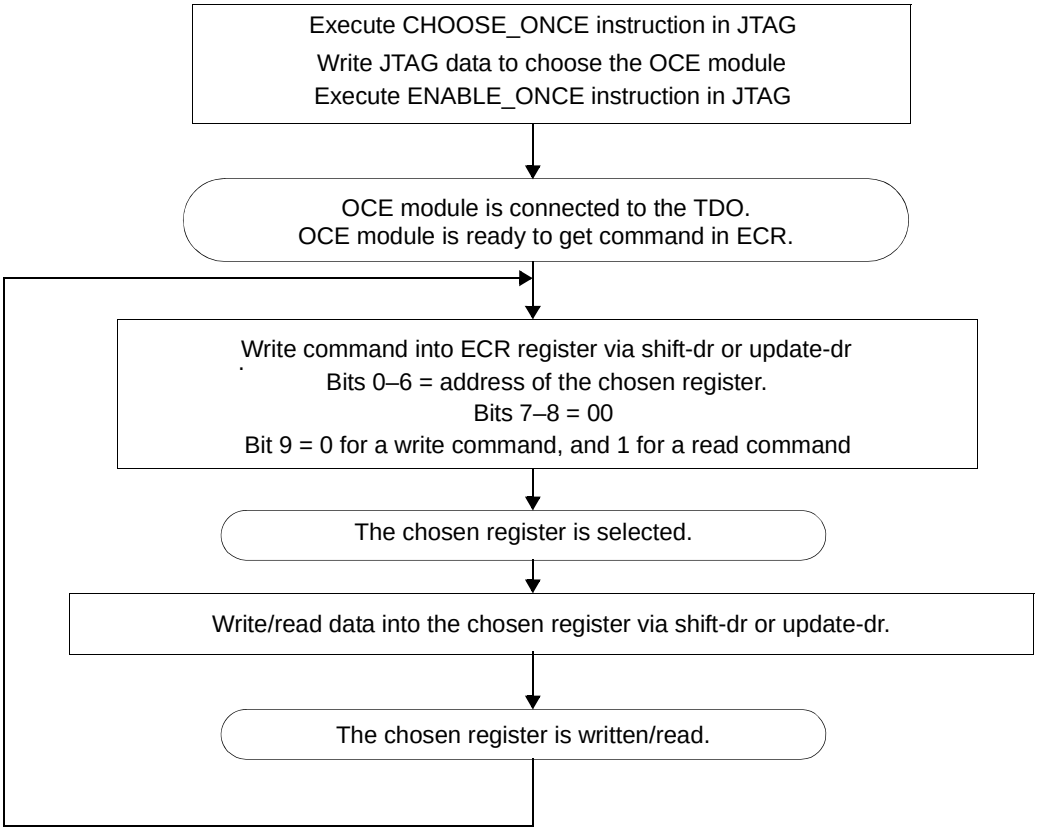

Figure 25-6. Reading and Writing OCE Registers Via the JTAG TAP

25.1.9 Signalling a Debug Request

The EE[0–1] signals connect to each of the MSC8157E OCE modules. EE0 is an input that signals a debug request; EE1 is an output signal that acknowledges the request or acts as an output of event detector 1.

Note: Asserting EE0 does not guarantee that the cores enter debug mode.The signal can be masked internally. Monitor the core status by shifting out the contents of PIREG or by issuing an instruction and observing the TDO value shifted out.

25.1.10 EE_CTRL Modifications for the MSC8157E

The relevant paragraph from the OCE module chapter of the *SC3850 DSP Core Reference Manual* is reproduced here with the appropriate amendments. See **Figure 7-20** in that manual for details.

EE_CTRL EE Control Register

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	—												EE1DEF		EE0DEF	
Type	R/W															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

The modes for EE[0–2] are restricted as follows:

Table 25-4. EE0 Definition (EE0DEF), Bits 1–0

EE0DEF		EE0 Definition
0	0	Reserved
0	1	Reserved
1	0	Input
1	1	Input: Debug Request

The EE0DEF bits program EE0, either to enable Address Event Detection Channel 0 by providing an input to the OCE module in the event detection unit and the event selector to or to generate an OCE event. EE0 can be programmed to enter the SC3850 core into Debug mode (the default) right after the SC3850 core is reset. Holding EE0 at logic value 1 during and after the reset puts the SC3850 core into Debug mode before the first dispatch occurs. In this mode, asserting EE0 also causes an exit from the STOP or WAIT processing states of the SC3850 core. If you want some SC3850 cores running and others in Debug mode, you must disable either the inputs of the running SC3850 cores or the outputs of the stopped SC3850 cores. To block EE0, set it as an input and mask the EE0 event in the event selector mask register (see the next section on programming the ESEL_DM Register).

Table 25-5. EE1 Definition (EE1DEF), Bits 3–2

EE1DEF		EE1 Definition
0	0	Output: Detection by EDCA1
0	1	Output: Debug Acknowledge
1	0	Reserved
1	1	Reserved

The EE1DEF bits program EE1. The signal can be programmed as an output of the OCE module to indicate detection by Address Event Detection Channel 1 (working as a toggle) or to indicate

that the DSP has entered Debug mode (Debug Acknowledge). To disable EE1, EDCA1 must be disabled and the mode set to 00.

Note: If the boot code is not executed, you must initialize the EE1DEF bits to 01 (output debug acknowledge) to activate EE1 as debug acknowledge. The default value (11) does not activate EE1 as debug acknowledge. If the EE1DEF bits are not initialized correctly, EE1 as a core output will always be 0, meaning that no debug acknowledge is sent to the other cores (as a trigger to enter Debug mode) or to the EE1 output. Therefore, if the boot code is bypassed, the user must initialize EE1DEF correctly to use the debug acknowledge.

25.1.11 ESEL_DM and EDCA_CTRL Register Programming

The Event Selector Mask Debug Mode (ESEL_DM) register in the OCE programs the event selectors for the debug events. From the EE pins, the MSC8157E only supports EE0 and EE1 signals. Also, there is a requirement to block triggering from EE0 if only some SC3850 cores must enter Debug mode. The EE_CTRL register can be used to enable the use of EE1 as the debug indicator. See the *SC3850 DSP Core Subsystem Reference Manual* for more information.

25.1.12 Real-Time Debug Request

All the SC3850 cores can enter Debug mode in several ways. The EE0 debug input request of all six SC3850 cores is wired to the output of an “OR” gate that sums the state of all EE1 outputs of the other SC3850 cores and the external EE0 signal (see **Figure 25-7**). Therefore, if any one SC3850 core sets its EE1 output (that is, enters Debug mode) or EE0 is asserted, the debug request input on all SC3850 cores is asserted. EE1 is activated when at least one of the SC3850 cores enters Debug mode.

Note: The EE0 input initiates Debug mode, and the EE1 output is the debug acknowledge indication.

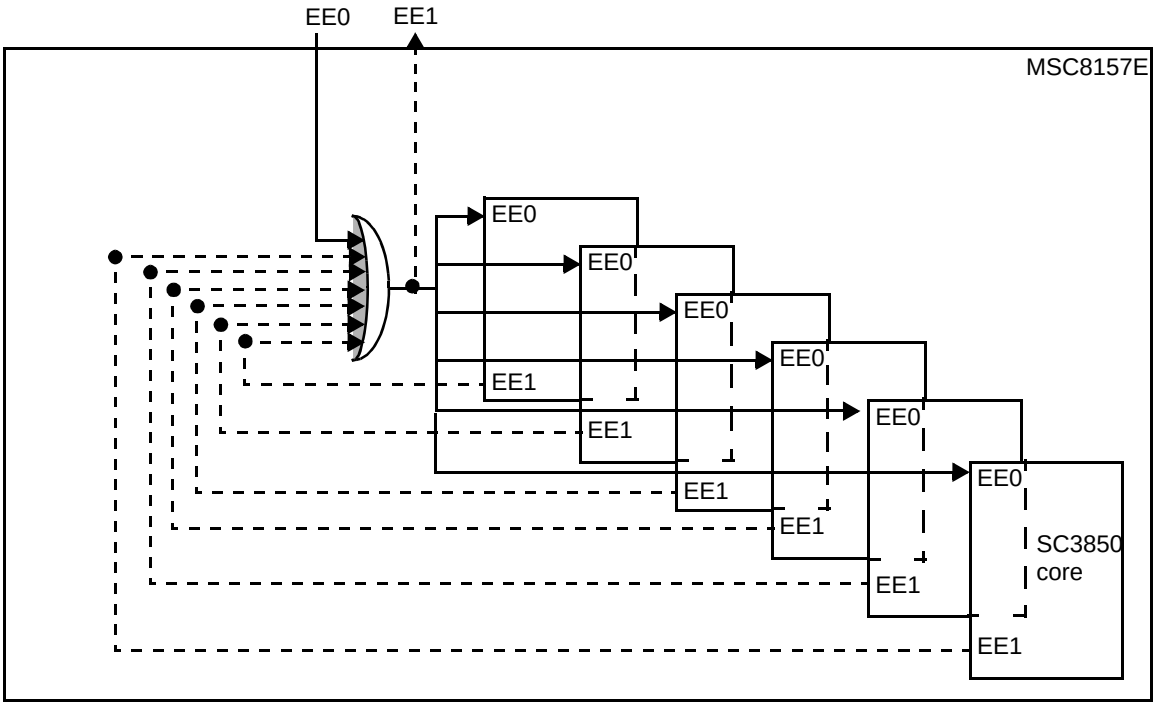

Figure 25-7. Selected SC3850 Core Issues a Debug Request to All Other SC3850 Cores

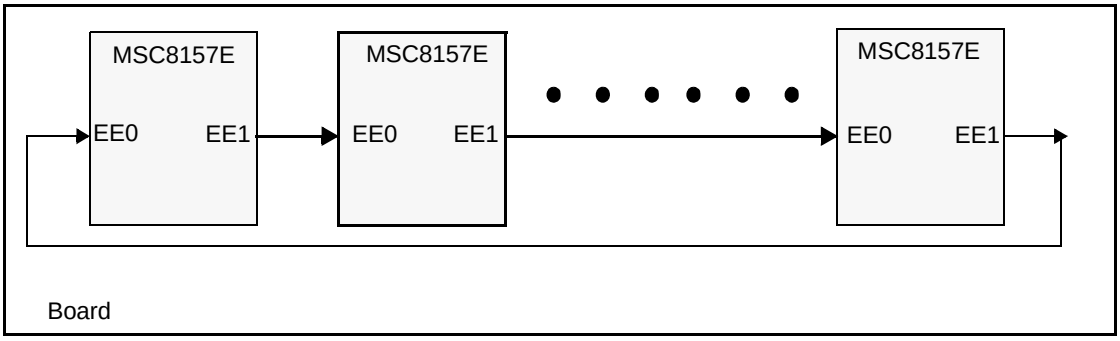

Figure 25-8. Board EE Signal Interconnectivity

25.1.13 Exiting Debug Mode

When an SC3850 core enters Debug mode (this is checked by OCE module status bits through JTAG as shown in **Table 25-2**), the EE0 internal signal of that SC3850 core OCE module is masked, preventing any more debug requests. When all the SC3850 cores exit Debug mode, the EE0 internal signals of all SC3850 cores are unmasked, enabling further debug requests. To restart the SC3850 cores, a **go** instruction is scanned into all six SC3850 cores. When the scan completes, the update launches all six SC3850 cores.

Note: When multiple cores are in Debug mode, issuing simultaneous **go** instructions to such cores does not guarantee that the cores exit Debug mode on the same clock cycle.

No retriggering occurs through EE0. For stepping, the same arrangement is used with the **step** instruction. All SC3850 cores are enabled via the CHOOSE_ONCE command, and then a **step** instruction is scanned into all six SC3850 cores. When the scan is done, the update launches all six SC3850 cores simultaneously. No retriggering occurs through EE0.

25.1.14 General JTAG Mode Restrictions

The control afforded by the output enable signals using the **bsr** and the **extest** instruction requires a compatible circuit-board test environment to avoid device-destructive configurations. You must avoid situations in which the MSC8157E output drivers are enabled into actively driven networks. There are two constraints on the JTAG interface.

- The TCK input does not include an internal pull-up resistor. To preclude mid-level input effects, do not leave this line unconnected.
- To ensure that the JTAG logic does not conflict with the system logic, always force the TAP into the test-logic-reset controller state by asserting the $\overline{\text{TRST}}$ input during power-up.

To save power when JTAG is not in use, the MSC8157E should be in the following state:

- To enter or to remain in the Low-Power Stop mode, the TAP controller must be in the test-logic-reset state. Leaving the TAP controller test-logic-reset state negates the ability to achieve low power but does not otherwise affect device functionality.
- The TCK input is not blocked in Low-Power Stop mode. To consume minimal power, the TCK input should externally connect to V_{CC} or ground.
- TMS and TDI include internal pull-up resistors. In Low-Power Stop mode, these two signals should remain either unconnected or connected to V_{CC} to achieve minimal power consumption.

25.1.15 JTAG and OCE Module Programming Model

25.1.15.1 Identification Register

The JTAG ID register is a 32-bit read-only factory-programmed register that distinguishes the component on a board according to the **IEEE** Std. 1149.6. The fields are defined as follows:

JTAGID JTAG Identification (ID) Register **JTAG port access only**

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	0	0	0	0	0	0	0	1	1	0	0	0	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0	1	1	1	0	1
	Version				Design Center						Sequence Number										Manufacturer identity											1

- Version information corresponds to the revision number. The MSC8157E first mask set is 0b0000.
- Design Center number is 0b000110.
- Sequence Number for the MSC8157E is 0b0010010100.
- Manufacture identity is 0b00000001110.
- The final 1 is required by the **IEEE** Std. 1149.6.

Note: The hexadecimal value stored in this register is 0x0189501D.

Later mask sets will have a different number. Refer to the website listed on the back cover of this manual for the information about the contents of this register for current device revisions.

25.1.15.2 Boundary Scan Register (BSR)

The MSC8157E BSR contains bits for most device signals and control signals. All MSC8157E bidirectional signals have two registers for boundary scan data and are controlled by an associated control bit in the BSR. The boundary scan bit definitions vary according to the specific chip implementation of the MSC8157E and are described by the BSDL file on the product website. **Figure 25-9** through **Figure 25-12** show various BSR cell types.

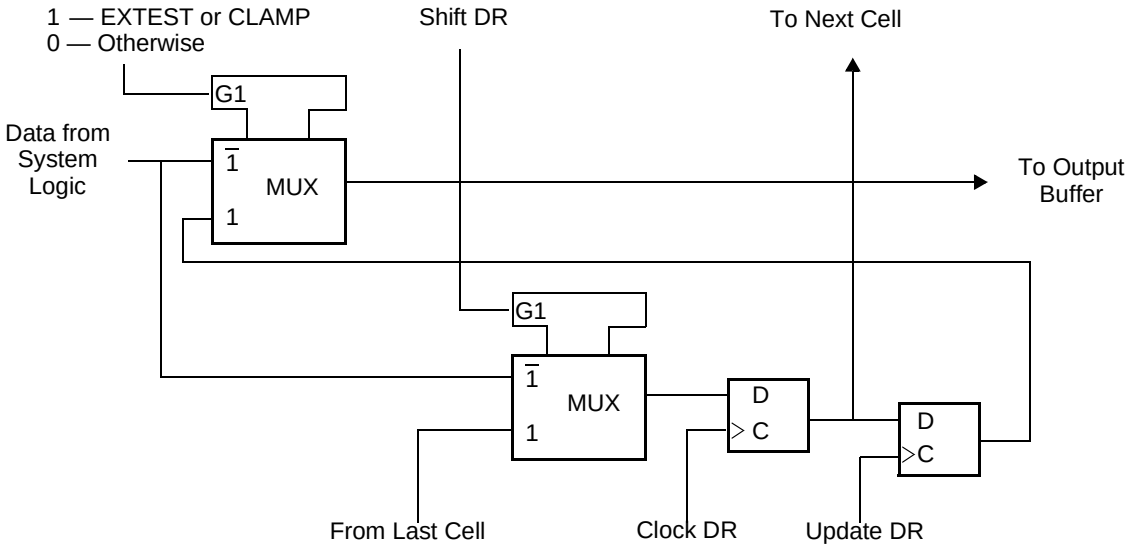

Figure 25-9. Output Signal Cell (O.PIN)

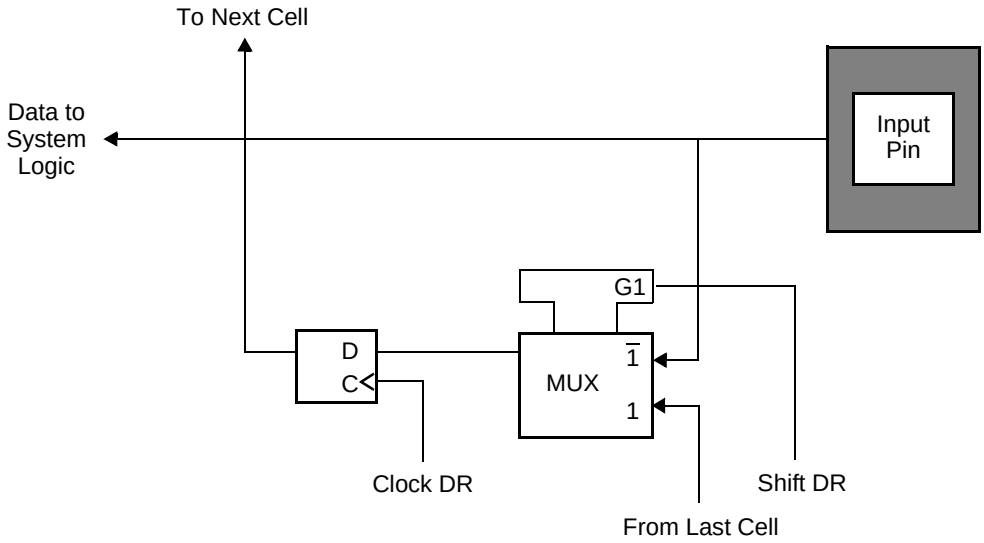

Figure 25-10. Observe-Only Input Signal Cell (I.OBS)

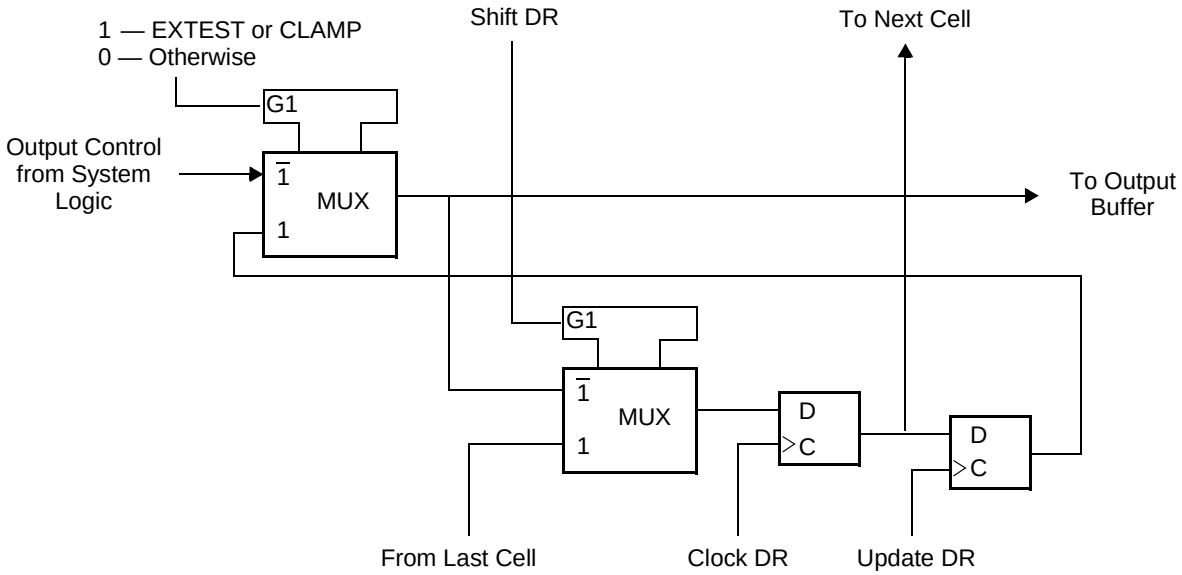

Figure 25-11. Output Control Cell (IO.CTL)

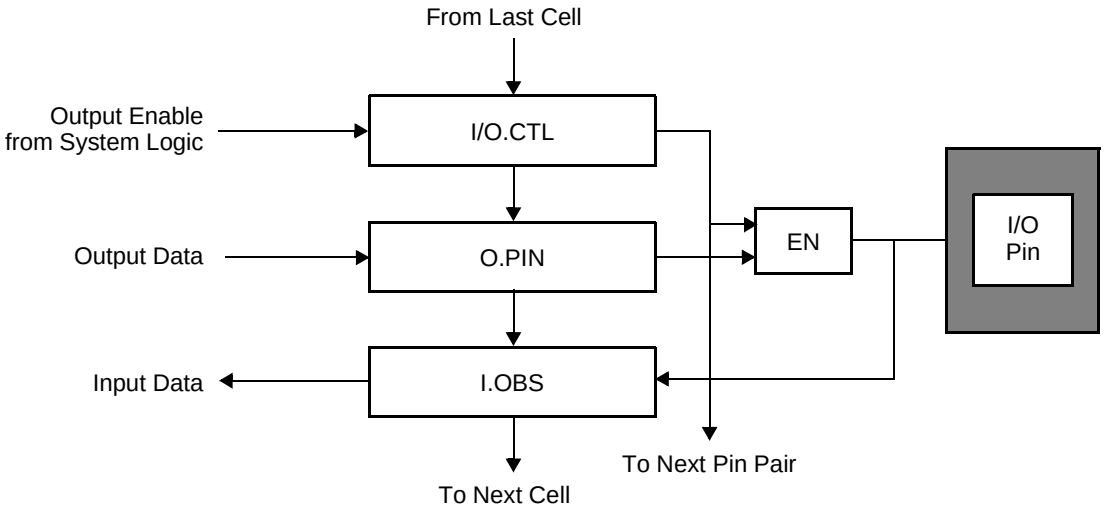

Figure 25-12. General Arrangement of Bidirectional Signal Cells

The control bit value controls the output function of the bidirectional signal. One or more bidirectional data cells can be serially connected to a control cell. Bidirectional signals include two scan cells for data (IO.Cell) as shown in **Figure 25-12**, and these bits are controlled by the cell shown in **Figure 25-11**. It is important to know the boundary scan bit order and signals that are associated with them. The BSDL file on the product website describes the boundary sca serial string. The three MSC8157E cell types described in this file are depicted in **Figure 25-9** through **Figure 25-11**, which describe the cell structure for each type.

25.1.15.3 Shift Registers

The shift registers include the Bypass Register, General-Purpose Register (GPR), BSR, Identification Register, and Parallel Input register.

25.1.15.4 Bypass Register

The Bypass Register is a single-bit shift register (see **Figure 25-13**). When selected, it creates a shift-register path of one bit from TDI to TDO. When the Bypass Register is selected, the shift-register stage is set to a logic zero on the rising edge of TCK in the CAPTURE-DR controller state.

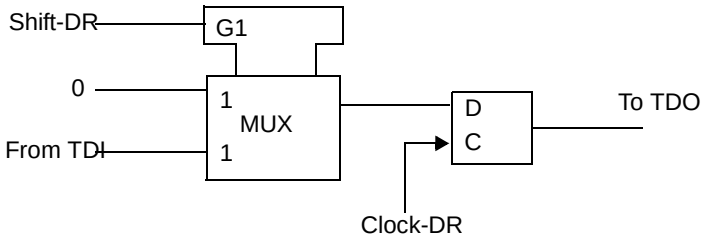

Figure 25-13. Bypass Register Configuration

25.1.15.5 Identification Register

When the Identification Register is selected, the shift-register stage is set to a logic value equal to IDCODE on the rising edge of TCK in the CAPTURE-DR controller state. It can then be shifted out in the SHIFT-DR controller state. See **Figure 25-14**.

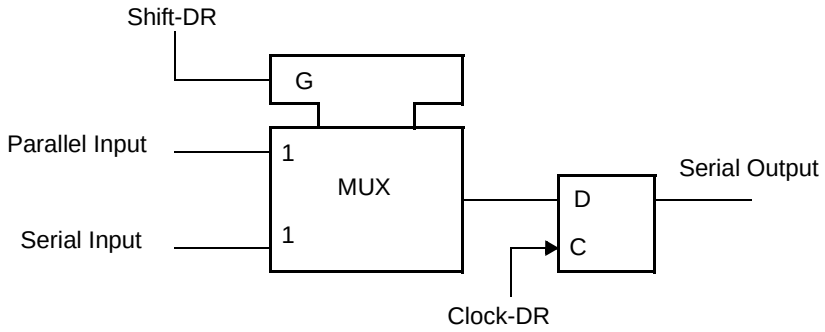

Figure 25-14. Identification Register Configuration (ID)

25.2 Debug and Profiling

The main debugging and profiling purposes are:

- Parallel counting of different events characterizing the operation of the MSC8157E device.
- Support for entering Debug mode upon detecting a predefined state of the MSC8157E device, for example, when counting a predefined number of events (watchpoint monitors).
- Support for tracing of various modes in the QUICC Engine module and DSP core subsystem.
- Debug errors (for example, a transaction request with an illegal address or peripherals errors).
- Support of reading and writing all MSC8157E registers and memories in debug mode by a host processor.

25.2.1 Features

Table 25-6 describes MSC8157E device debug and profiling features

Table 25-6. MSC8157E Debug and Profiling Features

Block Name	Number of Blocks in MSC8157E	Supports Internal Debug	Supports Internal Profiling	Supports Profiling by PM Block	Supports Profiling and Debug by a CLASS Module
DSP core subsystem	6	+	+	+	+
DMA	1	+	—	+	+
QUICC Engine subsystem	1	+	+	—	+

Table 25-6. MSC8157E Debug and Profiling Features

Block Name	Number of Blocks in MSC8157E	Supports Internal Debug	Supports Internal Profiling	Supports Profiling by PM Block	Supports Profiling and Debug by a CLASS Module
Class	2	+	+	—	+
PCI	1	+	—	—	+
RapidIO complex	1	+	—	+	+
eMSG complex	1	+	—	+	+
CPRI	1	+	—	+	+
L2/M2 memory	6	—	—	—	+
M3 memory	1	—	—	—	+
DDR memory	1	—	—	—	+
MAPLE-B2	1	—	—	—	+

Other features:

- The performance monitor block supports counting of RapidIO and DMA specific events.
- The watchdog timer (WDT) option prevents system lock if software becomes trapped in a loop operation with no controlled exit.
- JTAG port
  - — Support multiple core OCE control and interconnection for the DSP core subsystems.
  - — Supports QUICC Engine module debug control.
  - — Provides access to all shared and CCSR memory space.
- The MSC8157E provides access for all peripherals (QUICC Engine subsystem, RapidIO, PCI Express, DMA, and UART) to all shared and CCSR memory space.

25.2.2 Entering Debug Mode

The individual modules have their own Debug state, which can be entered as follows:

- *DSP core subsystem*. Enters the Debug state when one of the following events occur:
  - — Assertion of dedicated input signals (normally connected to the debugging agent)
  - — Execution of the DEBUG or DEBUGEV instructions by the core.
  - — A DPU event (depends on the configuration of the DPU and OCE).
  - — Initiator or peripheral writes a certain value to the GCR2 control register.
- *L1 ICache and DCache and L2 Cache*. Activated only when the DSP core subsystem is in the Debug state and certain values are written to their respective control registers. In this mode, the internal state of the caches (tags, valid bits, PLRU table and cache array) can be read with JTAG-inserted core commands.

Note: See *SC3850 DSP Core Reference Manual* and *SC3850 DSP Core Subsystem Reference Manual* for details. Both are available under NDA. Contact your local Freescale sales office or representative for details.

25.2.3 Exiting Debug mode

The modules with a Debug mode exit that mode as follows:

1. The ICache, DCache and L2 Cache blocks exit the Debug state when certain values are written to their respective control registers through the JTAG port or a reset signal is asserted.
2. The SC3850 DSP core subsystems exit the Debug state when they receive the proper transaction from the external debugging agent through the JTAG port, or a reset signal is asserted.

25.2.4 SC3850 Debug and Profiling

The MSC8157E device contains six extended DSP cores. Each DSP core subsystem supports the debug and profiling capabilities. When the DSP core subsystem is in the Debug state, the SC3850 core enters its Debug processing state, and instruction processing is halted. After a delay, all subsequent DSP core subsystem activity ceases (as reflected in the BUSY bit in the JTAG accessible OCE register RD_STATUS). In this state, a debugging agent external to the DSP core subsystem can access various internal DSP core subsystem registers and memory locations to develop and debug applications. The DSP core subsystem enters Debug state after one of the following occurs:

- Assertion of dedicated input signals (normally connected to the debugging agent).
- Execution of the DEBUG or DEBUGEV instruction by the core.
- An event is detected by the DPU (depending on the configuration of the DPU and OCE).
- An initiator or peripheral device writes a certain value to GCR2 control register.

Note: See the *SC3850 DSP Core Subsystem Reference Manual* for details.

The DSP core subsystem exits the Debug state when it receives the proper transaction from the external debugging agent through the JTAG port or a reset signal is asserted.

25.2.5 L1 ICache and DCache Debug and Profiling

The L1 ICache and DCache L2 Cache/M2 blocks in each DSP core subsystem have block-specific Debug modes that are ctivated only when the DSP core subsystem is in the Debug state and certain values are written to their respective control registers. In this mode, the internal state of the caches (tags, valid bits, PLRU table and cache array) can be read with JTAG-inserted core commands.

Note: See the *MSC3850 Core Subsystem Reference Manual* for details.

25.2.6 DMA Controller Debug and Profiling

The DMA controller can enter debug mode only as the result of an external debug request. When this occurs, the channel logic masks all channel requests generated towards the bus interface and finishes all pipelined requests in the bus interface and M bus. In this state, a debugging agent external to the MSC8157E can access the DMA controller PRAM through JTAG bus.

25.2.6.1 Debug Errors

The DMA support debugging errors and indications, such as:

- BD_SIZE, MD_BD_SIZE programmed with a value of zero
- Channel information that causes an illegal addresses on bus interface ports A/B.
- Early Dead Line serve First Violation.

When one of the errors occurs, the DMA controller generates the error interrupt listed in **Table 25-7**.

Table 25-7. DMA Debug Interrupt

DSP core subsystem Interrupt Number	Description of Interrupt
143	DMA errors interrupt

See **Chapter 14**, *Direct Memory Access (DMA) Controller* for details.

25.2.6.2 Profiling Unit

After configuration, all DMA events are connected to and monitored by the performance monitor (PM) block. See **Section 25.3**, *Performance Monitor* for details on how to use the information.

25.2.7 CLASS Modules

Each of the CLASS modules includes the ability to generate interrupts and perform profiling.

25.2.7.1 Debug

Each CLASS module can generate up to N + 1 interrupts, which are divided to 2 groups: N particular interrupts (one per MI M bus Initiator) and one general Interrupt. A specific interrupt is created when the CLASS module receives a transaction request with an illegal address. Illegal addresses are defined as one of the following two cases:

1. An address that does not belong to any of the address space windows of the enabled address decoders.
2. An address that falls within any of the address space windows of the enabled error address decoders.

The general interrupt is the logical OR of all the particular interrupts. Thus, the general interrupt is asserted when at least one of the particular interrupts is asserted.

Note: See **Chapter 4**, *Chip-Level Arbitration and Switching System (CLASS)* for details.

25.2.7.2 CLASS Debug Profiling Unit (CDPU)

The CLASS supports Debug and Profiling measurements by the class debug profiling unit (CDPU) sub-block. The main features are:

- Time-out mechanism. This mechanism does not generate an interrupt. The host must poll certain a bit in the respective CLASS register.
- Watch point mechanism profiling unit. The CLASS profiling unit provides the following profiling information:
  - Data acknowledges of write accesses.
  - Data acknowledges of read accesses.
  - Acknowledged accesses (req and req_ack).
  - Stall cycles due to write-after-read.
  - Cycles of non-acknowledged accesses.
  - Acknowledged supervisor accesses.
  - Acknowledged non-supervisor accesses.
  - Cycles when priority = 0.
  - Cycles when priority = 1.
  - Cycles when priority = 2.
  - Cycles when priority = 3.
  - Priority upgrades.
  - Cycles for which the priority was not upgraded because the upgradeable signal was low.
  - Acknowledged read accesses.
  - Acknowledged write with confirm accesses.
  - Acknowledged write without confirm accesses.
- Over-flow mechanism.

Table 25-8. Class0 Debug Interrupts

DSP Core Subsystem Interrupt	Description of Interrupt
Routed through General Interrupt Register 3 (GIR3)	Class0 watch point mechanism interrupt
Routed through General Interrupt Register 3 (GIR3)	Class0 over flow mechanism interrupt
Routed through General Interrupt Register 3 (GIR3)	Class0 error interrupt

Chapter 4, *Chip-Level Arbitration and Switching System (CLASS)* and **Chapter 8**, *General Configuration Registers* for details.

25.2.8 QUICC Engine Debug and Profiling

The QUICC Engine module has several means to debug and profile its operation as described in the following sections.

25.2.8.1 Trace Buffer

The QUICC Engine module provides chip-level testing capability through the trace buffer block (TRB). The TRB provides means of tracing the code ran by the CP (communication processor) in real time (through storing it non-intrusively) and reporting several internal CP/TRB events. The QUICC Engine module RISC has 4 kinds of breakpoints for on chip software debugging

- Instruction breakpoint
- Software breakpoint
- Data breakpoint
- External breakpoint

Note: See **Section 19.2**, *RISC Processors* for details.

25.2.8.2 Loopback Modes

SGMII supports an internal Loopback mode in the TBI MAC layer. RGMII supports internal Loopback mode in the MAC layer. The communication controllers support Diagnostic modes, including local and external loopback (transmitter-to-receiver) and normal operation. See the *QUICC Engine Block Reference Manual with Interworking Protocol* for details.

All serial interfaces (SGMII, Serial RapidIO, PCI Express, and CPRI) support digital loopback mode. See **Section 15.10.59** for details.

25.2.9 Serial RapidIO and eMSG Debug and Profiling

The SRIO/eMSG complex debugging system includes three error interrupts and the ability to connect to the profiling unit.

25.2.9.1 Debug Errors

The SRIO/eMSG complex asserts the error interrupts listed in **Table 25-9** when a system error is detected.

Table 25-9. eMSG Debug Interrupt

DSP core subsystem Interrupt Number	Description of Interrupt
86	ORed Serial RapidIO eMSG Queue Manager Receive Interrupt
87	ORed Serial RapidIO eMSG Queue Manager Transmit Interrupt
88	ORed Serial RapidIO eMSG Buffer Manager Interrupt

See **Chapter 16**, *Serial RapidIO Controller and Enhanced Message Complex* for details.

In addition, there are 27 eMSG-related interrupts that come out of the HSSI complex and are ORed in GIR7 and enabled for each core by GIER7_0 to GIER7_5.

25.2.9.2 Profiling Unit

All RapidIO/eMSG events can connect to Performance monitor (PM) block. See **Section 25.3**, *Performance Monitor* for details. The RapidIO PM uses the RapidIO clock.

25.2.10 CPRI Debug and Profiling

The CPRI system debugging system includes two error interrupts and the ability to connect to the profiling unit.

25.2.10.1 Debug Errors

The CPRI system asserts the error interrupt listed in **Table 25-10** when a system error is detected.

Table 25-10. CPRI Debug Interrupt

DSP core subsystem Interrupt Number	Description of Interrupt
89	ORed CPRI Receive Control Interrupt
90	ORed CPRI Transmit Control Interrupt

See **Section 17.3.10**, *Interrupts*, on page 17-54 for details.

25.2.11 Software Watchdog (SWT)

The watchdog timer (WDT) option prevents system lockup in cases where the software becomes trapped in a loop with no controlled exit. Watchdog timer operations are configured in the System Watchdog Control Register (SWCRR). See **Chapter 8**, *General Configuration Registers* for details.

25.2.12 Profiling Unit Programming Model

All DPU registers are memory-mapped and can be written or read by the core in Execution mode or through the OCE Core Command in Debug mode. See the *SC3850 DSP Core Subsystem Reference Manual* DPU chapter for details.

25.3 Performance Monitor

The MSC8157E includes a performance monitor facility that can be used to monitor and record selected behaviors of the integrated device. **Section 25.3.1.5** briefly describes the events that can be monitored. Refer to the individual module chapters for a better understanding of these events. Performance monitor up-counters (PMC0–PMC8) count events selected by the performance monitor local control registers. PMC0 is a 64-bit up-counter specifically designated to count cycles. PMC1–PMC8 are 32-bit counters that can monitor 64 specific events in addition to counting 64 reference events. Each counter is associated with two local control registers (A and B) that configure the events counted. In addition, there is a global control register that can be used to enable/disable all the counters at one time.

The benefits of an internal performance monitor are numerous, and include the following:

- Because some systems or software environments are not easily characterized by signal traces or benchmarks, the performance monitor can be used to understand the MSC8157E device behavior in any system or software environment.
- The performance monitor facility can be used to aid system developers when bringing up and debugging systems.
- System performance can be increased by monitoring memory hierarchy behavior. This can help to optimize algorithms used to schedule or partition tasks and to refine the data structures and distribution used by each task.

Figure 25-15 is a high-level block diagram of the performance monitor. The module consists of a global control register (PMGC), one 64-bit counter (PMC0), eight 32-bit counters, and two control registers per counter. The global control register PMGC affects all counters and takes priority over local control registers. Local control A registers control counter freezing, overflow condition enable, and event selection. Local control register PMLCA0, which controls counter PMC0, does not contain event selection because PMC0 counts only cycles.

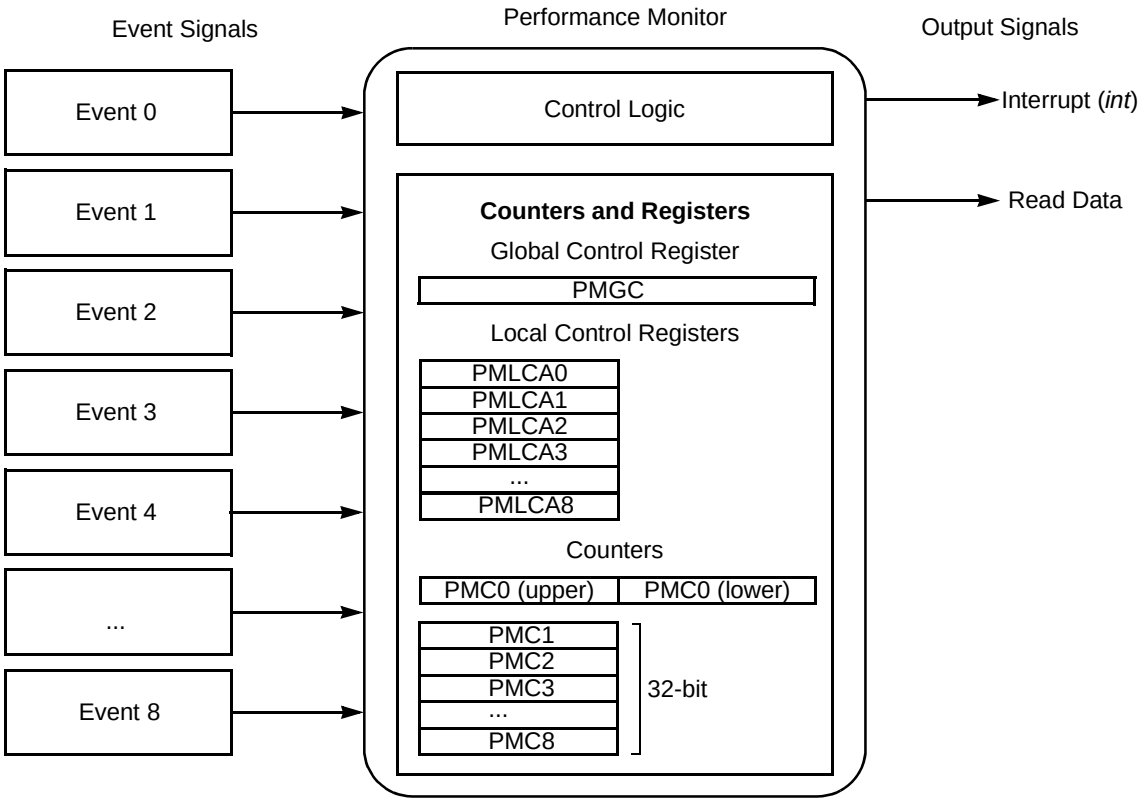

Figure 25-15. Performance Monitor Block Diagram

Performance monitor events are signalled by the functional blocks in the integrated device and are selectively recorded in the PMCs. Sixty-four of these events are referred to as reference events, which can be counted on any of the eight counters. Counter-specific events can be counted only on the counter for which the event is defined.

The performance monitor can generate an interrupt on overflow. Several control registers specify how a performance monitor interrupt is signalled. The PMCs can also be programmed to freeze when an interrupt is generated.

25.3.1 Functional Description

The MSC8157E performance monitor offers a rich set of features that permits a complete performance characterization of the implementation. These features include:

- One 64-bit counter exclusively dedicated to counting cycles.
- Eight 32-bit counters that count the occurrence of selected events.
- One global control register (all counters) and two local control registers per counter.
- Counts up to 64 reference events on any of the eight 32-bit counters.
- Ability to count up to 512 counter-specific events.
- Triggering and chaining capability.
- Quantity threshold counting.

- Ability to generate an interrupt on overflow.

The performance monitor does not drive any signals externally, but it does assert the internal interrupt signal when a monitored event or other interrupt condition occurs.

25.3.1.1 Performance Monitor Interrupts

The PMCs can generate an interrupt on an overflow when the msb of a counter changes from 0 to 1. For the interrupt to be signalled, the condition enable bit (PMLCA*n*[CE]) and performance monitor interrupt enable bit (PMGC[PMIE]) must be set. When an interrupt is signalled and the freeze-counters-on-enabled-condition-or-event bit (PMGC[FCECE]) is set, PMGC[FAC] is set by hardware and all of the registers are frozen. Software can clear the interrupt condition by resetting the performance monitor and clearing the most significant bit of the counter that generated the overflow.

25.3.1.2 Event Counting

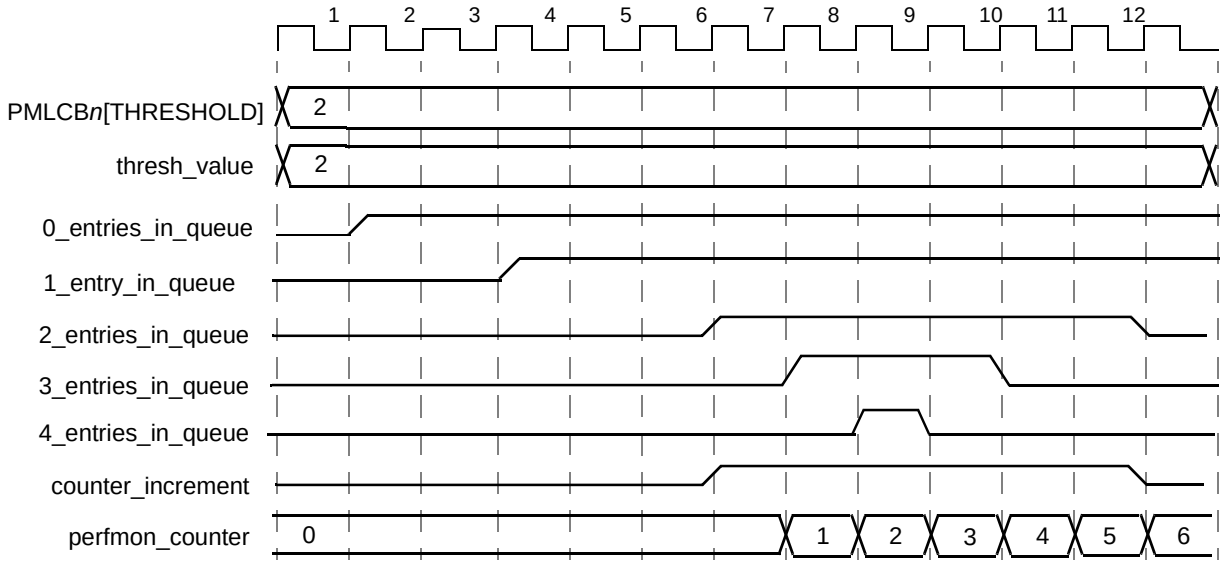
Using the control registers described in **Section 25.3.2**, the nine PMCs can count the occurrences of specific events. The 64-bit PMC0 is design to count only clock cycles. However, to provide flexibility, a total of 64 reference events can be counted on any of the 32-bit PMCs (PMC1–PMC8). Additionally, up to 64 unique events can be counted on each 32-bit counter. The performance monitor must be reset before event counting sequences. The performance monitor can be reset by first freezing one or more counters and then clearing the freeze condition to allow the counters to count according to the settings in the performance monitor registers. Counters can be frozen individually by setting PMLCAn[FC] bits, or simultaneously by setting PMGC[FAC]. Simply clearing these freeze bits will then allow the performance monitor to begin counting based on the register settings.

Note: Using PMLCAn[FC] resets only the specified counter. Performance monitor registers can be configured through reads or writes while the counters are frozen as long as freeze bits are not cleared by the register accesses.

25.3.1.3 Threshold Events

The quantity threshold event sequences the performance monitor counter is only incremented when the specified threshold event exceeds the threshold value. Threshold event is generally used to monitor the usage of buffers and queues. For example, the usage of a specific queue can be characterized by measuring the amount of time the queue is completely full or partially full. For this example the threshold field would be used to specify how many entries are required to be

valid in the queue for that event to be counted.A timing diagram for quantity threshold event counting is shown in **Figure 25-16**.



Note: For this example a threshold value of two indicates the user wishes to count the number of cycles. There are at least two valid entries in a particular queue.

Figure 25-16. Quantity Threshold Event Sequence Timing Diagram

25.3.1.4 Chaining

By configuring one counter to increment each time another counter overflows, several counters can be chained together to provide event counts larger than 32 bits. Each counter in a chain adds 32 bits to the maximum count. The register chaining sequence is not arbitrary and is specified indirectly by selecting the register overflow event to be counted. Selecting an event has the effect of selecting a source register because all available chaining events, as shown in **Table 25-11**, are dedicated to specific registers.

Note: The chaining overflow event occurs when the counter reaches its maximum value and wraps, not when the register msb is set. For this overflow to occur, PMLCA*n*[CE] should be cleared to avoid signalling an interrupt when the counter most significant bit is set. Several cycles may be required for the chained counters to reflect the true count because of the internal delay between when an overflow occurs and a counter increments.

25.3.1.5 Performance Monitor Events

Table 25-11 lists performance monitor events specified in PMLCA[1–8]. The event assignment column indicates the event type and number, using the following formats:

- Ref:#—Reference events are shared across counters PMC1–PMC8. The number indicates the event. For example, Ref:6 means that PMC1–PMC8 share reference event 6.

- C[0–8]:#—Counter-specific events. C8 indicates an event assigned to PMC8. Thus C8:62 means PMC8 is assigned event 62 (RapidIO DMA1 Channel 2 Write DW).

Note: With counter-specific events, an offset of 64 must be used when programming the field, because counter-specific events occupy the bottom 64 values of the 7-bit event field where events are numbered. For example, to specify counter-specific event 0, the event field must be programmed to 64.

Counter events not specified in **Table 25-11** are reserved.

Note: The DMA event frequency is different from the PM frequency. Therefore, these events pass through a synchronizer before entering the PM.

25.3.1.6 Performance Monitor Examples

Table 25-12 contains sample register settings for the three supported modes.

- Simple event performance monitoring example
- Threshold event performance monitoring example

The settings in **Table 25-12** are identical for all three examples.

Table 25-12. PMGC and PMLCA*n* Settings

Field	Setting	Reason
PMGC[FAC]	0	Counters must not be frozen.
PMGC[PMIE]	1	Performance monitor interrupts are enabled
PMGC[FCECE]	1	Counters should be frozen when an interrupt is signalled.
PMLCA*n*[FC]	0	Counters cannot be frozen for counting.
PMLCA*n*[CE]	1	Overflow condition enable is required to allow interrupt signalling.

For simple event counting, a non-threshold event is selected in PMLCA*n*[EVENT] and all other features are disabled by clearing all register fields except for CE.

For threshold counting, a threshold event must be specified in PMLCA*n*[EVENT] and threshold value in PMLCB*n*[THRESHOLD].

Table 25-13. Register Settings for Counting Examples

Register	Register Field	Simple Event	Threshold
PMGC	FAC	0	0
	PMIE	1	1
	FCECE	1	1
PMLCA*n*	FC	0	0
	CE	1	1
	EVENT	121	33

Table 25-13. Register Settings for Counting Examples (Continued)

Register	Register Field	Simple Event	Threshold
PMLCB*n*	TRIGONSEL	0	0
	TRIGOFFSEL	0	0
	TRIGONCNTL	0	0
	TRIGOFFCNTL	0	0
	THRESHOLD	0	3

The performance monitor must be reset before event counting sequences. The performance monitor can be reset by first freezing one or more counters and then clearing the freeze condition to allow the counters to count according to the settings in the performance monitor registers. Counters can be frozen individually by setting PMLCAn[FC] bits, or simultaneously by setting PMGC[FAC]. Simply clearing these freeze bits will then allow the performance monitor to begin counting based on the register settings.

Note that using PMLCAn[FC] to reset the performance monitor resets only the specified counter. Performance monitor registers can be configured through reads or writes while the counters are frozen as long as freeze bits are not cleared by the register accesses.

25.3.2 Performance Monitor Programming Model

The performance monitor system includes the following registers:

- Performance Monitor Global Control Register (PMGC), see **page 25-48**.
- Performance Monitor Local Control Register A0 (PMLCA0), see **page 25-49**.
- Performance Monitor Local Control Register A[1–8] (PMLCA[1–8]), see **page 25-50**.
- Performance Monitor Local Control Register B0 (PMLCB0), see **page 25-51**.
- Performance Monitor Local Control Register B[1–8] (PMLCB[1–8]), see **page 25-52**.
- Performance Monitor Counter 0 (PMC0), see **page 25-51**.
- Performance Monitor Counter 1–8 (PMC[1–8]), see **page 25-52**.

Note: Because accessing a PMC manually has priority over counter incrementation by the counted event, reading or writing a PMC while it is counting may affect the count. Likewise, accessing a performance monitor control register while its target counter is counting may also affect the count.

Note: The Performance Monitor block uses the base address: 0xFFFBB800.

25.3.2.1 Performance Monitor Global Control Register (PMGC)

PMGC Performance Monitor Global Control Register Offset 0x00

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FAC	PMIE	FCECE	—												
Type	R/W

	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PMGC globally configures the PMC operation. **Table 25-14** defines the PMGC bit fields.

Table 25-14. PMGC Bit Descriptions

Name	Reset	Description	Settings
FAC 31	0	**Freeze All Counters** Enables or freezes all counters. This bit is set by hardware when a performance monitor interrupt occurs and the FCECE bit is set.	0 PMCs increment if permitted by other control bits 1 PMCs do not increment.
PMIE 30	0	**Performance Monitor Interrupt Enable** Enables/disables the performance monitor interrupt. When enabled, the interrupt is asserted when a PMC overflows.	0 Interrupts disabled. 1 Interrupts enabled.
FCECE 29	0	**Freeze Counters on Enabled Condition or Event** Determines whether a PMC can continue increment if permitted by other control bits, or freezes when an enabled condition or event occurs.	0 PMCs increment. 1 PMCs freeze when the enabled condition or event occurs.
— 28–0	0	Reserved. Write to zero for future compatibility.	

25.3.2.2 Performance Monitor Local Control A0 Register (PMLCA0)

PMLCA0 Performance Monitor Local Control A0 Offset 0x10

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FC	—				CE	—									
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PMLCA0, along with PMLCB0, configures the PMC0 operation. **Table 25-15** defines the PMLCA0 bit fields.

Table 25-15. PMLCA0 Bit Descriptions

Name	Reset	Description	Settings
FC 31	0	**Freeze Counter 0** Enables or freezes PMC0.	0 PMC0 increments if permitted by other control bits. 1 PMC0 disabled and does not increment.
— 30–27	0	Reserved. Write to zero for future compatibility.	
CE 26	0	**Condition Enable** Controls the counter 0 overflow condition. An overflow condition occurs when PMC0[msb] is set	0 Overflow cannot occur. PMC0 cannot cause interrupts or freeze counters. 1 Overflow conditions are enabled and can generate interrupts and freeze counters.
— 25–0	0	Reserved. Write to zero for future compatibility.	

25.3.2.3 Performance Monitor Local Control A[1–8] (PMLCA[1–8])

PMLCA[1–8] Performance Monitor Local Control A[1–8] Offset 0x10 + n*0x10

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	FC	—				CE	—			EVENT						
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—															
Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PMLCA[1–8], along with PMLCB[1–8], configure the respective PMC[1–8] operation. **Table 25-16** defines the PMLCA[1–8] bit fields.

Table 25-16. PMLCA[1–8] Bit Descriptions

Name	Reset	Description	Settings
FC 31	0	**Freeze Counter** Enables or freezes PMCn.	0 PMCn increments if permitted by other control bits. 1 PMCn disabled and does not increment.
— 30–27	0	Reserved. Write to zero for future compatibility.	
CE 26	0	**Condition Enable** Controls the counter n overflow condition. This bit should be cleared when PMCn is selected for chaining. **Note:** An overflow condition occurs when PMCn[msb] is set.	0 Overflow cannot occur. PMCn cannot cause interrupts or freeze counters. 1 Overflow conditions are enabled and can generate interrupts and freeze counters.
— 25–23	0	Reserved. Write to zero for future compatibility.	
EVENT 22–16	0	**Event Selector** Selects the event to count.	Bit 22 is always set (1). This is because of the required offset of 64. See the first note in **Section 25.3.1.5**. The definitions for Bits [21:16] values 0x00 to 0x3F are Event Numbers defined in **Table 25-11**.
— 15–0	0	Reserved. Write to zero for future compatibility.	

25.3.2.4 Performance Monitor Counter 0 (PMC0)

PMC0 Performance Monitor Counter 0 Offset 0x18

Bit	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Type	R/W															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PMC[1–8] are used to count events selected by the corresponding performance monitor local control registers. **Table 25-18** defines the PMC[1–8] bit fields.

Table 25-18. PMC[1–8] Bit Descriptions

Name	Reset	Description	Settings
PMCn 31–0	0	**Performance Monitor Counter n** Contains the current PMCn count.	

26 Multi Accelerator Platform Engine, Baseband 2 (MAPLE-B2)

The MAPLE-B2 is a multi-standard baseband algorithm accelerator for Channel Decoding/Encoding, Fourier Transforms, UMTS chip rate processing, OFDMA and SC-FDMA equalization and CRC algorithms. The MAPLE-B2 consists of second generation Programmable-System-Interface (PSIF2), which is a programmable controller with DMA capabilities, and the following ten accelerators:

- *Enhanced Turbo/Viterbi Processing-Element (eTVPE).* Accelerates Turbo Decoding, Rate-De-Matching and HARQ combining.
- *Three enhanced FFT/DFT Processing-Elements (eFTPEs).* Accelerate various sizes of Fourier transforms and various pre/post transform processing.
- *Turbo Encoder Processing-Element (DEPE).* Accelerates Turbo Encoding and Rate Matching.
- *Equalization Processing-Element (EQPE).* Accelerates MMSE and MLD types of equalization algorithms and Matrix Inversion.
- Chip Rate Processing-Element (CRPE). Accelerates Downlink and Uplink UMTS chip rate processing.
- CRC Processing-Element (CRCPE). Accelerates CRC attachment or check.
- Code Generation Processing Element (CGPE). Accelerates UMTS code generation.
- Convolution and Filtering Virtual Processing Element (CONVPE). Accelerates convolutions and filtering in frequency domain by combining the eFTPE and EQPE.

In addition to the the accelerators, MAPLE-B2 provides options of internal chaining of multiple PE's using single job descriptor:

- Turbo Decoding and Re-encoding including rate matching uses a combination of eTVPE and DEPE.
- MMSE equalization combined with DFT and/or IDFT functions uses eFTPE and EQPE.

The PSIF2 integrates four 128-bit wide MBus master ports used by the MAPLE-B2 to transfer input and output data to and from system memory. It also integrates two 128-bit MBus Slave ports used for job descriptors access by Host and antenna data access by antenna interfaces. See **Section 26.4.3.1**, *MAPLE-B2 Second Generation Programmable System Interface (PSIF2)*, on page 26-23 for details.

26.1 Information Organization

Because the MAPLE-B2 is a complex module, this section provides a detailed guide as to the organization of the information in this chapter. The following sections contain the described information:

- MAPLE-B2 features (see **Section 26.2**). Includes a table that correlates broadband protocols with their respective MAPLE-B2 processing elements (PEs).
- Modes of operation (see **Section 26.3**). Defines the MAPLE-B2 operating modes.
- Function description (see **Section 26.4**). Includes the following information:
  - Initialization (see **Section 26.4.1**). Describes the use of the MAPLE-B2 application programmer interface (API).
  - Configuration and Control (see **Section 26.4.2**). Describes RAM-based parameters, descriptors (includes buffer descriptor (BD) rings, BDs, task and other descriptors), and registers used to configure, control, and monitor MAPLE-B2 and internal module operation. This section does not include detailed structure and programming information, described in detail in **Section 26.5**, *Programming Model*, on page 26-315.
  - Internal modules. Describes the functional information, including general operation and flow, input and output data and control structures (organized by specific modes) for each of the following modules:
    - PSIF2. Includes quad-RISC processor for system interface, handshake protocols and low-level control of PE's. See **Section 26.4.3.1**, *MAPLE-B2 Second Generation Programmable System Interface (PSIF2)*, on page 26-23.
    - eTVPE. See **Section 26.4.3.2**, *eTVPE HARQ, Rate De-Matching, and Turbo/Viterbi Decoding Flow,* on page 26-28.
    - eFTPE. See **Section 26.4.3.3**, *eFTPE FFT/iFFT/DFT/iDFT Operation*, on page 26-78.
    - DEPE. See **Section 26.4.3.4**, *DEPE Downlink Turbo Encoding Operation*, on page 26-117.
    - EQPE. See **Section 26.4.3.5**, *EQPE Equalization Processing Operation*, on page 26-144.
    - CRPE. See **Section 26.4.3.6**, *CRPE Uplink/Downlink UMTS Chip Rate Processing Operation*, on page 26-197. The functional description is divided into three parts:
      - **Section 26.4.3.6.1**, *Chip Rate Uplink Batch Processing Element*, on page 26-198
      - **Section 26.4.3.6.2**, *Chip Rate Uplink Fast Operation*, on page 26-234
      - **Section 26.4.3.6.3**, *Chip Rate Downlink Processing Operation*, on page 26-266
    - CRCPE. See **Section 26.4.3.7**, *CRC Operation*, on page 26-285
    - CGPE. See **Section 26.4.3.8**, *Code Generation Operation*, on page 26-290

- CONVPE. See **Section 26.4.3.9**, *CONVPE Convolution and Correlation Processing Operation*, on page 26-298

— External Master support using Serial RapidIO doorbells. See **Section 26.4.4**, *External Masters Support Using Serial RapidIO Doorbell*, on page 26-308
— MAPLE-B2 internal task control. See **Section 26.4.5**, *MAPLE-B2 Internal Task Control*, on page 26-312.
— MAPLE-B2 dynamic power gating. See **Section 26.4.6**, *MAPLE-B2 Power Gating Scheme*, on page 26-313
— MAPLE-B2 reset and initialization. See **Section 26.4.7**, *Reset*, on page 26-315.

- Programming model (see **Section 26.5**). Provides detailed descriptions of RAM-based configuration, control, and monitoring structures, including:
  — Initialization parameters (performed by the MAPLE-API)
  — Configuration and control parameters (configured by the host)
  — Descriptors (configured by the host)
  — Registers (configured via the SBus)

26.2 MAPLE-B2 Features

Table 26-1 lists the MAPLE-B2 support for specific communication protocol standards and how the individual PEs contribute to that support. **Table 26-2** lists the non-standard-related processing features of the individual PEs. **Table 26-3** lists the chained processing elements features (Virtual PEs). **Table 26-4** is a list of general MAPLE-B2 features.

Table 26-1. Support for Specific Protocol Standards

Protocol Standard	PE	Features
3GLTE (3GPP TS 36.212)	eTVPE	• Turbo decoding as specified in section 5.1.2.2. • Multiple input data structures support for multiple pre-processing options: —Support for HARQ scheme as specified in section 5.1.2.2: – Combining accumulator with new received punctured Code Block. – Outputting of new accumulator buffer for future HARQ transmissions. – 3 programmable weights. —Support of Sub-Block de-interleaving processing. • Multiple options of decoding output results: —Hard output results —2 optional types of Soft Output results: – 16 bits LLR of Aposteriori data for systematic bits only – 8 bits LLR of Aposteriori data for systematic, parities and tail bits. • Max Log Map with Non Linear Dynamic extrinsic Factorization • Hybrid Linear Log Map (MAX*) with programmable Linear Correction factor • Maximum decoded block size of 6144 • Optional Code Block CRC check on Hard Output results. • Optional Transport Block CRC check on Hard Output results if Transport Block size $\leq$ 6120. • Three different types of Stopping Conditions: —Aposteriori Quality (AQ) based Stopping condition. —CRC pass Stopping Condition —CRC result equals previous iteration CRC result. • Programmable maximum/minimum iteration counters • Programmable number of internal operational Turbo engines • Programmable ascending or descending bit or/and byte ordering for Hard Output data.
	DEPE	• DL-SCH and UL-SCH Turbo encoding and rate matching. • Optional Code Block CRC attachment. • Optional Transport Block CRC attachment for TB $\leq$ 6120. • Filler bits insertion. • Transport Block segmentation assist using bit read granularity. • Code Word generation assist in system memory using bit write granularity • Multiple concatenated jobs (up to 32) in single Buffer Descriptor.

Table 26-1. Support for Specific Protocol Standards (Continued)

Protocol Standard	PE	Features
WiMAX OFDMA IEEE 802.16e-2009/	eTVPE	• Turbo decoding processing. • Multiple input data structures support for multiple pre-processing options: —Support for HARQ scheme: – Combining accumulator with new received punctured Code Block. – Outputting of new accumulator buffer for future HARQ transmissions. – 3 programmable weights. —Support of Sub-Block de-interleaving processing. • Multiple options of decoding output results: —Hard output results —16 bits LLR of Aposteriori data for systematic bits only • Max Log Map with Non Linear Dynamic extrinsic Factorization • Hybrid Linear Log Map (MAX*) with programmable Linear Correction factor • Maximum decoded block size of 4800 • Optional CRC check for padded MAC PDU $\leq$ 4784. • Two different types of Stopping Conditions: —Aposteriori Quality (AQ) based Stopping condition. —CRC result equals previous iteration CRC result. • Programmable maximum/minimum iteration counters • Programmable number of internal Turbo engines • Programmable ascending or descending bit or/and byte ordering for Hard Output data.
	DEPE	• Turbo encoding and rate matching. • Optional CRC attachment for padded MAC PDU $\leq$ 4784. • Optional bit randomization for padded MAC PDU $\leq$ 4784. • Multiple concatenated jobs (up to 32) in single Buffer Descriptor.

Table 26-1. Support for Specific Protocol Standards (Continued)

Protocol Standard	PE	Features
UMTS TS 25.212 FDD, TS 25.222 TDD	eTVPE	• Turbo decoding processing. • Multiple input data structures support for multiple pre-processing options: —Rate De-Matching (depuncturing and de-repetition) as per section 4.8 —Support for HARQ scheme: – Combining accumulator with rate de-matched received Code Block. – Outputting of new accumulator buffer for future HARQ transmissions. – 2 programmable weights. • Multiple options of decoding output results: —Hard output results —2 optional types of Soft Output results: – 16 bits LLR of Aposteriori data for systematic bits only – 8 bits LLR of Aposteriori data for systematic, parities and tail bits. • Max Log Map with Non Linear Dynamic extrinsic Factorization • Hybrid Linear Log Map (MAX*) with programmable Linear Correction factor. • Maximum decoded block size of 5114 • Two different types of Stopping Conditions: —Aposteriori Quality (AQ) based Stopping condition. —CRC result equals previous iteration CRC result. • Programmable maximum/minimum iteration counters • Programmable number of internal Turbo engines • Programmable ascending or descending bit or/and byte ordering for output data.
	DEPE	• HS-DSCH and E-DCH (TDD and FDD) Turbo encoding and rate matching. • CRC attachment for Transport Block $\leq$ 5090. • Optional bit scrambling for Transport Block $\leq$ 5090 (FDD only). • Transport Block segmentation assist using bit read granularity. • Code Word generation assist in system memory using bit write granularity • Multiple concatenated jobs (up to 20) in single Buffer Descriptor.

Table 26-1. Support for Specific Protocol Standards (Continued)

Protocol Standard	PE	Features
UMTS TS 25.211, TS 25.213, TS 25.214	CRPE	• Downlink Chip Rate Processing: —Capacity of up to 512 Physical Channels including MIMO, STTD, TSTD and Closed Loop Mode 1 operation per channel. —Input data precision of 16 bit {8I,8Q} complex symbols. —Spreading with SF 4,8,16,32,64,128, and 256 using internally generated channelization codes. —Scrambling using internally generated, up to 32 independent codes, including support for compressed mode codes. —Supporting SF 1 special channels with spreading, scrambling bypass —Programmable complex gains per Physical Channel, with differentiation between data and control information, supporting various slot formats. —Physical channels combining and flexible assignment to up to 16 virtual antenna's. —Optional Beam Forming operation on combined Physical Channels. —Output data precision of 32 bit {16I,16Q} complex chips. • Uplink Batch Processing - for data and control channels with variable spreading factors —Capacity of up to 512 Physical Channels with up to 3328 total fingers from up to 96 antenna streams with up to 512 chips delay spread. —Optional pre-despreading support with up to 128 Physical Channels with SF 4 —Input data precision of 16 bit {8I,8Q} complex chips. —Optional Internal interpolation of x2 oversampled input stream, up to x16 resolution using 8 tap polyphase filter, with programable 8 bit weights per phase. —Despreading with SF 2,4,8,16,32,64,128,256 using internally generated channelization codes. —Descrambling by short or long codes, with up to 512 different, internally generated, scrambling codes. —Optional fingers combining using programable weights. —Optional frequency correction functionality using programable correction factor. —Multiple output formats: – 16 bit fixed point with user defined scaling/alignment or custom 32 bit (16-bit mantissa and 16-bit exponent) floating point formats for fingers combining option. – complex 32 bit {16I,16Q} for fingers combining bypass option.

Table 26-1. Support for Specific Protocol Standards (Continued)

Protocol Standard	PE	Features
UMTS TS 25.211, TS 25.213, TS 25.214	CRPE (cont.)	• Uplink Fast Processing - for (E)DPCCH, HS-DPCCH and RACH message processing —Capacity of up to 512 Physical channels with up to 3200 total fingers from up to 24 antenna streams. —Input data precision of 16 bit {8I,8Q} complex chips. —Optional Internal interpolation of x2 oversampled input stream, up to x16 resolution using 8 tap polyphase filter, with programable 8 bit weights per phase. —Descrambling by short or long codes with internally generated scrambling codes. —Despreading using SF 256. —Optional correlation with pilot sequence. —Programable slot format and early/on-time/late processing for various fields of control channels. —Output 32 bit {16I,16Q}, per finger, per channel, grouped into up to 18 different cyclic buffers. —Internal commands FIFO for flexible updates of fingers and channels association. —Latency up top 96 chips including processing and write back of results to system memory • PN Code Generator (CGPE) —Short or Long codes generation based on programable init values —Generates scrambling code or scrambling code multiplied by spreading code with programable spreading factor and OVSF. —Two output formats: – 16 bit {8I,8Q} format, with throughput of up to 4 Gsamples/sec – 2 bit {1I, 1Q} format, with throughput of up to 32 Gsamples/sec
WiMAX IEEE 802.16m/D3	ETVPE	• Turbo decoding processing. • Single input data structure support of separate vector per each data type (no HARQ combining support). • Multiple options of decoding output results: —Hard output results —16 bits LLR of Aposteriori data for systematic bits only • Max Log Map with Non Linear Dynamic extrinsic Factorization • Hybrid Linear Log Map (MAX*) with programmable Linear Correction factor • Maximum decoded block size of 4800 • Two different types of Stopping Conditions: —Aposteriori Quality (AQ) based Stopping condition. —CRC result equals previous iteration CRC result. • Programmable maximum/minimum iteration counters • Programmable number of internal Turbo engines • Programmable ascending or descending bit or/and byte ordering for Hard Output data.
	DEPE	—Turbo encoding and rate matching (without bit selection). —Code Block CRC attachment. —Bit randomization for padded MAC PDU ≤ 4784 —Multiple concatenated jobs (up to 32) in single Buffer Descriptor.

Table 26-2. Processing Engine (PE) Features

PE	Features
eTVPE	Viterbi Decoding with the following supported features: • Convolutional Decoding using programmable polynomials. • Encoding Rates of 1/2, 1/3 and 1/4 • Periodic depuncturing scheme for supporting various rate cases (for example, 1/3, 1/2, 2/3, 3/4, 5/6) • Decoding Convolutional codes with K= 5,6,7,8,9 • Maximum internal block sizes of: —6144 (K=5, Encoding Rate of 1/2 or 1/3) —4864 (K=5, Encoding Rate of 1/4) —4800(K=6) —2400 (K=7) —1200 (K=8) —600 (K=9) • Optional support for larger block sizes using multiple job descriptors. • Zero Tail decoding support • Tail biting decoding support using WAVA* (Wrap-Around-Viterbi-Algorithm)[1] • Ascending and descending bit and/or byte ordering for output data
eFTPE (three instantiations)	• Variable length FFT/iFFT processing of 128, 256, 512, 1024, 1536 and 2048 points. • Variable length DFT/iDFT processing of the form $2^k \cdot 3^m \cdot 5^n \cdot 12$, up to 1200 points: 12, 24, 36, 48, 60, 72, 96, 108, 120, 144, 180, 192, 216, 240, 288, 300, 324, 360, 384, 432, 480, 540, 576, 600, 648, 720, 768, 864, 900, 960, 972, 1080, 1152 and 1200 points • Variable input data size, supporting 16 bit {8I,8Q} or 32 bit {16I,16Q} • Programmable guard band insertion and removal for iFFT and FFT processing. • Programmable Cyclic Prefix insertion and removal. • Pre-Multiplication (“vector multiplication”) support by programable complex values vector. • Post-Multiplication (“vector multiplication”) support by programable complex values vector. • Post multiplication by configurable complex constant value. • Frequency correction argument generation for pre or post transform use. • Input data complex conjugate and re-ordering (1...N samples reversed to N...1) • Zero padding of input data • UMTS scrambled pilot samples generation in frequency domain • Programmable scaling method, supporting one of the following methods: —Automatic adaptive scaling using overflow detection between transform stages, and optional programmable overall scaling factor for the output data —User defined scaling between transform stages • Automatic or programmable input scale up for input data with small values, to increase calculation precision. • Multi-transform execution of same size transforms with single job descriptor (“repeat” operation). • Flexible allocation of double buffers to pre-multiplier, post-multiple or output buffer at configuration stage.
DEPE	• All functionality is standard related. See **Table 26-1** for functional details.

Table 26-2. Processing Engine (PE) Features (Continued)

PE	Features
EQPE	• MMSE (Minimum Mean Square Error) / ZF (Zero Forcing)/ IRC (Interference Rejection Combining) Equalization —Estimation of signal by MMSE/ZF/IRC equalizer using following inputs: – observations (antenna data in frequency domain), channel estimation, noise and transmitted layers covariance matrices and previously detected layer (for cancellation) —Inputs precision 32 bit {16I,16Q} with block floating point 8 bit scaling factor. —Supporting various Rx Antenna (1,2,4,8) and MIMO layers (1,2,3,4) configurations —Optional Channel Estimation interpolation with programmable weights. —Embedded support for advanced receivers with iterative interference cancellation schemes with internal single layer cancellation, rank reduction, layer discarding and Hermitian or diagonal MIMO layers covariance matrix. —Optional support for Hermitian noise & interference covariance matrix, with variable granularity, up to different matrix per sub-carrier (RE). —Flexible output format supporting 32 bit {16I,16Q} with block floating point representation using 8 bit scale factor per group of elements or optional full floating point representation using 8 bit scaling factor per element. • Maximum Likelihood estimation implemented with QRD-M tree search —Estimation of signal by QRD-M equalizer using following inputs: – observations, channel estimation, noise variance. —Supporting various Rx Antenna (1,2,4,8[2]) and MIMO layers (1,2,3,4) configurations. —Optional Channel Estimation interpolation with programable real weights. —Configurable search width, with M up to 64[3], providing performance-latency trade-off. —8 bits LLR output generation, with optional floating point (8e8) output support. • Matrix Inversion —Support for up to 4x4 matrix inversion. —Programming model optimized for batch job of multiple matrix inversions. • High precision floating-point arithmetic —Input samples are received in 32 bit {16I,16Q} block floating point (BLF) with 8-bit scale factor. —Internal calculations performed using custom floating-point (FLP) format: 40 bit {20I,20Q} mantissa and 8-bit exponent. —Matrix Inversion performed with QR-Decomposition using Givens-Rotations algorithm. —Output samples are available in three formats: floating-point, block floating-point or fixed-point.
CRCPE	• Eight available polynomials: —$D^{24} + D^{23} + D^6 + D^5 + D + 1$ —$D^{24} + D^{23} + D^{18} + D^{17} + D^{14} + D^{11} + D^{10} + D^7 + D^6 + D^5 + D^4 + D^3 + D + 1$ —$D^{16} + D^{12} + D^5 + 1$ —$D^{16} + D^{15} + D^2 + 1$ —$D^{32} + D^{26} + D^{23} + D^{22} + D^{16} + D^{12} + D^{11} + D^{10} + D^8 + D^7 + D^5 + D^4 + D^2 + D + 1$ —$D^{18} + D^{17} + D^{14} + D^{13} + D^{11} + D^{10} + D^8 + D^7 + D^6 + D^3 + D^2 + 1$ —$D^{12} + D^{11} + D^{10} + D^8 + D^5 + D^4 + 1$ —$D^6 + D^5 + D^3 + D^2 + D + 1$ • CRC Check or CRC calculation for block sizes of up to 64Kbyte. • Optional input/output byte reverse CRC processing • Optional initial value for continuous processing. • Optional output byte inverse presentation.

1. For details, on the exact implementation see **Section 26.4.3.2.6.7, *Tail Biting Viterbi Processing (WAVA*)***.
2. In case of 8 Rx antenna system, QR decomposition is executed by DSP cores externally to MAPLE-B2 and QR matrices are input to MLD equalization and detection.
3. M=64 supported for up to 2 layers, M=32 for higher number of layers

Table 26-3. Virtual Processing Elements Features

VPE	Features
CONV VPE	• Convolution and correlations processing utilizing eFTPE and EQPE processing elements. • Convolution and correlation are implemented in frequency domain, using internal flow of eFTPE->EQPE->eFTPE, performing FFT, MAC operations and IFFT respectively • Data transfers between eFTPE and EQPE are performed using internal DMA.
TD-TE VPE	• Turbo Decoding and Re-encoding including rate matching —Turbo Decoding including optional HARQ combining and Rate-De-Matching, supporting 3GLTE, UMTS and WiMAX technologies with hard decision output and optional CRC check. —Re-encoding and rate matching of decoding result. • Functionality performed using single job descriptor. • Data transfers between eTVPE and DEPE are performed using internal DMA.
EQ-IDFT-VPE	• 3G LTE Uplink Processing with SC-FDMA processing - chained acceleration • MMSE Equalization process followed by IDFT processing of equalization result • Executed on programable number of SC-FDMA symbols (1 to 12) • IDFT size is fixed for all time domain symbols and equal to MMSE equalization size (12 to 1200 with 3GLTE RB granularity) • Functionality performed using single job descriptor • Data transfers between EQPE and eFTPE are performed using internal DMA.
DFT-EQ-IDFT-VPE	• 3G LTE Uplink Processing with SC-FDMA including cancellation processing - chained acceleration • DFT, followed by MMSE Equalization using input data from DFT processing, followed by IDFT processing of equalization result • Executed on programable number of SC-FDMA symbols (1 to 12) • DFT and IDFT sizes are fixed for all time domain symbols and equal to MMSE equalization size (12 to 1200 with 3GLTE RB granularity) • Functionality performed using single job descriptor • Data transfers between eFTPE, EQPE and back to eFTPE are performed using internal DMA.

Table 26-4. General MAPLE-B2 Features

MAPLE-B2 General Features
• Buffer Descriptor (BD) based programming model: —Up to 8 High Priority BD rings and 8 Low Priority BD rings for each processing element for multiple master support —32KB of BD rings internal memory —TaskID for every BD • Simultaneous multi-technology support, allowing mixture of 3GLTE and UMTS jobs or 3GLTE and WiMAX jobs. • Flexible interrupt scheme —Up to 32 maskable BD ring interrupts —Programmable allocation of BD rings to interrupts —Single ECC maskable interrupt aggregating all MAPLE-B2 ECC interrupts. • Low Power design and features: —Optional clock gating for every Processing Element. —Dynamic supply gating for eTVPE and EQPE elements in case of temporal no operation —Static supply gating for CRPE element when not used, controlled by device level supply connectivity using dedicated pads. • Quad MBus master interfaces for data transfers to/from system memory • Dual MBus slave for accessing MAPLE-B2 for UMTS chip rate data, configuration, control and debug. • One SBus slave for PSIF2 control

26.3 Modes of Operation

The MAPLE-B2 supports two modes of operation defined by the required standard: 3G mode and WiMAX mode. Activating the operation mode is done during the activation sequence of the MAPLE-B2 using the API (see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)).

26.3.1 3G Technologies Operation Mode

In this operation mode, the MAPLE-B2 supports jobs of 3GLTE and UMTS standards and can dynamically switch the internal parameters and configuration registers between these standards according to the current job description. WiMAX jobs are not supported in this mode.

26.3.2 3GLTE and WiMAX Technologies Operation Mode

In this operation mode, the MAPLE-B2 supports jobs of 3GLTE and WiMAX **IEEE** 802.16e and 802.16m standards and can dynamically switch the internal parameters and configuration registers between these technologies according to the current job description. UMTS jobs are not supported in this mode.

26.4 Functional Description

The MAPLE-B2 functional description is divided into the following areas.

- Initialization. Includes initialization parameters configured by the MAPLE-B2 API. See **Section 26.4.1**.
- Configuration and Control. Includes the general configuration parameters, descriptions and registers used to configure and control MAPLE-B2 operation. Data management is handled by buffer descriptor rings, which are general to all PEs except the CRPE. See **Section 26.4.2.3** for BD ring operation description. Specific BD handling is also described for each PE except the CRPE under the accelerator specific functional descriptions in this subsection. In addition, MAPLE-B2 controls and arbitrates MAPLE-B2 access to the MBus. See **Section 26.4.2.4** for configuration details.
- Internal module operation. Provides detailed information about PE and VPE operation. Detailed information is provided for the MAPLE-B2 PSIF2, each of the PEs, and the VPE.
  - PSIF2 configuration and operation. See **Section 26.4.3.1** for details.
  - eTVPE FEC decoding flow. See **Section 26.4.3.2** for details.
  - eFTPEs FFT/iFFT/DFT/iDFT operation. See **Section 26.4.3.3** for details.
  - DEPE FEC encoding operation. See **Section 26.4.3.4** for details.
  - EQPE equalization and matrix inversion operation. See **Section 26.4.3.5** for details.
  - CRPE uplink/downlink UMTS Chip Rate processing operation. The functional description is divided by functionality into the following three subsections:

    - CRPE Uplink Batch Mode (CRPE-ULB). See **Section 26.4.3.6.1** for details.
    - CRPE Uplink Fast Processing (CRPE-ULF). See **Section 26.4.3.6.2** for details.
    - CRPE Downlink (CRPE-DL). See **Section 26.4.3.6.3** for details.
  - CRCPE CRC operation. See **Section 26.4.3.7** for details.
  - CGPE operation. See **Section 26.4.3.8** for details.
  - CONVPE convolution/correlation processing operation. See **Section 26.4.3.9** for details.
- External master support. MAPLE-B2 can work with external master through the Serial RapidIO Doorbells. See **Section 26.4.4** for details.
- MAPLE-B2 Internal Task Control. Permits configuration of BD search periods and forcing routine execution. See **Section 26.4.5** for details.
- MAPLE-B2 Power Saving Schemes. There are two types of power saving schemes. One is control of the clock source for not utilized PEs or RISCs. Second scheme is dynamic power gating, which shut's down the supply's of EQPE or eTVPE when not active, and turn's the power on when a new job arrives. All of these features are programmable. See **Section 26.4.6** for details.
- Reset. The MAPLE-B2 has two types of reset. See **Section 26.4.7** for details.

26.4.1 Initialization

Upon power-on reset deassertion, the MAPLE-B2 is in freeze state, that is, its internal RISC engines are denied access to the internal instruction memory. At this stage, the MAPLE-B2 API must be initiated to activate the MAPLE-B2. The MAPLE-B2 API detailed description is in *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)

26.4.1.1 MAPLE-B2 API

The MAPLE-B2 API is responsible for the following:

- Reset Data/Instruction internal memories if ECC is enabled, and enable the ECC feature. If no ECC is required, the API is to reset only the relevant parameters in the parameter RAM.
- Initialize the relevant parameters with default/reset values (as described in **Section 26.5.3.1**, *General Parameter RAM Description*)
- Initialize configuration parameters for the relevant PEs according to the API input parameters (see **Section 26.4.1.2**).
- Upload the program code into the MAPLE-B2 instruction RAM.
- Activate the RISC engines by allowing them to access to the program memory.

The MAPLE-B2 API must be used after every external reset. It can also be used to generate a soft reset internally to the MAPLE-B2. For details, see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG).

26.4.1.2 Initialization Parameters

During the MAPLE-B2 initialization (see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)), the following MAPLE-B2 parameters in the API must be initialized:

- General MAPLE initialization parameters:
  - MAPLE Mode Configuration x Parameters (MMCxP)—General MAPLE-B2 Initialization parameters (for details, see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*, on page 26-320 and **Section 26.5.2.2**, *MAPLE Mode Configuration 1 Parameter (MMC1P)*, on page 26-322).
- PE-specific initialization parameters:
  - eTVPE Mode Configuration Parameter (TVMCP)—General eTVPE related initialization parameter (for details, see **Section 26.5.2.3**, *MAPLE eTVPE Configuration Parameter (MTVCP)*, on page 26-325).
  - CRPE Down Link Output Mode Configuration Parameter (CDOMCP)—CRPE-DL Output mode related initialization parameter (for details, see **Section 26.5.2.4**, *CRPE-DL Output Mode Configuration Parameter (CDOMCP)*, on page 26-326)
  - CRPE Uplink Batch Mode Configuration Parameter (CRUBMCP)—CRPE-ULB General configuration Parameter (for details, see **Section 26.5.2.5**, *CRPE-ULB Mode Configuration Parameter (CRUBMCP)*, on page 26-328).

26.4.2 MAPLE-B2 Configuration and Control

After the MAPLE-B2 API has initialized the required initialization parameters and before actual processing begins, the host must configure the required PEs and the supporting RAM-based structures and registers to perform the required operations to support the specified protocol. See **Table 26-1** to identify the PEs used by the specific supported protocols. In addition, the host must also specify the arbitration methodology for BD/BD rings and MBus access.

26.4.2.1 PE Configuration

Configuration of each PE is done using specific RAM-based parameter fields, descriptor fields, and registers. Data management is done using a set of buffer descriptors usually organized as BD rings. The CONVPE also requires configuration of task descriptors because it combines the functionality of multiple PEs to create a virtual processing element (VPE). Configuration may also require configuration of special structures for the individual PE processing. In addition, each

PE requires special input and output data structures to support the PE operation. Each PE functional description includes processing flow and detailed information about required parameters and data structures. Detailed layout information for parameter fields, descriptor fields and registers is provided by PE in **Section 26.5**, *Programming Model*, on page 26-315.

26.4.2.2 PE Arbitration Between Different Clients

The MAPLE-B2 instantiate 3 eFTPE engines, each can be initiated due to one of the following events:

1. eFTPE Buffer Descriptor (BD) arrival. See **Section 26.4.2.3**, *Buffer Descriptor (BD) Ring Handling* and **Section 26.5.4.3**, *eFTPE Buffer Descriptor Structure* for eFTPE BD description and general BD handling.
2. EQPE BD arrival with *F_DFT* or *POST_IDFT* bits enabled. See **Section 26.5.4.5**, *EQPE BD Structure* for details.
3. CONVPE BD arrival. See **Section 26.5.4.9**, *CONVPE Buffer Descriptor Structure* for details.

The following describe how the MAPLE-B2 handles the arbitration between the 3 eFTPE units and the internal arbitration of each eFTPE unit with respect to the above clients.

26.4.2.2.1 Arbitration Between the Three eFTPE Engines

Each eFTPE engine is related to a dedicated set of eFTPE BD Rings hence there is no arbitration between the eFTPE engines with respect to eFTPE BDs. On internal arbitration between the eFTPE BDs related to the same eFTPE engine, see **Section 26.4.2.3.2**, *BD Arbitration*, on page 26-18.

If EQPE BDs with *F_DFT* or *POST_IDFT* bits enable are detected, the MAPLE-B2 maintain cyclic arbitration between the eFTPE engines with respect to EQPE BD assist: each DFT/iDFT job required by the EQPE BDs is assigned to the eFTPE engines in a cyclic manner, that is, the first eFTPE job (related to that BD) is assigned to eFTPE0, the second eFTPE job (of that EQPE BD or the next EQPE BD) is assigned to eFTPE1 and so forth.

The CONVPE BDs are executed using the FDU logic in the EQPE and the 3 eFTPE engines (see **Section 26.4.3.9**, *CONVPE Convolution and Correlation Processing Operation* for details). Assigning the eFTPE jobs related to the CONVPE BD to the eFTPE engines is done in a cyclic manner, that is, the first eFTPE job (related to the CONVPE BD) is assigned to eFTPE0, the second eFTPE job (of that CONVPE BD) is assigned to eFTPE1 and so forth. The last eFTPE engine index used by the CONVPE BD is kept, so that the next CONVPE BD starts with the following index (cyclic progress).

26.4.2.2.2 Internal eFTPE Arbitration

As described in **Section 26.4.2.2**, *PE Arbitration Between Different Clients*, each eFTPE engine has 3 potential clients which can assign it with eFTPE jobs. The following details the arbitration scheme by which the internal firmware assign the jobs from the different clients to the eFTPE:

For each potential client the internal firmware maintain a queue of jobs sourced from the client BDs. The eFTPE is assigned with jobs from the 3 queues in a cyclic manner thus preventing any potential starvation state for any of the queues. The following figure describe an example of the processing order of the eFTPE jobs given a certain queues state:

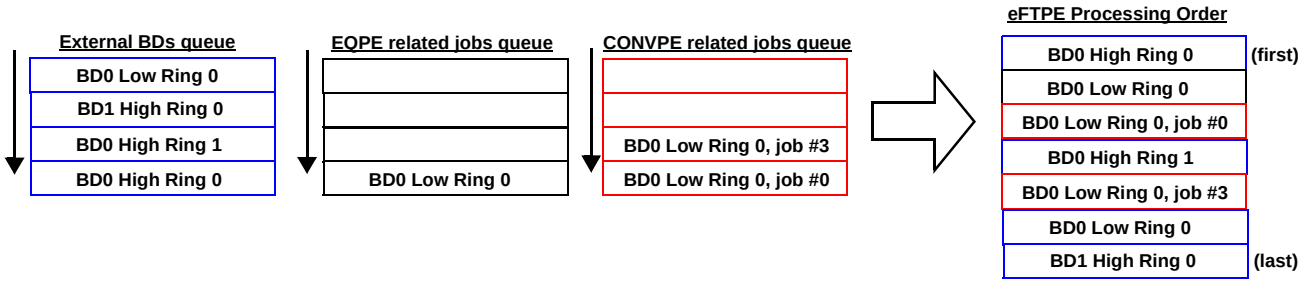

Figure 26-1. eFTPE processing order with respect to multiple internal queues

26.4.2.3 Buffer Descriptor (BD) Ring Handling

For all MAPLE-B2 internal Processing Elements (PEs) except the CRPE, the logical handshake between the DSP device cores and peripherals and the MAPLE-B2 is buffer-descriptor based. Up to 8 hosts are supported for each PE, with each host receiving one high-priority and one low-priority buffer descriptors ring. To enable higher number of hosts by special configuration, up to 16 hosts can be supported for each PE, with each host receiving only one buffer descriptors ring with the same priority assigned to all the rings. The MAPLE BD Rings Configuration Parameters 0 and 1 (MBDRCP[0–1]) control the arbitration order between the high and low rings for each PE. For details, see **Section 26.4.2.3.2**, *BD Arbitration*.

Note: The CRPE Programming model and handshake with host is not buffer-descriptor based and is described in detail in **Section 26.4.3.6.2**, *Chip Rate Uplink Fast Operation*, **Section 26.4.3.6.3**, *Chip Rate Downlink Processing Operation* and **Section 26.4.3.6.1**, *Chip Rate Uplink Batch Processing Element*.

26.4.2.3.1 BD Rings Arbitration

The MAPLE-B2 manages its buffer-descriptor rings using a set of configuration parameters for each PE:

- **M<pe>BRHPA$_x$P**. Defines the first set of attributes for High Priority Buffer-Descriptor ring x.

- **M<pe>BRHPB$_x$P.** Defines the second set of attributes for High Priority Buffer-Descriptor ring x.
- **M<pe>BRLPA$_x$P**. Defines the first set of attributes for Low Priority Buffer-Descriptor ring x.
- **M<pe>BRLPB$_x$P.** Defines the second set of attributes for Low Priority Buffer-Descriptor ring x.

Note: <pe> stands for the specified PE: TV for eTVPE; F0 for FTPE_0; F1 for FTPE_1; F2 for FTP#_2; DE for DEPE; EQ for EQPE; CRC for CRCPE, CG for CGPE and CONV for CONVPE.
x stands for the number of parameters for each type (x = 0 to 7).

Each set of parameters includes the following attributes for each BD-ring (high or low):

- BDR_BA—Base address for each of the BD-rings in the dedicated buffer descriptor memory. The BD ring base address must be aligned to a 256 bytes address, and can only be changed if the valid bit ([VLD]) of the ring configuration parameter is disabled.
- BDR_RD_PTR—Pointer to a BD in the BD-ring, which is the last BD job being processed. This pointer is increment by MAPLE-B2 once it starts with the BD processing. This field should be initialized by the host whenever the [BDR_BA] field is updated and with the same value as the [BDR_BA]. It must be done while the valid bit ([VLD]) of the ring descriptor is disabled.This field is used by MAPLE-B2 to locate the next BD in the ring. If the OWNER bit of the BD pointed by this field is cleared, the MAPLE-B2 assumes no jobs are available in the ring.
- INT_TRGT—Interrupt target. Describe which of the MAPLE-B2 BD rings interrupts (bdr_done0 to bdr_done31) is to be asserted on completion of a BD from this ring. If CRPE ULB is enabled to use interrupt, it consumes one of the bdr_doneX interrupts.
- VLD—Valid bit. When set, the MAPLE-B2 checks the owner bit of the BD pointed to by the [BDR_RD_PTR] in this ring. When the [VLD] bit is set, no changes are allowed in the M<*pe*>BR(H/L)P(A/B)xP parameters.

The following three parameters are valid only when the master of the ring is external to the DSP device and the MAPLE-B2 must communicate with it using the serial RapidIO doorbells. See **Section 26.4.4**, *External Masters Support Using Serial RapidIO Doorbell* for details.

- [HOST_ID]—Host ID in case of external master. This field is used by the MAPLE-B2 for the WORD3[EDID:DID] field in the Type10 Outbound Doorbell descriptor.
- [P_TR_IF]—Port Target Interface. Up to 16 possible RapidIO target interfaces. This field is used by the MAPLE-B2 for the WORD4[TINT] field in the Type10 Outbound Doorbell descriptor.
- [EXT_MST]—Specifies whether the master is connected to MAPLE-B2 via regular interrupt or Serial RapidIO Doorbell interrupt.

26.4.2.3.2 BD Arbitration

Having multiple BD rings with multiple priority data structures creates the need for arbitration between the following elements:

- High BD rings queue and low BD rings queue.
- Rings in the high/low BD rings.
- BDs in each of the rings.

The first level of arbitration uses the MBDRCP[<*pe*>_HL_ARB]. This field describes the arbitration order between the high BD rings and the low BD rings for each PE. It can be configured to scan the high BD rings only, to scan high/low BD rings equally (thus allowing up to 16 masters with each receiving one BD ring), or to scan the high BD rings more often than the low BD rings. See **Section 26.5.4.1.1**, *MAPLE BD Rings Configuration Parameter 0 (MBDRCP0)*. For example, if the chosen arbitration is H-H-L, the MAPLE-B2 searches for the first BD in the first valid high priority ring, the next BD is taken from the second valid high priority ring (if it does not exist then the following BD in the same high priority ring). The third BD is taken from the first low priority ring and the forth BD is taken from the next high priority ring again. It continues in this manner.

The second level of arbitration is a simple cyclic arbitration between the rings of the same priority. For example, if during a certain configuration of a certain PE, low priority rings #0, #1 and #3 are valid, the MAPLE-B2 executes BDs according to the following order: when the low priority rings are accessed, the MAPLE-B2 executes one BD from ring#0. On the next visit to the low priority rings it executes one BD from ring#1 and on the next visit one BD from ring#3 and so on. If during a certain visit in the certain ring there is no BD to process, the MAPLE-B2 continues to the next ring according to its cyclic order.

The MAPLE-B2 uses the MBDRCP[pe_R_LOOP] to determine the potential valid rings to be scanned in each ring queue. For example, if MBDRCP[TV_R_LOOP] equals 4, the MAPLE-B2 searches for valid rings only in ring #0 to ring #4 in its high/low ring queues.

Note: Allowing more potential rings than actually used causes the internal RISC engines to expand their search to more rings than required thus degrading the MAPLE-B2 performance.

Within each BD ring, MAPLE-B2 expects to find its next valid BD according to the M<pe>BR(H/L)PAxP[BDR_RD_PTR] field in the DRAM. If the [OWNER] bit of that BD is set, the MAPLE-B2 starts executing this BD (assuming the relevant PE is available). If the [OWNER] bit is not set, the MAPLE-B2 does not execute any BD from the ring and jumps to the next ring as described above.

Each BD (regardless of its type) includes a [WRAP] bit. This bit tells MAPLE-B2 how to update the M<pe>BR(H/L)PAxP[BDR_RD_PTR] when searching for next BD to process. If the

[WRAP] bit is not set then M<pe>BR(H/L)PAxP[BDR_RD_PTR] is increment with the BD size, that is, the next BD address is the current BD address plus the BD size. If the [WRAP] bit is set, then MAPLE-B2 updates the M<pe>BDR(H/L)PAxP[BDR_RD_PTR] with the value of M<pe>BR(H/L)PAxP[BDR_BA], that is, it expects to find the next BD at the base address of the current BD ring.

Note: The host must ensure that the last BD in its ring has the [WRAP] bit set. A state of one active BDR with single circular BD ([WRAP] bit is set) is forbidden for any of the PEs. Such a state may result in an unknown state of the MAPLE-B2.

BD handshake with external masters uses the [OWNER] bit. Each BD (regardless of its type) includes an [OWNER] bit. If the [OWNER] bit of the BD is set, MAPLE-B2 starts executing this BD and on BD completion, it clears the [OWNER] bit. If the [OWNER] bit is not set MAPLE-B2 continues to the next BD ring according to its arbitration scheme.

If no jobs are found in any of the BD-rings, or all of the accelerators are busy, the MAPLE-B2 hibernates and does not seek for new jobs. It wakes up due to one of the following reasons:

- Internal counter time-out. For power consideration, the MAPLE-B2 implements an internal dynamic time-out counter that is activated internally and wakes the internal engine periodically to scan for new BDs.
- A host accessing the PCR, as described in **Section 26.5.5.1.1**, *PSIF Command Register (PCR),* on page 26-501 and **Section 26.4.5**, *MAPLE-B2 Internal Task Control,* on page 26-312.
- Internal events from one of the PEs, such as job complete.

When a new BD job is found and the required accelerator is idle, the MAPLE-B2 proceeds with the BD execution. For details on job execution, refer to the specific accelerator used.

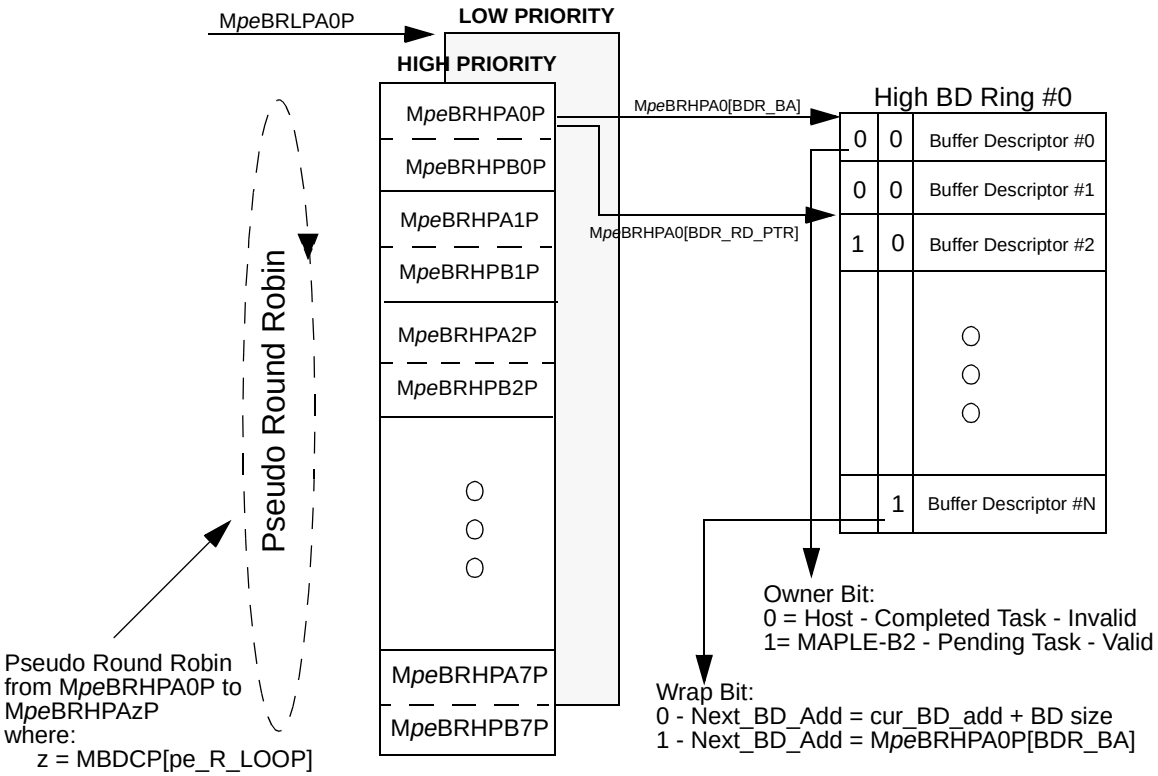
- **Section 26.4.3.8**, *Code Generation Operation,* on page 26-290
- **Section 26.4.3.9**, *CONVPE Convolution and Correlation Processing Operation,* on page 26-298

Note: The CRPE programming model is not based on Buffer Descriptor and is described in the CRPE related Sections (**Section 26.4.3.6.2, *Chip Rate Uplink Fast Operation***, **Section 26.4.3.6.3, *Chip Rate Downlink Processing Operation*** and **Section 26.4.3.6.1, *Chip Rate Uplink Batch Processing Element***).

When a job is completed, the MAPLE-B2 clears the [OWNER] field, and, if specified in the accelerator-specific BD, initiates an interrupt to the host. The MAPLE-B2 uses the M<pe>BDR(H/L)PBxP[INT_TRGT] field to define the target of this interrupt, with up to 32 different target interrupts possible.

If the M<pe>BRHPBxP[EXT_MST] is set to DSP device external master, the MAPLE-B2 initiates a door-bell interrupt via the serial RapidIO port (see **Section 26.4.4**, *External Masters Support Using Serial RapidIO Doorbell* for details).

Figure 26-2 illustrates the BD rings data structure and the mechanism of one PE in the PSIF2 DRAM of the MAPLE-B2.



Note: The figure describes arbitration scheme of one PE only. There cannot be two different types of <*pe*> in one ring or queue of rings

Figure 26-2. MAPLE-B2 Buffer Descriptor Data Structure and Mechanism of One PE

26.4.2.3.3 BDs Data Coherency

When each of the internal PEs completes its current job, it is up to the MAPLE-B2 to output the resulting data to the system memory and to negate the relevant [OWNER] bit. If interrupt is

required for this job ([INT_EN] = 1) it is assured by MAPLE-B2 that when the interrupt is asserted and the [OWNER] bit is negated, the internal DMA has completed all relevant data transfer and all result data is already placed in system memory. If no interrupt is required for this job ([INT_EN] = 0), the [OWNER] bit negation occur when all internal DMA configuration is completed but before the DMA has completed its relevant data transfers, hence the [OWNER] bit negation may occur before all the output data is located in system memory. That may cause coherency problems for a host polling the [OWNER] bit to continue with the result data processing, but enables faster response of MAPLE to next tasks. This would typically be very useful in cases of interrupts coalescing for multiple jobs.

Resolving a coherency problems for a host polling the [OWNER] bit instead of enabling the BD interrupt can be done as follows:

1. Assign the relevant BD Ring with an un-used BD Done interrupt (for example, set the M<pe>BRHPBxP[INT_TRGT] to 0x1F, that is, interrupt line #31).
2. Mask interrupt line 31 in the MAPLE PIC (reset BDR_DONE_M[31] in the PSPICMR0 register).
3. Set the interrupt enable ([INT_EN] = 1) for the BD which its [OWNER] bit is being polled.

These actions results in the MAPLE-B2 working assuming interrupt is required, that is, it assure all data is placed in system memory before negating the [OWNER] bit, but with no actual interrupt is asserted towards the host.

26.4.2.4 MBus Priority Scheme Configuration

The MBus masters interfaces support 4 priority levels 0 to 3, where the lowest priority is 0 and the highest is 3. The MAPLE-B2 allows a flexible priority scheme for its MBus master interfaces. There are a few optional priority schemes configurations that should be set during MAPLE-B2 initialization using the API parameters (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*). The following subsections describe each of these optional priory schemes.

26.4.2.4.1 MBus Fixed Priority Scheme

The MAPLE-B2 initiates all its MBus master accesses with fixed priority, set by the host during its initialization processing. Configure the MAPLE-B2 to work with MBus fixed priority using the following procedure:

1. Configure the [MB_PR_SCH] field of the MMC0P parameter during API initialization as 00.
2. Configure the [MBx_DF_PR] fields (x=0...3) of the MMC0P parameter during API initialization to the required fixed priority level for MBus<x> interface as described in **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*.

26.4.2.4.2 MBus Dynamic Priority Accesses Scheme

The MAPLE-B2 determines the priority of each job according to the [MB_PR] field of each BD. The priority configured in the [MB_PR] is valid for both the input data stage and the output data stage related to that BD. For the CRPE modules, where the programming model is not BD based, the [MB_PR] field is defined in their configuration parameters. Use the following procedure to configure the MAPLE-B2 to work with MBus Dynamic Priority Accesses Scheme:

1. Configure the [MB_PR_SCH] field of the MMC0P parameter during API initialization as 01.
2. Configure the [MB_PR] field of each Buffer Descriptor (BD) or CRPE configuration parameters to set the required priority for that BD or CRPE module.

When working with this priority scheme, it is guaranteed that each access gets its priority from its related [MB_PR] field only.

26.4.2.4.3 MBus Dynamic Priority Accesses with DMA Queue Upgrade

Each of the four MAPLE-B2 DMA engines include a DMA command queue of up to 48 entries, each with up to 384 bytes transfer, allowing the RISC engine to launch its DMA commands and continue to its following task while the DMA engines continue with data transfer. In this priority mode the MAPLE-B2 determines the initial priority of the DMA commands of each job according to the [MB_PR] field of its BD. If a certain BD includes MBus high priority requirements, once its DMA commands are placed in the DMA command queue, it automatically upgrades the priority of all preceding DMA commands currently exist in the DMA queue. This priority mode assure that a high priory DMA command is not delayed in the DMA command queue due to low priority commands previously launched to that same DMA engine.

The following example demonstrates the Mbus priority upgrade mechanism:

1. 8 commands (256 bytes size each) are pushed to DMA-0 with Mbus priority 0 due to eFTPE job completion.
2. 3 commands (256 bytes size each) are pushed to DMA-0 with Mbus priority 2 due to eTVPE job completion.
3. As all DMA commands are executed by order, once the first high Mbus priority command (of the eTVPE) is pushed into the DMA queue, all Mbus priority of the existing commands (of the eFTPE) are upgraded to Mbus priority 2, thus allowing higher priority in the system and fast execution of the eTVPE commands as well.

Use the following procedure to configure the MAPLE-B2 to work with MBus Dynamic Priority Accesses with DMA Queue Upgrade Scheme is done by:

1. Configure the [MB_PR_SCH] field of the MMC0P parameter during API initialization as 10.
2. Configure the [MB_PR] field of each Buffer Descriptor (BD) or CRPE configuration parameters to set the required priority for that BD or CRPE module.

26.4.3 Internal Modules

This section describes the MAPLE-B2 internal module functional information, including general operation and flow, specific protocol support, and input and output data and control structures (organized by specific modes) for each of the following modules:

- PSIF2. Includes memory error detection/correction and interrupt configuration and handling. See **Section 26.4.3.1**.
- eTVPE. See **Section 26.4.3.2**
- eFTPE. See **Section 26.4.3.3**
- DEPE. See **Section 26.4.3.4**
- EQPE. See **Section 26.4.3.5**
- CRPE. See **Section 26.4.3.6**
- CRCPE. See **Section 26.4.3.7**
- CGPE. See **Section 26.4.3.8**
- CONVPE. See **Section 26.4.3.9**.

26.4.3.1 MAPLE-B2 Second Generation Programmable System Interface (PSIF2)

The PSIF2 integrates four 128-bit wide MBus master ports used by the MAPLE-B2 to transfer input and output data to and from system memory. It also integrates two 128-bit MBus Slave ports for the following purposes:

- General purpose connection to the system interconnect CLASS fabric. This port is a read/write port and is referred to as MBus Slave0 port. This connection allows any host or peripheral to access the MAPLE-B2 internal memories for the following:
  - Place job-descriptors in the PSIF2 internal memories
  - Read or write data from or to the PE internal memories[1].
- Direct connection to the device Antenna interface (CPRI) for direct data transfer between Antenna interface and MAPLE-B2. This port is a write only port and is referred to as MBus Slave1 port.

1. Using this port antenna interface accesses MAPLE-B2 for antenna data read in Tx (Downlink) direction

The PSIF2 uses four internal RISC engines to manage the data flow and a programmable interrupt controller (PIC) to track events/errors that occur during operation. The PSIF2 internal registers are accessed using the SBus.

Figure 26-3 describes the MAPLE-B2 high level block diagram.

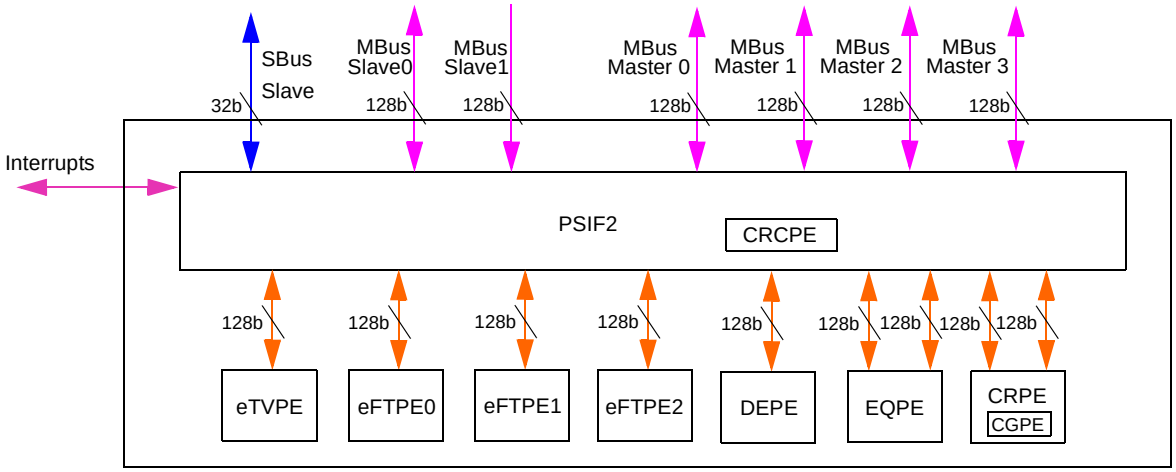


Figure 26-3. MAPLE-B2 High Level Block Diagram

The PSIF2 provides memory error correction/detection support. It uses a system of interrupts to indicate when data transfers are complete and whether system errors occur. The following subsections describes these functions in detail.

26.4.3.1.1 Memory Error Correction/Detection Support

Most of the MAPLE-B2 internal memories support either ECC (Error Correction Code) logic or Parity logic. ECC logic is capable of fixing single bit error or detecting multiple bit error in a single memory line while Parity logic is capable of detecting single bit error in a single memory line. Following is the list of groups of memories with ECC support:

- PSIF2:
  - DRAM memories- Data RAM memory which includes the MAPLE-B2 parameters, Buffer Descriptors and other internal configurations
  - IRAM memories- Instruction RAM which includes code used by the internal RISC engines.
- eTVPE:
  - DRE - Memories related to each of the Turbo engines (DREs)
  - EXT memories - Extrinsic memories which used for intermediate results and soft outputs.
  - HARQ memories - Used for the HARQ combining.
- eFTPE_<x>:
  - IBA memories - Input Buffer A memories. Holds the input data and the data between the radix stages.

- IBB memories - Input Buffer B memories. Holds the input data and the data between the radix stages.
- IBC memories - Input Buffer C memories. Holds the input data and the data between the radix stages.
- BP memories - Buffers Pool memories. Used as Output buffer, Pre-Multiplier buffer (if enabled) and Post Multiplier buffer (if enabled).

- EQPE:
  - Output buffers - Holds the EQPE results.
  - Output Scale buffer - Holds the EQPE output scale results.
  - Input Scale buffer - Holds the input data scales.
  - Interpolation Weights buffers - Holds the Interpolation weights.
  - Y buffers - Hold the input data from the Antenna I/F.
  - F buffers - Hold the Feedback input data.
  - S buffers - Hold the inverted noise covariance input matrices
  - H buffers - Hold the Channel estimation input matrices
- CRPE-DL:
  - Output buffers - Hold the resulting data of the CRPE-DL.
  - Virtual Antenna buffers - Internal memories for holding temporary antenna data.
  - TPC buffers - Internal memories for holding TPC data.
  - Input buffers - Hold the input data for the CRPE-DL.
  - General Control - Internal memories for holding the general control commands.
  - Input Buffer Write Pointers - Internal memories for holding the input buffers write pointers.
  - Slot Format LUT - Internal memories for holding the Look-up Table required for the Slot Format definition.
  - Slot Command List buffers - Internal buffers for holding the slot commands.
- CRPE-ULF:
  - Input Buffer - Holds input data for processing.
  - Command FIFO - Internal memory which holds the commands.
  - PCH Table - Internal memory which holds the Physical Channel parameters.
  - Finger Command Table - Internal memory which holds the fingers commands.
  - Finger List- Internal memory which holds the fingers list
  - Finger Table - Internal memory which holds the fingers tables
  - Packet Generation Table - Internal memory which holds tables for packet generation.
  - Packet Data FIFO - Internal memory which holds the data FIFO packets
  - Packet header FIFO - Internal memory which holds packet FIFO header
  - Magenta Initiator Buffer - Internal memory which holds the data buffer of the magenta initiator.
- CRPE-ULB:
  - Input Buffers. Holds input data for processing.

— Output Buffers. Hold the resulting data of the CRPE-ULB.
— FILE memory. Linked lists entries memory.
— FCQM memory. Fingers Command queue internal memory.
— PCQM memory. PCH command queue internal memory.
— PCHM memory. PCH parameters internal memory.
— OBPM memory. Output parameters internal memory.

Following is the list of groups of memories with Parity support:

- eTVPE. Channel Data (CDL) memories used for Turbo pre-processing.

Enabling/Disabling the ECC/Parity error support is done only during the MAPLE-B2 initialization (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*), by setting the [ECC_EN] bit in the MMC0P parameter. If ECC/Parity error is enabled, all relevant memories supporting ECC/Parity are initialized by the MAPLE-B2 during MAPLE-B2 API execution, to prevent false ECC/parity errors. If an PSIF2 ECC interrupt indication has occur, it is recommended to reset MAPLE-B2, because the error may be program code error (IRAM ECC) or parameters data error (DRAM). Any other ECC error is a data ECC error and should be handled by the host. For additional details in ECC interrupt see **Section 26.4.3.1.2.3**, *General ECC Error Event Interrupt*.

26.4.3.1.2 MAPLE-B2 Interrupts

The MAPLE-B2 supports up to 32 maskable BD done interrupts and single maskable general ECC interrupt. Detailed information on each type of interrupt is in the following subsections.

26.4.3.1.2.1 BD Rings Done Indication Interrupts

The MAPLE-B2 supports up to 32 BD ring regular interrupts. Each of the 8 High Priority BD rings and 8 Low Priority rings per PE can be mapped to any of the 32 interrupts using the [INT_TRGT] fields of the MAPLE-B2 BD ring configuration parameters. Mapping a given ring to a given interrupt means an interrupt assertion on completion of any BD tasks related to that ring, assuming:

- The [INT_EN] bit in the BD is set.
- The mask bit related to that interrupt in PSIF PIC Mask Register 0 (PSPICMR0) is set.

Each of these 32 interrupt lines can be configured to be either an edge interrupt or a level interrupt using PSIF PIC Edge/Level Register 0 (PSPICELR0). If edge configuration is chosen, the PSIF PIC Interrupts Assertion Clocks Register (PSPICIACR) determines the length of the edge interrupt (2, 4, 6, 8, 10, 12, or 16 MAPLE-B2 clock cycles). If level configuration is chosen, the PSIF_PIC holds an event bit for each of these interrupts in PSIF PIC Event Register 0 (PSPICER0), which is set once an interrupt event has occurred. This bit is cleared by the host when accessing the relevant bit by writing a value of 1 to the bit.

Each of these interrupts can be masked using a mask bit in PSIF PIC Mask Register 0 (PSPICMR0). Masking an interrupt means that only the interrupt line is not asserted; in case of level configuration the event bit related to that interrupt is still set.

Note: If CRPE-ULB is enabled, the BD ring interrupt number 32 is allocated for the CRPE-ULB functionality and must not be allocated to any of the PE's BD rings.

26.4.3.1.2.2 General Error Event Interrupt

The MAPLE-B2 supports a single interrupt line (ipi_general_error) indicating that one or more of the events specified by the PSIF PIC Event Register 1 (PSPICER1) has occurred: For each of these events, a dedicated event bit is located in the PSPICER1. Clearing each of these bits is done by writing 1 to the asserted event bit. Each of the event bits related to this interrupt has a dedicated mask bit in the PSIF PIC Mask Register 1 (PSPICMR1), which allows the host to control the events generating the general error interrupt. The general error interrupt is level interrupt only, allowing the host to access the PSPICER1 to identify the source of the interrupt.

26.4.3.1.2.3 General ECC Error Event Interrupt

The MAPLE-B2 supports a single general ECC/Parity interrupt, which can be triggered due to a multiple ECC/parity error event in any of the ECC/Parity supported memory groups described in **Section 26.4.3.1.1, *Memory Error Correction/Detection Support***.

26.4.3.1.2.3.1 Detecting the Error Source

Once the ECC/Parity general error is asserted, detecting the source of the ECC/Parity error should be done using the following steps:

1. Read the PSIF PIC Event Register 2 (PSPICER2) status register. It includes specific ECC error indications for the PSIF2 and eTVPE and general ECC error indication on the other PEs.
2. If eFTPE_x ECC indication is asserted (PSPICER2[8:6] bits), read the EFTPE_<x> ECC Interrupt Status Register (FTPE<x>ECCISR) to identify the exact memory group which generated the ECC error.
3. If EQPE ECC indication is asserted (PSPICER2[9] bit), read the EQPE ECC Event Register (EQ_ECCEVENT) to identify the exact memory group which generated the ECC error.
4. If CRPE-DL ECC indication is asserted (PSPICER2[10] bit), read the CRPE-DL ECC Status Register (CDECCSR) to identify the exact memory group which generated the ECC error.
5. If CRPE-ULB ECC indication is asserted (PSPICER2[11] bit), read the CRPE-ULB Event Status Register (CRUBESR) to identify the exact memory group which generated the ECC error.

6. If CRPE-ULF ECC indication is asserted (PSPICER2[12] bit), read the ULF ECC Status Register (ULFECCSR) to identify the exact memory group which generated the ECC error.

Reset an ECC/Parity interrupt by writing ‘1’ to the relevant bit in the relevant status register of the PE (for the cases of eFTPE_x, EQPE, CRPE-DL, CRPE-ULB and CRPE-ULF), followed by resetting the relevant bit in the PSPICER2 register.

Each of the event bits in PSPICER2 related to the interrupt has a dedicated mask bit in the PSIF PIC Mask Register 2 (PSPICMR2) that allows the host to control the events generating the general ECC error interrupt.

The general ECC error interrupt is level interrupt only, allowing the host to access the PSIF PIC Event Register 2 (PSPICER2) to identify the source of the interrupt.

26.4.3.1.2.3.2 Handling a General ECC Error Event

Due to the pipelined native operation flow of the internal PEs, it is impossible to detect the exact job on which the ECC event occurred, therefore the following suggests an optional flow for the host to deal with ECC error interrupt assertion in one of the internal PEs:

1. Reset event indication as specified above.
2. Invalidate all BD Rings related to the PE which the ECC event was sourced.
3. Wait for ~60usec to assure that the current BD already processed by MAPLE-B2 is completed.
4. Re-write all recently completed BDs and all un-completed BDs to the base address of the relevant BD Rings again.
5. Reset the relevant BDR_RD_PTR fields of the relevant BD Rings.
6. Validate the BD Rings.

26.4.3.2 eTVPE HARQ, Rate De-Matching, and Turbo/Viterbi Decoding Flow

The MAPLE-B2 supports Rate De-Matching and Turbo/Viterbi decoding for variable standards and configurations as described in **Section 26.2**, *MAPLE-B2 Features*. These operation are executed using the Enhanced Turbo Viterbi Processing Element (eTVPE).

26.4.3.2.1 eTVPE Pipelining

The eTVPE is a pipelined machine with the pipeline stages for 3GLTE and WiMAX processing shown in **Figure 26-4**:.

Figure 26-4. eTVPE Pipeline Stages for 3GLTE and WiMAX Processing

Figure 26-5 shows the pipeline stages for UMTS processing.

Figure 26-5. eTVPE Pipeline Stages for UMTS Processing

For 3GLTE and WiMAX the following is executed in each pipeline stage:

- HARQ. Rate De-Matching (depuncturing only) and HARQ combining.
- Channel Data. Sub-block de-interleaving and CTC interleaving of systematic data.
- Turbo/Viterbi. Turbo or Viterbi decoding, and optional CRC.

For UMTS the following is executed in each pipeline stage:

- Channel Data. Rate De-Matching.
- HARQ. HARQ combining and CTC interleaving of systematic data.
- Turbo/Viterbi. Turbo or Viterbi decoding.

The eTVPE is pipelined machine such as block N can be processed by the Turbo/Viterbi stage while block N+1 can be processed by the Channel-Data/HARQ stage and block N+2 can be processed by the HARQ/Channel Data stage.

26.4.3.2.2 Turbo Standard Parameter Assumptions

The MAPLE-B2 supports HARQ, Rate De-Matching and Turbo decoding according to the following technologies: WiMAX, 3GLTE and UMTS. For details on MAPLE-B2 operation

modes, refer to **Section 26.3**, *Modes of Operation*. **Table 26-5** lists some of the parameters assumed by MAPLE-B2 for each of supported standards:

Table 26-5. MAPLE-B2 Assumptions for Each Supported Standard

Technology	Turbo Rate	Turbo Trellis Termination Method	Turbo Encoding Method	Turbo Polynomials
3GLTE	1/3	Zero tail	Binary encoding	$g_0 = 1 + D^2 + D^3$ (feedback) $g_1 = 1 + D + D^3$ (parity)
UMTS	1/3	Zero tail	Binary encoding	$g_0 = 1 + D^2 + D^3$ (feedback) $g_1 = 1 + D + D^3$ (parity)
WiMAX	1/3	Tail biting	Duo-binary encoding	$g_0 = 1 + D + D^3$ (feedback) $g_1 = 1 + D^2 + D^3$ (Y parity) $g_2 = 1 + D^3$ (W parity)

26.4.3.2.3 eTVPE Initialization Parameter

During the MAPLE-B2 initialization (see *MAPLE-B Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)), certain eTVPE related parameter in the API must be initialized: See **Section 26.5.2.3**, *MAPLE eTVPE Configuration Parameter (MTVCP)* for details.

26.4.3.2.4 eTVPE Buffer Descriptor

eTVPE buffer descriptors are described in detail in **Section 26.5.4.2**, *eTVPE Buffer-Descriptor Structure*, on page 26-412.

26.4.3.2.5 eTVPE Input Data Structures

This section describes all possible input data structures for eTVPE supported by the MAPLE-B2. **Table 26-6** explains the meaning of the acronyms used in this section.

Table 26-6. Symbol Identification Acronyms

Acronym	Explanation
SD	Systematic Data
SDa	First Systematic Data (WiMAX Dou-Binary)
SDb	Second Systematic Data (WiMAX Duo-Binary)
SD~	Interleaved Systematic Data
SDa~	First Interleaved Systematic Data (WiMAX Dou-Binary)
SDb~	Second Interleaved Systematic Data (WiMAX Dou-Binary)
PF	Parity byte for non-interleaved half iteration
PFy	First Parity byte for non-interleaved half iteration (WiMAX Dou-Binary)
PFw	Second Parity byte for non-interleaved half iteration (WiMAX Dou-Binary)
PS	Parity byte for interleaved half iteration
PSy	First Parity byte for interleaved half iteration (WiMAX Dou-Binary)

Table 26-6. Symbol Identification Acronyms (Continued)

Acronym	Explanation
PSw	Second Parity byte for interleaved half iteration (WiMAX Dou-Binary)
P0	Viterbi Rate 1/2 or 1/3 or 1/4 - first parity
P1	Viterbi Rate 1/2 or 1/3 or 1/4- second parity
P2	Viterbi Rate 1/3 or 1/4 - third parity
P3	Viterbi Rate 1/4 - fourth parity
BS	Block Size

Table 26-7 describes the expected data types for each of the possible supported standards, with respect to the algorithm (Turbo/Viterbi) and the encoding rate.

Table 26-7. Turbo/Viterbi Input Data Type

No.	Technology	Descriptor Fields		Input Data	
		ALG[1]	ENC_RATE[2]	Systematic	Parity
1	3GLTE, UMTS	0 = Turbo	1 = 1/3	SD	PF, PS
3	WiMAX (Duo-Binary)	0 = Turbo	1 = 1/3	SDa,SDb	PFy,PFw,PSy,PSw
4	N/A[3]	1 = Viterbi	0 = 1/2	N/A[4]	P0,P1
5	N/A	1 = Viterbi	1 = 1/3	N/A	P0,P1,P2
6	N/A	1 = Viterbi	2 = 1/4	N/A	P0,P1,P2,P3

1. ALG is the Algorithm field in the eTVPE buffer descriptor - see **Section 26.5.4.2**, *eTVPE Buffer-Descriptor Structure*."
2. ENC_RATE is the Encoding Rate field in the eTVPE buffer descriptor - see **Section 26.5.4.2**, *eTVPE Buffer-Descriptor Structure*."
3. Viterbi configuration is not dependent on technology.
4. For Viterbi - there is no systematic data, only parity bits.

The input data for each configuration as described in **Table 26-7**, is composed of input samples stored as 8-bit 2s complement numbers, and is arranged in system memory in one of the supported input data structures as described in **Section 26.4.3.2.5**, *eTVPE Input Data Structures*

26.4.3.2.5.1 Input Samples Polarity

As mentioned above, the input data samples to the eTVPE are 8-bit 2's complement soft numbers ranging from –128 to +127. The configuration of which values (positive values or negative values) are to represent the logic 0 and the logic 1 of the input data is controlled by the [POL] field of the MTVCP parameter of the API (see **Section 26.4.3.2.3**, *eTVPE Initialization Parameter*). The two possible representations are:

- [POL] = 0:
  logic 0 is mapped to –1 (–128 in 2's complement representation)
  logic 1 is mapped to +1 (+127 in 2's complement representation)
- [POL] = 1:
  logic 0 is mapped to +1 (+127 in 2's complement representation)
  logic 1 is mapped to –1 (–128 in 2's complement representation)

26.4.3.2.5.2 LTE HARQ Input Data Structure

The LTE HARQ input data structure provides support for HARQ combining with rate de-matching and Sub-Block De-interleaving processing as appears in the 3GLTE (Evolved UTRA) turbo decoding as specified in 3GPP TS 36.212, section 5.1.2.2, and is valid only for 3GLTE technology.

Configuring the MAPLE-B2 to work with LTE HARQ input data structure is done by configuring the [IN_D_STRCT] field of the eTVPE as "000" and is allowed only if the following is applied:

- The [HE] bit of the MTVCP parameter (see **Section 26.4.3.2.3**, *eTVPE Initialization Parameter*) is set.
- The [STD] bit of the eTVPE BD is set, indicating 3GLTE job.

For the LTE HARQ input data structure, the eTVPE performs as shown in **Figure 26-6**.

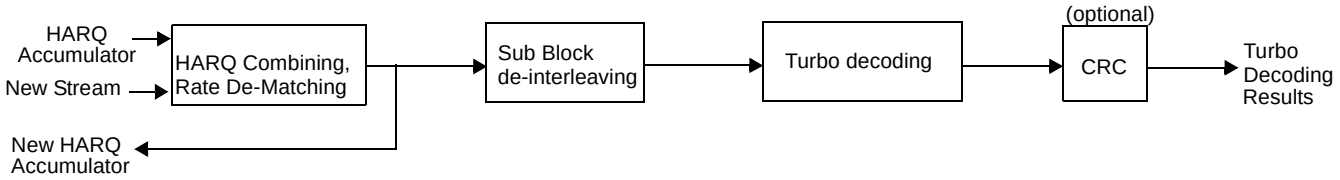

Figure 26-6. eTVPE Processing Flow for LTE HARQ Input Data Structure

The MAPLE-B2 expects two types of input vectors to be fetched into the eTVPE:

- HARQ accumulator buffer generated by the eTVPE while processing this Code Block in previous Redundancy Version transmission. If this is the first transmission of the Code Block and there is no HARQ accumulator exist than the [FTH] bit of the eTVPE BD must be set indicating that no HARQ accumulator buffer is required.
- New Redundancy Version transmission (channel data) to be combined with the existing HARQ accumulator buffer during eTVPE processing.

In addition to all Turbo related eTVPE BD fields, when working with LTE HARQ input data structure, the following fields must be set:

- [BASE_ADDR]: Pointer to the system memory where the new Redundancy Version transmission vector is located.
- All HARQ related fields as described in **Section 26.4.3.2.6.2**, *HARQ Combining*.

As described above, after the HARQ combining stage is completed in the eTVPE, the MAPLE-B2 outputs the new HARQ accumulator data into the system memory, while the eTVPE continues with its processing flow. For details on eTVPE processing flow, refer to **Section 26.4.3.2.6**, *eTVPE Processing*.

26.4.3.2.5.3 WiMAX HARQ Input Data Structure

The WiMAX HARQ input data structure provides support for HARQ combining, rate de-matching and Sub-Block De-interleaving processing as appears in the WiMAX OFDMA turbo decoding (IEEE 802.16e-2009 standard), and therefore is valid only for WiMAX technology.

Configuring the MAPLE-B2 to work with WiMAX HARQ input data structure is done by configuring the [IN_D_STRCT] field of the eTVPE be to 001 and is allowed only if the following applies:

- The [HE] bit of the MTVCP parameter (see **Section 26.4.3.2.3**, *eTVPE Initialization Parameter*) is set.
- The MAPLE-B2 is working under 3GLTE and WiMAX operation mode.

In WiMAX HARQ input data structure the eTVPE performs the operations shown in **Figure 26-7**.

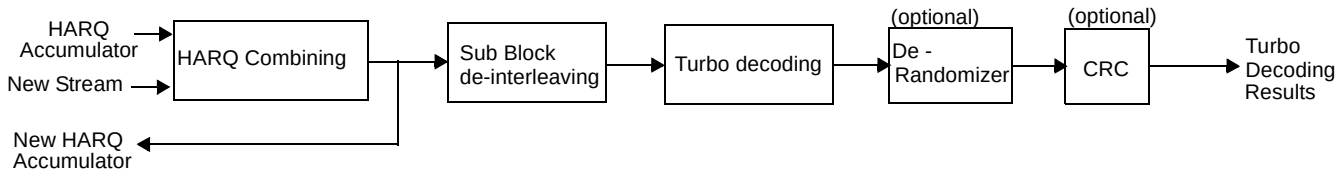

Figure 26-7. eTVPE Processing Flow for WiMAX HARQ Input Data Structure

The MAPLE-B2 expects two types of input vectors to be fetched into the eTVPE:

- HARQ accumulator buffer generated by the eTVPE while processing this Code Block in previous transmission. If this is the first transmission of the Code Block and there is no HARQ accumulator exist than the [FTH] bit of the eTVPE BD must be set indicating that no HARQ accumulator buffer is required.
- New Channel Data transmission to be combined with the existing HARQ accumulator buffer during eTVPE processing.

In additional to all Turbo related eTVPE BD fields, when working with WiMAX HARQ input data structure the following fields must be set:

- [BASE_ADDR]: Pointer to the system memory where the new Channel Data transmission vector is located.
- All HARQ related fields as described in **Section 26.4.3.2.6.2, *HARQ Combining***.

As described above, after the HARQ combining stage is completed in the eTVPE, the MAPLE-B2 outputs the new HARQ accumulator data into the system memory, while the eTVPE continues with its processing flow. For details on eTVPE processing flow, refer to **Section 26.4.3.2.6**.

26.4.3.2.5.4 E-DCH HARQ with Mixed Vector Input Data Structure

The E-DCH HARQ with Mixed Vector input data structure provides support for Rate De-Matching and HARQ combining processing as appears in the 3GPP TS 25.212 Multiplexing and channel coding standard, and therefore is valid only for UMTS jobs.

- Configuring the MAPLE-B2 to work with E-DCH HARQ with Mixed Vector input data structure is done by configuring the [IN_D_STRCT] field of the eTVPE to 010 and is allowed only if the following applies:
- The [HE] bit of the MTVCP parameter (see **Section 26.4.3.2.3**, *eTVPE Initialization Parameter*) is set.
- The [SEP_V] bit of the MTVCP parameter (see **Section 26.4.3.2.3**, *eTVPE Initialization Parameter*) is cleared.
- The MAPLE-B2 is working under 3G operation mode (3GLTE and UMTS technologies).
- The [STD] bit of the eTVPE BD is reset, indicating UMTS job.

In E-DCH HARQ with Mixed Vector input data structure, the eTVPE performs the procedure shown in **Figure 26-8**.

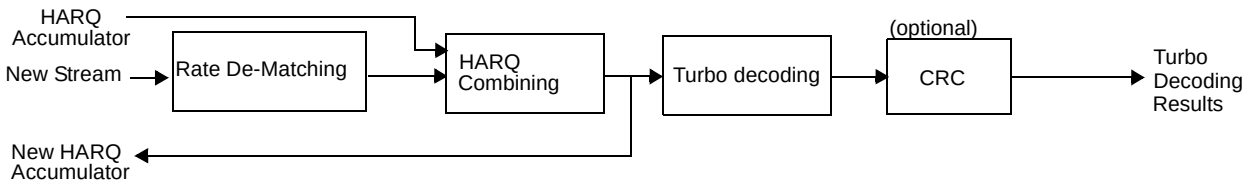

Figure 26-8. eTVPE Processing Flow for E-DCH HARQ Input Data Structure

The MAPLE-B2 expects two types of input vectors to be fetched into the eTVPE:

- HARQ accumulator buffer generated by the eTVPE while processing this Code Block in previous transmission. If this is the first transmission of the Code Block and there is no HARQ accumulator exist than the [FTH] bit of the eTVPE BD must be set indicating that no HARQ accumulator buffer is required.
- New Channel Data transmission to be Rate de-matched and then combined with the existing HARQ accumulator buffer during eTVPE processing.

In additional to all Turbo related eTVPE BD fields, when working with E-DCH HARQ input data structure the following fields must be set:

- [BASE_ADDR]: Pointer to the system memory where the new Channel Data transmission vector is located.
- [BUF_SIZE]: The size of the new Channel Data transmission vector to be fetched by MAPLE-B2 into the eTVPE. See **Section 26.4.3.2.6.1, *E-DCH Rate De-Matching*** For details, on calculating this field.
- HARQ related fields as described in **Section 26.4.3.2.6.2, *HARQ Combining***.

26.4.3.2.5.5 E-DCH HARQ with Separate Vectors Input Data Structure

The E-DCH HARQ with Separate Vectors input data structure provides support for Rate De-Matching and HARQ combining processing as appears in the 3GPP TS 25.222 Multiplexing and channel coding standard, and therefore is valid only for UMTS jobs.

Configuring the MAPLE-B2 to work with E-DCH HARQ with Separate Vectors input data structure is done by configuring the [IN_D_STRCT] field of the eTVPE be to 011 and is allowed only if the following applies:

- The [HE] bit of the MTVCP parameter (see eTVPE Initialization Parameter) is set.
- The [SEP_V] bit of the MTVCP parameter (see eTVPE Initialization Parameter) is set.
- The MAPLE-B2 is working under 3G operation mode (3GLTE and UMTS technologies).
- The [STD] bit of the eTVPE BD is reset, indicating UMTS job.

In E-DCH HARQ with Mixed Vector input data structure, the eTVPE performs the procedure shown in **Figure 26-9**.

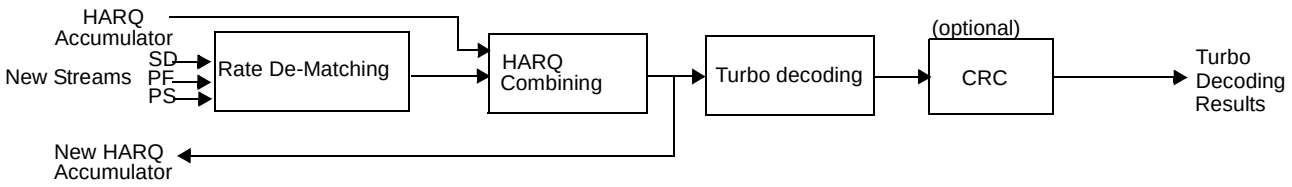

Figure 26-9. eTVPE Processing Flow for E-DCH HARQ Input Data Structure

The MAPLE-B2 expects the following four vectors to be fetched into the eTVPE:

- HARQ accumulator buffer generated by the eTVPE while processing this Code Block in previous transmission. If this is the first transmission of the Code Block and there is no HARQ accumulator exist than the [FTH] bit of the eTVPE BD must be set indicating that no HARQ accumulator buffer is required.
- SD vector of the new Channel Data transmission before Rate de-matching.
- PF vector of the new Channel Data transmission before Rate de-matching.
- PS vector of the new Channel Data transmission before Rate de-matching.

In additional to all Turbo related eTVPE BD fields, when working with E-DCH HARQ with Mixed Vectors input data structure the following fields must be set:

- [BASE_ADDR]: Pointer to the system memory where the SD vector of the new channel data vector is located.
- [VEC_OFFSET]: The offset of the beginning of the PF/PS vectors with respect to the beginning of the SD/PF vectors. The following table describe the expected start address with respect to [BASE_ADDR] and [VEC_OFFSET]:

Table 26-8. Expected Address of Input Vectors

Vector	Start Address
SD	[BASE_ADDR]
PF	[BASE_ADDR] + [VEC_OFFSET]
PS	[BASE_ADDR] + (2 * [VEC_OFFSET])

- [BUF_SIZE]: The size of the SD vector of the new Channel Data transmission to be fetched by MAPLE-B2 into the eTVPE. See
- [PF_BUF_SIZE]: The size of the PF vector of the new Channel Data transmission to be fetched by MAPLE-B2 into the eTVPE.
- [PS_BUF_SIZE]: The size of the PS vector of the new Channel Data transmission to be fetched by MAPLE-B2 into the eTVPE.
- HARQ related fields as described in **Section 26.4.3.2.6.2**, *HARQ Combining*.

See **Section 26.4.3.2.6.1**, *E-DCH Rate De-Matching* for details on calculating the BUF_SIZE fields. As described previously, after the HARQ combining stage is completed in the eTVPE, the MAPLE-B2 outputs the new HARQ accumulator data into the system memory, while the eTVPE continues with its processing flow. For details on eTVPE processing, refer to **Section 26.4.3.2.6**, *eTVPE Processing*

26.4.3.2.5.6 Sub-Block Interleaved Input Data Structure

The Sub-Block Interleaved input data structure provides support for Sub-Block De-interleaving processing as appears in the WiMAX OFDMA turbo decoding (IEEE 802.16e-2009 standard), and the 3GLTE turbo decoding, and therefore is valid only for 3GLTE and WiMAX technologies. Configuring the MAPLE-B2 to work with Sub-Block Interleaved input data structure is done by configuring the [IN_D_STRCT] field of the eTVPE to 100 and is allowed only if the following applies:

- The [HE] bit of the MTVCP parameter (see eTVPE Initialization Parameter) is reset.

In Sub-Block Interleaved input data structure the eTVPE performs the procedure shown in **Figure 26-10**.

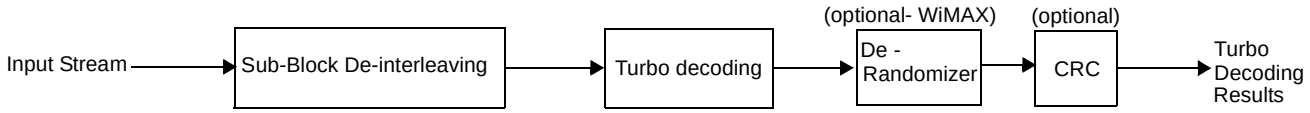

Figure 26-10. eTVPE Processing Flow for Sub-Block Interleaved Input Data Structure

The MAPLE-B2 expects one input vector, pointed by the [BASE_ADDR] field of the eTVPE BD, which should point to the system level post HARQ combining result buffer maintained by the host. In this input data structure, the HARQ combining is assumed being performed externally to MAPLE-B2.

26.4.3.2.5.7 UMTS Mixed Input Data Structure

The UMTS Mixed input data structure provides Turbo decoding support for the UMTS (FDD) standard in the case of Rate De-matching and HARQ processing are performed externally by the host. Configuring the MAPLE-B2 to work with UMTS Mixed input data structure is done by configuring the [IN_D_STRCT] field of the eTVPE be to 101 and is allowed only if the following applies:

- The [HE] bit of the MTVCP parameter (see eTVPE Initialization Parameter) is reset.
- The MAPLE-B2 is working under 3G operation mode (3GLTE and UMTS technologies) with the [STD] bit of the eTVPE BD is reset (UMTS standard).

In UMTS Mixed input data structure the eTVPE performs the procedure shown in **Figure 26-11**.

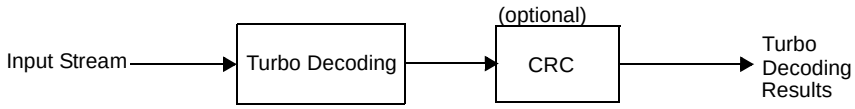

Figure 26-11. eTVPE Processing Flow for UMTS Mixed Input Data Structure

For UMTS Mixed input data structure the MAPLE-B2 expects single input stream, pointed by the [BASE_ADDR] field of the eTVPE BD. The expected structure of the stream is shown in **Figure 26-12**.

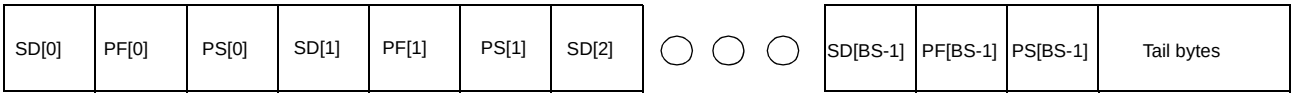

Figure 26-12. UMTS Mixed Stream Structure

The expected Tail bytes structure at the end of the stream is shown in **Figure 26-214**.

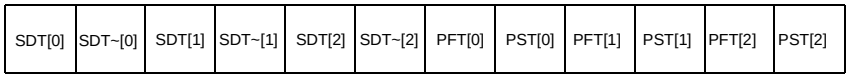

Figure 26-13. UMTS Mixed Tail Stream Structure

26.4.3.2.5.8 Separate Vectors Input Data Structure

The Separate Vectors input data structure provides Turbo decoding support for the 3GLTE, WiMAX (both 802.16e and 802.16m), and UMTS (TDD) technologies in the case of Rate De-matching and HARQ processing are performed externally by the host. Configuring the MAPLE-B2 to work with Separate Vectors input data structure is done by configuring the [IN_D_STRCT] field of the eTVPE be to 110 and is allowed only if the following applies: The [HE] bit of the MTVCP parameter (see eTVPE Initialization Parameter) is reset.

In Separate Vectors input data structure the eTVPE performs the procedure shown in **Figure 26-14**.

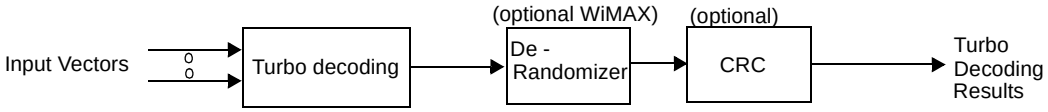

Figure 26-14. eTVPE Processing Flow for Separate Vectors Input Data Structure

In Separate Vectors input data structure, the MAPLE-B2 expects to find the different input data types (SD, PF, PS) in separate vectors as follows:

- For the 3GLTE and UMTS standards the expected vectors are: SD, PFa, PSa
- For the WiMAX technology (Duo-Binary decoding) the expected vectors are: SDa, SDb, PFy, PFw, PSy, PSw

The Tail bits should be added at the end of each vector as described in **Figure 26-15**.

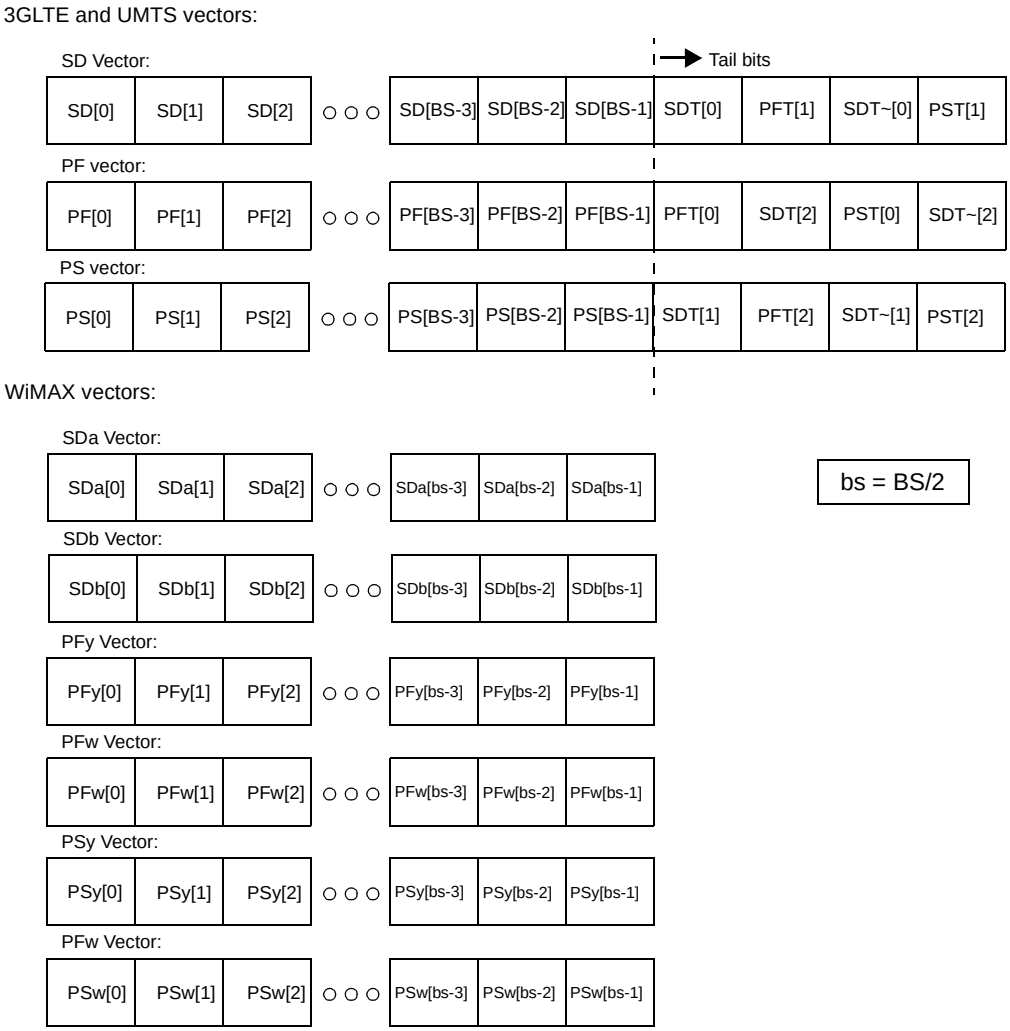

Figure 26-15. Expected Vectors Structure for Separate Vectors

Note: For the 3GLTE standard, the MAPLE-B2 expects three vectors with equal size of [BS] + 4. It requires zero padding of the beginning of the SD and PF vectors with number of zeros equal to the number of filler bits required during the encoding.

The MAPLE-B2 expect to find each of the input vector as described in **Table 26-9**:

Table 26-9. Expected Address of Input Vectors

Standard	Offset of Vector with respect to [BASE_ADDR]					
	no offset	[VEC_OFFSET]	2*[VEC_OFFSET]	3*[VEC_OFFSET]	4*[VEC_OFFSET]	5*[VEC_OFFSET]
3GLTE,UMTS	SD	PF	PS			
WiMAX	SDa	SDb	PFy	PFw	PSy	PSw

where the [VEC_OFFSET] field is a 16 bits field in the eTVPE BD.

26.4.3.2.5.9 Viterbi Periodically Punctured Stream Input Data Structure

The Viterbi Periodic Depuncturing input data structure is the only input data structure supported for Viterbi processing. As such, the MAPLE-B2 assume it is enabled whenever Viterbi processing is enabled ([ALG]=1).

The Periodically Punctured Stream input data structure is targeted for Viterbi processing only. By setting the [ALG] bit for Viterbi job ([ALG] = 1), the MAPLE-B2 assumes Periodically Punctured Stream input data structure is applied. For the Periodically Punctured Stream input data structure, the eTVPE performs the procedure shown in **Figure 26-16**.

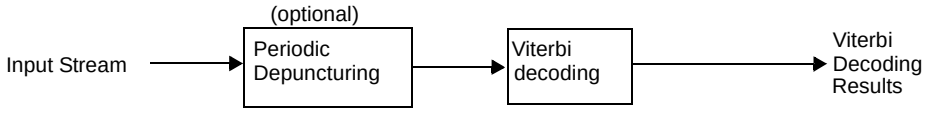

Figure 26-16. eTVPE Processing Flow for Periodically Punctured Stream Input Data Structure

For the Periodically Punctured Stream data structure, the MAPLE-B2 expects to find the relevant input data types in a single vector stream pointed by [BASE_ADDR] field of the eTVPE BD. The order of the symbols (after depuncturing) within the data stream is prescribed in **Table 26-10**.

Table 26-10. Default Symbol Ordering in PPCMS

Operation Mode	Rate	Default Symbol Ordering
All (Viterbi)	1/2	P0[n], P1[n], P0[n+1], P1[n+1], P0[n+2], P1[n+2], P0[n+3], P1[n+3]
All (Viterbi)	1/3	P0[n], P1[n], P2[n], P0[n+1], P1[n+1], P2[n+1]
All (Viterbi)	1/4	P0[n], P1[n], P2[n], P3[n], P0[n+1], P1[n+1], P2[n+1], P3[n+1]

From **Table 26-10**:

- For Viterbi rate 1/2 processing, the expected input stream (after depuncturing) is:

P0[0]	P1[0]	P0[1]	P1[1]	P0[2]	P1[2]	P0[3]	P1[3]	○	○	○	○

- For Viterbi rate 1/3 processing, the expected input stream (after depuncturing) is:

P0[0]	P1[0]	P2[0]	P0[1]	P1[1]	P2[1]	P0[2]	○	○	○	○	○

- For Viterbi rate 1/4 processing, the expected input stream (after depuncturing) is:

P0[0]	P1[0]	P2[0]	P3[0]	P0[1]	P1[1]	P2[1]	P3[1]	○	○	○	○

When working with the Viterbi Periodic Depuncturing input data structure, besides the [BS] field which indicates the decoded block size, the [BUF_SIZE] field must be initialized, as well, with the actual size of the input data stream in bytes. The value of [BUF_SIZE] should be calculated according to the following:

1. if ([ZTTB] == 1)

   tmp_buf_size = [BS] + *K* -1;

   else

   tmp_buf_size = [BS];
2. if (*EncRate* == 2)

   tmp_buf_size = (tmp_buf_size + 3) & 0xFFFC;

   else

   tmp_buf_size = (tmp_buf_size +1) & 0xFFFE;
3. [BUF_SIZE] = roundup(tmp_buf_size**PuncRate***EncRate* + 31) & 0xFFF0;

where:

[ZTTB], [BS]. Fields from the eTVPE BD.
K. Viterbi Constraint Length.
EncRate. Encoder rate. Should be equal 2, 3 or 4 for encoder rates of 1/2, 1/3 or 1/4 respectively.
PuncRate. Puncturing rate. For example 2/3, 3/4, and so forth.

For example: If [BS]= 164, [ZTTB] =1, *K*=9, Encoding rate of 1/3 and Puncturing rate of 2/3:

1. tmp_buf_size = 164 + 8 = 172
2. tmp_buf_size = (172 + 1) & 0xFFFE = 172
3. [BUF_SIZE] = roundup(172 * (2/3)*3 + 31) & 0xFFF0 = 375 & 0xFFF0 = 368

26.4.3.2.5.10 eTVPE Input Data Structures Summary

Table 26-11 describe the supported eTVPE input data structure with respect to the supported standard

Table 26-11. eTVPE Input Data Structures Summary

Input Data Structure	3GLTE	UMTS	WiMAX (802.16e)	WiMAX (802.16m)
LTE HARQ	Yes	No	No	No
WiMAX HARQ	No	No	Yes	No
E-DCH HARQ with Mixed Vector	No	Yes	No	No
E-DCH HARQ with Separate Vectors	No	Yes	No	No
Sub Block Interleaved	Yes	No	Yes	No
UMTS Mixed	No	Yes	No	No
Separate Vectors	Yes	Yes	Yes	Yes

26.4.3.2.6 eTVPE Processing

The following sections describe the processing algorithms performed in the eTVPE for the different supported algorithms and input data structures

26.4.3.2.6.1 E-DCH Rate De-Matching

The E-DCH Rate De-Matching processing is performed during E-DCH HARQ with Mixed Vector and E-DCH HARQ with Separate Vectors input data structure processing flows only. For these input data structure, the eTVPE executes Rate-De-Matching using depuncturing or using a de-repetition scheme. This scheme provides support for E-DCH, as defined in 3GPP TS 25.212/222 Multiplexing and channel coding, section 4.8.

Since the 3GPP TS 25.212/222 standard defines the rate-matching process over transport block (TB) and not code block (CB) and since the eTVPE works on CB only, the following parameters in the eTVPE BD must be initialized:

- *[E_PARAM_PTR]*. A pointer to a data structure in the system memory which includes the required parameters for the eTVPE for the Rate De-matching processing.
- *[DPNC]*. Indication to the eTVPE whether depuncturing scheme is required ([DPNC]=1) or de-repetition ([DPNC]=0).

The expected parameter structure pointed to by the [E_PARAM_PTR] pointer is shown in **Figure 26-17**.

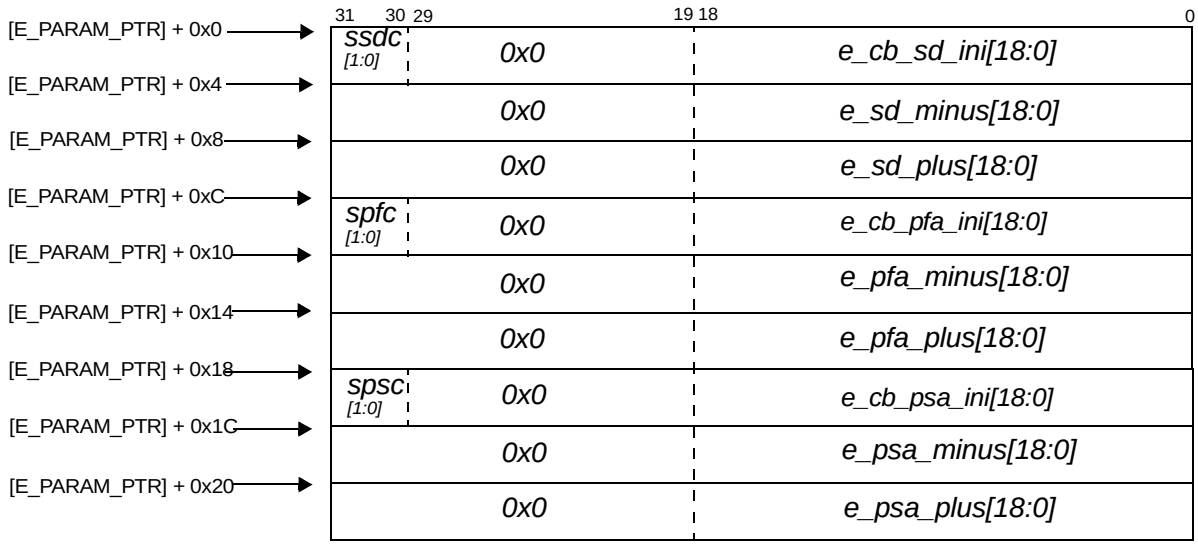

Figure 26-17. E parameters Data Structure Description

where:

e_cb_<xx>_ini[18:0]— The e_{init} parameter for SD, PF and PS (as defined in standard) with the additional offset of the current code block in the transport block for the systematic data. Details on calculating these parameters is described in **Section 26.4.3.2.6.1.4**, *Code Block e_ini Calculation.*

e_<xx>_minus[18:0]—The e_{minus} parameter for SD, PF and PS (as defined in standard)

e_<xx>_plus[18:0]—The e_{plus} parameter for SD, PF and PS (as defined in standard)

s<xx>c[1:0]—Skip SD, PF and PS count value. Details on calculating these parameters is described in **Section 26.4.3.2.6.1.2**, *Skip Count Calculation*

26.4.3.2.6.1.1 Rate Matched Code Block Size Calculation

To find the size of each code block before rate de-matching, the following calculations should be performed for each data type (SD, PF, and PS)

```
rate_matched_bits = rounddown(([BS]+ 4) * e_minus /e_plus)
e_ini_limit = (([BS]+ 4)* e_minus)mod(e_plus)
if (e_ini_limit >= e_cb_ini)
     rate_matched_bit = rate_matched_bits + 1
if ([DPNC] ==0) //repetition
     rate_matched_code_block_size = [BS] + 4 + rate_matched_bits
else //puncturing
     rate_matched_code_block_size = [BS] + 4 - rate_matched_bits
```

26.4.3.2.6.1.2 Skip Count Calculation

Calculating the skip count for each data type (s<xx>c[1:0] parameters) is performed as follows:

```
n - index of current CB in TB (n = 0, 1, 2...)
sd_prev_rm_bits(n) = 0
pf_prev_rm_bits(n) = 0
ps_prev_rm_bits(n) = 0

for (i=0; i < n; i++)
{
     sd_prev_rm_bits(n) = sd_prev_rm_bits(n) + sd_rate_matched_code_block_size(i)
     pf_prev_rm_bits(n) = pf_prev_rm_bits(n) + pf_rate_matched_code_block_size(i)
     ps_prev_rm_bits(n) = ps_prev_rm_bits(n) + ps_rate_matched_code_block_size(i)
}

min_prev_rm_bits(n) = min(sd_prev_rm_bits(n),pf_prev_rm_bits(n),ps_prev_rm_bits(n))

if ([DPNC]==0) //repetition
     ssdc[1:0] = sd_prev_rm_bits(n) - min_prev_rm_bits(n)
     spfc[1:0] = pf_prev_rm_bits(n) - min_prev_rm_bits(n)
     spsc[1:0] = ps_prev_rm_bits(n) - min_prev_rm_bits(n)
else // puncturing
     ssdc[1:0] = 0
     spfc[1:0] = 0
     spsc[1:0] = 0
```

Figure 26-18 describe a Transport Block example which consist of three Code Blocks and was repeated using the rate matching functionality at the transmitter. The figure shows the required input data into the TVPE for the middle CB and the skip count bits location.

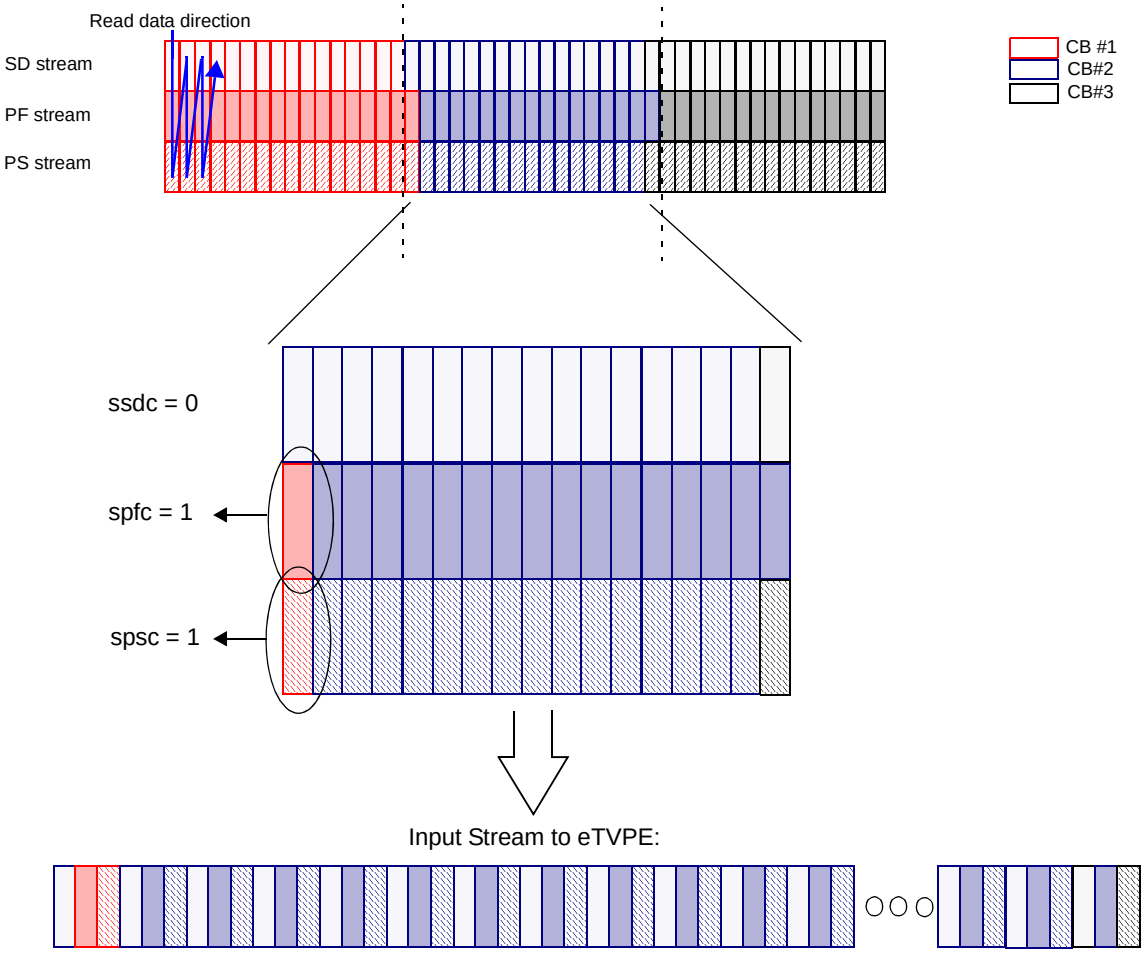

Figure 26-18. Skip Count Bits Location Example

26.4.3.2.6.1.3 Buffer Size Calculations

Calculating the BUF_SIZE fields is done using the parameters calculated in the previous sections according to the following:

- For the E-DCH HARQ with Mixed Vector input data structure:

```
[BUF_SIZE] = 3 * max(sd_rate_matched_code_block_size + ssdc,
pf_rate_matched_code_block_size + spfc, ps_rate_matched_code_block_size + spsc);
```

- For the E-DCH HARQ with Separate Vectors input data structure:

```
[BUF_SIZE] = 'sd_rate_matched_code_block_size'
[BUF_SIZE_PF] = 'pf_rate_matched_code_block_size'
[BUF_SIZE_PS] = 'ps_rate_matched_code_block_size'
```

26.4.3.2.6.1.4 Code Block e_ini Calculation

Calculating the e_cb_ini parameter for each of the data type is performed for each CB in the TB according to the following calculation:

```
e_cb_ini = [(e_ini - ([BS] + 4)* n *e_minus - 1)mod(e_plus)] + 1
e_cb_ini = e_cb_ini + s<xx>c*e_minus
```

where:

e_ini, *e_minus*, *e_plus*- As defined in standard.
[BS] - Block Size field in eTVPE BD
n - Current index of CB where for first CB “n=0”.
s<xx>c - Skip count parameters for each data type as described in Skip Count Calculation.

The calculated values should be used for the ***e_cb_<xx>_ini[18:0]*** parameters.

26.4.3.2.6.1.5 Parameters Calculation Example

The following example describe the parameters calculations required to generate eTVPE BDs for few CBs related to single TB in E-DCH HARQ with Mixed Vector input data structure:

Assuming TB with the size of 16,003 bits to be transmitted. The standard defines the following:

```
num_of_cb = roundup(16003/5114) = 4 // Number of CBs
cb_size = roundup(16003/4) = 4001 // Last CB is added with single padding bit
toal_bit_to_transmit = 3*(cb_size*num_of_cb) + 12*num_of_cb = 48060 // Ne,j
Nsys = Np1 = Np2 = 16020
```

Puncturing is required if $N_{e,data,j}$ is smaller than $N_{e,j}$ and repetition is required if $N_{e,data,j}$ is larger than $N_{e,j}$. In the example it is assumed $N_{e,data,j}$ = 26,007.

The s parameter indicated if systematic data is preferred over parity data. In the example it is assumed s=1, that is, systematic data is preferred, therefore:

$N_{t,sys} = N_{sys} = 16020$
$N_{t,p1} = \text{rounddown}((N_{data} - N_{t,sys}/2)) = 4993$
$N_{t,p2} = \text{roundup}((N_{data} - N_{t,sys}/2)) = 4994$

Calculating the e parameters according to the standard definition is described in the following table:

Table 26-12. e Parameters Calculation Results

Data Type	e_{plus}	e_{minus}	e_ini (first CB)
SD	N_{sys} = 16,020	0	16,020
PF	2 * N_{p1} = 32,040	2*(N_{p1}-$N_{t,p1}$) = 22,054	16,020
PS	N_{p2} = 16,020	N_{p2} - $N_{t,p2}$ = 11,028	16,020

Once all standard parameters are calculated, eTVPE BD parameters can be calculated. **Table 26-13** describe the parameters calculations for each of the BC in the TB

Table 26-13. eTVPE BD parameters calculations

Parameter	CB #1	CB #2	CB #3	CB #4
sd_rate_matched_code_block_size	4005	4005	4005	4005
pf_rate_matched_code_block_size	1249	1250	1249	1249
ps_rate_matched_code_block_size	1249	1249	1249	1249
ssdc	0	0	0	0
spfc	0	0	0	0
spsc	0	0	0	0
[BUF_SIZE]	6504	6504	6504	6504
e_cb_sd_ini	16,020	16,020	16,020	16,020
e_cb_pf_ini	16,020	8010	32,040	24,030
e_cb_ps_ini	16,020	16,020	16,020	16,020

26.4.3.2.6.2 HARQ Combining

The HARQ combining is enabled by setting the HARQ Enable ([HE]) bit of the MTVCP parameter during MAPLE-B2 initialization. It is performed during one of the following input data structures: LTE HARQ, WiMAX HARQ, and E-DCH HARQ.

26.4.3.2.6.2.1 eTVPE BD Parameter Initialization

When working with HARQ combining enabled, the following parameters of the eTVPE BD must be initialized:

1. [HA_IN_BASE_ADDR]. Pointer to the system memory where the HARQ accumulator buffer is located. MAPLE-B2 uses this pointer to fetch the HARQ accumulator buffer. if [FTH] bit is set, this field is ignored as no HARQ accumulator input buffer is expected.
2. [HA_OUT_BASE_ADDR]. Once HARQ combing is completed and the [HAOE] bit is enabled, the MAPLE-B2 use this pointer to write the new HARQ accumulator.
3. [HAOE]. HARQ Output Enable indication. Should be set if the HARQ accumulator buffer after the combining stage with the new stream is required to be output by MAPLE-B2 for future Redundancy Versions Transmissions.
4. [IHBSZ]. The size of the new Redundancy Version transmission vector to be fetched by MAPLE-B2 into the eTVPE. For UMTS standard this field is ignored.
5. [IHBSA]. The relative address of the new Redundancy Version transmission vector in the accumulator HARQ buffer. For UMTS standard this field is ignored. See **Section 26.4.3.2.6.2.3**, *Calculating the IHBSA Parameter* for details on calculating this parameter.
6. [FTH]. First HARQ buffer indication. Should be set if the current job is the first Redundancy Version transmission. If set, no HARQ accumulator is required to be fetched.

Figure 26-19 describes an example of the use of the above parameters.

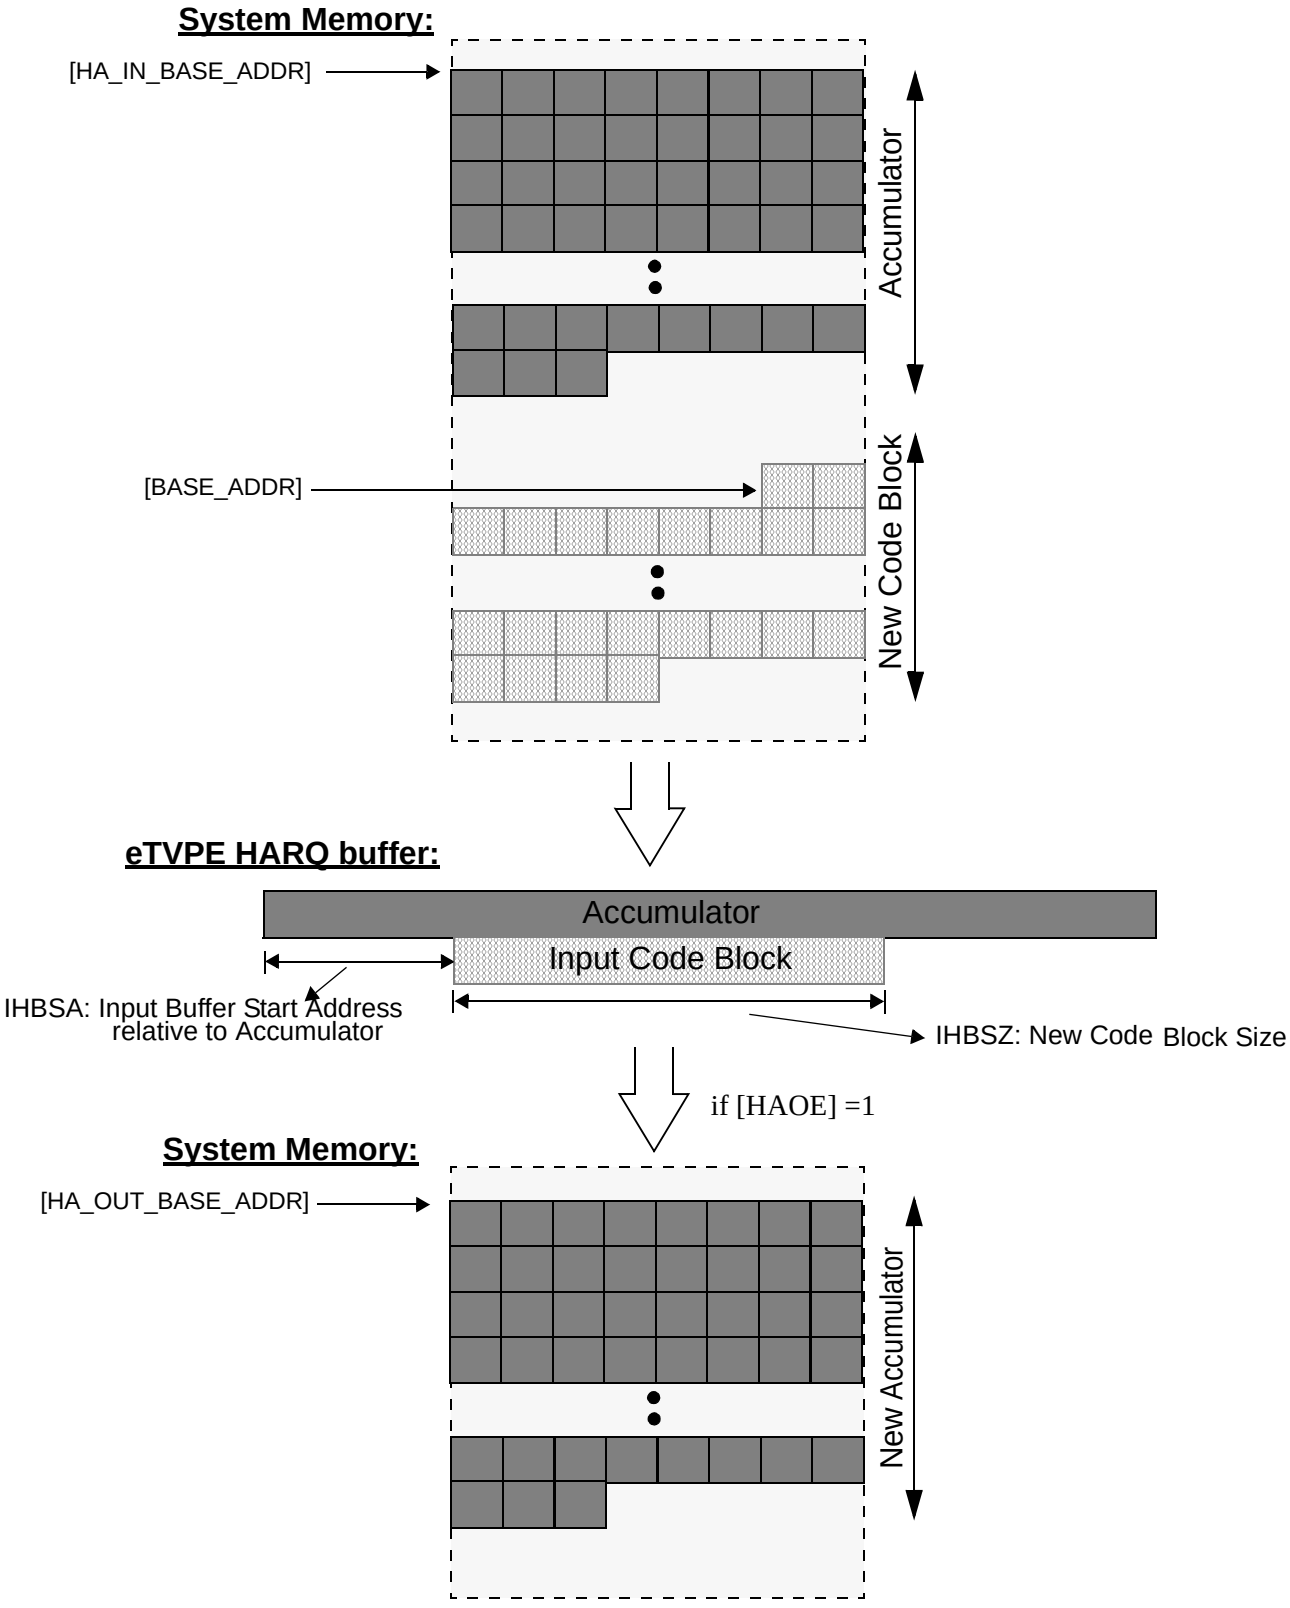

Figure 26-19. HARQ BD Parameters Usage Example

26.4.3.2.6.2.2 Setting the HARQ Combining Parameters

In addition to the above parameters, the following HARQ combining parameters must be set:

1. [HUS]. HARQ Up Scale indication. Allow up-scaling of the new input stream to be accumulated to the HARQ accumulator by 0 (no up-scaling), 2, 4 or 8 (shift left of each input sample by 0,1,2 or 3).
2. [W1E], [W2E], [W3E], [W1], [W2], [W3]. Weight Enable and Weight value. The HARQ accumulator and the new input stream are combined according to the following weight scheme:

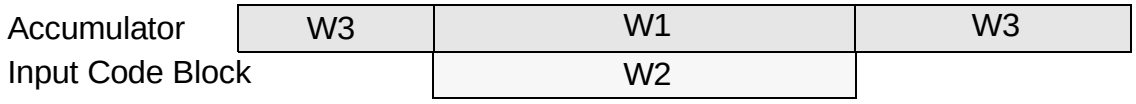

Figure 26-20. HARQ Weight Scheme

W1 - Data from HARQ accumulator which is covered by new input stream.

W2 - Data of new input stream

W3 - Data from HARQ accumulator which is **not** covered by new input stream.

Calculation each input of new HARQ accumulator for data which is covered by new input stream:

case ({[W1E],[W2E]})

‘00’: HARQ_new = HARQ_old + (DATA_new << [HUS])

‘01’: HARQ_new = HARQ_old + (W2/256)*(DATA_new << [HUS])

‘10’: HARQ_new = (W1/256)*HARQ_old + (DATA_new << [HUS])

‘11’: HARQ_new = (W1/256)*HARQ_old + (W2/256)*(DATA_new << [HUS])

Calculation each input of new HARQ accumulator for data which is **not** covered by new input stream:

```
if ([W3E] == 0)
    HARQ_new = HARQ_old
else if ([W3E] == 1)
    HARQ_new = HARQ_old * ([W3]/256)
```

During the HARQ combining calculations, overflow of LLRs may occur. In case of overflow, the eTVPE saturate the LLR results and count the total LLRs which required saturation. The [HSC] status field of the eTVPE BD holds the number of LLRs which were saturated due to overflow in the HARQ combing process.

26.4.3.2.6.2.3 Calculating the IHBSA Parameter

Calculation of the IHBSA parameter differs between the technologies:

For WiMAX technology, the IHBSA parameter equals the $S_{k,i}$ parameter as calculated in the standard.

For 3GLTE technology, calculating the IHBSA parameter is based on the K_0 parameter calculations as following:

```
Num_of_dummy_bits = [32 - (BS+4)%32]%32
IHBSA = K0 - IHBSATable[ RV<<2 + (Num_of_dummy_bits-4)>>3];
```

where:

```
BS - Block Size Parameter from eTVPE Buffer Descriptor.
K0 - Calculated as described in the standard.
RV - Redundancy Version Index (described in standard)
IHBSATable[0] = 1
IHBSATable[1] = 1
IHBSATable[2] = 2
IHBSATable[3] = 2
IHBSATable[4] = 4
IHBSATable[5] = 10
IHBSATable[6] = 17
IHBSATable[7] = 23
IHBSATable[8] = 8
IHBSATable[9] = 20
IHBSATable[10] = 32
IHBSATable[11] = 44
IHBSATable[12] = 10
IHBSATable[13] = 30
IHBSATable[14] = 48
IHBSATable[15] = 66
```

26.4.3.2.6.3 Sub-Block De-interleaving

The Sub-Block Interleaved Vectors input data structure provides support for Turbo decoding, as it appears in the WiMAX OFDMA turbo decoding (**IEEE** 802.16e-2009 standard), and the 3GLTE (Evolved UTRA) sub-block de-interleaving and rate matching, and therefore is valid only during the following input data structures: HARQ LTE, HARQ WiMAX, and Sub-Block Interleaved.

There are two types of sub-block de-interleaving executed by the eTVPE:

1. Singles sub-block de-interleaving. The eTVPE performs sub-block de-interleaving on one type of data, that is, on SD only (SDa only and SDb only for WiMAX). **Figure 26-21** describes an example of single sub-block de-interleaving:

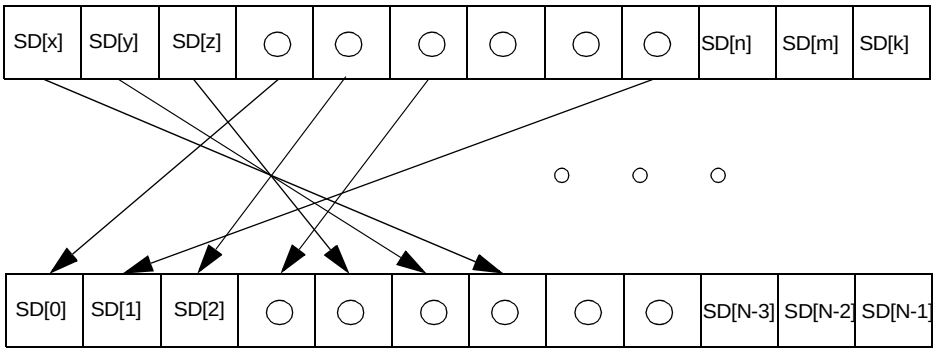

Figure 26-21. Single Sub Block De-Interleaving Example

2. Pairs sub-block de-interleaving. The eTVPE performs sub-block de-interleaving on pairs of data types, that is, on PF+PS, PFy+PSy and PFw+PSw. **Figure 26-22** describes an example of pairs sub-block de-interleaving:

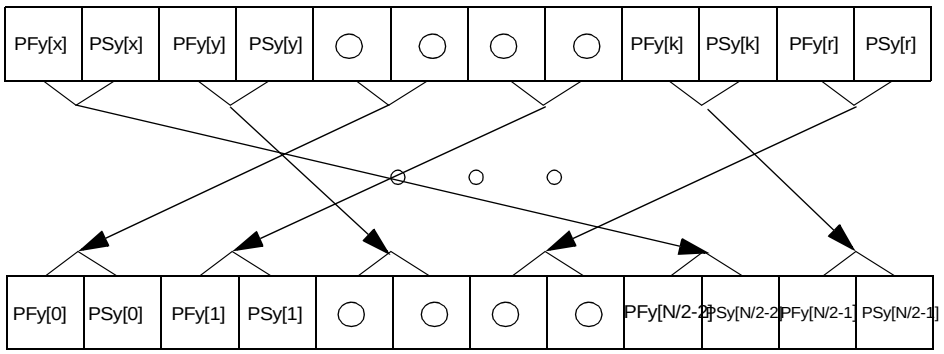

Figure 26-22. Pairs Sub Block De-Interleaving Example

Table 26-14 describes the type of sub-block de-interleaving executed for each of the technologies:

Table 26-14. Sub Block De-Interleaving With Respect to standard

standard	Single Sub-Block De-Interleaving	Pairs Sub-Block De-Interleaving
3GLTE	SD	PF+PS
WiMAX	SDa SDb	PFy+PSy PFw+PSw

26.4.3.2.6.4 Turbo Decoding

The MAPLE-B2 supports Turbo decoding for the different technologies according to its operation mode:

- For 3G operation mode:
  - 3GLTE technology
  - UMTS technology
- For WiMAX operation mode:
  - 3GLTE technology
  - WiMAX technology

Once the MAPLE-B2 operation mode is set during initialization (see **Section 26.4.1**, *Initialization*), it can process Turbo decoding as per the technologies supported in that operation mode only. For each operation mode, it can dynamically switch between the supported technologies.

26.4.3.2.6.4.1 Turbo Channel Data Interleaving

Before the eTVPE can start its decoding operation, the interleaved channel data must be generated. The eTVPE uses its internal parameters/registers, with additional information from the BD (such as Block Size) to internally determine the interleaving configuration. The interleaving process is executed internally and independently by the eTVPE.

26.4.3.2.6.4.2 Turbo Processing Implementation

The following equations describe the eTVPE Turbo implementation of the MAX* methods. The Radix-4 implementation is implemented for Binary decoding only.

- Gamma Calculation:

$$\gamma_k(s',s) = \frac{SD_n \cdot esd_n + SD_{n+1} \cdot esd_{n+1} + P_n \cdot ep_n + P_{n+1} \cdot ep_{n+1} + \frac{3}{4} \cdot (EXT_n \cdot esd_n + EXT_{n+1} \cdot esd_{n+1})}{2}$$

where SD_n, SD_{n+1}, P_n, and P_{n+1} are the 8 bit received systematic and parity channel data for bit n and n+1, and Ext_n, and Ext_{n+1} are the extrinsic values from the previous iteration

(0 on the first iteration), and esd_n, esd_{n+1}, epn, ep_{n+1} are the expected values for transition between states s and s.

- Alpha Recursion:

$$\alpha_k(s) = ACS4_{s' \subseteq S}(\alpha_{k-1}(s') + \gamma_k(s', s))$$

- Beta Recursion:

$$\beta_k(s) = ACS4_{s' \subseteq S}(\beta_{k+1}(s') + \gamma_{k+1}(s', s))$$

- Lambda Calculation:

$$\Lambda_k(u, v) = ACS8_{s' \subseteq S}(\alpha_{k-1}(s') + \gamma_k(s', s) + \beta_k(s))$$

where u and v are the inputs that cause a transition between state s and state s´.

- Hard Outputs are h_n and h_{n+1} such that:

$$\Lambda(h_n, h_{n+1}) = max(((\Lambda_k(0, 0), \Lambda_k(0, 1)), \Lambda_k(1, 0)), \Lambda_k(1, 1))$$

- ACS2 definition when using MaxLogMap is:

$$ACS2M = cmax(u, v)$$

where cmax is the cyclical max between u and v:

- ACS2 definition when using LinearLogMap is:

$$ACS2L = cmax(u, v) + f(u, v, lcf)$$

where lcf is the [LLMAP_LCF] field in the eTVPE BD and f is defined as:

$$f(u, v, lcf) = \begin{cases} \frac{lcf}{2} - \frac{|u - v|}{2}, & |u - v| < lcf \\ 0, & Otherwise \end{cases}$$

- ACS4 in the case of LinearLogMap is defined as:

$$ACS4L(u, v, w, y) = ACS2M((ACS2L[u, v]), ACS2L[w, y])$$

and in the case of MaxLogMap as:

$$ACS4M(u, v, w, y) = ACS2M((ACS2M[u, v]), ACS2M[w, y])$$

- ACS 8 in the case of LinearLogMap is defined as:

$$ACS8L(a, b, c, d, e, f, g, h) = ACS2M((ACS4L[a, b, c, d]), ACS4L[e, f, g, h])$$

and in the case of MaxLogMap as:

$$ACS8M(a, b, c, d, e, f, g, h) = ACS2M((ACS4M[a, b, c, d]), ACS4M[e, f, g, h])$$

26.4.3.2.6.4.3 Number of Turbo Processing Elements (DREs)

The eTVPE includes four DRE (Dual Recursion Element) engines used for Turbo processing. For different block sizes, it is possible to activate 1 DRE engine, 2 DRE engines, or 4 DRE engines. When activating more than one such engine during a given Turbo processing session, the eTVPE internally divides the block into internal sub-blocks for each of the active DREs, thus paralleling the decoding process and increasing the decoding speed of the eTVPE. The MAPLE-B2 allows two modes of operation with respect to the number of DRE engines:

- *Automatic number of DRE engines*. By setting the [ANDRE] bit of the MTVCP parameter (see **Section 26.5.2.3**, *MAPLE eTVPE Configuration Parameter (MTVCP)*), the eTVPE sets the number of DRE engines automatically to achieve maximum throughput performance.
- *BD controlled number of DRE engines.* By clearing the [ANDRE] bit of the MTVCP parameter, the eTVPE uses the number of DRE engines as configured in the [NDRE] field of the eTVPE BD.

As mentioned previously, when setting the [ANDRE] bit in the MTVCP parameter, the eTVPE internally configures its number of DRE engines to the maximum possible for a given Block Size. **Table 26-15** lists the maximum number of DRE engines used by the eTVPE if the [ANDRE] bit is set. The limitations also apply when working when the [ANDRE] bit is cleared.

Table 26-15. Maximum Possible Number of DRE Engines

Standard	Maximum Number of DRE Engines (NDRE)
3GLTE	if ([BS] < 64) {NDRE = 2} else {NDRE = 4}
WiMAX	if ([BS] < 96) {NDRE = 2} else {NDRE = 4}
UMTS	if ([BS] < 128) {NDRE = 2} else {NDRE = 4}

Note: Working with a number of DRE engines which exceed the limitations described in **Table 26-15** may result in an unknown state. Working with less DRE engines than described in **Table 26-15** results in fewer internally divided sub-blocks of the decoded block and may achieve slightly better BLER performance.

Activating less DRE engines for a given block size (with respect to the values in **Table 26-15**) should be done within the following limitations:

Table 26-16. Minimum Number of DRE Engines

Total Block Size[1]	Minimum number of DRE engines ([NDRE] value)
Total Block Size ≤ 1024	1 (00)
1024 < Total Block Size ≤ 2048	2 (01)
2048 < Total Block Size	4 (10)

1. The Total Block Size as defined in this table should include the 3 Tail bits (if they exist), that is, “Total Block Size” = [BS] + 3.

26.4.3.2.6.4.4 Turbo Stopping Criteria Configurations

The eTVPE offers the following 3 types of stopping criteria:

- Aposteriori Output Quality based Stopping Criteria
- CRC Check based Stopping Criteria
- Steady CRC based Stopping Criteria

Using any of the stopping criteria allow the eTVPE to stop the Turbo decoding before reaching the [MAX_ITER] values specified in the eTVPE BD. If stopping criteria is disabled, the eTVPE executes the number of iterations as specified in the [MAX_ITER] field. The [MIN_ITER] field describes the minimum number of iterations executed by the eTVPE when any of the stop criteria is enabled.

Note: It is possible to activate two stopping criteria conditions, but it is forbidden to enable both the CRC-Check-based and the Steady-CRC-based stopping criteria in parallel.

26.4.3.2.6.4.5 Aposteriori Output Quality Based Stopping Criteria

In order for the eTVPE to work with the Aposteriori Quality (AQ) based stopping criteria, the following parameters/eTVPE registers must be configured:

- MTVCP[AQC_AUTOSTOP] - Aposteriori Quality Stop Criteria enable bit of the MTVCP This bit must be set during MAPLE-B2 initialization.
- eTVPE register: TVAQCR[AQTH] - Threshold value, to be compared to the Aposteriori results after each internal iteration.

For each iteration output bit, the eTVPE calculates the following to determine if Aposteriori Output quality has been reached:

```
if ((| L_n[P(0)] - L_n[P(1)] | > TVAQCR[AQTH]) & (| L_n+1[P(0)] - L_n+1[P(1)] | > TVAQCR[AQTH]))
    counter = counter + 2
else if ((| L_n[P(0)] - L_n[P(1)] | > TVAQCR[AQTH]) | (| L_n+1[P(0)] - L_n+1[P(1)] | > TVAQCR[AQTH]))
    counter = counter + 1;
```

The stopping criteria is only checked starting from the iteration number defined in the [MIN_ITER] field, defined in the eTVPE BD, that is, The [MIN_ITER] field dictates the minimum number of iterations executed by the eTVPE regardless of the AQ Based Stopping criteria.

The [CMPLT_RSN] status field in the eTVPE BD, indicates whether the eTVPE completed its decoding process due to stopping criteria, or due to reaching the maximum iteration number given in the [MAX_ITER] field of the eTVPE BD.

The [ITER_CNT] status field in the eTVPE BD indicates the actual number of iterations executed for the current job. If no stopping criteria is enabled or if the stopping criteria has not reach its threshold, the value of the [ITER_CNT] is equal to the value of the [MAX_ITER]. If the stopping

criteria reached its threshold before the number of iterations specified in the [MAX_ITER] has executed, the [ITER_CNT] field contains the actual number of iterations executed until reaching the stopping criteria threshold.

Note: The higher the number of the Aposteriori Threshold value ([AQTH]), the better the decoding quality is. Recommended range of values is between 100 to 150.

26.4.3.2.6.4.6 CRC Check Based Stopping Criteria

The CRC check based stopping criteria means that the eTVPE runs CRC check on its Hard Output results after each full iteration. If the CRC check has passed, the eTVPE stops its operation and notify MAPLE-B2 on job completion.

If the CRC check based stopping criteria is enabled and if the [MIN_ITER] field of the eTVPE BD, which sets the minimum number of iterations to be executed by the eTVPE, is enabled (greater than 0), then the CRC checks on the Hard Outputs are executed only when the minimum number of iterations is reached.

If the CRC check based stopping criteria is enabled and if the [MAX_ITER] field of the eTVPE BD, which sets the maximum number of iterations to be executed by the eTVPE, is reached without passing the CRC check, the eTVPE stop the decoding operation and notify MAPLE-B2 on job completion. In such case, the MAPLE-B2 give a CRC fail indication in the status field of the eTVPE BD ([ERROR_STATUS]).

Enabling the CRC check based stopping criteria is done during MAPLE-B2 initialization by setting the [CRC_AUTOSTOP] bit of the MTVCP parameter (see **Section 26.5.2.3**).

The CRC polynomial configuration for the CRC based stop criteria is determined by the [CRC_POLY] field of the eTVPE BD. The eTVPE supports the following CRC polynomials:

1. CRC24. Polynomial: $D^{24} + D^{23} + D^6 + D^5 + D + 1$ ([CRC_POLY] = ‘00’)
2. CRC24. Polynomial: $D^{24} + D^{23} + D^{18} + D^{17} + D^{14} + D^{11} + D^{10} + D^7 + D^6 + D^5 + D^4 + D^3 + D + 1$ ([CRC_POLY]=‘01’)
3. CRC16. Polynomial: $D^{16} + D^{12} + D^5 + 1$ ([CRC_POLY]=‘10’).

26.4.3.2.6.4.7 Steady CRC Based Stopping Criteria

The Steady CRC stopping criteria means that the eTVPE compares the hard output bits from previous iteration to the hard output bits from current iteration. If the hard outputs bits of the two iterations is identical, the eTVPE stops its operation and notify MAPLE-B2 on job completion. The comparison of the hard outputs of two successive iterations is performed by calculating the CRC result of the hard output bits of each iteration and comparing their results. The [CRC_POLY] field of the eTVPE BD determines which of the existing CRC polynomials is used for the check (For details on the existing CRC polynomials see: CRC Check Based Stopping Criteria).

If the Steady CRC based stopping criteria is enabled and if the [MIN_ITER] field of the eTVPE BD, which sets the minimum number of iterations to be executed by the eTVPE, is enabled (greater than 0), then the hard outputs compare checks are executed only when the minimum number of iterations is reached.

If the Steady CRC based stopping criteria is enabled and if the [MAX_ITER] field of the eTVPE BD, which sets the maximum number of iterations to be executed by the eTVPE, is reached without passing the hard outputs comparison check, the eTVPE stops the decoding operation and notifies MAPLE-B2 on job completion.

Enabling the Steady CRC based stopping criteria is done during MAPLE-B2 initialization by setting the [SCRC] bit of the MTVCP parameter (see **Section 26.5.2.3**, *MAPLE eTVPE Configuration Parameter (MTVCP)*).

Note: For UMTS jobs, both CRC Check and Steady CRC stopping criteria checks are allowed only with ascending byte/bit ordering configuration of the hard outputs (see **Section 26.4.3.2.7, *eTVPE Output Data Structure***"). Any other byte/bit ordering results in a CRC fail.

26.4.3.2.6.4.8 Stopping Criteria Configuration Limitations

When MAPLE-B2 is configured to work in 3G operation mode (supporting dynamic transitions between 3GLTE and UMTS jobs), there are some limitations as to the Stopping Criteria configurations since these configurations share the two technologies:

1. If CRC Stop Criteria is required for 3GLTE, it should be disabled during UMTS jobs by setting the [MIN_ITER] field of the eTVPE BD to the same value as the [MAX_ITER] field of the eTVPE BD.
2. If CRC Steady or Aposteriori Quality based Stop Criteria is set, it is applied on both technologies. Disabling it for one of the technologies can be done by setting the [MIN_ITER] field to the same value of the [MAX_ITER] field of the eTVPE BD.

26.4.3.2.6.4.9 Stopping Criteria Status Reports

To increase eTVPE performance and to avoid performance degradation due to the Stopping Criteria implementation, the eTVPE performs the Stopping Criteria checks of iteration #n while executing iteration #(n+1). If the Criteria checks pass, the eTVPE stops with the decoding processing at the end of the current iteration (#(n+1)).If hard outputs are required, the eTVPE outputs and hard bits results of iteration #n, but if any of the soft output results are required, the soft results which are used, are of iteration #(n+1), although the Stopping condition passed for iteration #n. In some extreme cases it may happen that the stopping condition, although passed on iteration #n, fails on the results of iteration #(n+1). The MAPLE-B2 reports these cases in the ERR_ST field of the eTVPE BD:

- [ERR_ST] = ‘0010’ indicates that the CRC check or CRC steady stop criteria failed on last iteration (#(n+1)) although passed on previous iteration (#n)
- [ERR_ST] = ‘0100’ indicates that the AQC (Aposteriori Quality Check) stop criteria failed on last iteration (#(n+1)) although passed on previous iteration (#n)

26.4.3.2.6.5 Viterbi Decoding

The MAPLE-B2 (eTVPE) supports Viterbi decoding for the different technologies using configurable polynomials and Viterbi related parameters that can be updated for each Viterbi job. Such implementation makes the Viterbi processing to a non operation mode related, that is, it can perform any Viterbi processing (of any type and any technology), regardless of the current MAPLE-B2 operation mode. The following sections describe different aspects of the Viterbi processing.

26.4.3.2.6.5.1 Viterbi Periodic Depuncturing

The Viterbi Periodic Depuncturing input data structure supports a periodically punctured input data stream, and the MAPLE-B2 is capable of performing periodic depuncturing of the input stream. The MAPLE-B2 uses the MTVPVx(H/L)CP and MTVPPCyP parameters (see **Section 26.5.3.2.1**, *MAPLE Turbo Viterbi Puncturing Vector x High Configuration Parameter (MTVPVxHCP)* to **Section 26.5.3.2.3**, *MAPLE Turbo Viterbi Puncturing Period Configuration y Parameter (MTVPPCyP)*), with the [PUNC_SCHM] field of the eTVPE BD to configure the depuncturing scheme of the input stream. The MAPLE-B2 can be configured to hold up to 10 different sets of puncturing vectors (63 bits) and puncturing period parameters. The [PUNC_SCHM] field in the eTVPE BD chooses the correct set for the current job.

Each puncturing set includes two elements:

- Puncturing vector. 63-bit vector that describes where in the input stream depuncturing is expected. This is done by clearing the relevant bits in the vector.
- Puncturing period parameter. Describes how many bits in the puncturing vector are valid.

The following pseudo-code describes the depuncturing algorithm:

```
j=0; /* depunctured output block pointer */
i=0; /* punctured input block pointer */
foreach byte in the input buffer
    if PVEC[i%PPER] = 1 then depunctured_block[j] = input_block[i] and increment i & j;
    if PVEC[i%PPER] = 0 then depunctured_block[j] = 0 and j is increment;
```

where PVEC, the puncturing vector, and PPER, the puncturing period, are located in the MTVPVx(H/L)CP and MTVPPCyP parameters, respectively.

Figure 26-23 shows an example Viterbi decoding periodic depuncturing of a rate 1/3 encoder.

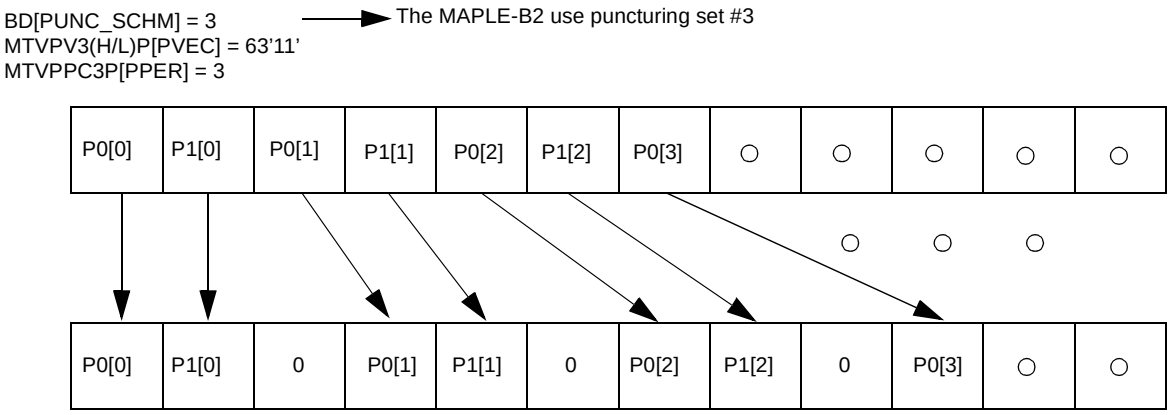

Figure 26-23. Viterbi depuncturing Process Example

Note: When [PPER] is set to 1 and [PVEC] is set to 0x0000_0000_0000_0001, the result is a non-punctured periodic mixed stream of symbols.

For Viterbi decoding, the Tail bytes are expected at the end of the input vector with the same order and with the same puncturing scheme as the body bytes. For example, for Viterbi rate 1/3, the expected order of the Tail bytes at the end of the vector then are:

$P0_t[0], P1_t[0], P2_t[0],..., P0_t[K-2], P1_t[K-2], P2_t[K-2].$

where K is the Viterbi Constraint length.

26.4.3.2.6.5.2 Viterbi Decoding Algorithm

The eTVPE is capable of Viterbi decoding ([ALG]=1) with the following configurable parameters:

- Constraint Length of 5,6,7,8 and 9 ([VIT_K]= 0,1,2,3,4, respectively).
- Encoding rate of 1/2, 1/3, and 1/4 ([ENC_RATE]=0,1,2, respectively).
- Tail Biting/Zero Tail trellis termination ([ZTTB] = 0,1, respectively)
- Supported block sizes of up to[1]:
  - 6144 for K=5 and encoding rate of 1/2 and 1/3.
  - 4864 for K=5 and encoding rate of 1/4.
  - 4800 for K=6
  - 2400 for K=7
  - 1200 for K=8
  - 600 for K=9

1. The maximum block sizes include the tail bits in case of zero tail decoding.

The Viterbi processing in the eTVPE is not standard related, and is fully configurable (including polynomials) regardless of the MAPLE-B2 operation mode. It is up to the host to configure all Viterbi related parameters/registers to process Viterbi decoding.

Viterbi processing executes internally using three steps: Feed forward calculations, find maximum likelihood path, and trace back calculation. Explanations for each of the stages follows.

26.4.3.2.6.5.3 Feed Forward

During this stage, the eTVPE calculates 2^{k-1} path Metrics per trellis step, each with length n, where K is the Constraint Length and n is the block size.

Figure 26-24 illustrates an example of a path metric (PM) calculation where path metric $PM_{n-1,s}$ and branch metric (BM) $BM_{n-1,s}$ are used for calculating the $PM_{n,s}$.

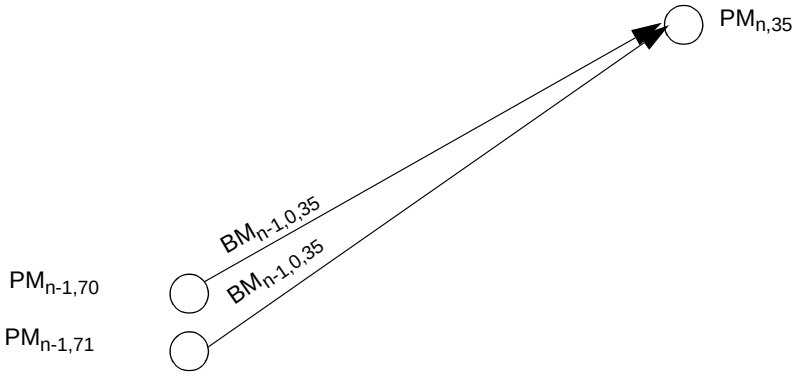

Figure 26-24. $PM_{n,35}$ Calculation

where:

PM $_{n,s,}$ - Path Metric of Viterbi Step n within the trellis. The s represent the current state. There are 2^{k-1} states in each step, where K is the Constraint Length.

BM $_{n-1,x,s}$ - Branch Metric for the transition calculation from step n-1 to step n. The X is either ‘0’ or ‘1’, and it represents the input bit to the Viterbi encoder.

To calculate the PM of trellis step n, state 35 (**Figure 26-24**), the PM of trellis step n-1, states 70 and 71 are needed.

The BMs are the correlations between the received parity bytes and the expected parity bytes.

$BMn,0,d =$

$$Parity_{0,n} * poly0_{<(d*2+0)\bmod num\ of\ pms>} +$$
$$Parity_{1,n} * poly1_{<(d*2+0)\bmod num\ of\ pms>} +$$
$$Parity_{2,n} * poly2_{<(d*2+0)\bmod num\ of\ pms>} +$$
$$Parity_{3,n} * poly3_{<(d*2+0)\bmod nuim\ of\ pms>}$$

$BMn,1,d =$

$$Parity_{0,n} * poly0_{<(d*2+1)\bmod num\ of\ pms>} +$$
$$Parity_{1,n} * poly1_{<(d*2+1)\bmod num\ of\ pms>} +$$
$$Parity_{2,n} * poly2_{<(d*2+1)\bmod num\ of\ pms>} +$$
$$Parity_{3,n} * poly3_{<(d*2+1)\bmod num\ of\ pms>}$$

where d is destination state, pms is path metric states and poly<x> is the Viterbi polynomials used.

To support dynamic switching of multiple Viterbi polynomial configurations, the MAPLE-B2 maintains three sets of polynomial configurations parameters which can be dynamically (per eTVPE BD) be replaced by the MAPLE-B2 firmware. The control of which set is being used for each eTVPE BD is done by the [VIT_SET] filed of the eTVPE BD. Configuring the [VIT_SET] to 01, 10 or 11 causes the MAPLE-B2 to use its MTVPVS1CxP, MTVPVS2CxP or MTVPVS3CxP parameters sets respectively for the current BD.

The expected parity bytes are the parities that are calculated on the source state using the parity polynomials described in **Figure 26-25**.

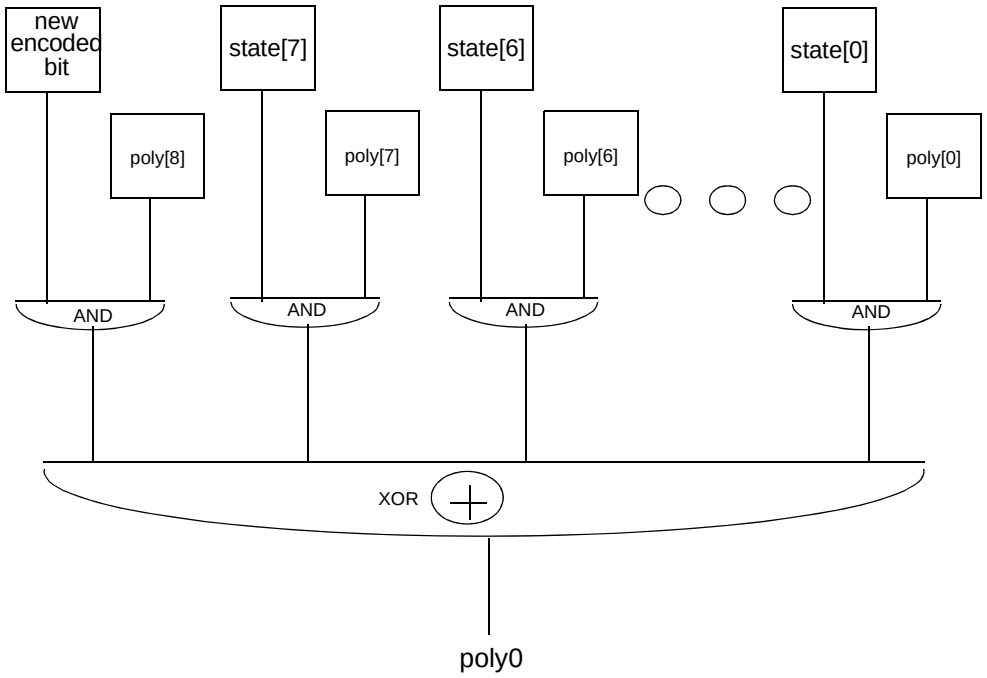

Figure 26-25. Calculation of a Parity of a Step

The Polynomial Generation fields described in any of the MTVPVSyCx Pares used for calculating the parity bits per state.

$polyz_{<x>}$ =

(new_encoded_bit & VI_POLYGEN‘z’[8]) ^

(x[7] & VI_POLYGEN‘z’[7]) ^

(x[6] & VI_POLYGEN‘z’[6]) ^

(x[5] & VI_POLYGEN‘z’[5]) ^

(x[4] & VI_POLYGEN‘z’[4]) ^

(x[3] & VI_POLYGEN‘z’[3]) ^

(x[2] & VI_POLYGEN‘z’[2]) ^

(x[1] & VI_POLYGEN‘z’[1]) ^

(x[0] & VI_POLYGEN‘z’[0])

where VI_POLYGEN is the field of MTVPVSyCx parameter and z = 0...3.

Note: If $poly3_{<x>}$ is not used (Rate > 1/4) and $poly2_{<x>}$ is not used (Rate > 1/3), they should be set to 0x0000; otherwise, the Viterbi Feed-Forward does not work properly.

Note: The value of the VI_POLYGEN fields must not exceed the $2^k - 1$ value, where K is the Viterbi Constraint Length.

The Path Metric is calculated using compare-select between the addition of the source states and their respective branch matrices as follows:

$PM_{n,d} = compare\_2\_select\ ((PM_{n-1,(d*2+0)mod\ pms} + BM_{n,0,d}), (PM_{(n-1,(d*2+1)mod\ pms} + BM_{n,1,d}))$; *for n>0*

where:

— n is the step index,
— pms is 2 ^ (VIT_K-1).
— d identifies the destination states 0<=d<=255.
— $Parity_{p,n}$ = base(PFp) + n
— compare_2_select(u,v) = (msbit of U) ^ (msbit of V) ^ ((lsbits of u) > (lsbits of v))

$PM_{0,d}$ is the initial $PM_{<d>}$ field kept in the eTVPE before execution.

26.4.3.2.6.5.4 Maximum Calculations

The eTVPE compares the final Path Metrics to find the state with the maximum path metric value. The PM value fields compared depend on the [VIT_K] field and are defined in **Table 26-17**.

Table 26-17. PM Values to be Compared for Finding the Maximum

VIT_K	K	PMs to be Compared
001	5	PM_0 -> PM_15
010	6	PM_0 -> PM_31
011	7	PM_0 -> PM_63
100	8	PM_0 -> PM_127
101	9	PM_0 -> PM_255

26.4.3.2.6.5.5 Trace-Back Calculations

The eTVPE, starting from a given trellis step traces back the winning path according to an internal history buffer. While tracing back the winning path, the eTVPE generates the Hard Output bits, which are then transferred to external memory.

26.4.3.2.6.6 Zero Tail Viterbi Processing

For Zero Tail Viterbi processing ([ALG]=1, [ZTTB]=1), the eTVPE performs the following sequence of operations:

1. Initialize state zero of the trellis step with maximum PM value.
2. Initiate Feed Forward calculations starting from the first step until the last step of the trellis.
3. Find the state with the maximum PM value.

4. According to the Maximum calculation result and the value of the [TBZE] bit in the eTVPE BD, the eTVPE executes the following:

```
case ({[TBZE], MAX_STATE}) //MAX_STATE =1 if the result state from the maximum
calculations is non zero
{
        '00': Start Trace-Back calculation from state zero
        '01': Start Trace-Back calculation from the maximum state result
        '10': Start Trace-Back calculation from state zero
        '11': Start Trace-Back calculation from state zero and set [ZT_MAX]
}
```

5. If the [HOE] bit of the eTVPE BD is set, then Hard Outputs bits are generated during the trace back calculations and the MAPLE-B2 outputs them to system memory according to the pointers given in the BD.

26.4.3.2.6.7 Tail Biting Viterbi Processing (WAVA*)

For Tail Biting Viterbi processing ([ALG]=1, [ZTTB]=0), the eTVPE perform the WAVA* (Wrap-Around-Viterbi-Algorithm). The sequence of events executed by the eTVPE when implementing Viterbi Tail biting using WAVA* is:

1. Initialize all (path metrics) PM values to zero.
2. Initiate Feed Forward calculation on the trellis
3. Initiate additional Feed Forward calculations on the same data, but without initializing the PM values, that is, the PM initial values are the results of the first Feed Forward calculation.
4. Initiate additional Feed Forward calculations on the same data, but without initializing the PM values, that is, the PM initial values are the results of the first Feed Forward calculation.
5. Find maximum PM value.
6. Find the initial state of that trellis (without generating Hard Outputs).
7. Use the last state found in the previous step, as the starting point for the actual Trace-Back which generates the Hard Outputs.

The following figure describes the WAVA* high level flow:

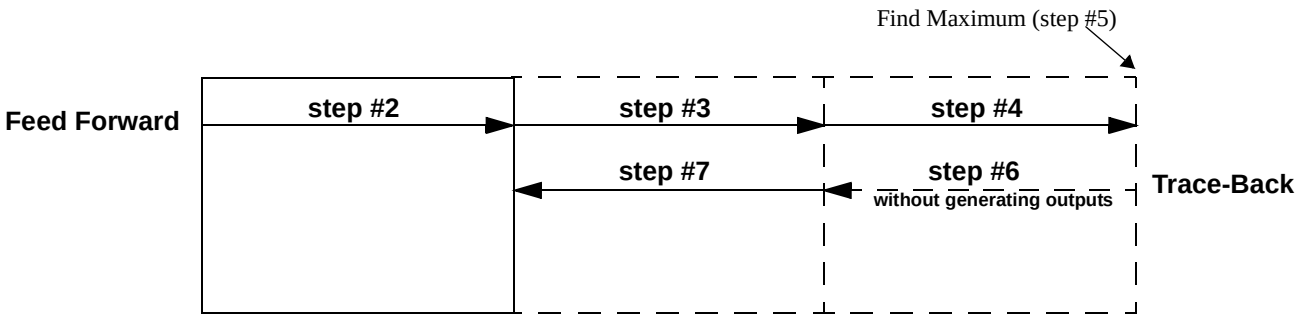

Figure 26-26. Viterbi Tail-Biting WAVA* flow

26.4.3.2.6.8 Viterbi Large Blocks Partitioning Support

The MAPLE-B2 allows Viterbi decoding of blocks with size of up to 32 KB using multiple BDs scheme and with the following limitation:

- Zero tail decoding only
- 'Direct' input data structure only
- Hard Outputs byte/bit ordering (see **Section 26.4.3.2.8.3.2, *Hard Output Byte and Bit Ordering***) supported for Viterbi large block sizes is either byte/bit ascending order or byte/bit descending order. The Hard Outputs data structure cannot use ascending byte order with descending bit order or vice versa.

Such multiply BDs scheme must be implemented for any block which is bigger than the sizes described in the 26-18:

Table 26-18. Viterbi Maximum Block Sizes Executed in Single Session With No Partitioning

Viterbi K	Max Block Size for single session[1]
5	8192
6	5376
7	2688
8	1344
9	672

1. The size includes the zero tail bits.

When Viterbi decoding is required for block which are larger than described in 26-18, the host must split the block into several chunks and each chunk should be described in different BD. When partitioning the large block into several chunks, the size of each chunk must not exceed the sizes as described in 26-19:

Table 26-19. Viterbi Maximum Chunk Sizes During Large Block Partitioning Scheme

Viterbi K	Max Chunk for Partitioning
5	8192
6	5376
7	2688
8	1280
9	640

To maximize decoding quality, the host must partition the large block into overlapping chunks, thus enabling "warm-up" section for both, the Feed-Forward stage and the Trace-Back stage. The size of the "warm-up" section in each block can be configured by the host using the BUF_SIZE

field of the eTVPE BD and must be a multiplication of 64. **Figure 26-27** describes an example of 24Kbit (24576) viterbi code and its partitioning into several chunks in the case of K=5:.

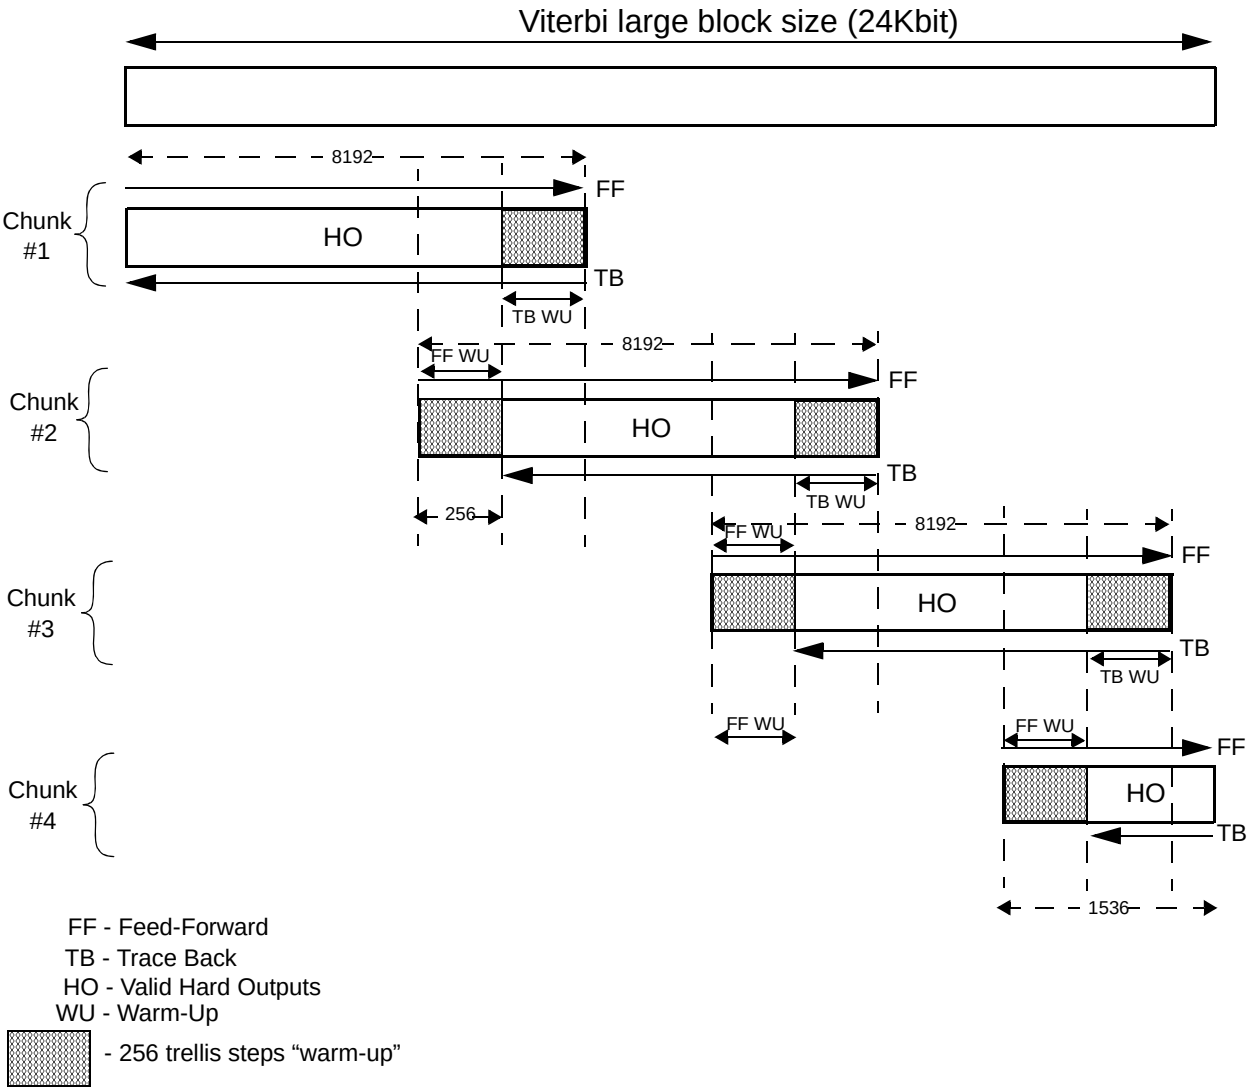

Figure 26-27. Viterbi Large Blocks Size Partitioning Example

For better understanding of the example, the following is assumed:

- Encoding rate: 1/2
- ‘Direct’ input data structure
- Hard outputs are required at address 0xc0050000
- First input vector (even index number, interlaced P0 and P1) is placed at address 0xc0000000
- Second input vector (odd index number, interlaced P0 and P1) is placed at address 0xc0020000

Table 26-20 describes the relevant fields in eTVPE BD for each chunk as described in **Figure 26-27**:

Table 26-20. eTVPE BD Fields of Viterbi Large Block Size Partitioned Into Chunks

Chunk #	Field name	Value	Comments
1	VIT_K	001	K = 5
	ZTTB	0	Zero Tail decoding
	ENC_RATE	00	Encoding rate: 1/2
	ALG	1	Viterbi decoding
	IN_D_STRCT	0	'Direct' input data structure
	BS	0x2000	Block size of 8192
	HOE	1	Enable hard outputs
	BUF_SIZE	1	For the first chunk only, the value of this field must be set to '1' to allow full trace-back
	HRD_RSLT_ADDR	0xc0050000	
	BASE_ADDR	0xc0000000	
	ADDR_OFFSET_0	0x0000	First vector is BASE_ADDR+0x00000
	ADDR_OFFSET_1	0x0800	Second vector is BASE_ADDR+0x20000
2	VIT_K	001	K = 5
	ZTTB	0	Zero Tail decoding
	ENC_RATE	00	Encoding rate: 1/2
	ALG	1	Viterbi decoding
	IN_D_STRCT	0	'Direct' input data structure
	BS	0x2000	Block size of 8192
	HOE	1	Enable hard outputs
	BUF_SIZE	0x100	Equals 256. Indicates the Feed-Forward warm-up and Trace back warm-up required by MAPLE-B2
	HRD_RSLT_ADDR	0xc00503E0	The start of the hard outputs for the second chunk should be (8192 - 256)/8 = 7936/8 = 0x3E0
	BASE_ADDR	0xc0000000	
	ADDR_OFFSET_0	0x00F0	The second chuck of input should start at offset of 8192 - 2*256 = 7680. Each input is represented by 4 bytes. Each vector include either Odd or Even index. Hence (7680*4/2)/64=120 =0xF0
	ADDR_OFFSET_1	0x08F0	The second chuck of input should start at offset of 8192 - 2*256 = 7680. Each input is represented by 4 bytes. Each vector include either Odd or Even index. Hence (7680*4/2)/64=120 =0xF0

Table 26-20. eTVPE BD Fields of Viterbi Large Block Size Partitioned Into Chunks

Chunk #	Field name	Value	Comments
3	VIT_K	001	K = 5
	ZTTB	0	Zero Tail decoding
	ENC_RATE	00	Encoding rate: 1/2
	ALG	1	Viterbi decoding
	IN_D_STRCT	0	'Direct' input data structure
	BS	0x2000	Block size of 8192
	HOE	1	Enable hard outputs
	BUF_SIZE	0x100	Equals 256. Indicates the Feed-Forward warm-up and Trace back warm-up to be executed by MAPLE-B2
	HRD_RSLT_ADDR	0xc00507A0	The start of the hard outputs for the third chunk should be (8192*2 - 256*3)/8 = 15616/8 = 0x7A0
	BASE_ADDR	0xc0000000	
	ADDR_OFFSET_0	0x01E0	The third chuck of input should start at offset of 8192*2 - 256*4= 15360. Each input is represented by 4 bytes. Each vector include either Odd or Even index. Hence (15360*4/2)/64=480 =0x1E0
	ADDR_OFFSET_1	0x09E0	The third chuck of input should start at offset of 8192*2 - 256*4 = 15360. Each input is represented by 4 bytes. Each vector include either Odd or Even index. Hence (15360*4/2)/64=480 =0x1E0
4	VIT_K	001	K = 5
	ZTTB	1	Zero Tail decoding
	ENC_RATE	00	Encoding rate: 1/2
	ALG	1	Viterbi decoding
	IN_D_STRCT	0	'Direct' input data structure
	BS	0x0600	The last chunk size equals: 24*1024 - (3*8192 - 6*256) = 1536 = 0x600
	HOE	1	Enable hard outputs
	BUF_SIZE	0x100	Equals 256. Indicates the Feed-Forward warm-up and Trace back warm-up to be executed by MAPLE-B2
	HRD_RSLT_ADDR	0xc0050B60	The start of the hard outputs for the forth chunk should be (8192*3 - 256*5)/8 = 23296/8 = 0xB60
	BASE_ADDR	0xc0000000	
	ADDR_OFFSET_0	0x02D0	The forth chuck of input should start at offset of 8192*3 - 256*6= 23040. Each input is represented by 4 bytes. Each vector include either Odd or Even index. Hence (23040*4/2)/64=720=0x2D0
	ADDR_OFFSET_1	0x0AD0	The forth chuck of input should start at offset of 8192*3 - 256*6 = 23040. Each input is represented by 4 bytes. Each vector include either Odd or Even index. Hence (23040*4/2)/64=720=0x2D0

26.4.3.2.6.9 De-Randomization

The eTVPE can execute de-randomization processing for the hard outputs results from the Turbo decoding as appears in the WiMAX OFDMA turbo decoding (IEEE 802.16e-2009).

Configuring the eTVPE to perform de-randomization is allowed only during WiMAX operation mode and is done by configuring the [RANE] field of the MTVCP parameter.

Figure 26-28 describe the eTVPE de-randomizer implementation:

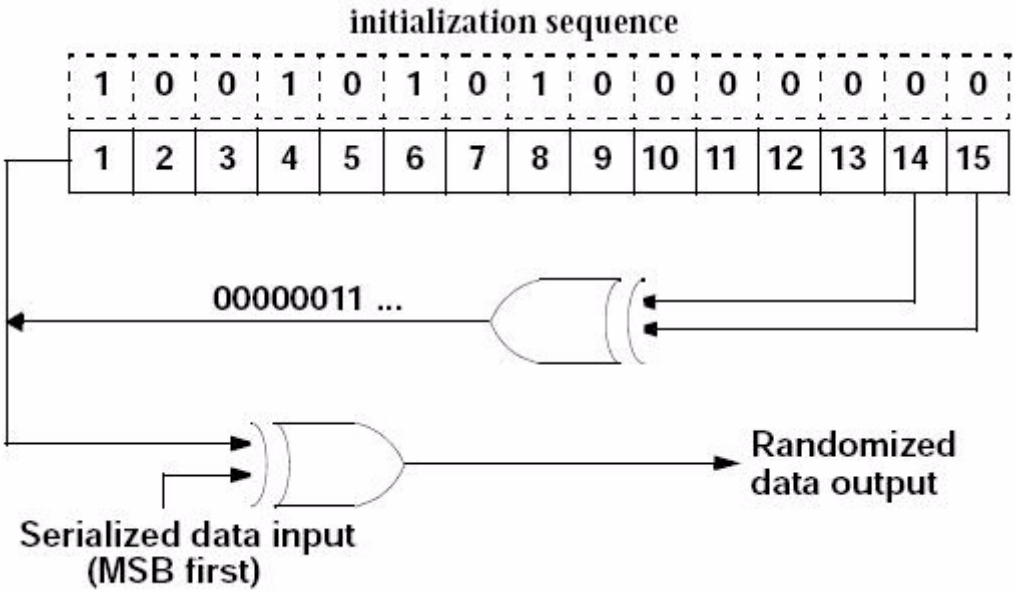

Figure 26-28. eTVPE De-Randomizer implementation

26.4.3.2.6.10 CRC Check

The eTVPE can execute a single CRC check on the Hard Outputs of the Turbo decoded blocks. The CRC check, which is executed internally by the eTVPE, supports 3 possible CRC polynomials determined by the [CRC_POLY] field of the eTVPE BD (as described in CRC Check Based Stopping Criteria).

To enable the CRC check for a given BD, the [CRC_EN] bit of the BD must be set. Once set, the eTVPE executes the CRC check on the Hard Output results, and only then indicates on job completion to MAPLE-B2. If the CRC check failed, the MAPLE-B2 gives a CRC fail indication in the [ERROR_STATUS] field of the eTVPE BD. If the CRC check passes no indication is given.

If CRC Check Based Stopping criteria is enabled (see CRC Check Based Stopping Criteria), the eTVPE executes a CRC check after every Turbo full iteration, regardless of the [CRC_EN] bit of the eTVPE BD.

Note: The eTVPE do not support TB CRC check for UMTS (for TB < 5090) as the UMTS technology dictates reversing the polynomial and it is not supported in the eTVPE.

26.4.3.2.7 eTVPE Output Data Structure

The eTVPE can generate few types of output data ordered internally according to two configuration bits. The following sections describe the output data types and output data structure.

26.4.3.2.8 Output Data Types

The eTVPE is capable of generating the following types of data:

- 16 bits of Extrinsic Output data (Systematic data only) - used for Debug purposes only.
- 16 bits LLR of Aposteriori Output data (Systematic data only)
- 8 bits LLR of Soft Output Data (Systematic + Parities)
- Hard Output bits

The Hard Output bits generation can be enabled regardless of the type of the required Soft Outputs.

26.4.3.2.8.1 Aposteriori/Extrinsic Output Data

Aposteriori/Extrinsic Output data generation is relevant only for Turbo decoding, and is enabled by enabling the [SOE] bits in the eTVPE BD. This option is relevant if additional processing (external to the MAPLE-B2) is needed on the data before calculating the final Hard Outputs, or for debug purposes.

The eTVPE can generate two types of such outputs:

- If [SOE] = 01, the eTVPE generates Aposteriori output.
- If [SOE] = 10, the eTVPE generates Extrinsic output

26.4.3.2.8.1.1 Aposteriori Output Data

The eTVPE generates the Aposteriori Outputs differently when executing Duo-Binary Turbo decoding (WiMAX) and Binary Turbo decoding (3GLTE, UMTS). **Table 26-21** describes the Aposteriori Output data for both cases.

Table 26-21. Aposteriori Output Description

Turbo Code	Structure	Notes
Binary	APP[0],APP[1],...,APP[BS[1]-1]	Each APP is the result of subtracting the Aposteriori probability of receiving '1' from the Aposteriori probability of receiving '0': APP[x] = Ln[$P_x(1)/P_x(0)$];
Duo-Binary	MLLR_1[0],MLLR_2[0],MLLR_3[0],MLLR_1[1],MLLR_2[1], MLLR_3[1]... MLLR_1[BS/2-1],MLLR_2[BS/2-1],MLLR_3[BS/2-1],	Each stage of duo-binary decoding results in 4 aposteriori values (APP_00, APP_01, APP_10, APP_11). The MLLR_x values are derived from the APP_xx values as follows: $MLLR\_1_{xy}$ = Ln[APP_00/APP_01] $MLLR\_2_{xy}$ = Ln[APP_00/APP_10] $MLLR\_3_{xy}$ = Ln[APP_00/APP_11]

1. BS: block size.

The following equations describe how to reconstruct the approximated APPxx values from the MLLR_x values for WiMAX decoding:

$$APP\_00[x] \sim= max(MLLR\_1[x], MLLR\_2[x], MLLR\_3[x], 0)$$
$$APP\_01[x] \sim= max(-MLLR\_1[x], -MLLR\_1[x] + MLLR\_2[x], -MLLR\_1[x] + MLLR\_3[x], 0)$$
$$APP\_10[x] \sim= max(-MLLR\_2[x], -MLLR\_2[x] + MLLR\_1[x], -MLLR\_2[x] + MLLR\_3[x], 0)$$
$$APP\_11[x] \sim= max(-MLLR\_3[x], -MLLR\_3[x] + MLLR\_1[x], -MLLR\_3[x] + MLLR\_2[x], 0)$$

The size of a single element of the Aposteriori Output data structure for both, Binary and Duo binary decoding (APP[x] and MLLR_x[y], respectively), is 16 bits. Upon job completion, the MAPLE-B2 outputs the Aposteriori Output data to system memory in the location specified in the [SFT_RSLT_ADDR] field of the eTVPE BD. The structure of the Aposteriori Output results differs according to the decoding method (Binary for 3G technologies and Duo binary for WiMAX technology). **Figure 26-29** gives an example of a Aposteriori Output results buffer for the 3G technologies in a 128 bit wide system memory:

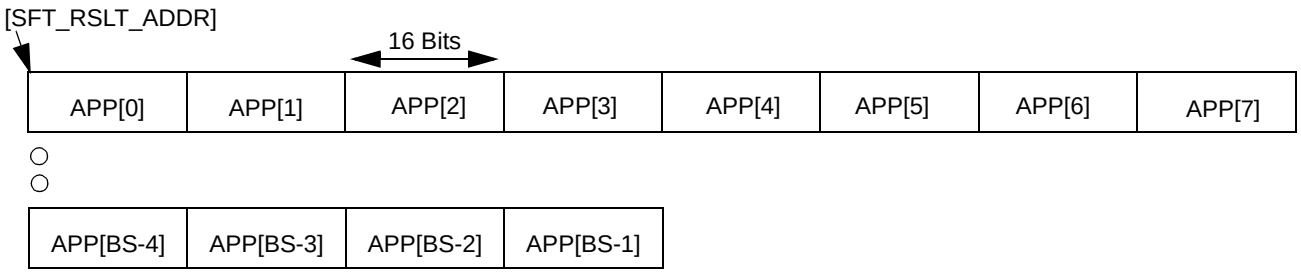

Figure 26-29. Example of Aposteriori Output Results Buffer for 3G Technologies in a 128-Bit System Memory

Figure 26-30 gives an example of a Aposteriori Output results buffer for the WiMAX technology in a 128 bit wide system memory:

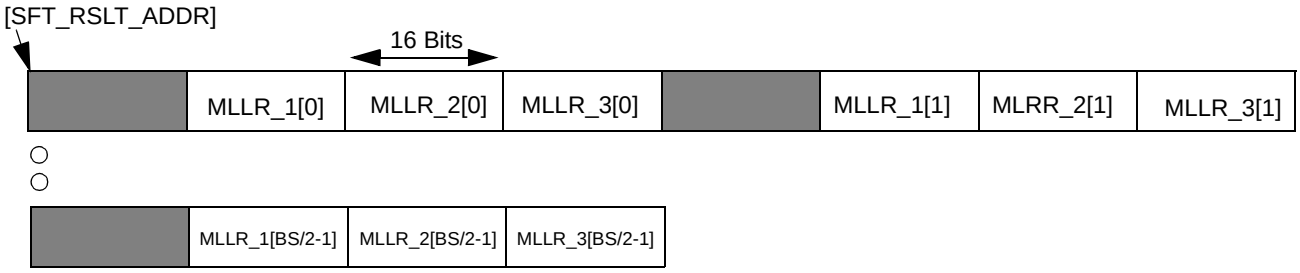

Figure 26-30. Example of Aposteriori Output Results Buffer for WiMAX technology in a 128 Bit System Memory

26.4.3.2.8.1.2 Extrinsic Output Data

The eTVPE is capable of generating the Extrinsic data information instead of the Aposteriori data. The Extrinsic data is different when executing Duo-Binary Turbo decoding (WiMAX technology) and Binary Turbo decoding (3GLTE and UMTS technologies). **Table 26-22** describes the Extrinsic Output data for both cases.

Table 26-22. Extrinsic Output Description

Turbo Code	Structure	Notes
Binary	EXT[0],EXT[1],...,EXT[BS[1]-1]	Each EXT is the result of subtracting from the APP value the EXT value from the previous iteration and the Systematic bit (its soft representation: $EXT_i[x] = APP_i[x] - EXT_{i-1}[x] - SD[x]$. (i is the current iteration)
Duo-Binary	EXT_1[0],EXT_2[0],EXT_3[0],EXT_1[1],EXT_2[1],EXT_3[1]... EXT_1[BS/2-1],EXT_2[BS/2-1],EXT_3[BS/2-1],	Each set of 3 Extrinsic values hold information on pair of bits. The equations for each of the EXT values for iteration #i is: $EXT\_1_{xy,i} = MLLR\_1_{xy} - EXT\_1_{xy,i-1} - 2*SDb$ $EXT\_2_{xy,i} = MLLR\_2_{xy} - EXT\_2_{xy,i-1} - 2*SDa$ $EXT\_3_{xy,i} = MLLR\_3_{xy} - EXT\_3_{xy,i-1} - 2*SDa - 2*SDb$

1. BS: block size.

The size of a single element of the Extrinsic Output data structure for both, Binary and Duo binary decoding (EXT[x] and EXT_x[y], respectively), is 16 bits.

Upon job completion, the MAPLE-B2 outputs the Extrinsic Output data to system memory in the location specified in the [SFT_RSLT_ADDR] field of the eTVPE BD. The structure of the extrinsic Output results differs according to the decoding method (Binary for 3G technologies and Duo binary for WiMAX technology). **Figure 26-31** gives an example of an extrinsic Output results buffer for the 3G technologies in a 128 bit wide system memory:

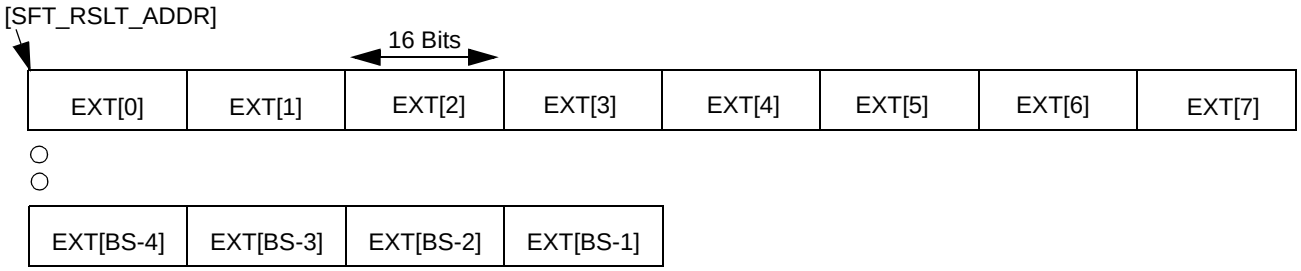

Figure 26-31. Example of Extrinsic Output Results Buffer for 3G Technologies in a 128-Bit System Memory

Figure 26-32 gives an example of a Extrinsic Output results buffer for the WiMAX technology in a 128 bit wide system memory:

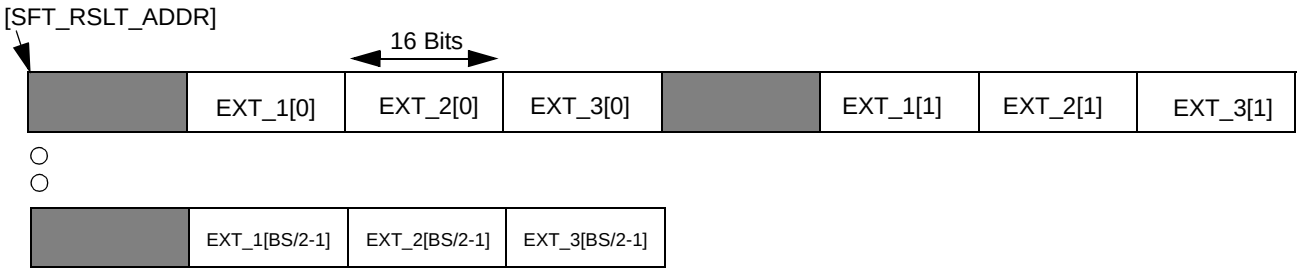

Figure 26-32. Example of Extrinsic Output Results Buffer for WiMAX technology in a 128-Bit System Memory

26.4.3.2.8.2 Soft Output Data

The Soft Output data generation is relevant only for Turbo decoding and only for the UMTS or 3GLTE technologies and is enabled by configuring the [SOE] bit of the eTVPE BD to 11. The Soft Output support is required to implement various iterative turbo aided receivers.

The eTVPE internal soft output data structure is composed of 16 bits LLR samples for each systematic and parity bit, but the MAPLE-B2 outputs only 8 bits of each LLR. Determining which 8 bits out the internal 16 bits are being output is done by the [LLR_OUT_SF] field of the eTVPE BD according to the following:

$$OUT\_LLR[7:0] = INTERNAL\_LLR[(7 + LLR\_OUT\_SF): (0 + LLR\_OUT\_SF)]$$

For example if *[LLR_OUT_SF]* = 3, then *OUT_LLR[7:0] = INTERNAL_LLR[10:3]*

When Soft Output data is required, the MAPLE-B2 outputs three vectors for each data type (SD, PF and PS). At the end of each vector there are 4 Tail bytes arranged as described in **Figure 26-33**:

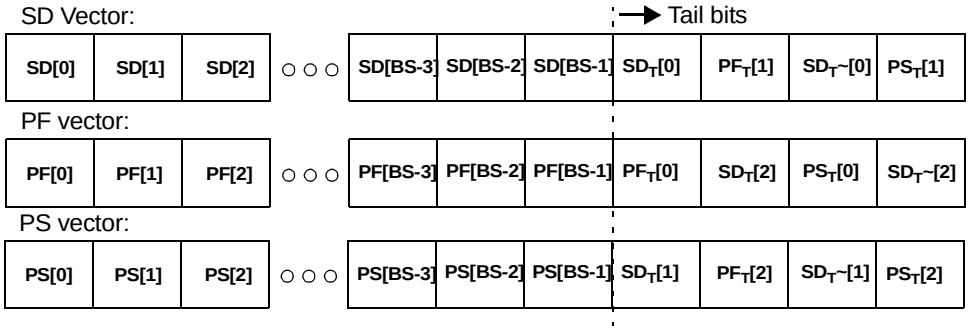

Figure 26-33. Soft Output Data Vectors

The MAPLE-B2 outputs the three Soft Output vectors to the system memory according to the following ruling:

- SD Vector is placed in [SFT_RSLT_ADDR]
- PF Vector is placed in [SFT_RSLT_ADDR] + 256 * 2^[SFT_RSLT_OFF]
- PS Vector is placed in [SFT_RSLT_ADDR] + 512 * 2^[SFT_RSLT_OFF]

For example, if [SFT_RSLT_ADDR] == 0x1000 and [SFT_RSLT_OFF] == 4, then:

- SD Vector is placed in 0x1000
- PF Vector is placed in 0x2000
- PS Vector is placed in 0x3000

Note: Overrun of one vector by the other may occur if offset between vectors is smaller than vector size.

Note: When working with Soft Output Data (*SOE*=11), the following must apply: *(MIN_ITER* $\geq$ 2)

26.4.3.2.8.3 Hard Output Data

The Hard Output data generation is relevant for both Turbo and Viterbi decoding and is enabled by setting the [HOE] bit in the eTVPE BD.

The Hard Outputs for the Turbo decoding are generated from the Aposteriori data as follows:

- For Binary decoding (3GLTE, UMTS):
  - if APP[i] > 0 then the Hard Output bit with the index [i] equals ‘1’, otherwise it equals ‘0’.
- For Duo-Binary code (WiMAX):
  - reconstruct APP_xx[i] from the MLLR_x.

— find: Max (APP_00[i], APP_01[i], APP_10[i], APP_11[i]).
— The APP_ab[i] winner means bits [2i] and [2i + 1] equal a and b respectively.

Upon job completion, the MAPLE-B2 outputs the Hard Output data to system memory in the location specified in the [HRD_RSLT_ADDR] field of the eTVPE BD.

26.4.3.2.8.3.1 Hard Output Offset

The MAPLE-B2 allows outputting the hard outputs with a bit resolution address. Configuring the [HOFF] field of the eTVPE BD determines the location of the first valid bit in the first byte of the hard outputs. Along with the byte resolution of the [HRD_RSLT_ADDR] pointer, the host is capable of determining the exact bit location in the system memory of the first valid bit. Supporting bit resolution of the hard bits output enabled concatenating hard outputs of all CBs related to a single TB thus eliminating the need to concatenate them by the host.

The following figure describe an example of concatenating 3 CB into single TB:

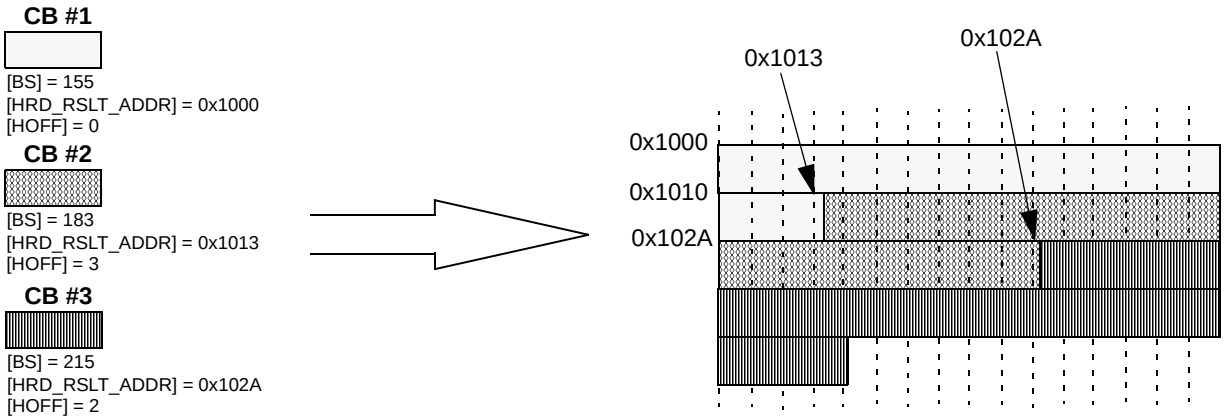

Figure 26-34. Concatenating Hard outputs

Note: For Viterbi processing the Hard Output Offset is applicable only if the DOSBY/DOSBI configuration bits of the eTVPE Configuration 0 Register (TVPEC0R) are set.

26.4.3.2.8.3.2 Hard Output Byte and Bit Ordering

The Hard Outputs byte and bit order of the eTVPE can be programmed by setting the TVPEC0R[DOSBY] and the TVPEC0R[DOSBI] to one of the following configurations:

- DOSBY, DOSBI = 0b11. Ascending Byte and Bit ordering. The eTVPE hard Outputs are ordered in ascending byte and ascending bit order as illustrated in the example in **Figure 26-35**.

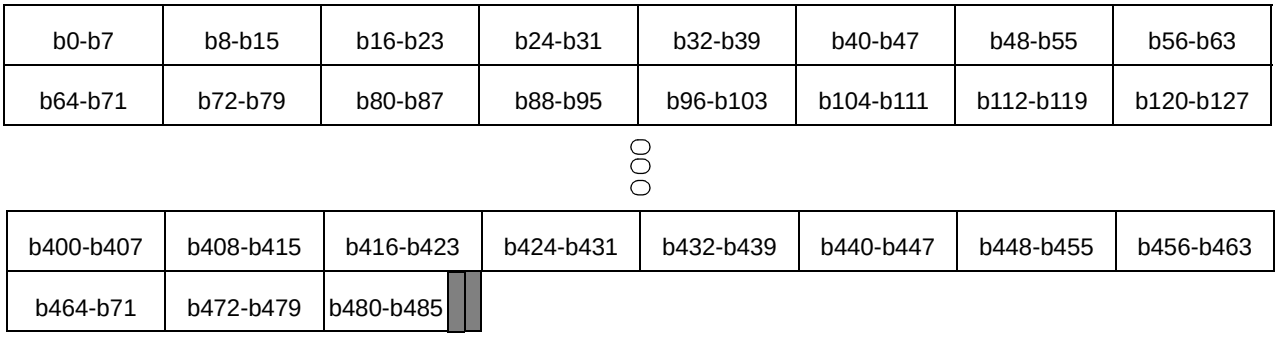

Figure 26-35. Ascending Byte and Bit Ordering example (DOSBY=1, DOSBI=1)

- DOSBY, DOSBI = 0b10. Ascending Byte and descending Bit ordering. The eTVPE hard Outputs are ordered in ascending byte order and descending bit order as illustrated in the example in **Figure 26-36**.

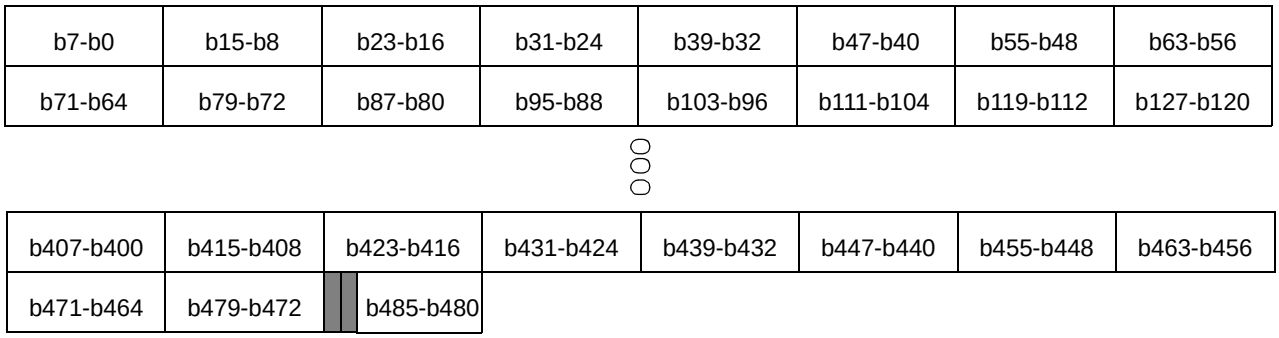

Figure 26-36. Ascending Byte and Descending Bit Ordering Example (DOSBY=1, DOSBI=0)

- DOSBY, DOSBI = 0b01. Descending Byte and ascending Bit ordering. The eTVPE hard Outputs are ordered in Descending byte order and ascending bit order as illustrated in the example in **Figure 26-37**.

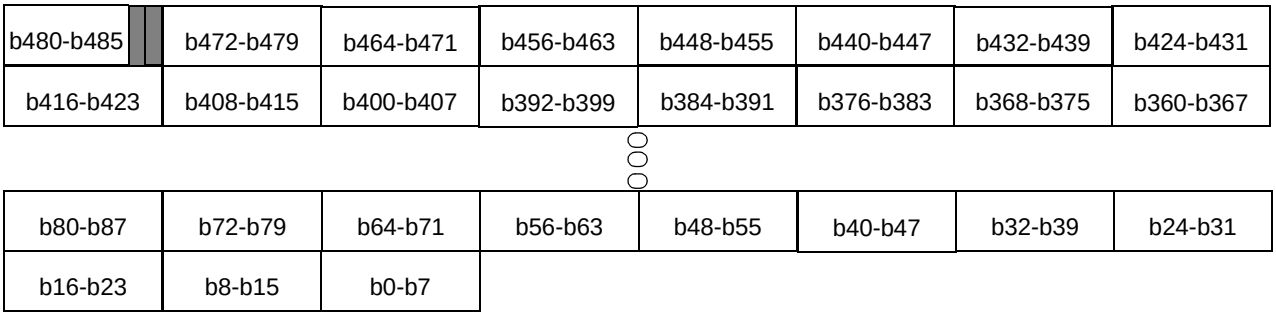

Figure 26-37. Descending Byte and Ascending Bit Ordering Example (DOSBY=0, DOSBI=1)

- DOSBY, DOSBI = 0b00. Descending Byte and descending Bit ordering. The eTVPE hard Outputs are ordered in Descending byte order and descending bit order as illustrated in the example in **Figure 26-38**.

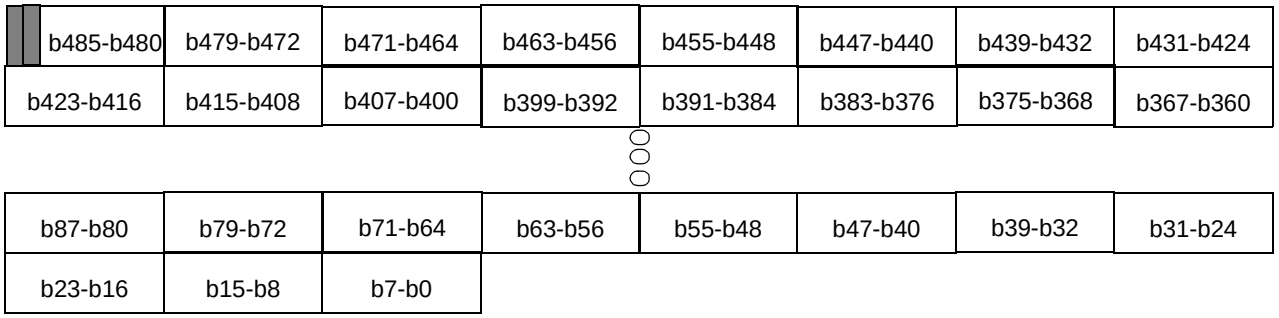

Figure 26-38. Descending Byte and Descending Bit Ordering Example (DOSBY=0, DOSBI=0)

Note: The **default** value of MAPLE-B2 is ascending byte and ascending bit ordering

26.4.3.2.8.3.3 Byte/Bit Ordering Limitations

When working with Byte/Bit ordering other than the default configuration (DOSBI=DOSBY=1) the following must be considered:

- The DOSBI/DOSBY configuration must not be changed while there are active eTVPE BDs in MAPLE-B2. It is recommended to configure this register only once (after MAPLE-B2 activation), and leave it fixed for the whole operation duration.
- For UMTS jobs, all CRC calculations (CRC check based stopping criteria, CRC Steady based stopping criteria and CRC check on Hard Outputs) assume the default Byte/Bit ordering only (ascending byte/bit ordering). Working with different configuration results in incorrect CRC results.

26.4.3.2.9 eTVPE Debug

The eTVPE includes some debug capabilities which allow a host to view its intermediate results. By allowing the eTVPE to output its internal extrinsic/Aposteriori results (using the [SOE] field in the eTVPE BD), and by allowing it to limit the number of executed iterations (using the [MAX_ITER] field of the eTVPE BD), it is possible to generate a flow by which the eTVPE outputs its extrinsic/Aposteriori results after every iteration.

For example, configuring the [SOE] field to 10 and the MAX_ITER to 0001 results in the eTVPE executing two iterations only and on completion the MAPLE-B2 output the extrinsic results from the eTVPE internal memories to the system memory to the address described in the [SFT_RSLT_ADDR] field of the eTVPE BD. If the extrinsic results of the third iteration are also of interest, it can be done by configuring the MAPLE-B2 with an additional BD, identical to the previous one, excluding the [MAX_ITER] field which should now be configured to 0010 and with different [SFT_RSLT_ADDR] so the previous results are not overrun. By doing so, it is possible to get the extrinsic/Aposteriori results of every iteration.

26.4.3.3 eFTPE FFT/iFFT/DFT/iDFT Operation

The MAPLE-B2 supports FFT/iFFT/DFT/iDFT operations in variable block sizes as listed in **Section 26.2**, *MAPLE-B2 Features* using three identical eFTPE modules instantiated in MAPLE-B2. These three eFTPE modules share the same programming model, the same operation flow, and, therefore, the same operational description.

Note: The FFT/iFFT/DFT/iDFT processing executed by the eFTPE modules is not standard related and, therefore, is not affected by the MAPLE-B2 operation mode.

Note: In this section, an FFT/iFFT job refers to a job with a Transform Length indicating one of the following sizes: 128, 256, 512, 1024, 1536 or 2048. All other sizes are referred to as DFT/iDFT jobs.

26.4.3.3.1 eFTPE Buffer Descriptors

eFTPE buffer descriptors are described in detail in **Section 26.5.4.3**, *eFTPE Buffer Descriptor Structure*, on page 26-423. eFTPE buffer descriptor extensions are described in detail in **Section 26.5.4.3.2**, *eFTPE Buffer Descriptor's Extension*, on page 26-433.

26.4.3.3.2 BD Repeat Option

The MAPLE-B2 allows the user to generate a single eFTPE Buffer Descriptor to describe up to 128 different jobs to execute. To work in this mode, several conditions must be met:

1. All the jobs must share the following parameters:
   - *SCL_TYPE* - Scaling Type (User define or Adaptive scaling. See **Section 26.4.3.3.9.4**, *eFTPE Internal Scaling Calculations*)
   - *OVA_SCL* - Overall Scaling (enabled or disabled. See **Section 26.4.3.3.9.4**, *eFTPE Internal Scaling Calculations*)
   - *ITE* - Inverse Transform Enable. See **Section 26.4.3.3.9.2**, *Inverse Transform Processing*
   - *TL_ID* - Transform Length ID. See **Section 26.5.4.3.3**, *Transform Length Encoding*
   - *USR_SCLx* - User Defined Scaling for stage 0 to stage 5. See **Section 26.4.3.3.9.4**, *eFTPE Internal Scaling Calculations*
   - *IN_SCL* - Input Scaling. See **Section 26.4.3.3.9.4**, *eFTPE Internal Scaling Calculations*
   - *ADP_OVA_SCL* - Adaptive Overall Scaling. See **Section 26.4.3.3.9.4**, *eFTPE Internal Scaling Calculations*
   - *GI* - Guard Insertion. See **Section 26.4.3.3.4.1.1**, *Guard Band Insertion for iFFT*
   - *PME* - Pre-Multiply Enable. See **Section 26.4.3.3.5.1**, *Pre-Multiplication Processing Support in the eFTPE*
   - *PSMTE* - Post Multiplier Enable. See **Section 26.4.3.3.6**, *Scalar Post Multiplication in eFTPE*
   - *GR* - Guard Removal. See **Section 26.4.3.3.4.2.1**, *Guard Band Removal for FFT*
   - *CPIE* - Cyclic Prefix Enable. See **Section 26.4.3.3.4.2.2**, *Cyclic Prefix Insertion for iFFT*

- *PSTMV* - Post multiply vector. See **Section 26.4.3.3.5.2**, *Post-Multiplication processing support in the eFTPE*
- *PO_SCL* - Post multiplier scaling. See **Section 26.4.3.3.9.4.2**, *User Defined Scaling*
- *AIUS* - Adaptive input scaling. See **Section 26.4.3.3.9.4.3**, *Adaptive Scaling*
- *EXS* - Extra scaling. See **Section 26.4.3.3.9.4.3**, *Adaptive Scaling* and **Section 26.4.3.3.3**, *Identical Output Scale Alignment for BD Repeat*
- All frequency correction related fields. See **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*
- *LSS* See **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*
- *SSN* See **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*
- *CL* See **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*
- *NNPI* See **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*

2. All the input data for the jobs must be located in system memory sequentially, starting from [IBA] (Input Buffer Address), as described in **Figure 26-41**.
3. The BD_RPT field in the BD must be initialized with value range 1 to 127 to execute 2 to 128 jobs, respectively.

If all the above conditions are met, when the MAPLE-B2 starts the BD execution, it sequentially executes all the jobs. The MAPLE-B2 writes the output data from the jobs sequentially into system memory, starting at the address described in the *OBA* (Output Buffer Address) field of the eFTPE BD.

The *OWNER* bit is cleared by the MAPLE-B2 after all job executions are done.

If the *INT_EN* (Interrupt Enable) bit is set in the BD, an interrupt is issued only after all the job executions of the BD are complete.

To save the status fields of each job processed during the BD repeat option, the MAPLE-B2 uses the *BD_STAT_PTR* field of the eFTPE BD as a pointer into system memory where it copies the two status fields of each job (*CMP_RSN*[2:0] and *ADP_OVA_SCL_ST*[7:0]).

Figure 26-39 describes the data structure of the status fields in system memory:

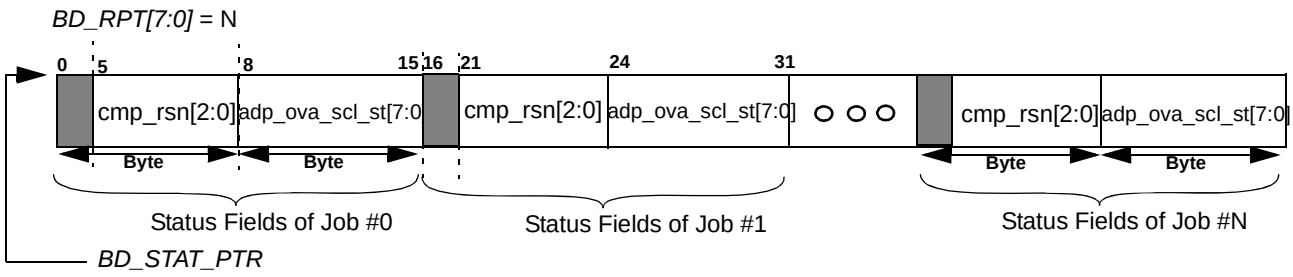

Figure 26-39. Status Table Data Structure in System Memory in Case of BD Repeat

For details, on the *ADP_OVA_SCL_ST* field see **Section 26.4.3.3.9.4**, *eFTPE Internal Scaling Calculations*.

For details, on the CMP_RSN field see **Table 26-230**

Note: The repeat option is highly recommended for use since it reduces the overhead of finding and parsing the following BD, thus increasing MAPLE-B2 performance.

Note: It is possible to disable the status fields update to the system memory by clearing the *BD_STAT_PTR* field in the BD (*BD_STAT_PTR*=0x0). Doing so may slightly improve the throughput performance of the eFTPE.

Note: The *BD_STAT_PTR* field is relevant for non repeat jobs as well. If enabled (*BD_STAT_PTR* > 0), the MAPLE-B2 outputs the status fields regardless of the repeat option.

26.4.3.3.3 Identical Output Scale Alignment for BD Repeat

The MAPLE-B2 supports the option of forcing identical Output Scale value for all the tasks included in the BD (in case the BD Repeat is enabled) without the need to force User Defined Scaling on the BD (see **Section 26.4.3.3.9.4.2**). Enabling this option is done by setting the *AFS* bit of the eFTPE BD. To support such option, the following flow is executed internally for all the tasks in the BD:

1. The First task is configured to run in Adaptive Scale mode (**Section 26.4.3.3.9.4.3**) and with Adaptive Overall Scaling Disabled (**Section 26.4.3.3.9.4.4**).
2. Once this first task is completed, the Adaptive Overall Scaling Status indication is being read.
3. The following tasks in the BD are configured to run in Adaptive Scale mode and with Adaptive Overall Scaling enabled where the Adaptive Overall Scaling value used is the Adaptive Overall Scaling Status indication of the first task in the BD.

The result of the above flow is that the output results of all the tasks in the BD shares the same Adaptive Overall Scaling results.

If the Extra Scaling (*EXS* field of the eFTPE BD) is enabled (see **Section 26.4.3.3.9.4.8**, *Extra Scaling*) in case of BD Repeat, the MAPLE-B2 applies the extra down scaling for the first task only. The following tasks of the BD Repeat are configured with *EXT*=0. This allows reducing the risk of multiple saturated samples in all the tasks which use the Adaptive Overall Scaling value result of the first task in the BD Repeat.

26.4.3.3.4 eFTPE Data Structures

The input data to the eFTPE is fetched by the MAPLE-B2 internal DMA. The location of the input data in system memory should be specified in the *IBA*[31:3] field of the eFTPE BD. Upon job completion, the output data of the eFTPE is transferred to system memory by the MAPLE-B2 internal DMA. The address to transfer the data is specified in the *OBA*[31:3] field of the eFTPE BD. The following sections describe the MAPLE-B2 expected input and output data structures in system memory.

26.4.3.3.4.1 Input Data Structures

After parsing the eFTPE BD, MAPLE-B2 starts fetching the input data into its internal memories for the processing operation. The eFTPE supports two types of input data structure:

1. Each input sample is 32 bits: 16 bits real component following by 16 bits imaginary component. **Table 26-23** describe a 128 bits bus structure for this case.
2. Each input sample is 16 bits: 8 bits real component following by 8 bits imaginary component. **Table 26-24** describe a 128 bits bus structure for this case.

Table 26-23. Four 32 Bits Samples As They are Expected to Arrive From System Memory

Bits	127:112		111:96		95:80		79:64		63:48		47:32		31:16		15:0	
Bytes	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Samples	Sample k				Sample k+1				Sample k+2				Sample k+3			
Value	Real		Imag.		Real		Imag.		Real		Imag.		Real		Imag.	

Table 26-24. Eight 16 Bits Samples As They are Expected to Arrive From System Memory

Bits	127:120	119:112	111:104	103:96	95:88	87:80	79:72	71:64	63:56	55:48	47:40	39:32	31:24	23:16	15:8	7:0
Bytes	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Samples	Sample k		Sample k+1		Sample k+2		Sample k+3		Sample k+4		Sample k+5		Sample k+6		Sample k+7	
Value	Real	Imag.	Real	Imag.	Real	Imag.	Real	Imag.	Real	Imag.	Real	Imag.	Real	Imag.	Real	Imag.

Enabling any of the above two input data structure options is done by the *SINS* field of the eFTPE BD according to the following:

— *SINS*=0: Input sample structure is 32 bits (16I, 16Q)
— *SINS*=1: Input sample structure is 16 bits (8I, 8Q)

Figure 26-40 shows an example of a DFT block of Transform Length 12, because it should be placed in a 128-bit memory structure and for 32 bits sample structure (*SINS*=0). The base address of the example buffer is 0x18:

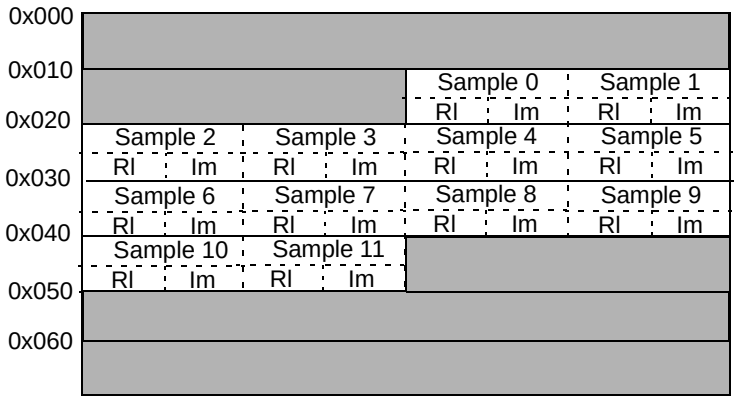

Figure 26-40. DFT Block, Transform Length 12, Start Address 0x18, *SINS*=0

Note: The Input Buffer Address in the external memory must be aligned to a 64 bit address, as shown in the example in **Figure 26-40**.

If the *BD_RPT* field in the eFTPE BD is enabled (*BD_RPT* > 0), then the Input Buffer Address should point to the location in system memory, where all the tasks related to that BD are located successively. **Figure 26-41** illustrates an example of how the data should be arranged in a 128 bit wide system memory if 5 tasks of Transform Length 24 are assigned to one BD:

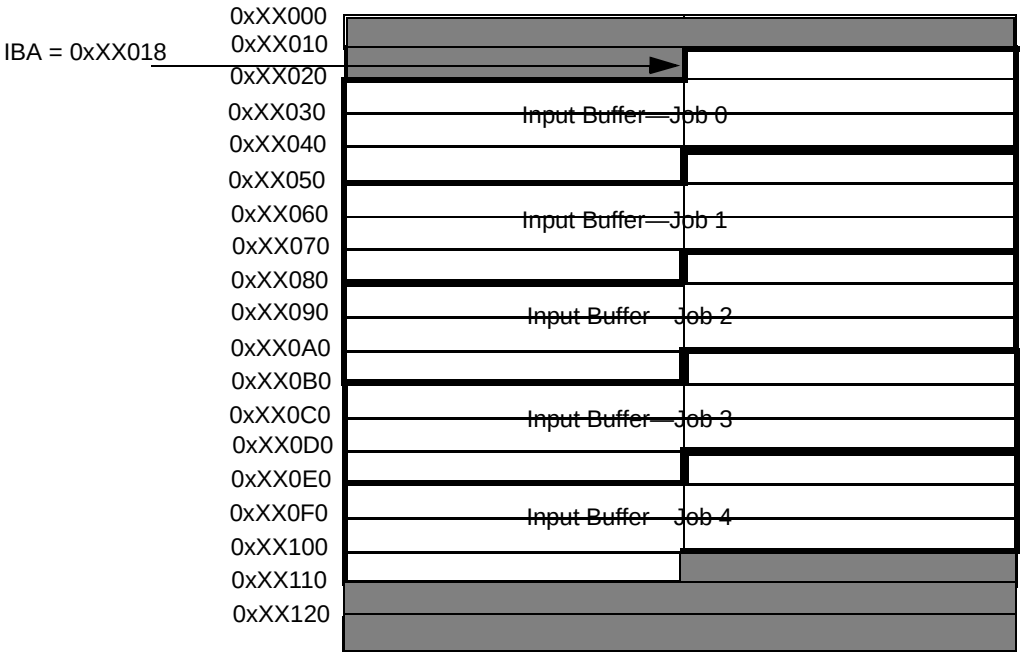

Figure 26-41. Input Buffer Structure for *BD_RPT*= 4, Transform Length = 24 and *SINS*=1

26.4.3.3.4.1.1 Guard Band Insertion for iFFT

To reduce system loading, the eFTPE supports a special input data structure for iFFT processing. This special input data structure allows the MAPLE-B2 to fetch only the relevant parts of the input data, and the eFTPE can internally generate the whole input data block structure.

Figure 26-42 is an example of the internal structure in the frequency domain of a 1024 samples Transform to be input for iFFT processing:

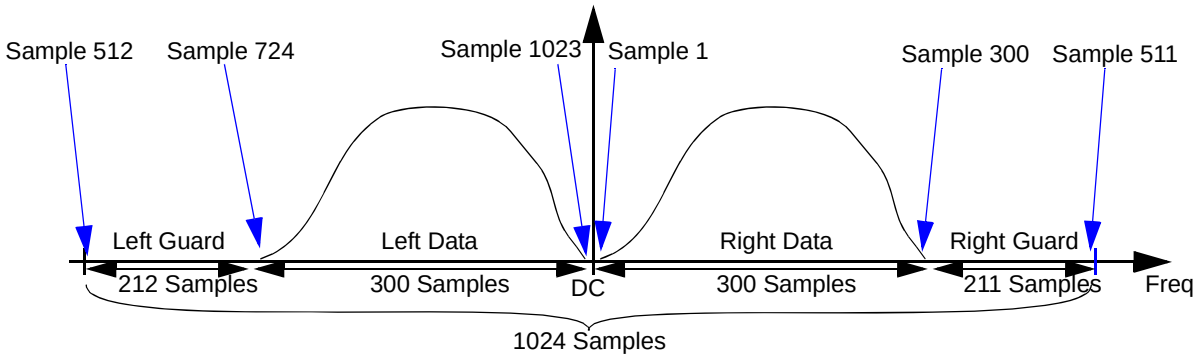

Figure 26-42. 1024 Samples Frequency Domain Example

As seen in **Figure 26-42**, the symbol is built from the following elements:

- Left data and right data which are equal in size
- Left guard and right guard
- One sample of DC

The Right/Left guards as well as the DC sample are all zero value samples.

When the Guard Insertion bit (*GI* bit in the eFTPE BD) is enabled, the MAPLE-B2 fetches only the Left-data following by the Right-data from system memory, and the eFTPE internally generates the whole symbol structure as seen in **Figure 26-43**.

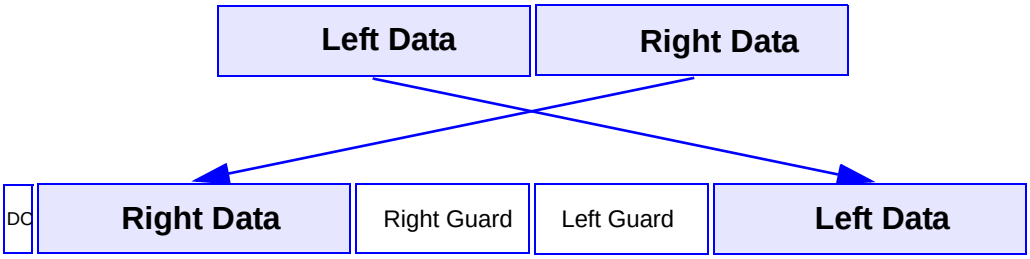

Figure 26-43. Generating Whole iFFT Data Structure Using the Right/Left Data

The size of the Right/Left data for each of the possible transform lengths are described in the eFTPE FTPEDSRx registers (**Section 26.5.3.3.1** to **Section 26.5.3.3.3**). **Table 26-25** describes

which fields in these registers relate to which Transform Length, and also the reset value for each of the fields.

Table 26-25. FTPEDSRx Fields and the Related Transform Length

Register [Field]	Transform Length	Reset Value for 3GLTE
FTPEDSR0[DS0]	128	36
FTPEDSR0[DS1]	256	90
FTPEDSR1[DS2]	512	150
FTPEDSR1[DS3]	1024	300
FTPEDSR2[DS4]	1536	450
FTPEDSR2[DS5]	2048	600

Updating the values in these registers can be done by one of the following options:

1. Host writing to these registers once during initialization. For each eFTPE BD with *GI* bit set, the value of the Data Size Set (*DSS)* field is ‘000’ indicating the MAPLE-B2 that the registers values were initialized once and require no update. Working this way requires no initialization of the FTPEDSSxPy parameter sets (see **Section 26.5.3.3.1**, *eFTPE Data Size Set x Parameter 0 (FTPEDSSxP0)* to **Section 26.5.3.3.3**, *eFTPE Data Size Set x Parameter 2(FTPEDSSxP2)*).
2. Host initialize the FTPEDSSxPy sets during initialization (see **Section 26.5.3.3.1**, *eFTPE Data Size Set x Parameter 0 (FTPEDSSxP0)* to **Section 26.5.3.3.3**, *eFTPE Data Size Set x Parameter 2(FTPEDSSxP2)*) and for each BD, set the *DSS* field of the eFTPE BD according to the required configuration parameter set. Once *DSS* field is set to any value between ‘001’ to ‘111’, MAPLE-B2 copy the relevant parameter set into the FTPEDSRx[DSy] registers (see **Section 26.5.5.3.1**, *EFTPE_<x> Data Size Register 0 (FTPE<x>DSR0)* to **Section 26.5.5.3.3**, *EFTPE_<x> Data Size Register 2 (FTPE<x>DSR2)*) in the relevant eFTPE module.

NOTE

- The *GI* bit can be used only while processing an iFFT job. It must be cleared for any other operation.
- Guard band insertion can’t be enabled together with Zero Padding process enabled by *ZP* bit in the same BD.
- Guard band insertion can’t be enabled when source of samples is internal code generation, enabled by the *CG* bit of the eFTPE BD.

The eFTPE derives the size of the DC +Left Guard + Right Guard (DC + LG + RG), which is the number of zero samples it needs to generate, according to the following equation:

DC + LG + RG = Transform Length - 2 * FTPEDSRx[DSy]

where the *x* and *y* of the FTPEDSR*x*[DS*y*] are derived from the Transform Length value and according to **Table 26-25**.

26.4.3.3.4.1.2 Zero Padding Support

To reduce system loading, the eFTPE supports zero padding of the input data. This feature allows the MAPLE-B2 to input only the relevant part of the data while the eFTPE internally pads the input data to reach the required transform Length. To enable the Zero Padding feature, configure the following eFTPE BD parameters:

- *ZP* = 1: Zero padding Indication. Indicates the eFTPE that Zero Padding is required for the current job.
- *DSTZP* = <Size of data to be padded>: Indicates the Actual data size to be fetched by the MAPLE-B2 into the eFTPE and to be internally padded to reach the required Transform Length.

The eFTPE use the *DSTZP* field to calculate the required Zero Padding according to the following equation:

Required Zero Padding = (Transform Length) - (*DSTZP*)

The Zero Padding is added at the end of the input data. **Figure 26-44** describe an example of the input buffer of the eFTPE after the Zero Padding completion:

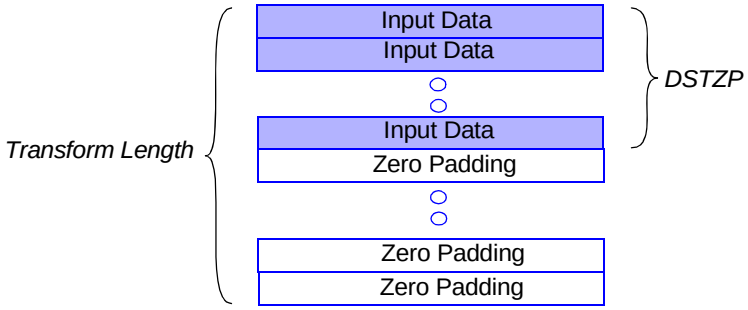

Figure 26-44. eFTPE internal Input Buffer description after Zero Padding

Note: The size of the Zero Padding is limited to numbers which are product of 4 samples and it must be smaller than the Transform Length (Transform Length > *DSTZP*).

26.4.3.3.4.1.3 Cyclic Prefix Removal for FFT BD Repeat

To reduce required BD configurations of the MAPLE-B2, and to improve usage of BD Repeat option (see **Section 26.4.3.3.2**, *BD Repeat Option*), the MAPLE-B2 supports removing of the Cyclic Prefix (CP) addition from the FFT inputs received from the Antenna Interface. **Figure 26-45** describe an example of the assumed input data received from the Antenna. By enabling the *CPRE* bit and by setting the *CPS* field to the cyclic prefix size in the eFTPE BD while BD repeat

is enabled, the MAPLE-B2 skips the cyclic prefix and fetches only the FFT inputs as described in the example in **Figure 26-45**

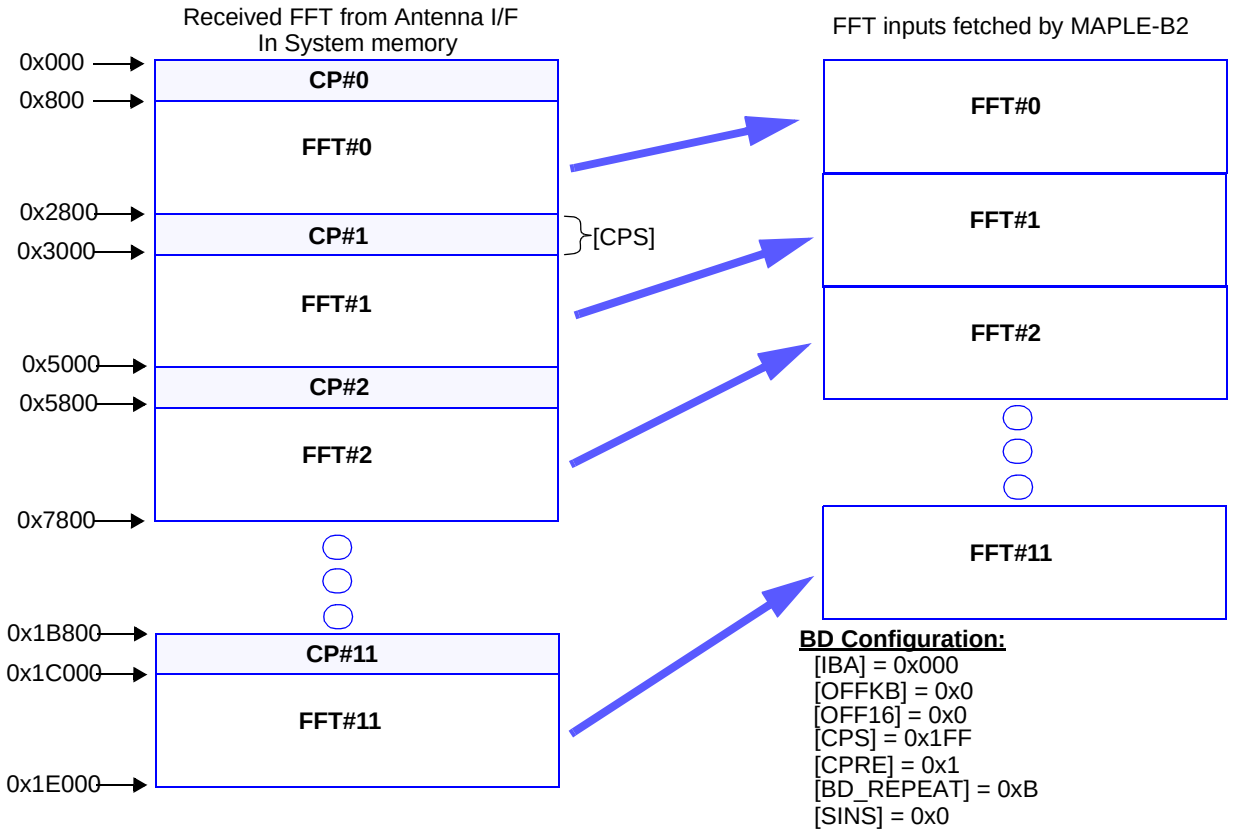

Figure 26-45. Cyclic Prefix Removal During BD Repeat

As can be seen in **Figure 26-45**, if the Cyclic Prefix Removal Enable bit (CPRE) in the eFTPE BD is set during BD Repeat, the MAPLE-B2 jump over the cyclic prefix while fetching the next FFT job. The size of the cyclic prefix should be set in the CPS field of the BD.

Note: In this configuration the *CPS* must not exceed the Transform Length.

26.4.3.3.4.1.4 Input Buffers Offset (in KBs) for FFT BD Repeat

To reduce required BD configurations of the MAPLE-B2, and to improve usage of BD Repeat option (see **Section 26.4.3.3.2**, *BD Repeat Option*), the MAPLE-B2 supports fixed offset between the input buffers required for the BD repeat option during FFT operation. The target of this feature is to allow using the BD repeat option for multiple receive antennas buffers located in fixed offsets in the system memory. **Figure 26-46** describe an example of the assumed input data received from N+1 Antennas. By enabling the *OFFKB* bit and by setting the *CPS* field to the offset size (in KBytes) in the eFTPE BD while BD repeat is enabled, the MAPLE-B2 fetches the FFT inputs as described in the example in **Figure 26-46**

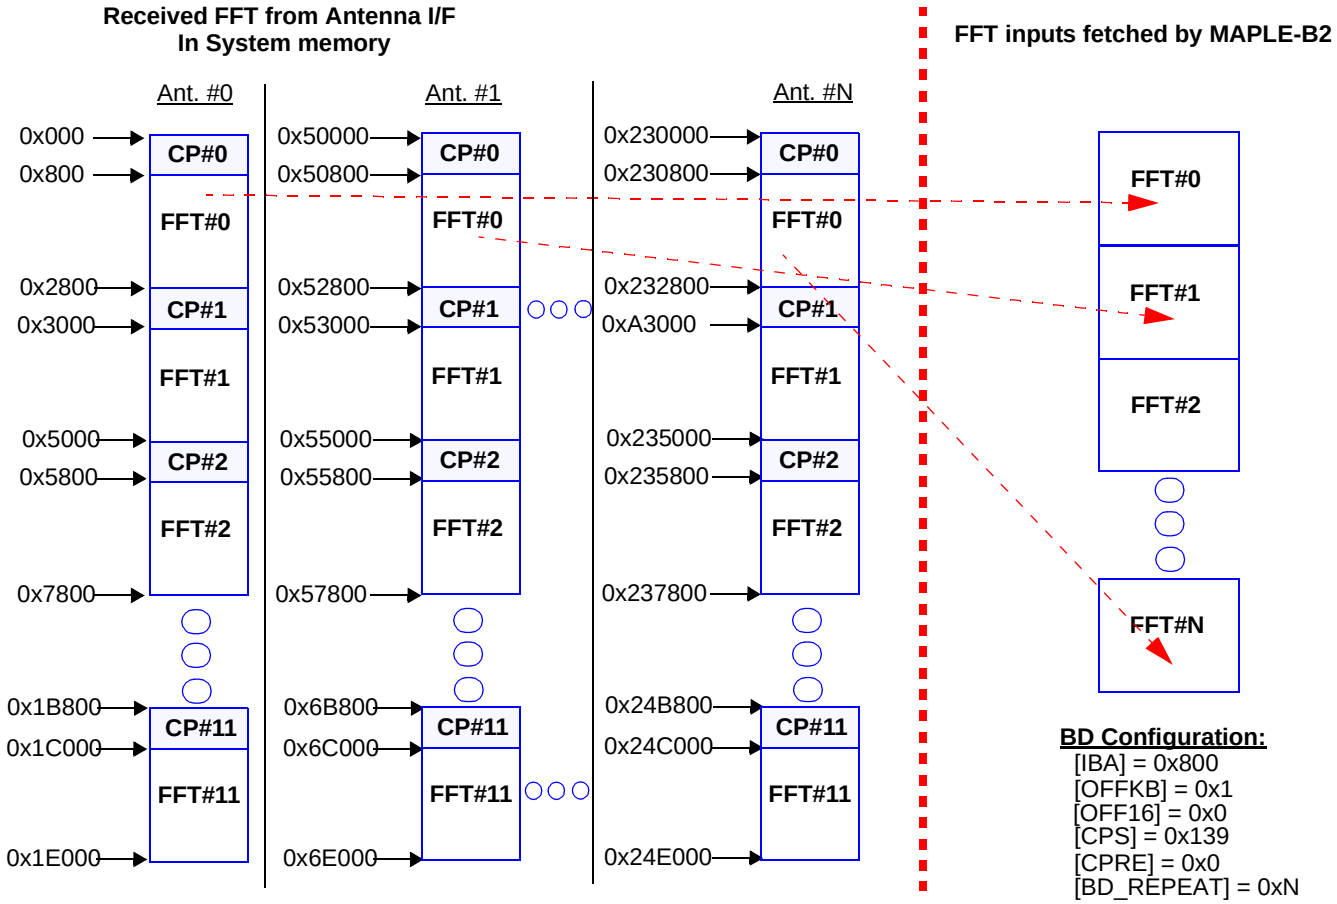

Figure 26-46. Input Buffers Offset (in KBs) During BD Repeat

26.4.3.3.4.1.5 Input Buffers Offset (in 16 Bytes multiplication) for DFT/iDFT BD Repeat

To reduce required BD configurations of the MAPLE-B2, and to improve usage of BD Repeat option (see **Section 26.4.3.3.2**, *BD Repeat Option*), the MAPLE-B2 supports fixed offset between the input buffers required for the BD repeat option during DFT/iDFT operation. **Figure 26-47** describe an example of using the 16 bytes multiplication offset usage. By enabling the *OFF16* bit and by setting the *CPS* field to the offset size (in multiplications of 16 bytes) in the eFTPE BD while BD repeat is enabled, the MAPLE-B2 fetches the DFT/iDFT inputs as described in the example in **Figure 26-47**

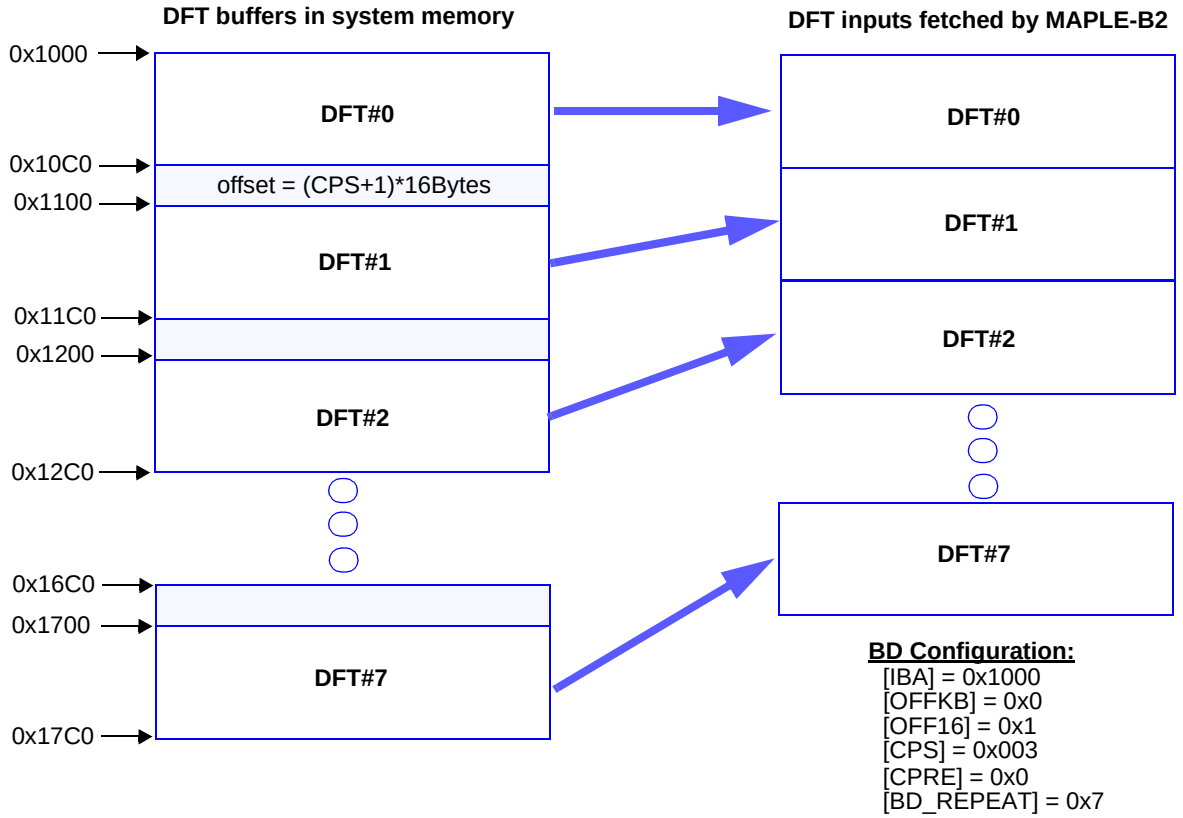

Figure 26-47. Input Buffers Offset (16 bytes multiplications) During BD Repeat

26.4.3.3.4.2 Output Data Structure.

Once the eFTPE has completed its processing, it outputs the processed data to system memory. The address it uses is specified in the *OBA* field of the BD.

The output data structure of the eFTPE is identical to the 32 bits sample input data structure as described in **Table 26-23**, that is, it is composed of 32 bit samples, and it is written to system memory with the same structure as the input data buffer (see **Figure 26-40**).

If *BD_RPT* is enabled (*BD_RPT* > 0), the MAPLE-B2 outputs the data of all the related jobs to successive addresses starting at the *OBA* (Output Buffer Address). The structure of the output data is arranged successively in memory and is similar to the structure of the input data for this case. (see example in **Figure 26-41**).

26.4.3.3.4.2.1 Guard Band Removal for FFT

To reduce system loading, the eFTPE supports a special output data structure for FFT processing only (*ITE* = 0). This special output data structure allows the MAPLE-B2 to output only the relevant parts of the output data.

Figure 26-48 is an example of the internal structure in the frequency domain of a 1024 samples Transform after FFT Processing[1].

As seen in **Figure 26-48**, the symbol is built from the following elements:

- Left data and right data which are equal in size
- Left guard and right guard
- One sample of DC (not relevant for UL FFT processing of 3GLTE)

When the Guard Removal bit (*GR* bit in the eFTPE BD) is enabled, the MAPLE-B2 outputs only the Left-data following by the Right-data to system memory as seen in **Figure 26-48**.

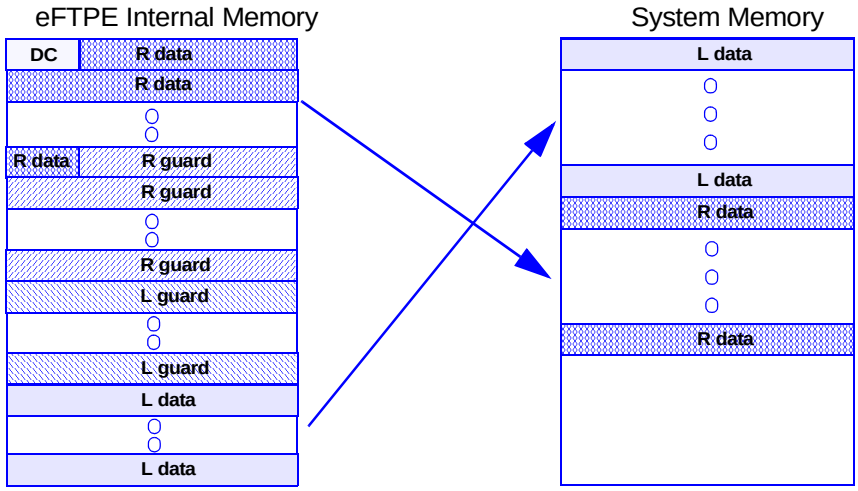

Figure 26-48. Output Data Structure of FFT Processing When *GR* Is Enabled

The *GRDC* bit of the eFTPE BD indicates MAPLE-B2 if the DC sample in the eFTPE output buffer should be regarded as data or as DC thus should be skipped during the output data stage. If the *GRDC* bit is set, MAPLE-B2 read the first R_data sample (see **Figure 26-48**) from offset 0x4 of the eFTPE output buffer. If the *GRDC* is cleared, MAPLE-B2 read the first R_data sample from offset 0x0.

The size of the Right/Left data for each of the possible transform lengths (R_data & L_data in **Figure 26-48**) should be specified to MAPLE-B2 as follows:

1. During MAPLE-B2 initialization one (or more) of the FTPEDSSxP parameter sets (see **Section 26.5.3.3.1**, *eFTPE Data Size Set x Parameter 0 (FTPEDSSxP0)* to **Section 26.5.3.3.3**, *eFTPE Data Size Set x Parameter 2(FTPEDSSxP2)*) must be initialized with the Data Size values for the relevant FFT Transform Lengths.
2. The Data Size Set (*DSS)* field of the eFTPE BD should get a value between ‘001’ to ‘111’ indicating the MAPLE-B2 which of the FTPEDSSxP parameter sets (which was initialized during MAPLE-B2 initialization as described in step #1) should be used for this job. The MAPLE-B2 read the relevant parameter set and output the required data from eFTPE output buffer accordingly.

1. For 3GLTE standard the DC sample does not exist after UL FFT processing.

Note: The *GR* bit can be used only while processing an FFT job (*ITE* = 0). It must be cleared for any other operation.

Note: The FTPEDSSxP parameter sets are shared to all eFTPE modules.

26.4.3.3.4.2.2 Cyclic Prefix Insertion for iFFT

To reduce system loading, the MAPLE-B2 supports generating cyclic prefix addition to the iFFT results while written into the system memory. By enabling the *CPIE* bit and the *CPS* field in the eFTPE BD, the MAPLE-B2 generates the following data structure in the system memory:

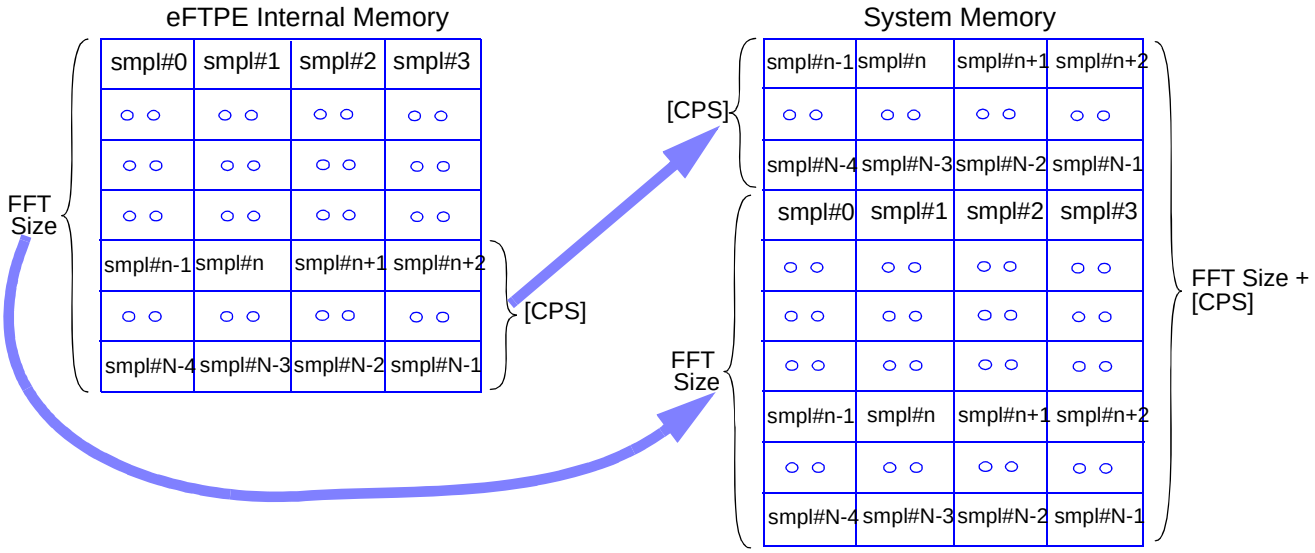

Figure 26-49. Cyclic Prefix Insertion in System Memory for iFFT Processing

As shown in **Figure 26-49**, if the Cyclic Prefix Insertion Enable bit (*CPIE*) in the eFTPE BD is set, the MAPLE-B2 first outputs the number of samples as described in the Cyclic Prefix Size (*CPS*) to the system memory, following by the whole FFT size as being processed by the eFTPE.

Note: The *CPS* must not exceed the Transform Length.

Note: If the Repeat mode is enabled (*BD_RPT* > 0) while the Cyclic Prefix Generation is enabled, the MAPLE-B2 generates the data structure as described in **Figure 26-49** for each of the repeated jobs.

Note: Disabling the Cyclic Prefix Generation (*CPIE* = 0) may slightly improve the eFTPE performance as the data output stage becomes shorter thus enabling the eFTPE to start with the next job earlier.

26.4.3.3.5 Pre and Post Vector Multiplication Support

The eFTPE supports pre and/or post vector multiplication of the processed samples. Pre multiplication means each sample of the input vector is multiplied (before the DFT/FFT

processing) by each sample of the pre-multiplier buffer in the eFTPE. Post multiplication means each sample of the DFT/FFT processing result is multiplied by each sample of the post-multiplier buffer in the eFTPE. The following sections elaborate on these features.

26.4.3.3.5.1 Pre-Multiplication Processing Support in the eFTPE

The eFTPE includes a pre-multiplication unit which allows array multiplication of the eFTPE input samples with a different complex number represented by a 16-bit fractional fixed point representation of 1q15 for the real part and for the imaginary part.

Enabling the pre-multiplication feature in the eFTPE is done by configuring the *PME* field of the eFTPE BD as follows:

- *PME* = 00: Pre-multiplication is disabled.
- *PME* = 01: Pre-multiplication is enabled. No pre-multiplication memory update is required.
- *PME* = 11: Pre-multiplication is enabled. The MAPLE-B2 is required to update the pre-multiplication memory before the beginning of the processing. The MAPLE-B2 update the content of the pre-multiplication memory with data pointed by the *PRM_PTR* field of the eFTPE BD.

The order of the multiplications of the complex numbers in the pre-multiplication memory is always executed according to the order to the input samples stream, that is, the first input sample is multiplied by the complex number located in address 0x0 of the pre-multiplication memory, the second input sample is multiplied by the complex number located in address 0x4 of the pre-multiplication memory and so forth. The pre-multiplication memory size is 8KB to fit the maximum FFT size of 2048 (4 bytes for each complex number). Consequently, for smaller Transform Length sizes the pre-multiplication memory is not fully utilized.

Figure 26-50 describes the pre-multiplication memory utilization for the different TL sizes and the order of multiplications of its complex numbers for FFT/iFFT operation. This functionality is applicable for DFT/iDFT operation as well with similar memory organization:

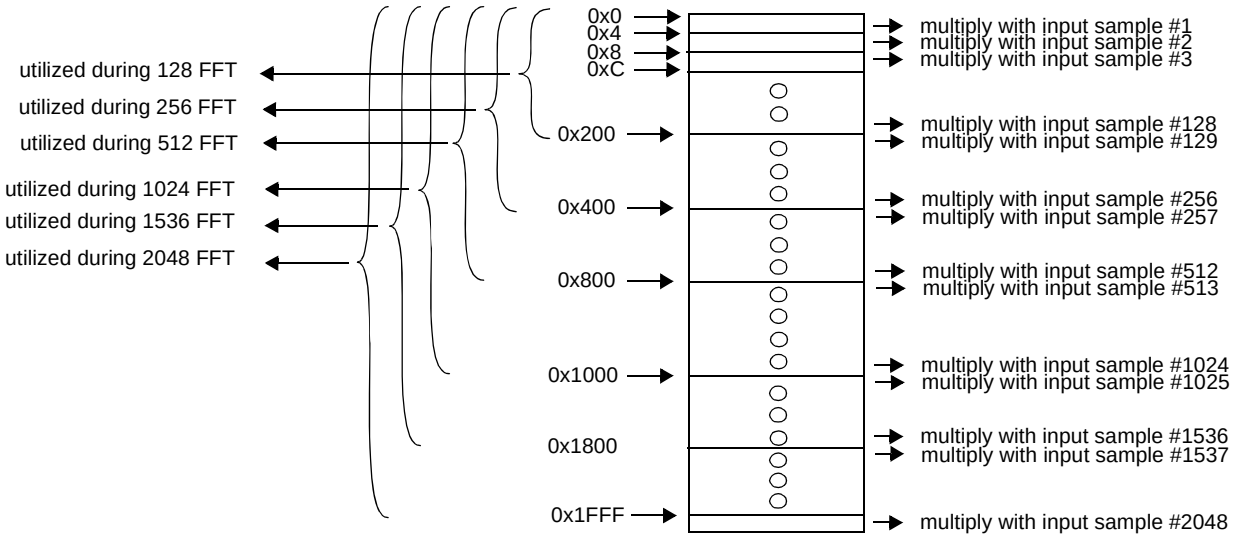

Figure 26-50. Pre- Multiplication Memory Utilization for the Different FFT Sizes

Note: If the *GI* bit of the eFTPE BD is asserted during iFFT processing, the expected input data is different (see **Section 26.4.3.3.4.1.1**, *Guard Band Insertion for iFFT*). In that case, if the pre-multiplication option is enabled, the content (order and amount of complex numbers) of the pre-multiplication memory should be adjusted according to the input data order during *GI*. For example in case of 2048 points iFFT in 3GLTE technology with *GI* enabled, the pre-multiplier memory should contain 1200 samples, starting with Left data pre-multiplier samples followed by Right data pre-multiplier samples. The data structure is similar to the one shown in **Figure 26-43**.

Note: It is recommended to minimize the pre-multiplication memory update to allow maximum eFTPE throughput performance. Frequent updating of the pre-multiplication memory degrades eFTPE performance.

The pre-multiplier operation can be used to eliminate the half sub-carrier shift, in FFT processing of the UL SC-FDMA signals as described in 3GPP TS 36.211, section 5.6 as well as for many other purposes in various technologies.

Note: Pre-multiplication can not be enabled when Frequency Correction is done on input samples. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*.

When Pre-Multiplication is enabled with a BD Repeat option enabled (*BD_RPT* > 0), there are three options to handle the pre multiplication vector update for the internal tasks of the BD:

- All the tasks in the BD Repeat use the same pre-multiplication vector which is already placed in the eFTPE Pre-Multiplier internal memory. To enable this work flow the *PME* field should be set to the value of 1 and the pre-multiplication memory in the eFTPE must contain the required pre-multiplication vector. For details on initializing the pre-multiplication buffer see **Section 26.4.3.3.5.3**, *'One-Shot' Initialization of the Pre/Post Multiplication buffers*.
- All the tasks in the BD Repeat use the same pre-multiplication vector, but it is a new pre-multiplication vector which requires fetching from system memory. Enabling this work flow requires the following BD configuration: *PME*=3 and *PRMUR*=1. For this configuration the MAPLE-B2 fetches a single pre-multiplication vector expected at the address pointed by the *PRM_PTR* field and with the size of a single task as implied by the *TL_ID* field of the BD.
- Each of the tasks in the BD Repeat use a different pre-multiplication vector, which requires fetching from the system memory. Enabling this work flow requires the following BD configuration: *PME*=3 and *PRMUR*=0. For this configuration the MAPLE-B2 fetches a different pre-multiplication vector for each of the tasks in the BD Repeat. Each of the pre-multiplication vectors is expected to be with the size of the single task as implied by the TL_ID field of the BD. All the pre-multiplication vectors are expected to be placed successively in the system memory at the address pointed by the *PRM_PTR* field of the BD.

Note: Setting the *PME* to the value of 1 indicates that pre-multiplication is enabled and that all the tasks in the BD repeat use the same pre-multiplication vector already placed in the eFTPE pre multiplication internal buffer. Clearing the *PRMUR* indicates that the pre-multiplication buffer requires update between each task in the BD Repeat. Such configuration creates a contradiction hence forbidden.

Figure 26-51 described an example of the expected pre-multiplication data for the above options #2 and #3 (for option #1 no pre-multiplication data is expected).

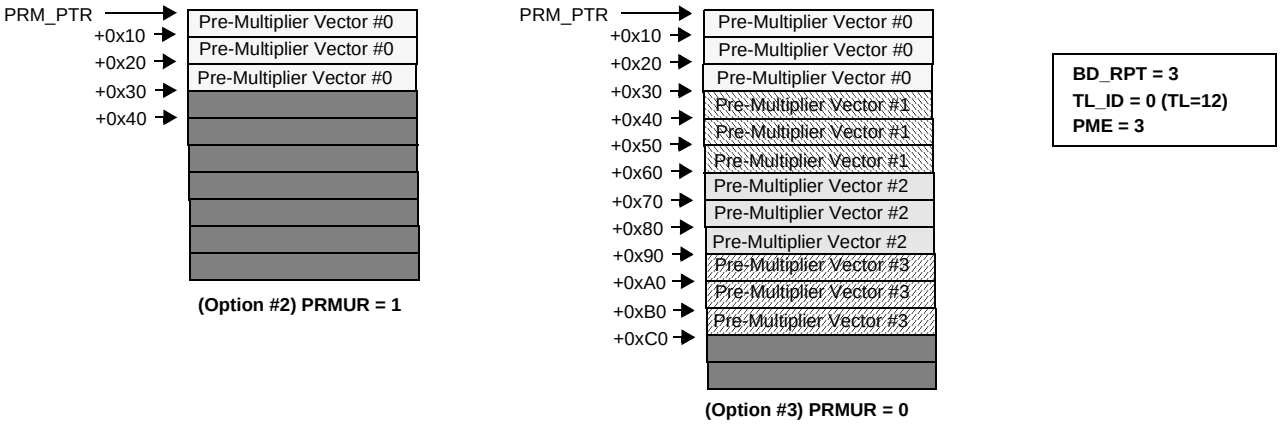

Figure 26-51. Pre-Multiplication Expected Vectors Example

26.4.3.3.5.2 Post-Multiplication processing support in the eFTPE

The eFTPE includes Apost-multiplication unit which allows array multiplication of the eFTPE samples after DFT/FFT processing with a different complex number represented by a 16-bit fractional fixed point representation of 1q15 for the real part and for the imaginary part.

Enabling the post-multiplication feature in the eFTPE is done by configuring the *PSTMV* field of the eFTPE BD as follows:

- *PSTMV* = 00: Post-multiplication is disabled.
- *PSTMV* = 01: Post-multiplication is enabled. No post-multiplication memory update is required.
- *PSTMV* = 11: Post-multiplication is enabled. The MAPLE-B2 is required to update the post-multiplication memory before the beginning of the processing. The MAPLE-B2 update the content of the post-multiplication memory with data pointed by the *POM_PTR* field of the eFTPE BD.

The order of the multiplications of the complex numbers in the post-multiplication memory is always executed according to the order to the input samples stream, that is, the first input sample (after DFT/FFT processing) is multiplied by the complex number located in address 0x0 of the post-multiplication memory, the second input sample is multiplied by the complex number located in address 0x4 of the post-multiplication memory and so forth. The post-multiplication memory size is 8KB to fit the maximum FFT size of 2048 (4 bytes for each complex number). Consequently, for smaller Transform Length sizes the post-multiplication memory is not fully utilized.

Figure 26-50 on page 26-92 describes the post-multiplication memory utilization (identical to the pre-multiplication memory utilization) for the different TL sizes and the order of multiplications of its complex numbers

When Post-Multiplication is enabled with a BD Repeat option enabled (*BD_RPT* > 0), there are three options to handle the post multiplication vector update for the internal tasks of the BD:

- All the tasks in the BD Repeat use the same post-multiplication vector which is already placed in the eFTPE Post-Multiplier internal memory. To enable this work flow the *PSTMV* field should be set to the value of 1 and the post-multiplication memory in the eFTPE must contain the required post-multiplication vector.For details on initializing the pre-multiplication buffer see **Section 26.4.3.3.5.3**, *‘One-Shot’ Initialization of the Pre/Post Multiplication buffers*.
- All the tasks in the BD Repeat use the same post-multiplication vector, but it is a new post-multiplication vector which requires fetching from system memory. Enabling this work flow requires the following BD configuration: *PSTMV*=3 and *PSMUR*=1. For this configuration the MAPLE-B2 fetches a single post-multiplication vector expected at the

address pointed by the *POM_PTR* field and with the size of a single task as implied by the *TL_ID* field of the BD.

- Each of the tasks in the BD Repeat use a different post-multiplication vector, which requires fetching from the system memory. Enabling this work flow requires the following BD configuration: *PSTMV*=3 and *PSMUR*=0. For this configuration the MAPLE-B2 fetches a different post-multiplication vector for each of the tasks in the BD Repeat. Each of the post-multiplication vectors is expected to be with the size of the single task as implied by the TL_ID field of the BD. All the post-multiplication vectors are expected to be placed successively in the system memory at the address pointed by the *POM_PTR* field of the BD.

Note: Setting the *PSTMV* to the value of 1 indicates that post-multiplication is enabled and that all the tasks in the BD repeat use the same post-multiplication vector already placed in the eFTPE post multiplication internal buffer. Clearing the *PSMUR* indicates that the post-multiplication buffer requires update between each task in the BD Repeat. Such configuration creates a contradiction hence forbidden.

Figure 26-51 described an example of the expected post-multiplication data for the above options #2 and #3 (for option #1 no post-multiplication data is expected).

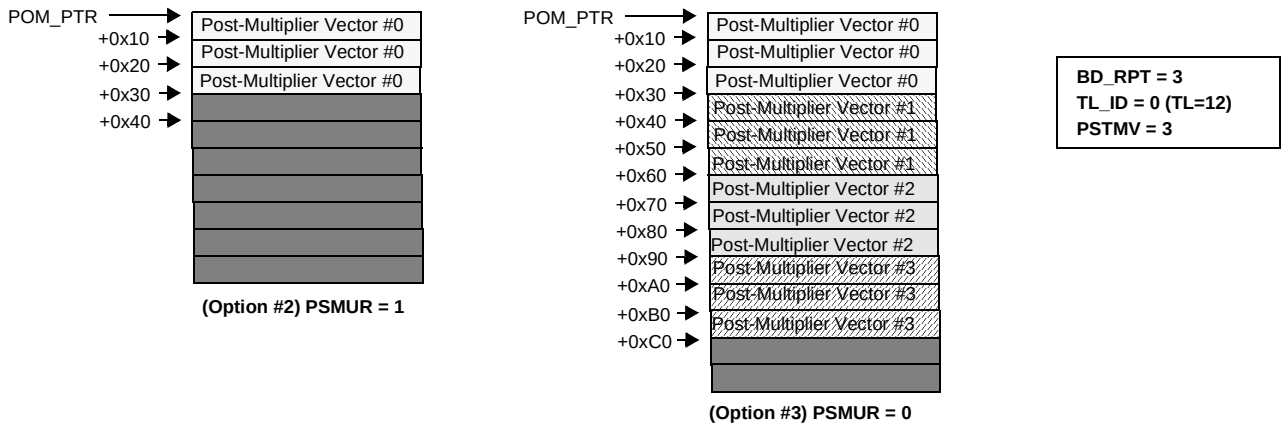

Figure 26-52. Post-Multiplication Expected Vectors Example

Note: It is recommended to minimize the post-multiplication memory update between BDs to allow maximum eFTPE throughput performance. Frequent updating of the post-multiplication memory degrades eFTPE performance.

Note: Post-multiplication can not be enabled when Frequency Correction (FC) is enabled on output samples (*FCPRE* = 0), as the FC on output samples uses the post multiplication buffer to keep the generated FC samples. Such implementation implies that when FC on output samples is enabled, the post-multiplication buffer is invalid and needs to be reloaded on the next job that the vector post-multiplication feature is enabled. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*.

26.4.3.3.5.3 'One-Shot' Initialization of the Pre/Post Multiplication buffers

In case no frequent update of the pre/post multiplication buffers is required, the MAPEL-B2 support initiating a dedicated internal routine ('Maple_eftpe_update_pre_post_buffers') which allows single update of the pre/post multiplication buffers of each of the eFTPE modules. To initiate the 'Maple_eftpe_update_pre_post_buffers' routine, the following should be done:

1. Set the *FTPExUPRMBPP*, *FTPExUPSMBPP* and *FTPExUBSP* parameters as described in **Section 26.5.3.3.4** to **Section 26.5.3.3.6**
2. Clear the *FTPECUBRP[UBC]* field (see **Section 26.5.3.3.7**, *eFTPE Complete Update Buffers Routine Parameter (FTPECUBRP)*).
3. Access the PCR register with opcode of '010000' (see **Section 26.4.5**, *MAPLE-B2 Internal Task Control*).

Once initiated the routine performs (for each eFTPE module) the following:

1. Check if *FTPExUPRMBPP[PRE_BUF_PTR]* is initialized, that is, has a different value than zero. If yes, the value is assumed to point to the new pre-multiplication buffer in the system memory and the MAPLE-B2 fetched the new table into the relevant eFTPE pre-multiplication buffer. The size of the table is determined according to the *FTPExUBSP[PRE_BUF_SIZE]* configuration. For details see **Section 26.5.3.3.4** and **Section 26.5.3.3.6**
2. Check if *FTPExUPSMBPP[PRE_BUF_PTR]* is initialized, that is, has a different value than zero. If yes, the value is assumed to point to the new post-multiplication buffer in the system memory and the MAPLE-B2 fetched the new table into the relevant eFTPE post-multiplication buffer. The size of the table is determined according to the *FTPExUBSP[PST_BUF_SIZE]* configuration. For details see **Section 26.5.3.3.5** and **Section 26.5.3.3.6**

Activating this routine should be done with the following limitations:

- All relevant eFTPE modules are in idle and there are not pending jobs (Buffer Descriptors) in their BD Rings.
- All relevant eFTPE modules output buffer configuration (see **Section 26.4.3.3.10.1**, *eFTPE Configuration Register*) meet the following: *BC* != 4.

Once the 'Maple_eftpe_update_pre_post_buffers' routine is initiated, no new Buffer Descriptors should be written into MAPLE-B2 internal memory until the MAPLE-B2 has completed the routine. The completion of the routine is indicated by MAPLE-B2 by setting the *FTPECUBRP[UBC]* bit to '1'.

26.4.3.3.6 Scalar Post Multiplication in eFTPE

The eFTPE allows multiplication of all resulting samples with a single constant complex value. Using this feature can resolve, for example, the need to multiply all DFT output samples with the value of 1/n (or 1/sqrt(n)), where n is the DFT size. Enabling this feature is done by setting the Post Multiplication Enable bit (*PSTME*) in the eFTPE BD, and by assigning the required multiplication value to the *PSTM_REAL* and *PSTM_IMG* fields of the eFTPE BD. The single limitation when using the Post Multiplication feature is that the values of the complex multiplication number represented by the *PSTM_REAL* and *PSTM_IMG* fields of the eFTPE BD must maintain the following equation:

$$(PSTM\_REAL)^2 + (PSTM\_IMG)^2 < 2$$

where *PSTM_REAL* and *PSTM_IMG* are 1q15 representation numbers as described in **Figure 26-249**.

26.4.3.3.7 Frequency Correction Support in eFTPE

The eFTPE support vector multiplication of the transform vector with internally generated Frequency Correction (FC) function. The function is a sequence of Phasor arguments with a constant shift between each argument. The FC arguments generation is executed “on the fly” in the eFTPE internal pipe, therefore doesn’t have any impact on the eFTPE performance.

When enabling the FC option, the following eFTPE BD parameters should be initialized:

- ***FC_CG***: Should be set. Indicates the MAPLE-B2 that the BD extension, where all FC related parameters are placed, is valid (see **Section 26.5.4.3.2**, *eFTPE Buffer Descriptor’s Extension*).
- ***FCG***: FC Generation indication. Setting this bit enables the FC Generation in the eFTPE.
- ***FCPRE***: FC as Pre-Multiplier. The eFTPE supports applying the FC function on either samples data before the DFT/FFT processing or samples data after the DFT/FFT processing. By assigning the value of ‘0’ to the *FCPRE*, the FC multiplication is performed on samples after the DFT/FFT processing. By assigning the value of ‘1’ to the *FCPRE*, the FC multiplication is performed on samples before the DFT/FFT processing.
- ***FCB_REAL***, ***FCB_IMAG***: FC Base value (Real part and Imaginary part). Used as the initial value to be used for the first sample.
- ***FCS***: FC Size. Indicates the eFTPE the amount of samples (out of the total Transform Length) which the FC function should be applied.
- ***FCSS***: FC Step Size. Indicates the number of input samples that should use the same correction factor before it is increment by the shift value.
- ***FCISC***: FC Input Step Counter. Indicates the initial value of the step counter which determines when to increment the correction factor. For example, if for a certain job the Step Size (*FCSS*) is set to 20, and the Step Counter init value (*FCISC*) is set to 16, the

eFTPE uses the FC Base value for the first 4 samples before incrementing it by the shift value.

- ***FCS_REAL***, ***FCS_IMAG***: FC Shift Value (Real part and Imaginary part). Used as the step value whenever Correction factor increment (complex multiplication) is required.

The following pseudo code illustrates the eFTPE usage of the above parameters:

```
if ((FC_CG==1) and (FCG==1))
{
      correction_factor = FCB_REAL, FCB_IMAG; //correction factor init value
      correction_step = FCISC;
      for (i=1; i ≤ FCS; i++) // increment every input sample (starting the input first sample)
      {
           Sample = Sample * correction factor;
           if (FCSS==1) {correction_factor = correction_factor * {FCS_REAL, FCS_IMAG};}
           else
           {
                correction_step += 1;
                if ((correction_step % FCSS)==0)
                {correction_factor = correction_factor * {FCS_REAL, FCS_IMAG};}
           }
      }
}
```

where “Sample” is either the input data before DFT/FFT processing (*FCPRE*=1) or after DFT/FFT processing (*FCPRE*=0).

Some notes regarding FC usage:

- The FC can not be enabled in the following cases:
  - If the Guard Insertion feature is enabled (*GI* bit of the eFTPE BD. See **Section 26.4.3.3.4.1.1**).
  - If Pre-multiplication is enabled (*PME* field of the eFTPE BD. See **Section 26.4.3.3.5.1**) then FC can not be enabled as Pre-Multiplication (*FCPRE*=1).
  - If Post-multiplication is enabled (*PSTMV* field of the eFTPE BD. See **Section 26.4.3.3.5.2**) then FC can not be enabled as Post-Multiplication (*FCPRE*=0).
- FC can be enabled along with the Code Generation feature. In that case, the “Sample” expression refers to the internally generated data as described in **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*
- Frequent switching between FC as Pre (*FCPRE*=1) and FC as Post (*FCPRE*=0) is not recommended because it degrades eFTPE performance.

The MAPLE-B2 returns the following FC related status fields in the eFTPE BD on BD completion:

- ***FCF_REAL_ST***, ***FCF_IMAG_ST***: FC Factor (Real part and Imaginary part). Indicates the correction factor value end state. Can be used as the *FCB_REAL* and *FCB_IMAG* values for the next (successive in time domain) job.
- ***SCOS***: Step Counter State. Indicates the end state of the step counter. Can be used as the FCISC value for the next (successive in time domain) job.

26.4.3.3.7.1 Frequency Correction Support during BD Repeat

When enabling the Frequency Correction (FC) feature and BD Repeat is enabled (*BD_RPT*>0), the MAPLE-B2 assume continuous FC is required and the following is applied by the MAPLE-B2:

1. The first repeated job is using all configuration parameters as described in the BD.
2. The followed repeated job (job #n) use the results of the previous job (job #(n-1)) in the repeat chain as follows:
   a. The FC factor results (*FCF_REAL_ST* and *FCF_IMAG_ST* status fields) of the previous job are used as the FC Base values (*FCB_REAL* and *FCB_IMAG*) for the current job .
   b. The step counter state (*SCOS* status field) of the previous job is used as the FC initial step counter (*FCISC*) for the current job
3. All other BD fields are valid for all jobs in the repeated BD.

Note: When enabling the FC during BD repeat, the output results of each job in the repeated BD are used as input control for the following job in the repeated BD. This flow prevents full utilization of the eFTPE as the internal pipeline between repeated jobs cannot be implemented.

26.4.3.3.8 WCDMA Scrambled Pilot Code Generation

The eFTPE supports WCDMA processing assist tasks which include FFT processing on scrambled and spread symbols of pilot fields generated internally in the eFTPE. The eFTPE can internally produce the scrambled symbols (according to given parameters) and perform FFT processing on the generated sequence according to given FFT parameters, thus both reducing system traffic and external core load required for these sequences generation.

When enabling the Code Generation (CG) option, the following eFTPE BD parameters should be initialized:

- ***FC_CG***: Should be set. Indicates the MAPLE-B2 that the BD extension, where all CG related parameters are placed, is valid (see **Section 26.5.4.3.2**, *eFTPE Buffer Descriptor's Extension*).
- ***CG***: Code Generation indication. Setting this bit enables the internal CG in the eFTPE.

- ***CNPI***: Current Number of Pilots. Indicates the N_{pilot} value (see 3GPP 25.211 section 5.2) of the current frame which the code start at. There are six valid values (0 to 5) indicating N_{pilot} values of 3 to 8.
- ***NNPI***: Next Number of Pilots. Indicates the N_{pilot} value of the next frame. Required for the case where the required code starts at the current frame and cross to the next frame during its generation. There are six valid values (0 to 5) indicating N_{pilot} values of 3 to 8.
- ***CO***: Chip Offset indication. Indicates the chip offset from the beginning of the current frame where the scrambling code generation is to start. The chip offset can be any value from 0 to 38399 (number of chips in frame).
- ***SGO***: Slot Generation Off. Each of this 4 bits field represent a slot, starting from the current slot (bit [0]) and until the following 3 slots. A value of '1' in a bit indicates that the pilot code generation for the slot it is representing is disabled.
- ***LSS***: Long Scrambling Sequence. Indicates the eFTPE the scrambling sequence generation mode. There are two supported modes: long and short. Setting this field indicated the eFTPE that long scrambling sequence mode is required. Resetting this field indicates short scrambling sequence generation mode is required.
- ***SSN***: Scrambling Sequence Number. A 24 bits number (0 to $(2^{24} - 1)$) which is used for the scrambling code generation.
- ***CL***: Code Length. Indicates the total number of the scrambled symbols to be generated in the current job.
- ***SN***: Slot Number. Indicates the index of the current slot in the frame.

The above parameters are used to generate the pilots and the scrambling code which are then combined to generate the final scrambled code to be used as input to the FFT processing. The following sections elaborate on Pilot generation, scrambling code generation and the combining process of the two.

26.4.3.3.8.1 Pilot Symbols Generation and Spreading

The eFTPE generates pilot symbols from DPCCH to be scrambled according to DPCCH definition in 3GPP 25.211. The pilot symbols are chosen from an internal table according to the slot format (*CNPI*), slot number (*SN*), and the chip offset in the slot (*CO*). Also, there are "silent" slots, which indicate slots that do not contain any relevant pilot symbols, and therefore create 0 symbols for the slot. For these slots, the pilot generation is disabled. Enabling silent slots is done by setting the relevant bits in the Slot Generation Off (*SGO*) field. The first bit of the *SGO* field specified the silent indication of the current slot in which the first chip is required. The next bits of the *SGO* specify the silent indication for the following slots, in case the chip index is crossing slots boundaries during pilot generation.

Figure 26-53 describe the internal processing of pilot symbols generation:

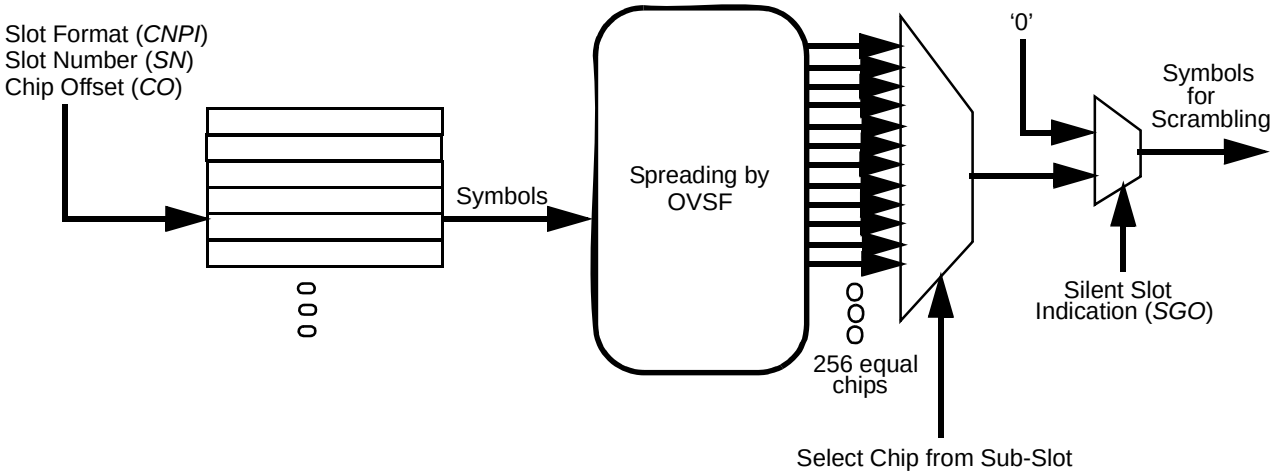

Figure 26-53. Pilot Generation Illustration

As can be seen in **Figure 26-53**, the symbols generation is done using a table (taken from the 3GPP 25.211 standard) which uses the current slot format, slot number and chip offset to extract the symbol, which is then spread using Orthogonal Variable Spreading Factor (OVSF). For DPCCH symbols, the OVSF equals 256 '1's. Note that if during the pilot generation a frame boundary is crossed, the eFTPE uses the slot format number specified in the *NNPI* field for the following symbols generation. The resulting chips either continue *as is* to scrambling or replaced with zero in case the current slot is silent slot. The values of the generated pilots before scrambling are either 1 or -1 (representing j or -j), and when the current slot is silent (or when current chip offset is bigger than the spread number of pilots), the symbols value is 0.

Note: To maximize internal calculations precision the generated pilots are created with the values of +0.5/-0.5 and the input scale value is assumed as +1. For details on eFTPE scaling see **Section 26.4.3.3.9.4**, *eFTPE Internal Scaling Calculations*

26.4.3.3.8.2 Scrambling Code Generation

The scrambling machine is designed to implement the 3GPP 25.213 section 4.3.2, including supporting long and short scrambling sequences. To get the requested scrambling code, the machine uses the Chip Offset (*CO*), Long/Short Scrambling Sequence indication (*LSS*) and the Scrambling Sequence Number (*SSN*) parameters as described in the standard.

26.4.3.3.8.3 Combining Pilot Symbols and Scrambling Code

The final generated code sample to be written to input data buffer (SP[i]), is combined from the scrambling machine result for the requested chip (PN[i]), and the pilot symbols machine result for the same requested chip (P[i]).

Creating SP[i] is done by multiplying (complex multiplication) PN[i] with P[i]:

SP[i] = PN[i]*P[i].

The final code samples results could be one of the following: 1+j, 1-j, -1+j, -1-j and 0.

26.4.3.3.8.4 Code Generation with BD Repeat

When enabling the Code Generation (CG) feature and BD Repeat is enabled (*BD_RPT*>0), the MAPLE-B2 assume continuous CG is required and the following is applied by the MAPLE-B2:

1. The first repeated job is using all configuration parameters as described in the BD.
2. The followed repeated job (job #n) use the results of the previous job (job #(n-1)) in the repeat chain as follows:
   a. The Next Number of Pilots results (*NNPIS* status field) of the previous job is used as the Current Number of Pilots (*CNPI* field) for the current job.
   b. The Next Slot Generation Off indication (*NSGO* status field) of the previous job is used as the Slot Generation Off indication (*SGO*) for the current job.
   c. The Next Slot Number result (*NSN* status field) of the previous job is used as the Slot Number (*SN*) indication for the current job.
   d. The Next Chip Offset results (*NCO* status field) of the previous job is used as the Chip Offset (*CO*) field for the current job
3. All other BD fields are valid for all jobs in the repeated BD.

Note: When enabling the CG during BD repeat, the output results of each job in the repeated BD are used as input control for the following job in the repeated BD. This flow prevents full utilization of the eFTPE as the internal pipeline between repeated jobs cannot be implemented.

Note: The generated codes included in the BD Repeat should not be spread over more than 4 slots.

26.4.3.3.8.5 Code Generation with Zero Padding

In some cases the required pilot code size is not aligned with the supported FFT sizes. In that case it is possible to instruct the eFTPE to add zero padding to the generated code to reach the required FFT size. Enabling the zero padding can be done as follows:

1. Configure *TL_ID* according to the required FFT size (see **Table 26-246**)
2. Configure the required Code Length in the *CL* field of the eFTPE BD.
3. If (*CL* < Transform Length,) then set the Zero Padding field (*ZP*) and configure the Data Size to Zero Padding (*DSTZP*) field must to the same value as the *CL* field, which directs the eFTPE to add zero padding to the generated code to reach the required Transform length

26.4.3.3.8.6 Code Generation Status

The MAPLE-B2 returns the following CG related status fields in eFTPE BD:

- ***NNPIS***: Next Number of Pilot State. If the current job crossed a frame boundary during its CG processing, then that value of this field equals the *NNPI* field, else it equals the *CNPI* field.
- ***NSGO***: Next Slot Generation Off. If the current job crossed slots boundaries during its CG processing, then the value of this field would be:

  NSGO = *SGO* >> (number of slot boundaries crossed)

  else it would be equal to *SGO* field.
- ***NSN***: Next Slot Number. If the current job crossed slots boundaries during its CG processing, then the value of this field would be:

  NSN = (*SN* + (number of slot boundaries crossed)) % 15

  else it would be equal to *SN* field.
- ***NCO***: Next Chip Offset. The value of this field would be:

  NCO = (*CO* + *CL*) % 38400

These statuses can be used as configuration inputs for the next BD (if required).

26.4.3.3.9 eFTPE Processing

The following sections describe the different aspects of the eFTPE processing.

26.4.3.3.9.1 eFTPE Algorithm

The FFT/DFT transformation is calculated using a mixed Radix algorithm. This algorithm is based on DIF (Decimation In Frequency) partitioning of the transform length into 2 or more operands whose multiplication equals the transform length.

The following figures show an example of Mixed Radix DIF (Decimation in Frequency) partitioning of a transform length 24 into three stages[1]. During the first stage the eFTPE executes DFT-4 using its Radix-4 module; during the second stage the eFTPE executes DFT-3 using its Radix-3 module; and in the third and last stage, it executes DFT-2 using its Radix-2 module. **Figure 26-54** describes the mathematics of stage 0 partitioning into DFT-4 and DFT-6:

1. This example is for explanatory purposes only, not representing exactly the implementation of DFT24 in eFTPE.

$$X(k) = \sum_{n=0}^{N-1} x(n) \cdot e^{-j\frac{2\pi nk}{N}} \qquad k = 0, \ldots, N-1$$

$$X(k) = \sum_{n=0}^{23} x(n) \cdot e^{-j\frac{2\pi nk}{24}} = \sum_{n=0}^{5} x(n) \cdot e^{-j\frac{2\pi nk}{24}} + \sum_{n=6}^{11} x(n) \cdot e^{-j\frac{2\pi nk}{24}} + \sum_{n=12}^{17} x(n) \cdot e^{-j\frac{2\pi nk}{24}} + \sum_{n=18}^{23} x(n) \cdot e^{-j\frac{2\pi nk}{24}}$$

$$= \sum_{n=0}^{5} x(n) \cdot e^{-j\frac{2\pi nk}{24}} + \sum_{n=0}^{5} x(n+6) \cdot e^{-j\frac{2\pi nk}{24}} \cdot e^{-j\frac{\pi k}{2}} + \sum_{n=0}^{5} x(n+12) \cdot e^{-j\frac{2\pi nk}{24}} \cdot e^{-j\pi k} + \sum_{n=0}^{5} x(n+18) \cdot e^{-j\frac{2\pi nk}{24}} \cdot e^{-j\frac{3\pi k}{2}}$$

$$= \sum_{n=0}^{5} \{x(n) + (-j)^k x(n+6) + (-1)^k x(n+12) + (j)^k x(n+18)\} \cdot e^{-j\frac{2\pi nk}{24}}$$

$$X(4k) = \sum_{n=0}^{5} \{x(n) + x(n+6) + x(n+12) + x(n+18)\} \cdot e^{-j\frac{2\pi nk}{6}}$$

$$X(4k+1) = \sum_{n=0}^{5} [x(n) - jx(n+6) - x(n+12) + jx(n+18)] \cdot e^{-j\frac{2\pi n}{24}} \cdot e^{-j\frac{2\pi nk}{6}}$$

$$X(4k+2) = \sum_{n=0}^{5} [x(n) - x(n+6) + x(n+12) - x(n+18)] \cdot e^{-j\frac{4\pi n}{24}} \cdot e^{-j\frac{2\pi nk}{6}}$$

$$X(4k+3) = \sum_{n=0}^{5} [x(n) + jx(n+6) - x(n+12) - jx(n+18)] \cdot e^{-j\frac{6\pi n}{24}} \cdot e^{-j\frac{2\pi nk}{6}}$$

DFT 6 DFT 4 Twiddles DFT 6

Figure 26-54. Example Mixed Radix Partitioning of Transform Length 24 (First Stage Mathematics)

Figure 26-55 shows the first stage partitioning implementation:

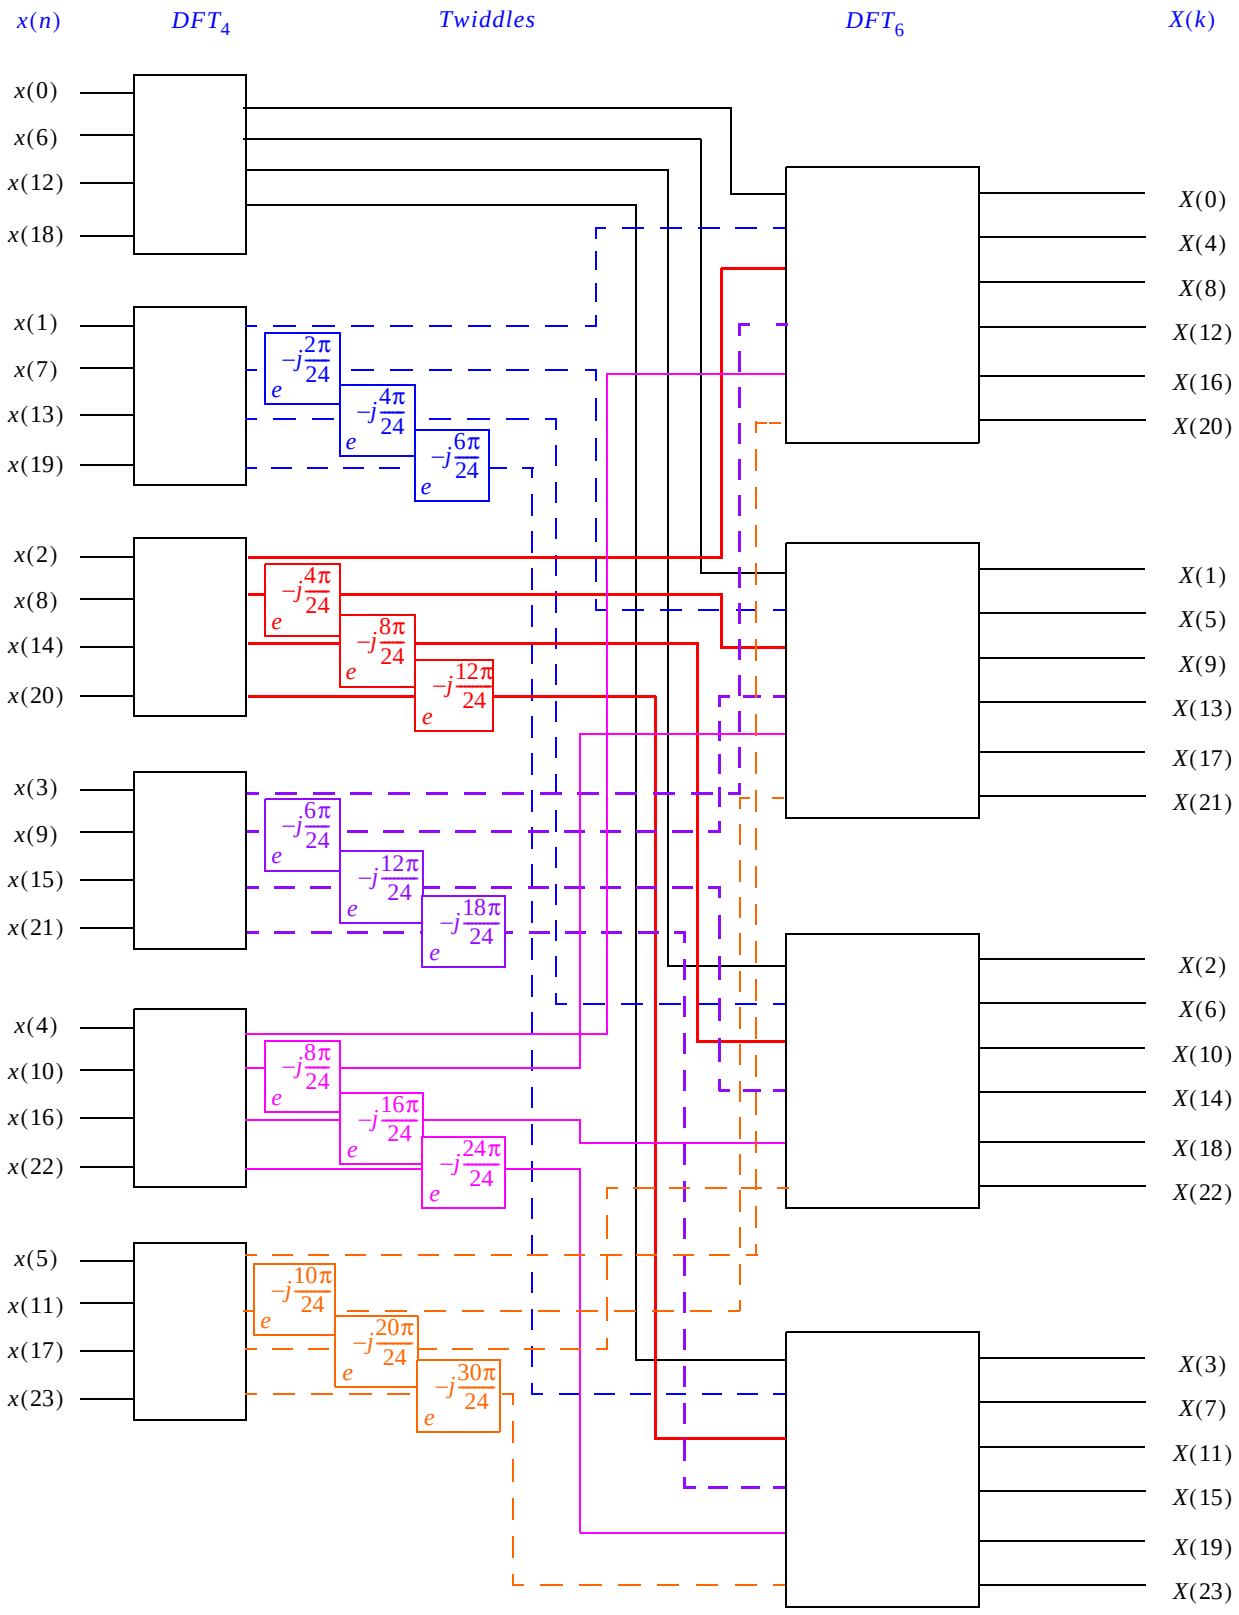

Figure 26-55. Example Mixed Radix Partitioning of Transform Length 24 (First Stage Implementation)

Figure 26-56 describes the second and third stage partitioning into DFT-3 and DFT-2, which are executed using the Radix-3 and Radix-2 modules, respectively

$$X(k) = \sum_{n=0}^{5} x(n)\cdot e^{-j\frac{2\pi nk}{6}} = \sum_{n=0}^{1} x(n)\cdot e^{-j\frac{2\pi nk}{6}} + \sum_{n=2}^{3} x(n)\cdot e^{-j\frac{2\pi nk}{6}} + \sum_{n=4}^{5} x(n)\cdot e^{-j\frac{2\pi nk}{6}}$$

$$= \sum_{n=0}^{1} x(n)\cdot e^{-j\frac{2\pi nk}{6}} + \sum_{n=0}^{1} x(n+2)\cdot e^{-j\frac{2\pi nk}{6}}\cdot e^{-j\frac{4\pi k}{6}} + \sum_{n=0}^{1} x(n+4)\cdot e^{-j\frac{2\pi nk}{6}}\cdot e^{-j\frac{8\pi k}{6}}$$

$$= \sum_{n=0}^{1}\left\{x(n) + x(n+2)\cdot e^{-j\frac{2\pi k}{3}} + x(n+4)\cdot e^{-j\frac{4\pi k}{3}}\right\}\cdot e^{-j\frac{2\pi nk}{6}}$$

$$X(3k) = \sum_{n=0}^{1}\{x(n) + x(n+2) + x(n+4)\}\cdot(-1)^{nk}$$

$$X(3k+1) = \sum_{n=0}^{1}\left\{\left[x(n) + x(n+2)\cdot e^{-j\frac{2\pi}{3}} + x(n+4)\cdot e^{-j\frac{4\pi}{3}}\right]\cdot e^{-j\frac{2\pi n}{6}}\right\}\cdot(-1)^{nk}$$

$$X(3k+2) = \sum_{n=0}^{1}\left\{\left[x(n) + x(n+2)\cdot e^{-j\frac{4\pi}{3}} + x(n+4)\cdot e^{-j\frac{8\pi}{3}}\right]\cdot e^{-j\frac{4\pi n}{6}}\right\}\cdot(-1)^{nk}$$

DFT 2 DFT 3 Twiddles DFT 2

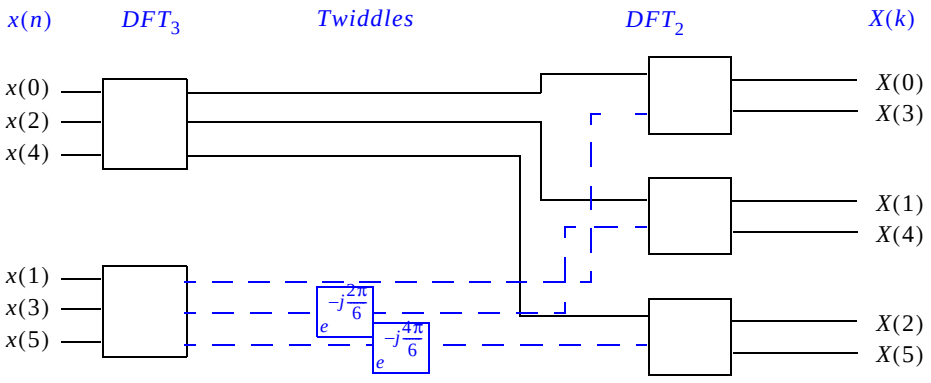

Figure 26-56. Example Mixed Radix Partitioning of Transform Length 24 (Second and Third Stage Mathematics)

26.4.3.3.9.2 Inverse Transform Processing

The eFTPE can calculate an Inverse transform. Calculating an Inverse Fourier transform is identical to calculating a Fourier transform except that in the Inverse Fourier transform the multiplication factor is $e^{j\frac{2\pi nk}{N}}$ instead of $e^{-j\frac{2\pi nk}{N}}$ as in the Fourier transform.

To calculate the Inverse Fourier transform, the *ITE* (Inverse Transform Enable) bit in the eFTPE BD must be set.

26.4.3.3.9.3 Transform Length Partitioning

For each possible DFT/iDFT/FFT/iFFT transform length (as listed in **Section 26.2**, *MAPLE-B2 Features*) the eFTPE has a fixed partitioning algorithm, which determines the number of partitioning stages, the order of the stage execution, and the Radices used for each stage.

The implemented Radices in the eFTPE are: Radix- 8, Radix- 5, Radix- 4 and Radix- 3.

The Transform Length of each job is determined in the *TL_ID* field of the eFTPE BD (see **Table 26-246**).

Table 26-26 describes the partitioning of all the possible DFT transform lengths of the eFTPE. Each stage column describes the executed Radix for that stage.

Table 26-26. Partitioning Path for Supported DFTPE Transforms

Transform Length	Stage 0	Stage 1	Stage 2	Stage 3	Stage 4	Stage 5
12	4	3				
24	8	3				
36	4	3	3			
48	4	4	3			
60	5	4	3			
72	8	3	3			
96	8	4	3			
108	4	3	3	3		
120	8	5	3

26.4.3.3.9.4 eFTPE Internal Scaling Calculations

The eFTPE supports two main types of scaling methods, which are applied in between the DFT/FFT calculation stages and are targeted to reduce or eliminate the need to saturate samples to avoid overflow.

The scaling methods are:

- User Defined Scaling
- Adaptive Scaling

Along with these two scaling methods, which are applied during the transform processing, there are additional parameters which affect to total scaling calculations in the eFTPE:

- Overall Scaling Amount Configuration. Allows to align the final scaling results during Adaptive Scaling mode to a required value. For more see **Section 26.4.3.3.9.4.4**, *Overall Scaling Amount Programming*.
- Input Exponent. Allows inputting the eFTPE with the input exponent (scale) value of the current job. Used by the eFTPE when calculating the Overall Scaling. For details see **Section 26.4.3.3.9.4.5**, *Input Exponent*
- User Defined Input Scaling. Allows to up-scale the input samples by a configurable number. For details see **Section 26.4.3.3.9.4.6**, *User Defined Input Scaling*
- Adaptive Input Scaling. If enabled the eFTPE performs maximal up scale of all the input samples to maximize precision and avoid overflow. for details see **Section 26.4.3.3.9.4.7**, *Adaptive Input Scaling*.
- Extra Scaling. Allows incrementing the final scale results (exponent value) during Adaptive Scaling mode on the expenses of the output samples data (mantissa). for details see **Section 26.4.3.3.9.4.8**, *Extra Scaling*.

Some of the above scaling configurations may results in internal overflow of the samples data (mantissa) and therefore requires saturation. For details see **Section 26.4.3.3.9.4.9**, *Saturation*.

26.4.3.3.9.4.1 Scaling During Internal Radix Calculations.

In the eFTPE implementation, each Radix module inputs a different number of bits. The number of input bits to each Radix depends on the maximum bit expansion of the Radix. The number of output bits of all the Radix stages is 20, with data representation of 5q15[1]. The number of input bits to each Radix stage is described in **Table 26-27**.

Table 26-27. Input Bits per Radix

Radix	Input Bits	Input data representation
3	17	2q15
4	17	2q15
5	16	1q15
8	16	1q15

1. The (x)q(y) representation indicates the location of the mathematical point where all the bits to its right represent the fraction and all the bits to it left represent the integer. For example 2q15 means 2 bits left of the mathematical point (one sign bit and one integer bit) and 15 fractional bits.

26.4.3.3.9.4.2 User Defined Scaling

Given the information on the number of input and output bits for each Radix (**Table 26-27**), and the Radix stage order for each transform length (**Table 26-26**), the eFTPE can be programmed to execute down scaling after each stage according to user programming, to prevent the need to saturate overflown samples. To enable User Defined Scaling, the *SCL_TYPE* bit in the eFTPE BD must be set. Using the *USR_SCLx* (x = 0... 5) fields, the *PM_SCL* field and the *PO_SCL* field of the eFTPE BD, the eFTPE can be programmed to execute down scaling after each of the possible stages. For example, by assigning a value to *USR_SCL0*, the eFTPE performs down scaling on the output of the Radix which was applied during stage 0 with the scaling factor in the *USR_SCL0*.

The *USR_SCLx* fields can be programmed with values from 0 to 4 as the amount of down scaling to be performed. The *PM_SCL* field can be programmed with values of 0 or 1 as the potential down scaling after the pre-multiplication processing (see **Section 26.4.3.3.5.1**, *Pre-Multiplication Processing Support in the eFTPE*) is 1. The *PO_SCL* field can be programmed with values of 0 to 2 as the potential down scaling after the post-multiplication processing (see **Section 26.4.3.3.5.2**, *Post-Multiplication processing support in the eFTPE*) is 2.

26.4.3.3.9.4.3 Adaptive Scaling

In Adaptive Scaling mode the eFTPE performs down scaling after each processing stage if needed. The amount of scaling applied after each processing stage is the minimum down scaling necessary to prevent overflow of any of the samples during the next processing calculation.

To enable Adaptive Scaling, the *SCL_TYPE* bit of the eFTPE BD must be cleared.

The total amount of down or up scaling performed by the eFTPE during the transform processing using Adaptive Scaling mode is accumulated and then written to the *ADP_OVA_SCL_ST* field of the eFTPE BD.

If *BD_RPT* is enabled, which means more than one task for a single BD, the total overall scaling amount for all the jobs is transferred to system memory to the address pointed to by the *BD_STAT_PTR* field in the eFTPE BD as described in **Section 26.4.3.3.2**, *BD Repeat Option*.

Figure 26-57 shows an example of data flow through the Radices and scaling stages with respect to the number of bits at the input to each Radix stage. The execution of the example is explained for each stage:

1. 16 bits of data from the input buffer are scaled up by 5 according to the input scaling configuration (see **Section 26.4.3.3.9.4.6**, *User Defined Input Scaling*)
2. The 16 bits after input scaling are sign-extended to 17 bits as required for the Radix 3 stage input.
3. The output of the Radix 3 is a 20 bit sample.
4. Since the next stage performs Radix 2, the output samples of the current Radix (Radix 3) are scaled down by 2 bits to fit the Radix 2 input size (18 bits).

5. To fit the 16 bits output requirement, the 20 bit results of the Radix 2 as described in **Figure 26-57** are scaled down by 1 bit and the 3 msbs are removed (since the 4 msbs are identical the eFTPE consider the 3 msbs as sign extension).

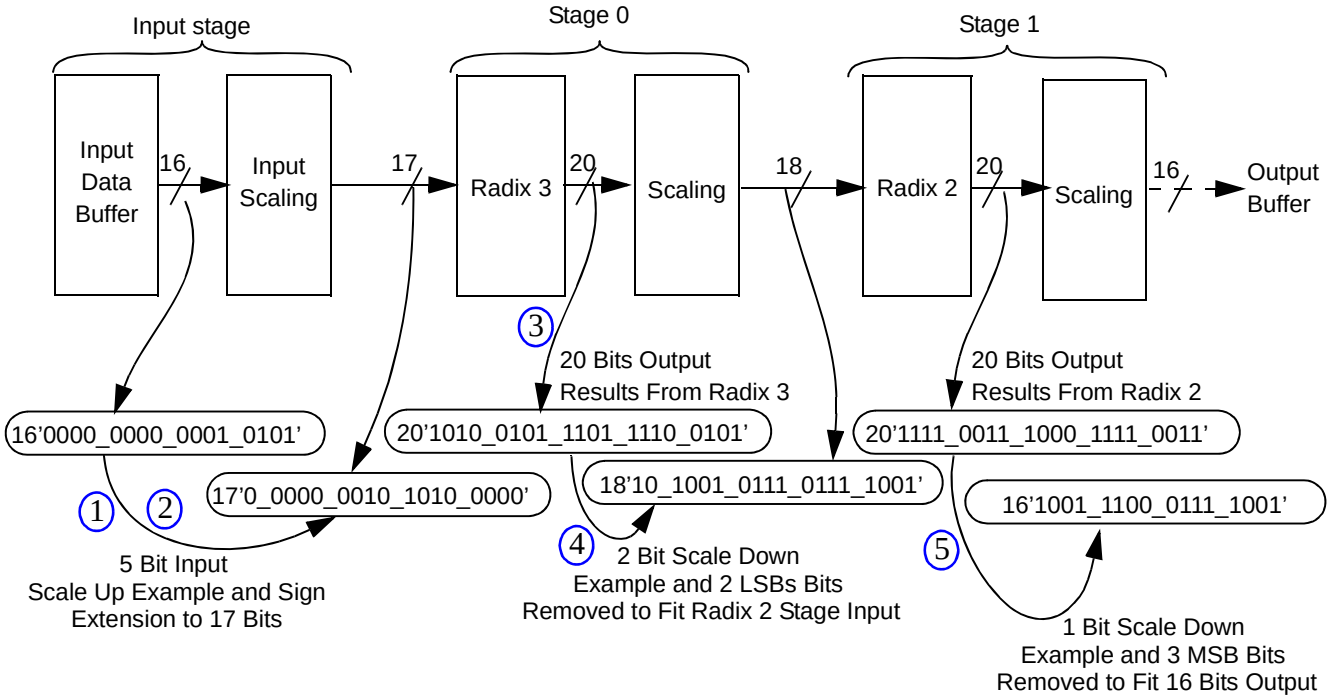

Figure 26-57. Input Scaling Example and Stage Scaling Example (Adaptive or User Defined)

Note: The previous example describes a partitioning of transform length of 6 (3x2), which is not a supported transform length of the eFTPE. The example is for explanation only.

26.4.3.3.9.4.4 Overall Scaling Amount Programming

The host can define the overall amount of scaling to be applied during the transform processing when using Adaptive Scaling mode. If enabled, the eFTPE adjusts its accumulated scaling amount to the Overall Scaling factor programmed by the host. The scaling the eFTPE applies at the end of the transform to fit the overall scaling factor can be either up-scaling or down-scaling. For example, if the accumulated adaptive scaling of a given transform is 6 (down scaling), and the required Overall Scaling is 4 (down scaling), the eFTPE upscales the final results by 2. If the required Overall Scaling is 8 (down scaling), the eFTPE downscales the final results by 2.

To enable the Overall Scaling factor, the *OVA_SCL* bit in the eFTPE BD must be set, and the *ADP_OVA_SCL* field in the eFTPE BD, must contain the Overall Scaling factor. If Overall Scaling is enabled, the *ADP_OVA_SCL_ST* status indications in the eFTPE BD is equal to the *ADP_OVA_SCL* field of the eFTPE BD, since the later determines the overall scaling which is applied during the transform processing.

26.4.3.3.9.4.5 Input Exponent

In general, the eFTPE assume the block floating point scale value (exponent) of the input data is zero. It is possible to define any other input block floating point scale (exponent) value by configuring the *INP_EXP_PTR* field (bits [31:24]) of the eFTPE BD. This scale value is used as the base scale value for the calculations of the Adaptive Overall Scaling Status calculations as described in **Section 26.4.3.3.9.4.3**, *Adaptive Scaling*, that is, the internal accumulated scaling in the eFTPE is added to the input exponent value configured in the *INP_EXT_PTR* field and reported to the *ADP_OVA_SCL_ST*.

If Overall Scaling Amount Programming is used (see **Section 26.4.3.3.9.4.4**, *Overall Scaling Amount Programming*), the eFTPE add the configurable exponent value (configured in the *INP_EXP_PTR* field of the eFTPE BD) to the total Overall Scaling Amount required to calculate the required alignment of the output results. For example, if the configured Input Exponent is 2, the internal eFTPE scaling result is 4 and the required Overall Scaling amount is 8, then the eFTPE aligns the output results by additional 2 to reach the required results.

If BD Repeat option is enabled (*BD_RPT* > 0), the eFTPE allows different Input Exponent values for each of the input blocks. As the eFTPE BD can not include all the Input Exponent values of all the potential tasks of the BD (up to 128), the *INP_EXP_PTR* field should contain an address pointer to the system memory where the Input Exponent values of all the tasks of the BD should be placed. The MAPLE-B2 expect to find the Input Exponent values (8 bits value) of all the tasks of the BD as described in the following figure:

Figure 26-58. Input Exponent Vector in Case of BD Repeat

By setting the value of the *INP_EXP_PTR* to zero, the MAPLE-B2 assume that the input scale value of all the tasks in this repeat job is zero.

26.4.3.3.9.4.6 User Defined Input Scaling

This feature is relevant for input data to the eFTPE that is characterized as small value samples which, with additional scale up, results in more precise output results.

The eFTPE can be programmed to scale up the input data by up to 2^{15} (15 left shifts). This is done by configuring the *IN_SCL* field of the eFTPE BD with values between 1 to 15. The value of 0 means no input scaling is performed. If overflow occurs due to input scaling, the eFTPE uses the largest/smallest number possible (sign dependent), instead of the overflown sample.

User Defined Input scaling can only up scale (shift left) the input data.

The User Defined Input Scaling value, if enabled, is also included in the final Adaptive Overall Scaling Status indication reported in the *ADP_OVA_SCL_ST* field of the eFTPE BD. For example, if the User Defined Input Scaling value configuration is 3, that is, the input data samples (mantissa) are being shift left by 3 bits (up scale), and the total scaling accumulated in the processing is 1 (down scale), the reported Adaptive Overall Scaling Status is “-2”.

If Overall Scaling Amount is enabled (see **Section 26.4.3.3.9.4.4**, *Overall Scaling Amount Programming*), the User Defined Input Scaling value is also included in the total Scaling calculation required to reach the required Scale value as configured in the *ADP_OVA_SCL* field of the eFTPE BD. The following example describe the internal eFTPE scaling calculation:

Assuming:

- Input Exponent value (*INP_EXP_PTR*) is 4.
- User Defined Input Scaling value (*IN_SCL*) is 2.
- Internal eFTPE processing scaling results is 3.

The Adaptive Overall Scaling Status would be: 4 - 2 + 3 = 5

Note: On the MAPLE-B, used in the MSC8156 devices, the Input Scaling value, if enabled, was not included in the final Adaptive Overall Scaling Status nor in the Overall Scaling Amount (if enabled). To keep backwards compatibility with the MAPLE-B block, an additional bit is added to the eFTPE Configuration Register (see EFTPE_<x> Configuration Register (FTPE<x>CR): *BCIS*. If set, the eFTPE does not include the Input Scaling configuration in either the final Adaptive Overall Scaling Status or the Overall Scaling Amount (if enabled).

26.4.3.3.9.4.7 Adaptive Input Scaling

In additional to the User Defined Input Scaling (see **Section 26.4.3.3.9.4.6**, *User Defined Input Scaling*), the eFTPE supports automatic increment of the scale value of the input data samples to reach maximum precision during the calculations. By setting the *AIUS* bit of the eFTPE BD, the eFTPE adaptively up-scales the input data samples thus gaining maximum precision during calculations. Up scaling of the input samples means finding the maximum allowed shift-left operations to be executed on each of the input samples so that none of the samples is overflown thus saturated. Note that this automatic increment of the scale values is limited to 9 bits only.

The Adaptive Input Scaling, if enabled, is also included in the final Adaptive Overall Scaling Status indication reported in the *ADP_OVA_SCL_ST* field of the eFTPE BD. For example, if the eFTPE has up-scaled the input samples by 3 (due to enabling the Adaptive Input Scaling), that is, the input data samples (mantissa) are shift left by 3 bits (up scale) to reach maximum precision, and the total scaling accumulated in the processing is 1 (down scale), the reported Adaptive Overall Scaling Status is -2.

If Overall Scaling Amount is enabled (see **Section 26.4.3.3.9.4.4**, *Overall Scaling Amount Programming*), the Adaptive Input Scaling value is also included in the total Scaling calculation required to reach the required Scale value as configured in the *ADP_OVA_SCL* field of the eFTPE BD

26.4.3.3.9.4.8 Extra Scaling

In general, when using Adaptive Input Scaling (*AIUS*=1) with Adaptive Scaling (*SCL_TYPE*=0) with Overall Scaling Amount disabled (*OVA_SCL*=0), the eFTPE output data samples are normalized, that is, at least one of the real or imaginary parts of one of the samples begin with 01 (for positive value) or 10 (for negative values). To allow complex scaling schemes (see **Section 26.4.3.3.2**, *BD Repeat Option*), the eFTPE supports increasing the scale value by up to 2 while shifting right the mantissa value by up to 2. To enable the Extra Scaling, configure the *EXS* field of the eFTPE BD with the required number (0 to 2). **Figure 26-59** describe an example of the Extra Scaling functionality:

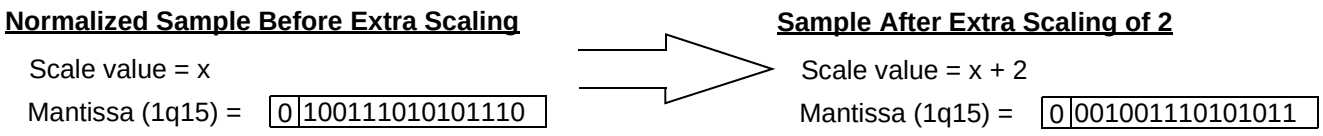

Figure 26-59. Extra Scaling Functionality Example

The Extra Scaling, if enabled, is also included in the final Adaptive Overall Scaling Status indication reported in the *ADP_OVA_SCL_ST* field of the eFTPE BD. For example, if the total accumulate scaling of the internal eFTPE processing is 6 and the Extra Scaling configuration is set to 1, the reported Adaptive Overall Scaling Status in the *ADP_OVA_SCL_ST* field is 7 and the samples mantissas are right shifted by one.

26.4.3.3.9.4.9 Saturation

When using User Defined Input scaling (see **Section 26.4.3.3.9.4.6**, *User Defined Input Scaling*) or User Defined Scaling (see **Section 26.4.3.3.9.4.2**, *User Defined Scaling*) or Overall Scaling (see **Section 26.4.3.3.9.4.4**, *Overall Scaling Amount Programming*), some of the data samples may overflow due to the internal calculations. To avoid the overflow, the eFTPE uses the largest/smallest number possible (depending on the sign bit) instead of the overflown sample. This is called saturation. When such saturation event occur, an indication bit is set by MAPLE-B2 in the *CMP_RSN* status field of the eFTPE BD (see **Section 26.4.3.3.11**, *eFTPE Status Indications*).

26.4.3.3.10 eFTPE Initialization Configuration

After the MAPLE-B2 initialization (see *MAPLE-B Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)), initialize the following eFTPE configuration registers:

26.4.3.3.10.1 eFTPE Configuration Register

The EFTPE_<x> Configuration Register (FTPE<x>CR) includes basic eFTPE configuration fields that must be initialized once for each eFTPE instance (after MAPLE-B2 initialization) and remain unchanged for the whole operation duration. The relevant configuration fields are:

- ***BCIS*** - Backward Compatible Input Scaling indication. Determines whether the User Defined Input Scaling (see **Section 26.4.3.3.9.4.6**, *User Defined Input Scaling*) is included in the Overall Scaling Amount calculations (see **Section 26.4.3.3.9.4.4**, *Overall Scaling Amount Programming*) and in the Adaptive Overall Scaling Status indication. In the MAPLE-B of the MSC8156 family of devices the User Defined Input Scaling was not included in the Overall Scaling Amount calculations and in the Adaptive Overall Scaling Status indication. If backward compatibility is required with respect to these features, set this field.
- ***BC*** - Buffers Configuration Indication. In general, each eFTPE instance includes a pre-multiplier input buffer, Apost-multiplier input buffer and an output buffer. In some applications, where vector pre-multiplication or vector post multiplication are not required, it is possible to configure the eFTPE to use the redundant buffer for other usage to boost eFTPE performance. The following buffer usage configurations are allowed after MAPLE-B2 initialization:
  - (BC = 0): Single Pre-Multiplier buffer, Single Post Multiplier Buffer and Single Output buffer.
  - (BC = 1): Single Pre-Multiplier buffer, no Post Multiplier buffer and Double Output buffer.
  - (BC = 2): No Pre-Multiplier buffer, single Post Multiplier Buffer and Double Output buffer.
  - (BC = 4): No Pre-Multiplier buffer, Double Post Multiplier Buffer and Single Output buffer.

In general, allowing double buffer for the Post Multiplication Input Buffer or for the Output buffer may in some cases boost the eFTPE total performance. It allows more flexibility to the MAPLE-B2 and reduces the time at which the eFTPE is halted due to waiting for the next post multiplication input data or due to waiting for the output buffer to be empty by the MAPLE-B2 DMA. Enabling double buffer does not require any change in the eFTPE programming model as is handled internally by the MAPLE-B2.

Note: If Frequency Correction is scheduled to be enabled as post-multiplication (*FC*=1 and *FCPRE*=0), then the post-multiplication buffer must be allocated in the *BC* configuration (*BC* = 0,2,4) because the FC is using the post-multiplication buffer to maintain the FC samples before multiplying them with the processed data.

Note: Enabling a double post multiplication buffer is highly recommended when frequent change of the post multiplication vector is required.

Note: If either vector pre-multiplication is not required or vector post-multiplication is not required, it is recommended to work with any of the double output buffer configurations thus increasing eFTPE performance.

26.4.3.3.10.2 Data Size Registers

The Data Size Registers (see **Section 26.5.5.3.1** to **Section 26.5.5.3.3**) holds the values of the data for the Guard band Insertion. If working with fixed values per Transform Length then it is recommended to initialize these values during the eFTPE initialization. If different data values are required for each job, it can be implemented by working with the Data Size parameters (see **Section 26.5.3.3.1**, *eFTPE Data Size Set x Parameter 0 (FTPEDSSxP0)* to **Section 26.5.3.3.3**, *eFTPE Data Size Set x Parameter 2(FTPEDSSxP2)*) as described in **Section 26.4.3.3.4.1.1**, *Guard Band Insertion for iFFT*. In that case there is no need to initialize these registers.

26.4.3.3.11 eFTPE Status Indications

The eFTPE BD has the following status indicators which are fetched from the eFTPE after each BD completion.

- *CMP_RSN* —This field in the eFTPE BD describes the status of the completed job. It indicates whether the job completed OK or completed with saturation events during the processing.
- *ADT_OVA_SCL_ST* —This field in the eFTPE BD describes the Adaptive Overall Scaling accumulated in the current job. For details see **Section 26.4.3.3.9.4**, *eFTPE Internal Scaling Calculations*
- *NNPIS*—This field in the eFTPE BD is valid only if Code Generation is enabled. It describes the next number of pilot state for pilot generation. For details see **Section 26.4.3.3.8.6**, *Code Generation Status*
- *NSGO*—This field in the eFTPE BD is valid only if Code Generation is enabled. It describes the next slot generation off period for pilot generation. For details see **Section 26.4.3.3.8.6**, *Code Generation Status*.
- *NSN*—This field in the eFTPE BD is valid only if Code Generation is enabled. It describes the next slot number for pilot generation. For details see **Section 26.4.3.3.8.6**, *Code Generation Status*
- *NCO*—This field in the eFTPE BD is valid only if Code Generation is enabled. It describes the next chip offset for pilot generation. For details see **Section 26.4.3.3.8.6**, *Code Generation Status*
- *FCF_REAL_ST*—This field in the eFTPE BD is valid only if Frequency Correction is enabled. It describes the frequency correction real part after job ends. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*

- *FCF_IMAG_ST*—This field in the eFTPE BD is valid only if Frequency Correction is enabled. It describes the frequency correction imaginary part after job ends. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*
- *SCOS*—This field in the eFTPE BD is valid only if Frequency Correction is enabled. It describes the step counter state after job completion.

26.4.3.3.12 eFTPE ECC Support

As part of the MAPLE-B2 ECC support (see **Section 26.4.3.1.1, *Memory Error Correction/Detection Support***), the eFTPE include a status register which specify the exact memory module in which the ECC error has occurred.

If the general ECC error indication of the MAPLE-B2 is asserted, and by reading the PSIF PIC Event Register 2 (PSPICER2), an eFTPE instance ECC indication bit is asserted, it means that the source of the ECC error is in that certain eFTPE instance. Reading the EFTPE_<x> ECC Interrupt Status Register (FTPE<x>ECCISR) gives indication as to which internal eFTPE memory was the source of the ECC error. Resetting an eFTPE ECC error bit indication is done by writing ‘1’ to the relevant bit.

The following steps indicate the required actions to identify the source of the ECC interrupt:

1. Read the PSIF PIC Event Register 2 (PSPICER2) to detect which PE is the source of the ECC interrupt
2. If any of the EFxECC bits is asserted than the source of the ECC interrupt is in one of the eFTPEs.
3. Read the relevant FTPExECCISR register to identify the exact memory module which was the source of the ECC interrupt.

To reset the ECC interrupt, the following action must occur:

1. Clear the ECC error bit indications in the EFTPE_<x> ECC Interrupt Status Register (FTPE<x>ECCISR) by writing ‘1’ to the relevant bits.
2. Clear the *EFxECC* error bit from the PSIF PIC Event Register 2 (PSPICER2) by writing ‘1’ to the bit.

26.4.3.4 DEPE Downlink Turbo Encoding Operation

The MAPLE-B2 supports Turbo Encoding and Rate-Matching for each of its operation modes as described in **Section 26.2**, *MAPLE-B2 Features* using the Downlink Encoder Processing Element (DEPE).

26.4.3.4.1 DEPE Buffer Descriptors and Header Structures

The DEPE uses BDs to configure the general DEPE operation. In addition, the DEPE uses header structures to specialize the operations for 3GLTE, WiMAX, and UMTS operations. DEPE buffer descriptors are described in detail in **Section 26.5.4.4.1**, *DEPE Buffer Descriptor Structure*, on page 26-439. The header structures are described as follows:

- 3GLTE, see **Section 26.5.4.4.3.1**, *DEPE Header Structure for 3GLTE*, on page 26-448.
- WiMAX, see **Section 26.5.4.4.3.2**, *DEPE Header Structure for WiMAX (802.16e)*, on page 26-450. and **Section 26.5.4.4.3.3**, *DEPE Header Structure for WiMAX (802.16m)*, on page 26-452
- UMTS, see **Section 26.5.4.4.3.4**, *DEPE Header Structure for UMTS*, on page 26-454.

26.4.3.4.2 DEPE Multiple Headers (tasks) in single BD support

To reduce host BD write overhead and to enhance its encoding throughputs performance, the MAPLE-B2 is capable of receiving several CB encoding tasks in a single BD. By configuring the [NOH] field of the DEPE BD to any number greater than zero (up to 32 tasks), the MAPLE-B2 assumes multiple CB encoding tasks are assigned for the current BD. Due to BD fixed size limitations, it can not include multiple tasks Headers, therefore the MPALE-2B expect to find the concatenated tasks Headers in the system memory at the address pointed by the [HBA] field of the DEPE BD. **Figure 26-60** describe an example of the expected Headers data structure in the system memory with respect to the standard.

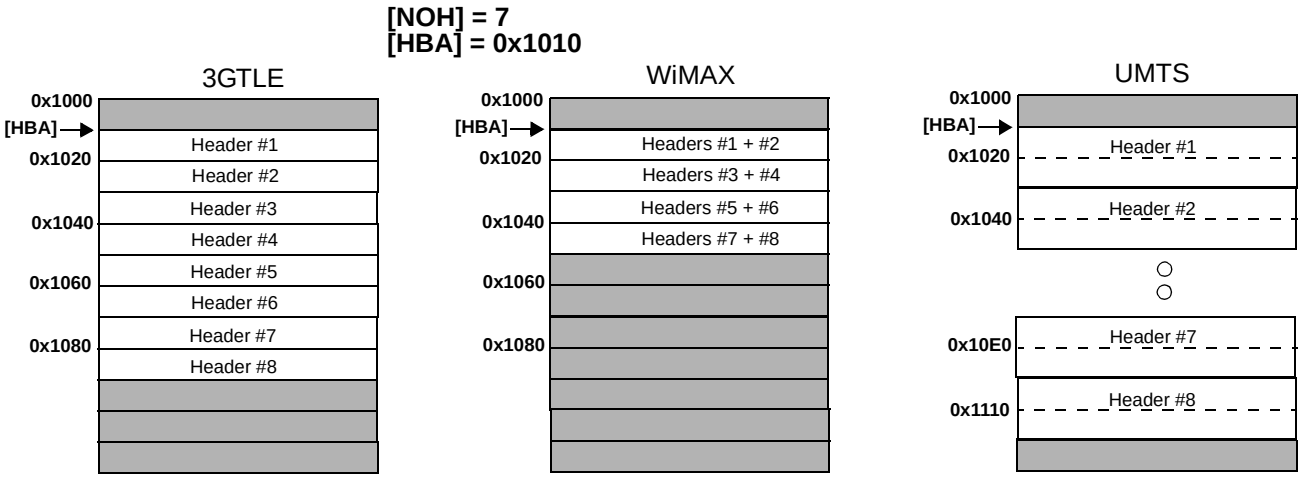

Figure 26-60. Expected Concatenated Headers in System Memory

Due to DEPE input buffer size limitation and to maintain internal pipeline between DEPE jobs, the total size of the tasks (Headers + data) in multiple task BD must not exceed 100 lines of 64 bits (or 800 bytes). Due to the different Header sizes for each standard, this limitation impose

different maximum number of tasks allowed for each of the standards. **Table 26-28** describe the maximum number of allowed tasks for each standard assuming minimal Code Block size.

Table 26-28. Maximum number of allowed tasks (Header + Data)

Technology	Minimum Code Block Size	Maximum Number of tasks in BD
WiMAX	48	32
UMTS	40	20
3G-LTE	40	32

- The expected data structure of the input data in case of multiple task BD is described in **Section 26.4.3.4.4.2**, *Input Data Structure for Multiple Tasks*.
- The data structure of the output data in case of multiple task BD is described in **Section 26.4.3.4.6.2**, *Output Data Structure for Multiple Tasks*
- The data structure of the status fields in case of multiple task BD is described in **Section 26.4.3.4.5.1**, *3GLTE Processing*.

26.4.3.4.3 [LH] Indication in DEPE Header

Each DEPE Header includes a Last Header ([LH]) indication bit. This bit indicates the DEPE whether the current Header is the last Header in the current BD. This bit must be configured as follows: if the current BD includes single DEPE Header ([NOH] = 0), the [LH] bit of this single Header must be set. If the current BD includes multiple Headers ([NOH] > 0), only the [LH] bit of the last Header must be set while the [LH] bit of all previous Headers must be reset.

26.4.3.4.4 DEPE Input Data Structure

The DEPE expected inputs are data bits to be encoded and rate matched. The [IBA] field of DEPE BD points to the address in the system memory where the MAPLE-B2 is to fetch the input data stream into the DEPE. The address pointed by [IBA] must be 4 bytes aligned.

The [IBS] field of the DEPE BD describe the total number of 4 bytes words which should be fetched by the MAPLE-B2 into the DEPE input buffer. As the DEPE input buffer is 64 bit aligned, the straightforward calculation for the [IBS] field is:

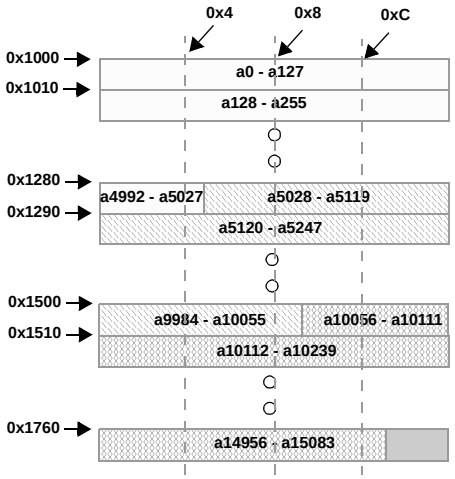
```
[IBS]= 2 * roundup([Code Block Size]/ 64)
```

Due to the multiple tasks support and to the input buffer offset support, the total number of 4 bytes words which should be fetched by MAPLE-B2 may not always be calculated straightforward. For details, see **Section 26.4.3.4.4.2**, *Input Data Structure for Multiple Tasks* and **Section 26.4.3.4.4.1**, *Input Buffer Offset Support (3GLTE and UMTS only)*.

26.4.3.4.4.1 Input Buffer Offset Support (3GLTE and UMTS only)

The DEPE supports up to 31 bits offset of the input stream with respect to the input address pointed by [IBA] field of the DEPE BD. Configuring the [IBO] field of the DEPE Header instruct the DEPE at which offset of the first 4 bytes word the first valid bit of the current CB is located. Supporting this offset along with the 32 bits resolution support of the Input Base Address pointer [IBA] of the DEPE BD allows pointing on the input stream with resolution of a single bit, thus eliminating the need to align the input CBs after segmentation to 4 bytes aligned buffers.

Figure 26-61 describe an example of 15084 bits Transport Block (TB) located in system memory. After segmentation this TB is divided into 3 CB each of 5028 bits. The following figure describe how to configure the [IBA] and [IBO] fields of the DEPE BDs/Headers to direct MAPLE-B2 into each of the CBs.



# BD	[IBA]	[IBO]
1	0x1000	0x0
2	0x1284	0x4
3	0x1508	0x8

Figure 26-61. Input buffer bit resolution pointer example using [IBA] and [IBO] fields

The Input Buffer Offset field is valid only for single task BD. For multiple task BD it is assumed that each task is different TB therefore it is required to be 64 bits aligned in the system memory.

When Input Buffer Offset is set to a value different than 0x0, the [IBS] field should be calculated as follows:

```
[IBS]= 2 * roundup(([Code Block Size]+ [IBO]) / 64)
```

Note: For [IBS] calculations, the *Code Block Size* value should consider additional supplements added by the DEPE in some cases. For example, if CRC is enabled or if the [NOF] field is enabled then the actual code block size would be:

```
Code Block Size = Code Block Size - 24 - [NOF]
```

26.4.3.4.4.2 Input Data Structure for Multiple Tasks

When multiple tasks in a BD is enabled (by configuring [NOH] > 0), the MAPLE-B2 expect to find the input data buffers of all the tasks successively in the system memory. Since the DEPE internal input buffer is 64 bits width, each input data buffer of each task must be 64 bits aligned.

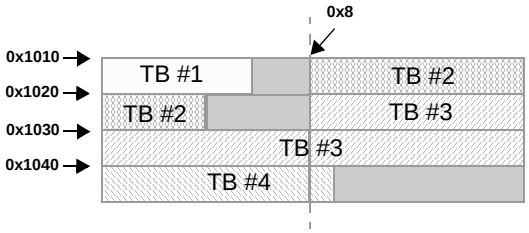
The expected Headers data structure for multiple tasks BD is described in **Section 26.4.3.4.2**, *DEPE Multiple Headers (tasks) in single BD support*.

When [NOH] is set to a value different than 0x0, the [IBS] field should be calculated as follows:

```
[IBS] =0;
for (i=0; i < [NOH]+1; i++)
      [IBS] = [IBS]+ [IBS[i]]
```

where $IBS_{[i]}$ is the Input Buffer Size of task [i].

Figure 26-62 describe an example of the expected input data structure for multiple tasks BD which includes multiple small Transport Blocks.



[NOH] = 3
[IBA] = 0x1010
[IBS] = 16

Task #	Task Size	[IBO]
1	40	0x0
2	96	0x0
3	192	0x0
4	72	0x0

Figure 26-62. Expected Input Buffer Data Structure for Multiple Tasks BD

Note: The above [IBS] calculations and expected input buffer data structure are not relevant when UMTS BD job is given with Transport Block indication ([TB] bit is set). In that case the expected input buffer is different and the [IBS] field is ignored. For details see **Section 26.4.3.4.5.4.6**, *UMTS Transport Block (TB) Support*.

26.4.3.4.5 DEPE Processing

The DEPE encoding and rate matching processing is different for each of the supported technologies. As per the current MAPLE-B2 operation mode, the DEPE uses the [STD] bit of the DEPE BD to determine if the job is of 3GLTE type ([STD] = 1), or of UMTS/WiMAX type ([STD] = 0). The following sections describe the DEPE encoding processing for each of the standards.

26.4.3.4.5.1 3GLTE Processing

The 3GLTE DEPE processing includes the following processing chain:

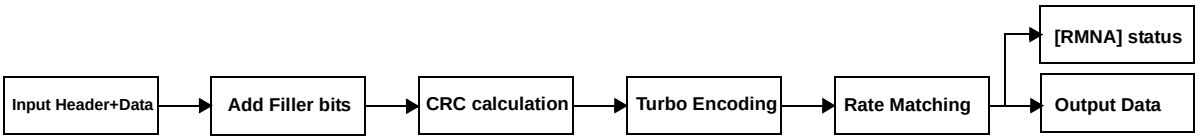


Figure 26-63. 3GLTE DEPE Processing chain

the block sizes allowed in the 3GLTE standards includes 188 possible types and varies from block size of 40 to block size of 6144. The Code Block size should be set in the [CBSI] field of the DEPE LTE Header according to the encoding described in **Table 26-263**.

26.4.3.4.5.1.1 Add Filler Bits

If the [NOF] field of the DEPE 3GLTE Header is greater than 0x0 the DEPE add [NOF] filler bits at the most significant bits of the first data line and concatenates the data block to the filler bits. **Figure 26-64** describe an example of the data buffer in the DEPE after adding the filler bits.

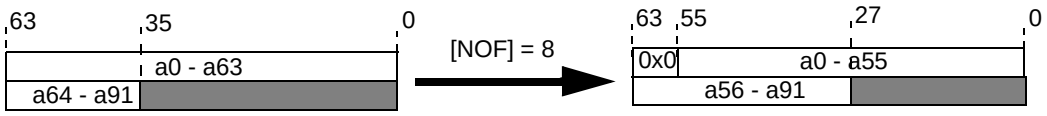

Figure 26-64. DEPE Data Buffer After Adding Filler Bits ([NOF]=8)

26.4.3.4.5.1.2 CRC Calculation

If the CRC Disable ([CD]) bit of the DEPE LTE Header is set, the CRC calculation is bypassed. If the [CD] bit of the DEPE LTE Header is reset, the CRC is calculated and attached to the end of the data block. The CRC machine is reset to zero for each new block encoded. The CRC Mode ([CM]) controls the CRC polynomial type as described in **Table 26-29**:

Table 26-29. 3GLTE CRC Polynomials

[CM] configuration	CRC SIZE	CRC TYPE	Polynomial
0	24	CRCA	$D^{24} + D^{23} + D^6 + D^5 + D + 1$
1	24	CRCB	$D^{24} + D^{23} + D^{18} + D^{17} + D^{14} + D^{11} + D^{10} + D^7 + D^6 + D^5 + D^4 + D^3 + D + 1$

26.4.3.4.5.1.3 Turbo Encoding

During Turbo Encoding process the data buffer is being encoded and forwarded to the Rate Matching process. The DEPE uses a binary encoder for the 3GLTE encoding as described in the 3GLTE standard. In addition the Turbo Encoding process uses a dedicated interleaver which interleaves the block according to the 3GLTE interleaving scheme. The 3GLTE interleaver scheme is selected for each block according to its size which is described in the [CBSI] field of the DEPE LTE Header.

26.4.3.4.5.1.4 Rate Matching

The 3GLTE Rate Matching process consists of the following steps:

1. Interleave the sub-block of each of the encoder output streams separately (systematic stream, 1^{st} parity stream and 2^{nd} parity stream).
2. Collect the 3 interleaved streams into a single virtual circular buffer
3. Select the output bits out of the virtual circular buffer.

Figure 26-65 describes the 3GLTE Rate Matching scheme:

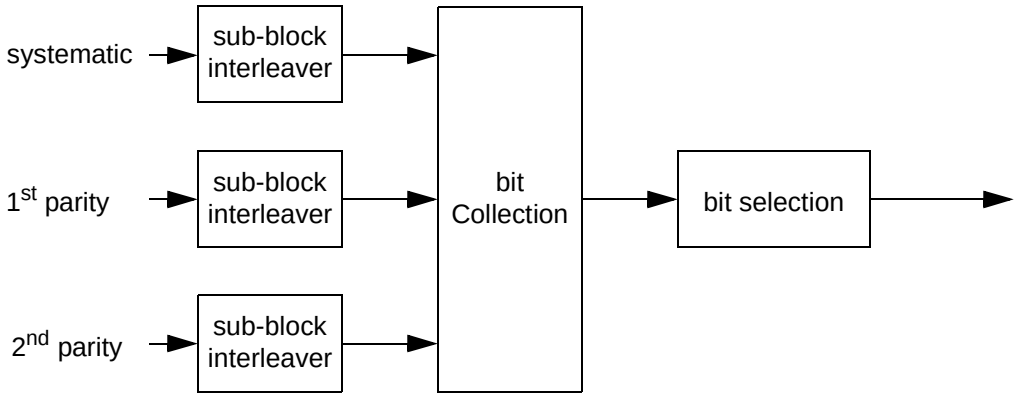

Figure 26-65. 3GLTE Rate Matching Scheme

Prior to sub-block interleaving, the number of filler bits ([NOF] field of the DEPE LTE Header) of the systematic and 1st parity streams are marked as NULL. Then the systematic, parity-1st and parity-2nd streams, are sub-block interleaved according to the 3GLTE sub-block interleaving scheme for each encoded stream, and with specific interleaving functions derived from code block size. The interleaved streams are collected into a virtual circular buffer such that the interleaved parity streams are interlaced and concatenated to the interleaved systematic stream. Bit collection is described in **Figure 26-66**

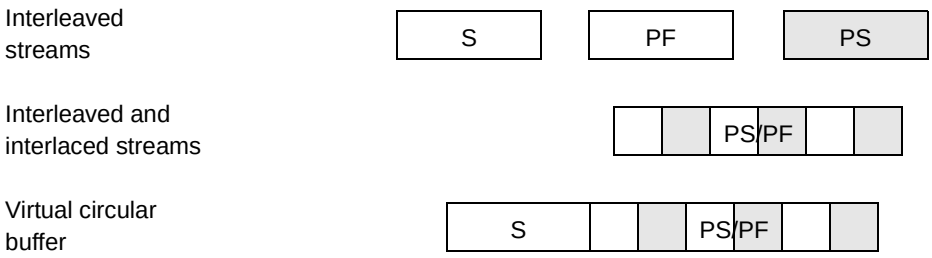

Figure 26-66. LTE Bit Collection

The bit selection scheme is executed using to the following configurations described in the DEPE LTE Header:

- [RMS]. Rate Matching Start bit. Describes the start bit index in the virtual buffer from which the output stream starts. This index equivalent to the RV index of the 3GLTE standard.
- [RMNI]. Rate Matching number of input bits. Limits the number of bits in the virtual buffer. This value is equivalent to the N_{cb} parameter of the 3GLTE standard.
- [RMNO]. Rate Matching Number of Output bits. Describes the required number of output bits after Rate Matching. Due to memory size limitation the 3GLTE Rate Matching

process in the DEPE does not support repetition. If repetition is required, the Rate Matching process should be programmed to produce a reduced circular buffer in which each encoded bit is written once. Repetition may be implemented by reading circularly from the MAPLE-B2 output circular buffer as many bits as required. This restriction limits the allowed size of the [RMNO] field to be equal or less to the value of [RMNI].

The bit selection is done according to the following pseudo code:

```
#given circular buffer
let N = 3*CBS + 12
let n0,n1 to nN-1 be the bits in the virtual circular buffer

#selecting output bits o0,o1 to oRMNO-1
k=0
j=0
while(k<[RMNO])
{
          let i = (j + [RMS])% [RMNI]
          if(ni≠ NULL)
{
          ok = ni
          k=k+1;
          }
          j = j +1
}
```

The Rate Matching circular buffer, which its size is defined by [RMNI], includes, in addition to the valid encoded bits, also dummy bits added during the Sub-block interleaving process and filler bits added prior to the encoding. These bits are not included in the DEPE output buffer. Since calculating the number of the dummy bits and filler bits is not a straightforward calculation, the value of [RMNO], which is limited by the value of [RMNI] only, may be larger than the actual number of valid encoded bits in the circular buffer. In this case the MAPLE-B2 does not output the value described in the [RMNO] field, but the actual number of valid encoded bits. The MAPLE-B2 indicates the actual number of output bits in the [RMNA] status field of the DEPE BD.

If the DEPE BD includes multiple tasks ([NOH] > 0), the [RMNA] status fields of all the tasks included in this BD are placed by MAPLE-B2 in the system memory at the address pointed by

the [BD_STS_PTR] field of the DEPE BD. **Figure 26-67** describe the data structure of the DEPE status fields in case multiple tasks are assigned in single BD:

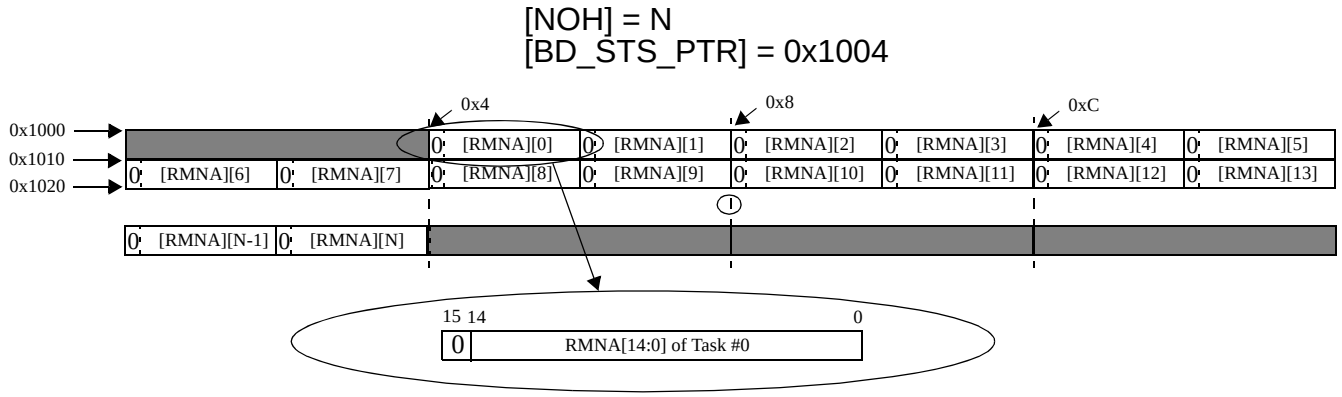

Figure 26-67. DEPE Status Data Structure for Multiple Task BD

26.4.3.4.5.2 WiMAX Processing (802.16e)

The WiMAX DEPE processing includes the following processing chain:

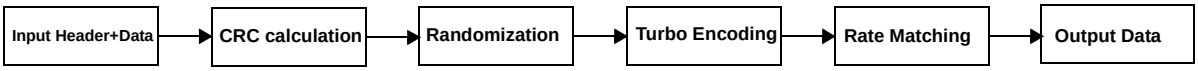

Figure 26-68. WiMAX DEPE Processing chain

The block sizes allowed in the WiMAX standards includes 17 possible types and varies from block size of 48 to block size of 4800. The Code Block size should be set in the [CBSI] field of the DEPE WiMAX Header according to the encoding described in **Table 26-264**.

26.4.3.4.5.2.1 CRC Calculation

If the CRC Disable ([CD]) bit of the DEPE WiMAX Header is set, the CRC calculation is bypassed. If the [CD] bit of the DEPE WiMAX Header is reset, the CRC is calculated and attached to the end of the data block. The CRC machine is initialized to its initial state as described in X.25 ITU-T standard for each new block encoded. The CRC polynomial used for WiMAX CRC processing is: $D^{16} + D^{12} + D^5 + 1$ hence the number of bits attached to the end of the Code Block is 16.

26.4.3.4.5.2.2 Randomization

If the Randomization Disable ([RD]) bit of the DEPE WiMAX Header is set, the Randomization processing is bypassed. If the [RD] bit is reset, the randomization processing is performed as follows:

The Randomizer is initialized to 011011100010101 for each new block encoded. The randomizer randomizes the input stream using the circuit described in **Figure 26-69**.

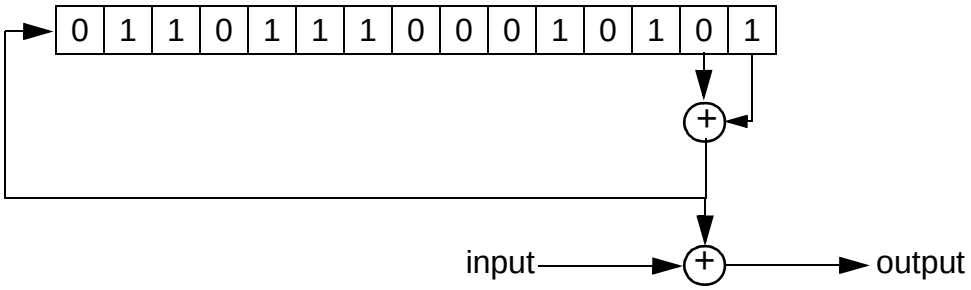

Figure 26-69. WiMax Randomizer

26.4.3.4.5.2.3 Turbo Encoding

During Turbo Encoding process the data buffer is being encoded and forwarded to the Rate Matching process. The DEPE uses a duo- binary encoder for the WiMAX encoding as described in the WiMAX standard. In addition the Turbo Encoding process uses a dedicated interleaver which interleaves the block according to the WiMAX interleaving scheme. The WiMAX interleaver scheme is selected for each block according to its size which is described in the [CBSI] field of the DEPE WiMAX Header.

26.4.3.4.5.2.4 Rate Matching

The WiMAX Rate Matching process consists of the following:

1. Interleave the sub-block of each of the six encoder output streams separately.
2. Collect the 6 interleaved streams into single virtual circular buffer.
3. Select the output bits out of the virtual circular buffer.

Figure 26-70 describes the WiMAX Rate Matching scheme:

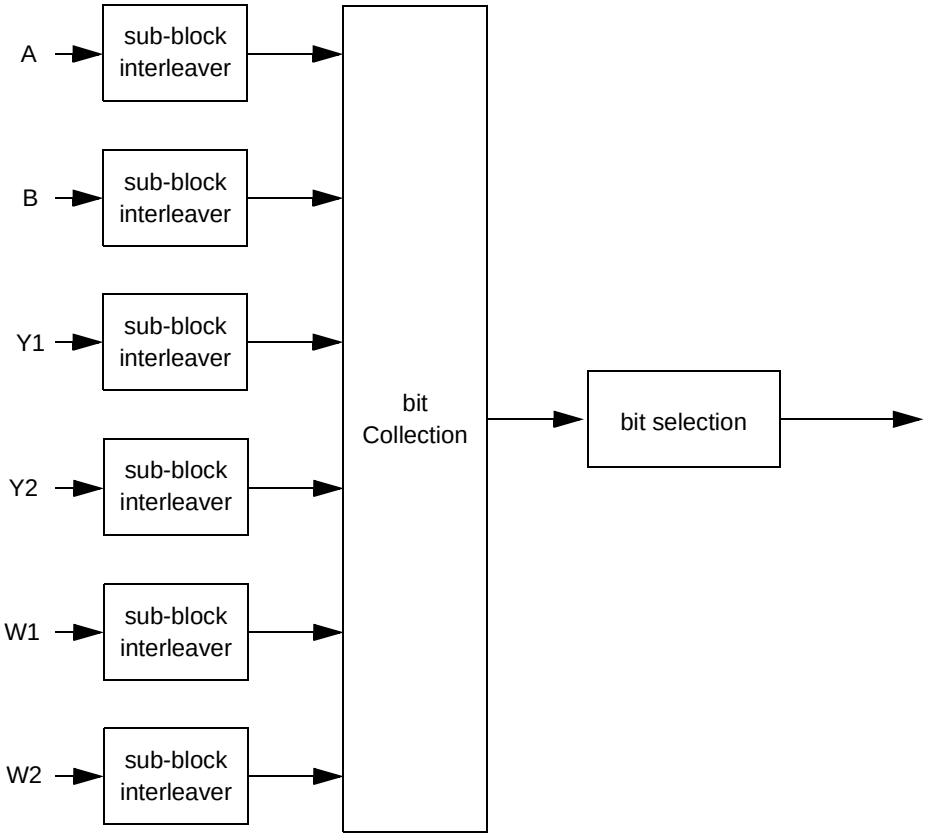

Figure 26-70. WiMAX Rate Matching Scheme

A, B, Y1, Y2, W1 and W2 are sub-block interleaved according to sub-block interleaving scheme of the WiMAX standard for each encoded stream, and with specific interleaving functions derived from code block size described in the [EBCS] field of the DEPE WiMAX Header. The interleaved stream are collected into a virtual circular buffer such that the interleaved B stream is concatenated to the interleaved A stream. The interleaved Y1 and Y2 streams are interlaced and concatenated to the interleaved B stream, and the interleaved W1 and W2 streams are interlaced and concatenated to the interlaced and interleaved Y1 and Y2 stream. Bit collection is described in **Figure 26-71**

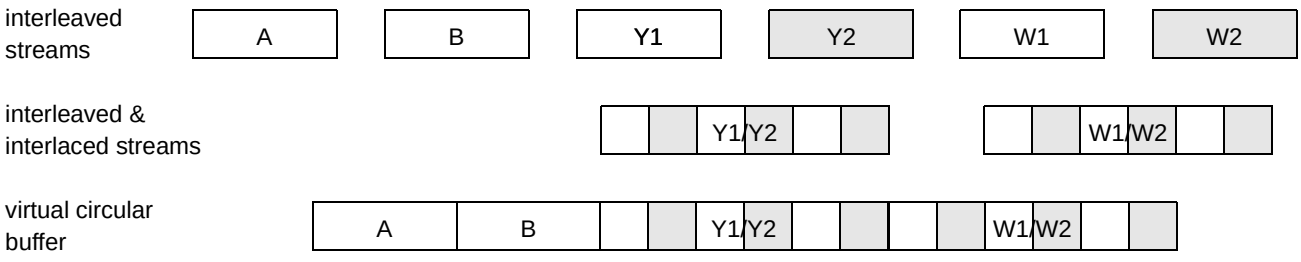

Figure 26-71. Wimax Bit Collection

The bit selection scheme is executed using to the following configurations described in the DEPE WiMAX Header:

- [RMS] - Rate Matching Start bit. Describes the start bit index in the virtual buffer from which the output stream starts.
- [RMNO] - Rate Matching Number of Output bits. Describes the required number of output bits after Rate Matching. Due to memory size limitation the WiMAX Rate Matching process in the DEPE does not support repetition. If repetition is required, the Rate Matching process should be programmed to produce a reduced circular buffer in which each encoded bit is written once. Repetition may be implemented by reading circularly from the MAPLE-B2 output buffer as many bits as required. This restriction limits the allowed size of the [RMNO] field to be equal or less to the value of 3*[Code Block Size] which is represented by the [CBSI] field of the DEPE WiMAX Header.

The output bits are selected according to the following pseudo code

```
#given circular buffer
let N = 3*CBS
let n0,n1 to nN-1 be the bits in the virtual circular buffer

#selecting output bits o0,o1 to oRMNO-1
         k=0
         j=0
while(j<[RMNO])
{
let i = (j + JH[RMS])% N
         oi = ni
         j = j +1
}
```

26.4.3.4.5.3 WiMAX Processing (802.16m)

The WiMAX 802.16m DEPE processing includes the following processing chain:

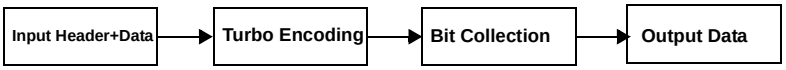

Figure 26-72. WiMAX 802.16m DEPE Processing chain

The block sizes allowed in the WiMAX standards includes 39 possible types and varies from block size of 48 to block size of 4800. The Code Block size should be set in the [CBSI] field of the DEPE WiMAX 802.16m Header according to the encoding described in **Table 26-266**.

26.4.3.4.5.3.1 Turbo Encoding

During Turbo Encoding process the data buffer is being encoded and forwarded to the Bit collection Matching process. The DEPE uses a duo- binary encoder for the WiMAX 802.16m encoding as described in the WiMAX 802.16m standard. In addition the Turbo Encoding process uses a dedicated interleaver which interleaves the block according to the WiMAX 802.16m interleaving scheme. The WiMAX 802.16m interleaver scheme is selected for each block

according to its size which is described in the [CBSI] field of the DEPE WiMAX 802.16m Header.

26.4.3.4.5.3.2 Bit Collection

The WiMAX 802.16m Rate Matching process consists of the following:

1. Interleave the sub-block of each of the six encoder output streams separately.
2. Collect the 6 interleaved streams into single virtual circular buffer.
3. Select the output bits out of the virtual circular buffer.

For WiMAX 802.16m, the DEPE supports only points #1 and #2 of the above. The output size of the bit collection scheme is always ‘Code Block Size’ * 3, hence the RMNO field of the DEPE WiMAX 802.16m field must be set to this value.

Figure 26-70 describes the DEPE WiMAX 802.16m processing scheme:

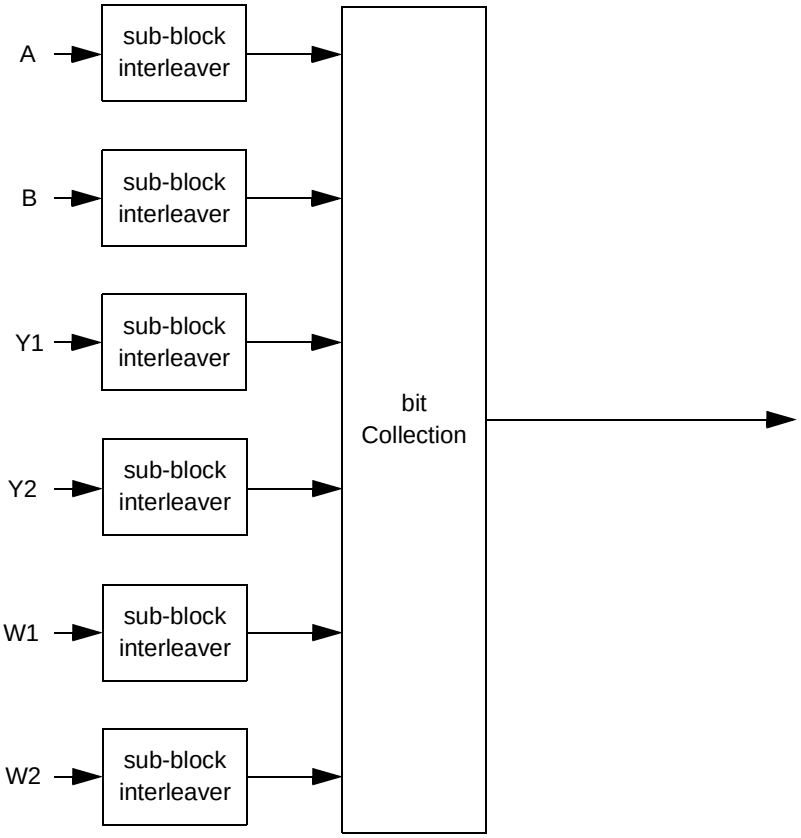

Figure 26-73. DEPE WiMAX 802.16m processing Scheme

A, B, Y1, Y2, W1 and W2 are sub-block interleaved according to sub-block interleaving scheme of the WiMAX 802.16m standard for each encoded stream, and with specific interleaving functions derived from code block size described in the [CBSI] field of the DEPE WiMAX 802.16m Header. The interleaved stream are collected into a virtual circular buffer such that the interleaved B stream is concatenated to the interleaved A stream. The interleaved Y1 and Y2

streams are interlaced and concatenated to the interleaved B stream, and the interleaved W1 and W2 streams are interlaced and concatenated to the interlaced and interleaved Y1 and Y2 stream. Bit collection is described in **Figure 26-71**

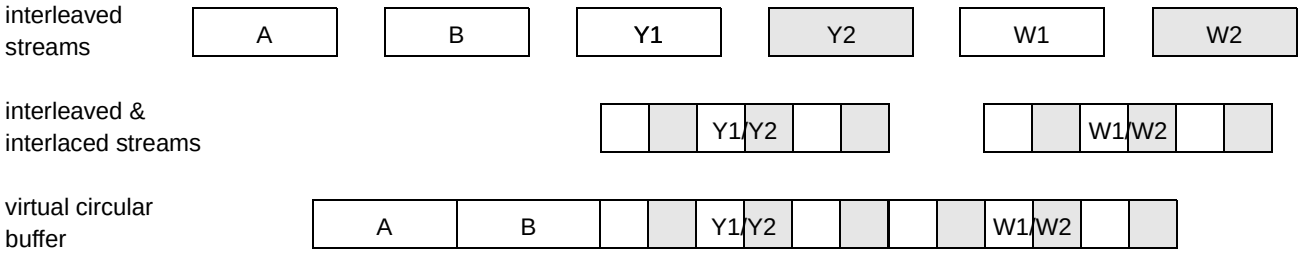

Figure 26-74. Wimax Bit Collection

The bit selection scheme is executed using to the following assumptions :

- The Rate Matching Start bit is assumed to be Zero, indicating that the start bit index of the virtual buffer from which the output stream starts is always zero.
- The Rate Matching Number of Output bits (*RMNO* field of the DEPE WiMAX 802.16m Header) is always assumed as 3*[Code Block Size] which is represented by the [CBSI] field of the DEPE WiMAX 802.16m Header.
- The Sub-Block interleaving scheme includes optional shift left of the interleaved buffers. The DEPE allows left shift execution of the Y, B and W buffers (by setting the *CLSY*, *CLSB* and *CLSW* fields of the DEPE Header respectively). As per described in the WiMAX 802.16m standard the following constraints must apply on these fields:
  - *CLSY* =1
  - *CLSB* = *CLSW*

26.4.3.4.5.4 UMTS Processing

The UMTS DEPE processing includes processing chains for FDD (**Figure 26-75**) and TDD (**Figure 26-76**).

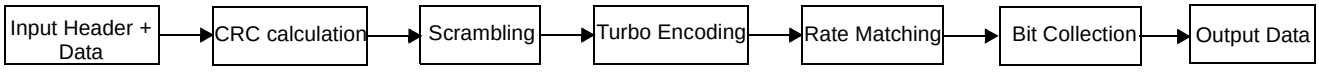

Figure 26-75. UMTS FDD DEPE Processing Chain

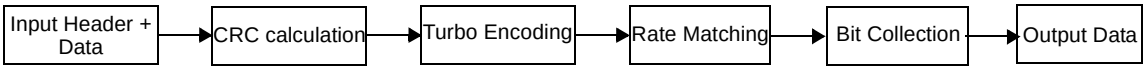

Figure 26-76. UMTS TDD DEPE Processing Chain

The block sizes allowed in the UMTS standards includes all possible sizes varies from block size of 40 to block size of 5114. The Code Block size should be set in the [CBS] field of the DEPE UMTS Header as described in **Table 26-267**.

26.4.3.4.5.4.1 CRC Calculation

If the CRC Disable ([CD]) bit of the DEPE UMTS Header is set, the CRC calculation is bypassed. If the [CD] bit of the DEPE UMTS Header is reset, the CRC is calculated and attached to the end of the data block. The UMTS standard defines CRC calculation for TB only, therefore the [CD] bit should be reset only for the cases that TB include single CB, that is, no segmentation is required. The CRC machine is reset to zero for each new block encoded. The CRC polynomial used for UMTS CRC processing is: $D^{24} + D^{23} + D^6 + D^5 + D + 1$ hence the number of bits attached to the end of the data block is 24.

26.4.3.4.5.4.2 Scrambling (FDD Only)

If the Scrambling Disable ([SD]) bit of the DEPE UMTS Header is set, the Scrambling processing is bypassed. If the [SD] bit is reset, the Scrambling processing is performed as follows:

The Scrambler is initialized to 1000000000000000 for each new block encoded. The Scrambler scrambles the input stream using the circuit described in **Figure 26-77**.

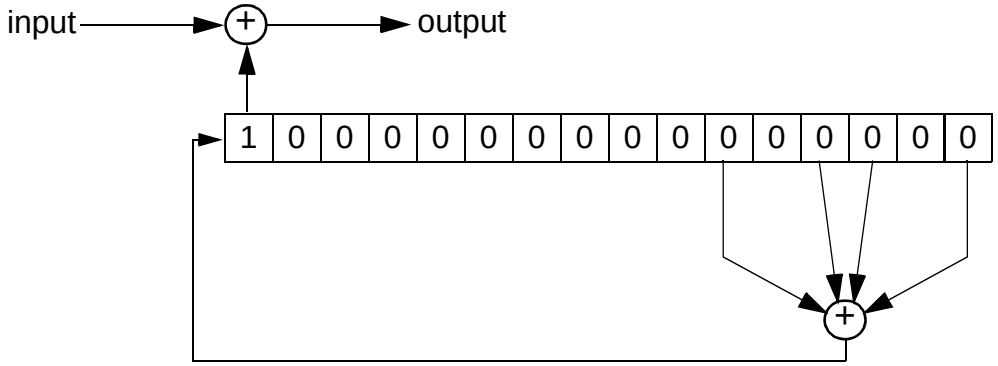

Figure 26-77. UMTS Scrambler

The UMTS standard defines Scrambling for TB only, therefore the [SD] bit should be reset only for the cases that TB include single CB, that is, no segmentation is required.

26.4.3.4.5.4.3 Turbo Encoding

During Turbo Encoding process the data buffer is being encoded and forwarded to the Rate Matching process. The DEPE uses a binary encoder for the UMTS encoding as described in the UMTS standard. In addition the Turbo Encoding process uses a dedicated interleaver which interleaves the block according to the UMTS interleaving scheme. The UMTS interleaver scheme is selected for each block according to its size which is described in the [CBS] field of the DEPE UMTS Header.

26.4.3.4.5.4.4 Rate Matching

The UMTS Rate Matching is done in parallel on the three encoded streams: systematic stream, first parity stream and second parity stream. The Rate Matching is divided into two phases: RM1 and RM2. RM1 performs puncturing on the parity streams only (should be disabled during E-DCH processing). RM2 performs either puncturing or repetition on all streams. When the [REP] bit of DEPE UMTS Header is reset, RM2 does puncturing on all streams and when the [REP] is set RM2 does repetition on all streams. The output of RM2 is written to the DEPE output buffer. UMTS Rate Matching processing is described in **Figure 26-78**:

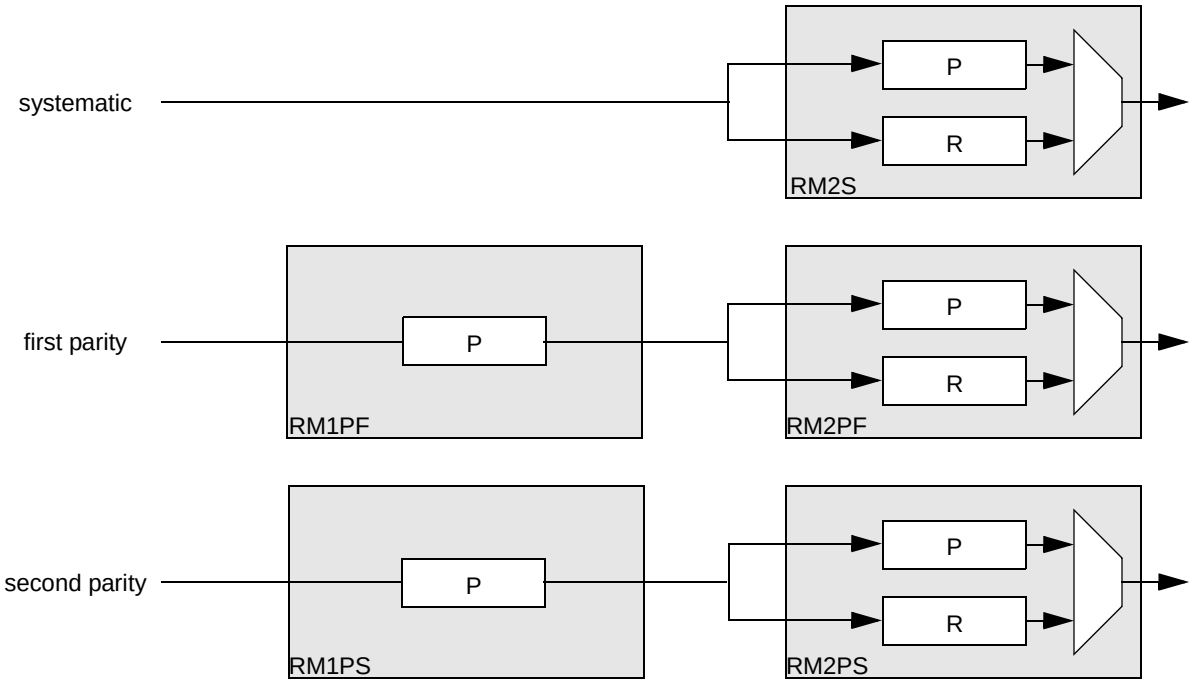

Figure 26-78. UMTS Rate Matching Processing

Note: For E-DCH processing the RM1 machine must be disabled by clearing its e_{minus} parameters to zero and configuring its e_{ini} parameters to any value greater than zero

Note: The size of the DEPE output buffer allocated for encoded data is 43200 bits. If the number of encoded bits after repetition of a single BD job (either of a single task BD or multiple tasks BD) is greater than this number, the RM2 processing should be disabled by clearing its e_{minus} parameters to 0 and configuring its e_{ini} parameters to any value greater than zero.

The following pseudo code describes the puncturing and repetition algorithms:

```
#Puncturing:

e = e_int #Init error
foreach input bit do
{
```

```
            e = e - e_minus                 #Update error
            if(e<=0)
            {
            e = e + e_plus              #Update error
            }
            else
            {
               Output current bit
            }
}

#Repetition:

e = e_ini #Init error
foreach input bit do
{
            e = e - e_minus                 #Update error
            Output current bit
            while(e <= 0)
            {
                 Output current bit
                 e = e + e_plus              #Update error
            }
}
```

Each of the Puncturing and Repetition machines are programmed by three parameters: e_{ini}, e_{plus} and e_{minus}. **Table 26-30** describes the e_{ini}, e_{plus} and e_{minus} calculations executed in the DEPE for RM1 and RM2 for each of the data streams (systematic, first parity and second parity)

Table 26-30. UMTS RM Programming

Machine[1]	e_{plus}	e_{minus}	e_{ini}
RM1PF	2*X	2**Floor*(PEM1/2)	PFEI1
RM1PS	X	*Ceil*(PEM1/2)	PSEI1
RM2S	X	SEM2	SEI2
RM2PF	2*(X - *Floor*(PEM1/2))	PFEM2	PFEI2
RM2PS	X - *C*eil(PEM1/2)	PSEM2	PSEI2

1. see **Figure 26-78**

Where:

```
X = ([CBS] + 4) * [NCB]          #[CBS] and [NCB] are defined in DEPE UMTS Header
SEM2= {[ESEM],[SEM]}                          #Defined in DEPE UMTS Header
SEI2= {[ESEI],[SEI]}                          #Defined in DEPE UMTS Header
PEM1 = {[EPEM1],[PEM1]}                       #Defined in DEPE UMTS Header
PFEM2= {[EPFEM2],[PFEM2]}                     #Defined in DEPE UMTS Header
PSEM2= {[EPSEM2],[PSEM2]}                     #Defined in DEPE UMTS Header
PFEI1= {[EPFEI1],[PFEI1]}                     #Defined in DEPE UMTS Header
PSEI1= {[EPSEI1],[PSEI1]}                     #Defined in DEPE UMTS Header
PFEI2= {[EPFEI2],[PFEI2]}                     #Defined in DEPE UMTS Header
PSEI2= {[EPSEI2],[PSEI2]}                     #Defined in DEPE UMTS Header
```

26.4.3.4.5.4.5 Bit Collection

The bit collection processing in the DEPE is controlled by the following parameters in the DEPE UMTS Header:

- *Bit Collection Mode ([BCM])*

  0 = Indicated the DEPE to collect the bits in the following order: Systematic, first parity and second parity are interlaced. This configuration should be used for E-DCH (FDD only).

  1 = Bit collection mode is done according to [BCT] configuration. This configuration should be used for E-DCH (TDD only) and HS-DSCH (FDD+TDD).
- *Bit Collection Type ([BCT])*—Valid only if [BCM] = 1

  00 = Bit collection is disabled. The DEPE outputs each of the Systematic, first parity and second parity in separate vectors. For details, see **Section 26.4.3.4.6.3**, *Separate Vectors Output Data Structure for UMTS*. This configuration should be used only if the required output buffer (after repetition) is bigger than the maximum DEPE output buffer (43200 bits).

  01, 10 or 11 = Systematic, first parity and second parity are interleaved by a rectangular interleaver with 2,4, or 6 rows respectively.
- *Number of Physical channels ([P])*—Valid only if [BCM] = 1 and [BCT] > 0.

  0 to 15 = Number of physical channels allocated for this task.

26.4.3.4.5.4.6 UMTS Transport Block (TB) Support

The DEPE is capable of supporting TB based processing and bit collection with the following limitations:

- TB size does not exceed the size of 43200 bits.
- One of the following configurations is required:
  - The required Bit Collection scheme is: Systematic, first parity and second parity are interlaced ([BCM] = 0) and the required Rate matching scheme is: Repetition ([REP] = 1)
  - The required Bit Collection scheme is: Systematic, first parity and second parity bits are interleaved by a rectangular interleaver ([BCM] = 1 and [BCT] ≠ 0).

Accumulating a whole TB in its output buffer requires inputting the DEPE successively and in order all the CB jobs related to that TB. To support that and to ease required BD configuration, the MAPLE-B2 allows configuring a single BD with single Header for full TB processing.

Configure a BD for TB processing using the standard layout with the following exceptions:

- The Input Buffer Size ([IBS]) field is ignored and should be set to zero. The MAPLE-B2 uses the [CBS] field of the DEPE Header to calculate the amount of data required for each CB in the TB.

- The Output Buffer Size ([OBS]) should be set to the size of the TB to be output from the DEPE output buffer.
- The Input Buffer Address ([IBA]) should point to the location of the TB in the system memory.
- The Transport Block Indication ([TB]) bit in the BD must be set indicating the MAPLE-B2 that the current BD is for a whole TB.

Configure a Header for TB processing using the standard layout with the following emphasis:

- The Code Block Size ([CBS]) field should be set the CB size of all segmented CBs in the TB.
- The Output Buffer Offset ([OBO]) should be set to zero assuming the output buffer of the whole TB does not require any offset.
- The Continuous Bit Collection indication should be set to zero ([CBC]=0)
- The Reset Rate Matching indication should be set to zero ([RRM]=1), indicating the DEPE to reset its internal Rate Matching machine.
- The Last Header indication should be set to zero ([LH]=0).
- The CRC Disable must be set ([CD]=1). The DEPE does not support continuous CRC calculation of a TB over several CBs.
- The Scrambling Disable must be set ([SD]=1). The DEPE does not support continuous Scrambling calculation of a TB over several CBs.
- The Number of Headers indication ([NOH]) should be set to zero indicating the DEPE that this Header represent single CB job.

The MAPLE-B2 uses the Header attached to the DEPE Transport Block BD as the Header of the first CB to launch into the DEPE. For the following CBs, use the specified modification for the CB Header into the DEPE:

1. Calculate the required Input Buffer Offset ([IBO]) according to the initial TB Input Buffer Offset, the CB size and the current index of the CB in the TB.
2. Calculate the required Output Buffer Offset ([OBO]) to concatenate the current CB output to the previous CB output of that TB.
3. Set the Continuous Bit Collection bit ([CBC]=1), indicating the DEPE that these CBs belong to the same TB.
4. Reset the ‘Reset Rate Matching’ bit ([RRM]=0), indicating the DEPE not to reset its RM machines as the current CBs belong to the same TB.

The MAPLE-B2 clears the BD [OWNER] bit only after the completion of the whole TB.

26.4.3.4.5.4.7 UMTS Processing Summary

Table 26-31 summarizes the optional configurations for the DEPE UMTS Header parameters with respect to the job type

Table 26-31. UMTS (FDD) Processing Functions Summary

Function	HS-DSCH TBS<=5090	HS-DSCH TBS>5090	E-DCH TBS<=5090 Puncturing ([REP] = 0)	E-DCH TBS<=5090 Repetition ([REP] = 1)	E-DCH TBS>5090 Puncturing ([REP] = 0)	E-DCH TBS>5090 Repetition (REP] = 1)

26.4.3.4.5.4.8 Code Blocks Encoding Order

When the number of bits in the input stream (after CRC attachment) is greater than 5114, the input stream should be segmented to few Code Blocks (CB). In case segmentation was required, there are two ways to process the CBs using the MAPLE-B2:

1. Program the MAPLE-B2 with single Transport Block BD as described in **Section 26.4.3.4.5.4.6**, *UMTS Transport Block (TB) Support*.
2. Work with the MAPLE-B2 on a Code Block base where each BD represent a single Code Block

In case option #2 is chosen, two possible ways of working with the MAPLE-B2 are described, as follows:

- Successive And In Order Encoding. Encoding of the CB segments can be executed in the DEPE successively and in order. For such case the first segmented CB should reset the Rate Matching machine (by setting [RRM] bit of the DEPE UMTS Header) thus the initial error variables are loaded into the error variables. For the following CBs (non-first segments) related to the same Transport Block (TB), the Rate Matching machine is not reset (by resetting the [RRM] bit of the DEPE UMTS Header) such that the error variable

calculated by encoding the previous CB segment is used as initial error for the current segment.

Figure 26-79 describes an example of encoding three TBs each segmented to three CBs. When encoding TB_0CB_0 the error variables are initialized by the initial error variables programmed in the DEPE UMTS Header ([RRM] bit is set). When encoding TB_0CB_1 the initial error variables fields in the DEPE UMTS Header are ignored ([RRM] is reset) and the Error variables keep the values calculated while encoding TB_0CB_0. When encoding TB_0CB_2 the initial error variables field in the Header are ignored ([RRM] is reset) and the Error variables keep the value calculated while encoding TB_0CB_1. When encoding TB_1CB_0 the error variables are again initialized by the initial error variables programmed in the UMTS Header ([RRM] is set), and so on.

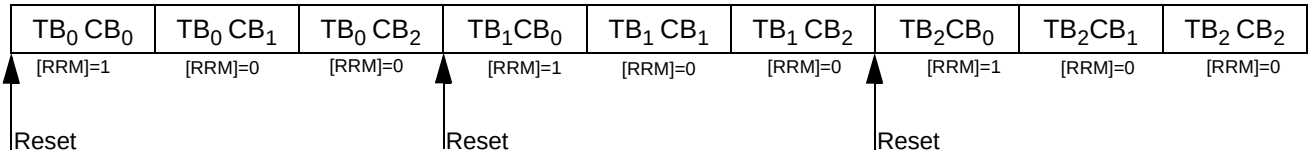

Figure 26-79. Rate Matching of Successive and In Order Code Blocks

Note: Working successively and in order in MAPLE-B2 can be promised only when working with single DEPE Buffer Descriptor's Ring thus assuring that the order of the BDs is executed as their input order into the BD Ring.

- Non-Successive or Out-of-Order Encoding. Encoding of the CB segments is executed in the DEPE either non successively or out of order. For such case the [RRM] bit should be set for all the segmented CB, and it is up to the host to calculate and initialize the error variables of the DEPE UMTS Header for each of the CB segments. **Figure 26-80** describe the required [RRM] configuration for such case:

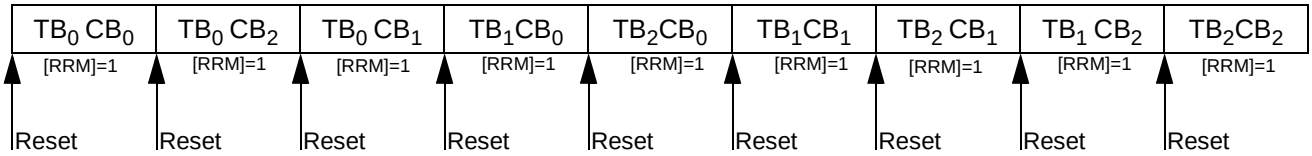

Figure 26-80. Rate Matching of Non-Successive or Out Of Order Code Blocks

Calculating the non-first segmented CB initial error variables (denoted by e^i_{ini}) may be calculated according to the following pseudo code:

```
Let e_ini be the TB initial error
Let e_minus be the TB error decrement variable
Let e_plus be the TB error increment variable
Let CBS^i be the i^th code block size

if(i==0)
{
        e^0_ini = e_ini
}
else
```

```
{
        e^i_ini = (e^(i-1)_ini -(CBS^(i-1) + 4)*e_minus)%e_plus
}
if(e^i_ini = 0) then e^i_ini = e_plus
```

26.4.3.4.6 DEPE Output Data Structure

The DEPE outputs are encoded bits after Rate Matching. The [OBA] field of DEPE BD points to the address in the system memory where the MAPLE-B2 is to write the output data from the DEPE output buffer. The address pointed by [OBA] must be 4 bytes aligned.

The [OBS] field of the DEPE BD describe the total number of 4 bytes words which should be written by the MAPLE-B2 to the system memory. Its straight forward calculation depends on the current technology:

- 3GLTE. [OBS] field is ignored as the MAPLE-B2 uses the [RMNA] status field and the [OBO] field to determine the output size. The number of 4 bytes word which the MAPLE-B2 outputs is calculated as follows:

  ```
  Output Data Size = roundup(([RMNA] + [OBO]) / 32)
  ```

- WiMAX. [OBS] field should be derived from the [RMNO] field of the DEPE WiMAX Header as follows:

  ```
  [OBS] = roundup([RMNO] / 32)
  ```

- UMTS. The output buffer stream size should be calculated using the error variables calculated according to **Table 26-30**. Following is the output buffer stream size calculation flow:

1. Calculate the number of bits which were removed or added (depend if puncturing or repetition were required) in each Rate Matching machine according to the following equation:

   $$Delta = rounddown((N * e_{minus} - e_{init} + e_{plus}) / e_{plus})$$

   Where:

   N = The number of input stream to the RM machine.

   — Following is the Delta calculation for each RM1 machine:

   $$RM1PF\_Delta = rounddown((([CBS] + 4) * e_{minus\_rm1pf} - e_{init\_rm1pf} + e_{plus\_rm1pf}) / e_{plus\_rm1pf})$$
   $$RM1PS\_Delta = rounddown((([CBS] + 4) * e_{minus\_rm1ps} - e_{init\_rm1ps} + e_{plus\_rm1ps}) / e_{plus\_rm1ps})$$

   — Following is the Delta calculation for each RM2 machine:

   $$RM2S\_Delta = rounddown((([CBS] + 4) * e_{minus\_rm2s} - e_{init\_rm2s} + e_{plus\_rm2s}) / e_{plus\_rm2s})$$
   $$RM2PF\_Delta = rounddown((([CBS] + 4 - RM1PF\_Delta) * e_{minus\_rm2pf} - e_{init\_rm2pf} + e_{plus\_rm2pf}) / e_{plus\_rm2pf})$$
   $$RM2PS\_Delta = rounddown((([CBS] + 4 - RM1PS\_Delta) * e_{minus\_rm2ps} - e_{init\_rm2ps} + e_{plus\_rm2ps}) / e_{plus\_rm2ps})$$

2. Calculate the size of each stream at the output of RM2 machine:

   — If puncturing is required ([REP] = 0):

RM2S_Out = [CBS] + 4 - RM2S_Delta
RM2PF_Out = [CBS] + 4 - RM1PF_Delta - RM2PF_Delta
RM2PS_Out = [CBS] + 4 - RM1PS_Delta - RM2PS_Delta

— If repetition is required ([REP] = 1):

RM2S_Out = [CBS] + 4 + RM2S_Delta
RM2PF_Out = [CBS] + 4 - RM1PF_Delta + RM2PF_Delta
RM2PS_Out = [CBS] + 4 - RM1PS_Delta + RM2PS_Delta

3. The total output stream size is:

Out_Stream_Size = RM2S_Out + RM2PF_Out + RM2PS_Out

Once calculated, calculating the [OBS] is done as follows:

```
[OBS] = roundup([Out_Stream_Size] / 32)
```

Due to the multiple tasks support, the output buffer offset support and the separate vectors support the total number of 4 bytes words which should be written by MAPLE-B2 may not always be calculated straightforward. For details, see **Section 26.4.3.4.6.2**, *Output Data Structure for Multiple Tasks*, **Section 26.4.3.4.6.1**, *Output Buffer Offset and Concatenate Output Support (3GLTE and UMTS)* and **Section 26.4.3.4.6.3**, *Separate Vectors Output Data Structure for UMTS*.

26.4.3.4.6.1 Output Buffer Offset and Concatenate Output Support (3GLTE and UMTS)

The DEPE supports up to 31 bits offset of the output stream with respect to the output address pointed by the Output Buffer Address ([OBA]) field of the DEPE BD. Configuring the Output Buffer Offset ([OBO]) field of the DEPE Header instructs the DEPE at which offset of the first 4 bytes word the first valid bit of the current output data buffer is to be written to. Setting the Concatenate Output Enable ([COE]) bit of the DEPE BD indicates the MAPLE-B2 that the [OBO] field of the DEPE Header has been initialized with a value greater than 0x0, hence bit combination operation is required on the first 4 bytes word of the DEPE output buffer in the system memory. **Figure 26-81** describe a 3GLTE example of the MAPLE-B2 operation when using the [OBO] and [COE] fields to concatenate in the system memory two CBs executed in different BDs.

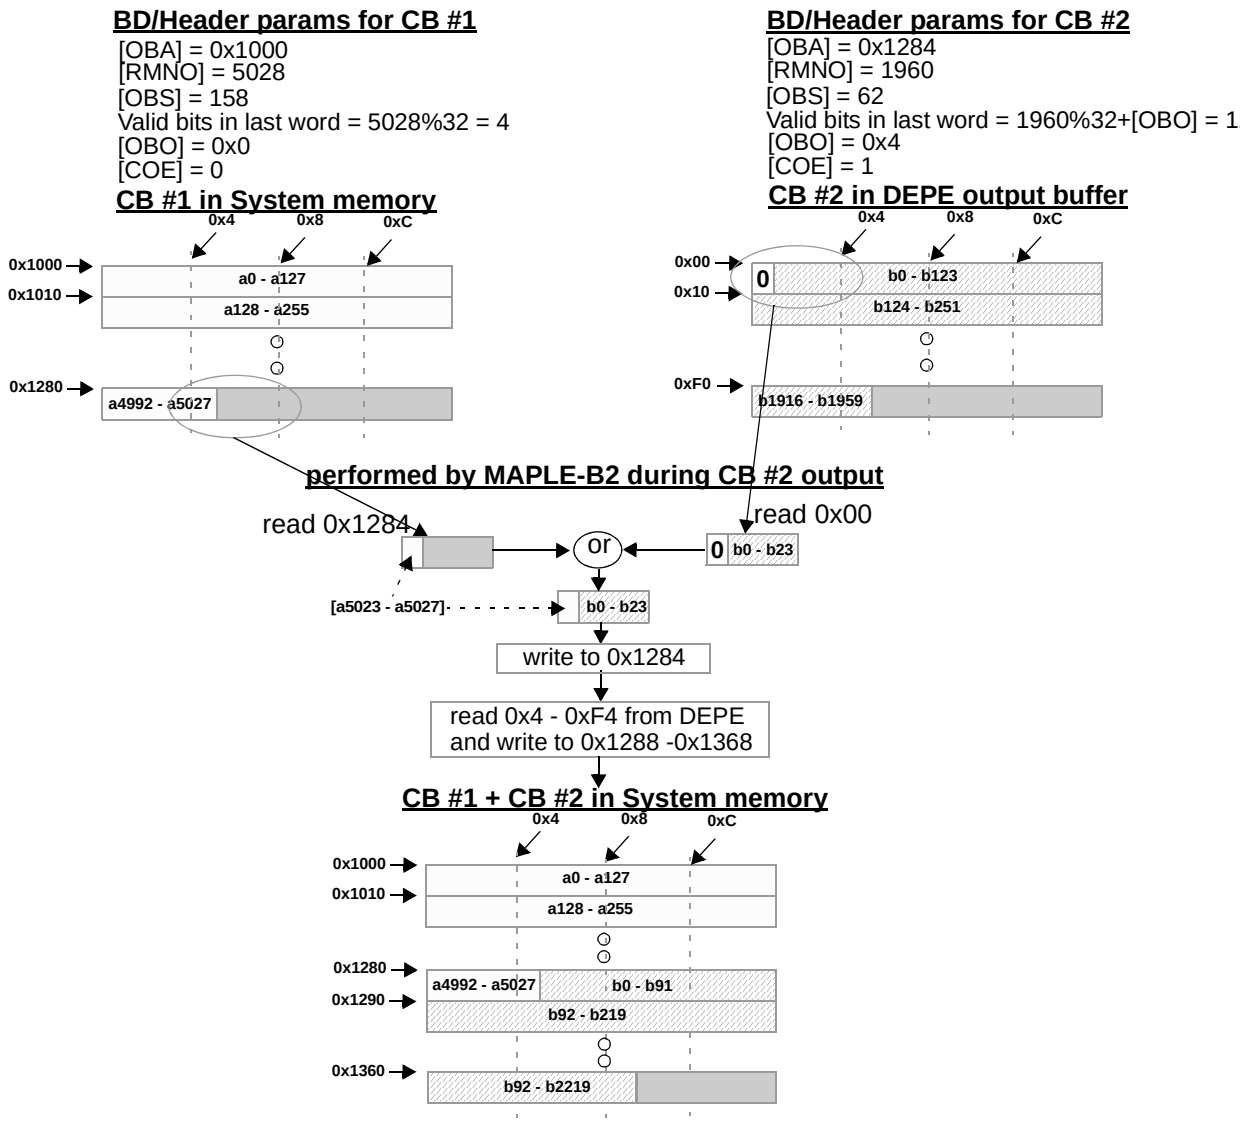

Figure 26-81. Using [OBO] and [COE] to Concatenate CB in System Memory

Supporting the Output Buffer Offset ([OBO]) along with the 32 bits resolution support of the Output Base Address pointer ([IBA]) of the DEPE BD allows writing the output stream with resolution of a single bit, thus eliminating the need to concatenate the output CBs after encoding.

When Output Buffer Offset is set to a value different than 0x0, the [OBS] field should be calculated as follows:

- 3GLTE. [OBS] field is ignored as the MAPLE-B2 uses the [RMNA] status field and the [OBO] field to determine the output size. The number of 4 bytes word which the MAPLE-B2 outputs is calculated as follows:

```
Output Data Size = roundup(([RMNA] + [OBO]) / 32)
```

- WiMAX. [OBS] field should be derived from the [RMNO] field of the DEPE WiMAX Header (see **Section 26.4.3.4.5.2**, *WiMAX Processing (802.16e)*) as follows:

```
[OBS] = roundup([RMNO]+ [OBO]/ 32)
```

- UMTS. The output buffer stream size should be calculated from the error variables calculations as described in **Section 26.4.3.4.5.4**, *UMTS Processing*. Once calculated, calculating the [OBS] is done as follows:

```
[OBS] = roundup([Out_Stream_Size] + [OBO] / 32)
```

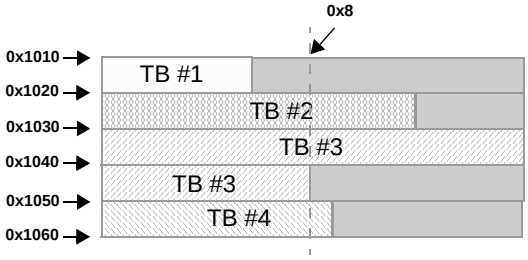
26.4.3.4.6.2 Output Data Structure for Multiple Tasks

When multiple tasks in a BD is enabled (by configuring [NOH] > 0), the MAPLE-B2 writes the output data buffers of all the tasks successively in the system memory, where the beginning each task is aligned to 128 bits line.

When [NOH] is set to a value different than 0x0, the [OBS] field should be calculated as follows:

```
[OBS] =0;
for (i=0; i < [NOH]+1; i++)
        [OBS] = [OBS]+ 4* roundup([Task[i]Output Size] / 128);
```

Figure 26-82 describe an example of the output data structure for multiple tasks BD.



[NOH] = 3
[OBA] = 0x1010
[OBS] = 20

Task #	Task Size	[OBO]
1	40	0x0
2	96	0x0
3	192	0x0
4	72	0x0

Figure 26-82. Expected Input Buffer Data Structure for Multiple Tasks BD

26.4.3.4.6.3 Separate Vectors Output Data Structure for UMTS

When processing a UMTS job in the DEPE and the Bit Collection processing is disabled (see **Section 26.4.3.4.5.4.5**, *Bit Collection*), the DEPE outputs a separate vector for each of the Rate Matching output streams: systematic, first parity and second parity. In order for the MAPLE-B2 to work in separate vectors output data structure the following parameters must be initialized:

- *[BCM], [BCT]*. DEPE UMTS Header parameters which indicate the DEPE the required Bit Collection scheme. For separate vectors output data structure (bit collection disable) they must be set to 1 and 00 respectively.
- *[SVE]*. Separate Vectors Enable indication, which indicate the MAPLE-B2 that the DEPE is working in separate vectors mode thus 3 separate vectors must be read from its output buffer and into the system memory. This bit must be set to 1 if separate vectors in DEPE is enabled.
- *[ESVO]*. Encoded Separate Vectors Offset. Indicates the MAPLE-B2 which offset to use between the vectors in the system memory. When [SVE] bit is set, the MAPLE-B2 places the systematic vector at the address pointed by the [OBA] field of the DEPE BD. The first parity vector is placed at address which equals ([OBA] + [Separate Vector Offset]) and the second parity is placed and address which equals ([OBA] + (2 * [Separate Vector Offset])). This parameter should be initialized according to the total size of each output vector so that no overlapping between the vectors occur.
- *[OBS],[PFS],[PSS]*. DEPE BD parameters which indicates the MAPLE-B2 the size of the systematic, parity first and parity second vectors size respectively. Calculating the size of each vector is described in **Section 26.4.3.4.5.4**, *UMTS Processing*. When calculating each vector size, its offset as initialized in [OBO],[PFO] and [PSO] must be considered.
- *[OBO],[PFO],[PSO]*. DEPE UMTS Header parameters which indicate the DEPE how to arrange the vectors in its output buffer. The [OBO] indicate the DEPE the offset of the first valid bit in the systematic vector with respect to the beginning of the first 32 bits word in the DEPE output buffer. The [PFO] indicate the DEPE the offset of the first valid bit of the first parity vector with respect to the first valid bit of the systematic vector. This offset must be greater than or equal to the number of systematic bits of the current code block after rate matching. The [PSO] indicate the DEPE the offset of the first valid bit of the second parity vector with respect to the first valid bit of the systematic vector. This offset must be greater than or equal to the number of systematic bits plus the number of the first parity bits.

Figure 26-83 and **Table 26-32** illustrate an example of a CB processing with Separate vectors enabled. In this example, the number of bits in each one of the systematic, first parity, and second parity vectors after Rate Matching is 144 bits. **Table 26-32** describe an example of possible configuration of the parameters of the BD:

Table 26-32. Separate Vectors Parameter Configuration Example

Parameter	BD configuration	Remarks
[BCM], BCT]	[BCM] = 1, [BCT] = 0	Bit collection is disabled
[SVE]	[SVE] = 1	Separate vectors is enabled
[ESVO]	[ESVO] = 1	Each vector is of 144 bits hence 256 bits offset prevent overlapping
[OBA]	[OBA] = 0x1000	
[OBS],[PFS],[PSS]	[OBS] = [PFS] = [PSS] = 5	Size of each vector is: roundup(144/32) = 5
[OBO],[PFO],[PSO]	[OBO] = 0 [PFO] = 256 [PSO] = 512	Each vector starts in new 128 bits line.

Figure 26-83 describe the DEPE output buffer content and the system memory content after BD completion:

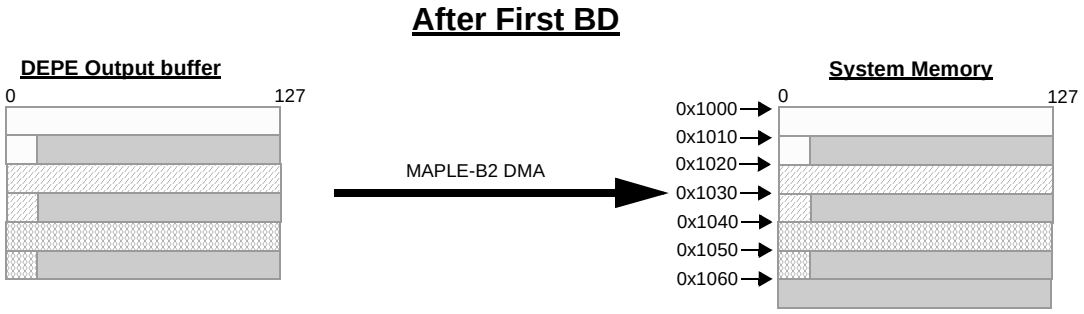


Figure 26-83. Example of DEPE Output Buffer and System Memory Content in Separate Vectors

Note: The Separate Vectors Output data structure is supported for single Headers job only, that is, is *NOH* must be set to '0' if *SVE* is set to '1'.

26.4.3.4.7 BD Status Indications

On BD completion, the MAPLE-B2 returns the RMNA status fields to the DEPE BD (relevant for 3GLTE BDs only). This field indicates the actual number of output bits in the output buffer. For details, refer to **Section 26.4.3.4.5.1**, *3GLTE Processing*

26.4.3.5 EQPE Equalization Processing Operation

The MAPLE-B2 supports Linear Equalization (LNEQ) processing (MMSE/ZF), Maximum Likelihood Equalization (MLEQ) using QRD-M algorithm, Tree Search processing (QR Decomposition is performed externally), and General Matrix Inversion operations (MIV) as described in **Section 26.2**, *MAPLE-B2 Features* using the Equalization Processing Element (EQPE).

The EQPE also includes a Frequency Domain Unit (FDU) targeted for vectors multiplication and accumulation (MAC). This unit is involved with the CONVPE processing (see **Section 26.4.3.9**, *CONVPE Convolution and Correlation Processing Operation*) by executing all the vector MAC operation required by the CONVPE. As the Equalization and Matrix Inversion related logic and the FDU related logic share the same resources, at a given time the EQPE can either work in FDU mode or in EQPE mode (Equalization and Matrix Inversion).

In general, this section describes the EQPE mode only (Equalization and Matrix Inversion), excluding **Section 26.4.3.5.7**, *CONVPE Support—FDU Processing* which describe the FDU processing as part of the CONVPE processing (see **Section 26.4.3.9**, *CONVPE Convolution and Correlation Processing Operation*).

26.4.3.5.1 EQPE Initialization Configuration

After the MAPLE-B2 initialization routine (see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)) and before the first Buffer Descriptor is applied to the EQPE, the EQ_THRESH configuration register should be initialized: This register holds the threshold value that indicates matrix singularity. For a detailed register description see **Section 26.5.5.4.1**, *EQPE Threshold Register (EQ_THRESH)*. For additional details on matrix singularity reports see **Section 26.4.3.5.10**, *EQPE Status Indications*.

The EQPE can generate false ECC double error indications that may mask real double ECC errors from the EQPE. This can occur if the ECC logic is enabled during MAPLE-B2 initialization or if the EQPE is set to Automatic Power Switch Mode (EQPE_PWR=0) during API. To prevent this occurrence, use the following steps:

1. Disable the ECC logic of the MAPLE-B2 during API initialization (logic is disabled for the MAPLE-B2 memories).
2. Set the EQPE power mode to "power on" (EQPE_PWR=1) during the API initialization (EQPE does not power down during idle periods; impact depends on EQPE utilization).
3. Ignore the ECC double error sourced from the EQPE only by masking its enable bit in PSPICER2. This allows enabling of both the ECC logic (single errors are fixed) and the automatic power switching mode (however, real double ECC errors from the EQPE are also masked, but single ECC errors are fixed because the ECC logic is enabled).

26.4.3.5.2 EQPE BD Structure

EQPE buffer descriptors are described in detail in **Section 26.5.4.5**, *EQPE BD Structure*, on page 26-457.

26.4.3.5.3 EQPE Sub-Carrier Grid

The EQPE sub-carrier grid defines the geometry of the equalization tasks. The grid is defined by 2 parameters: *ROWS* and *COLS* configured in the EQPE BD (see **Section 26.5.4.5**, *EQPE BD Structure*), which specify the number of rows and columns in the grid. The sub-carrier grid is defined for equalization tasks only, that is, it does not exist for MIV mode.

The grid allows controlling the following:

1. The size of the processing task - *(ROWS+1)* x *(COLS+1)*. **Figure 26-84** shows an example of an EQPE job containing 36 x 12 = 432 sub-carriers. The maximal size of the grid is *ROWS*=2047 and *COLS*=15 meaning the largest job size is 32,768 sub-carriers.

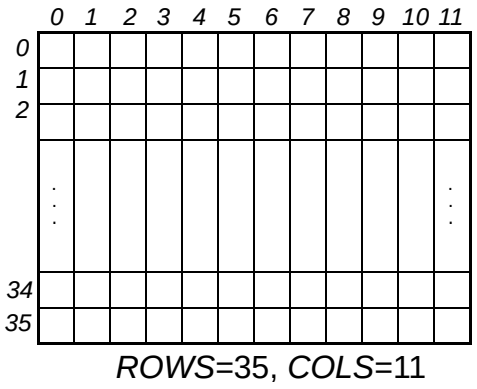

Figure 26-84. The EQPE Sub-Carrier Grid

2. Allows defining the connection between the ***H*** samples and interpolation weights (***W***s) - controlling to which sub-carrier each belong.
3. The processing order and the order of the output. The EQPE processing order is *"vertical order"* (column by column). **Figure 26-85** shows an example of an EQPE job of 36x12=432 elements and the order in which they are processed by the EQPE. The

processing order for each mode is chosen to reduce the total latency in case further processing inside the MAPLE-B2 is required.

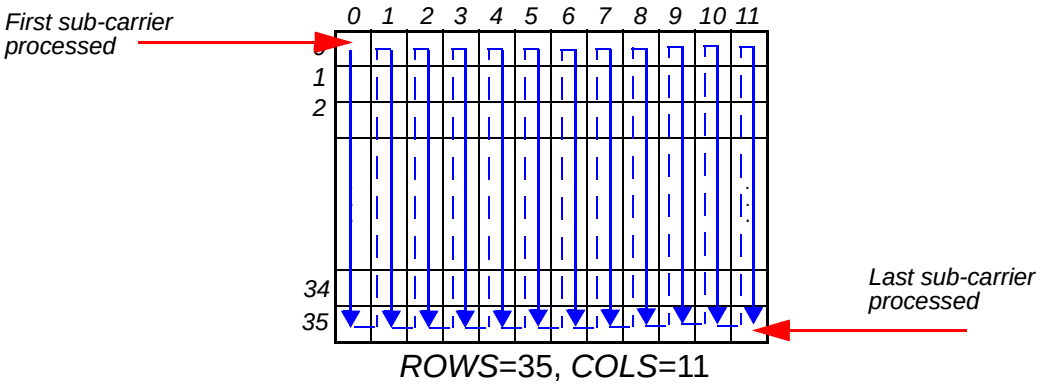

Figure 26-85. EQPE Processing Order

4. Allows defining the granularity of the S matrices and W samples see **Section 26.4.3.5.4.5**, *S Matrix* and **Section 26.4.3.5.4.7**, *W Samples*.

Note: In TS mode, if *RM_SCL_TYPE*=1 then the size of the sub-carrier grid is limited to 4096, that is (*ROWS* + 1) x (*COLS* + 1) <=4096.

26.4.3.5.4 EQPE Input Samples and Data Structures

The input data buffers required for each new EQPE job varies with respect to the current processing mode (LNEQ, MLEQ, TS and MIV) and enabling/disabling additional features related to each processing mode. **Table 26-33** summarize some of the expected input buffers type for each processing mode with respect to related features that affects input data buffers. The following sections describe the expected data structure for each of the input buffer types.

Table 26-33. Expected Input Buffers with Respect to EQPE Processing mode

EQPE Mode	Mode Parameters	Y Buffer	H0/R/M Buffer	H1 Buffer	H2 Buffer	H3 Buffer	S Buffer	W Buffer	F Buffer	C Buffer
LNEQ	INTRP=0, F_EN=1, C_EN=1	Yes	Yes	Yes	No	No	Yes	Yes	Yes	Yes
	INTRP=1, F_EN=1, C_EN=0	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No
	INTRP=2, F_EN=0, C_EN=1	Yes	Yes	No	No	No	Yes	No	No	Yes
	INTRP=3, F_EN=0, C_EN=0	Yes	Yes	No	No	No	Yes	No	No	No
MLEQ	INTRP=0	Yes	Yes	Yes	No	No	Yes	Yes	NA	NA
	INTRP=1	Yes	Yes	Yes	Yes	Yes	Yes	Yes	NA	NA
	INTRP=2,3	Yes	Yes	No	No	No	Yes	No	NA	NA
TS		Yes	Yes	NA	NA	NA	Yes	NA	NA	NA
MIV		NA	Yes	NA	NA	NA	NA	NA	NA	NA
Note: This table only includes major combination examples and not all possible combinations.										

The following sections describe the expected data buffers structure of the EQPE related input buffers in each of its supported modes.

26.4.3.5.4.1 Y Samples

The following subsection define the Y sample requirements.

26.4.3.5.4.1.1 Y Samples Input Data Structure

The ***y*** samples in the Y buffers are the baseband samples from the receive antennas after FFT operation and are used only for equalization jobs (ALG=0,1,2). Each ***y*** sample is an *((Rx)* x *1)* vector for each sub-carrier in the grid or *((Lx)* x *1)* vector for TS mode[1]. Each ***y*** sample is represented by a 16-bit fractional fixed point representation of 1q15 (*V*) real and imaginary parts (16I, 16Q) and a scale factor (*Y_SCL*) such that the actual value of the sample is: $V \times 2^{Y-SCL}$.

The expected amount of Y samples for the entire job is:

— LNEQ, MLEQ: *(Rx+1)* x (*COLS+1)* x (*ROWS+1)* x *4 Bytes*
— TS: *(Lx+1)* x *(COLS +1*)x(*ROWS+1)* x *4 Bytes*.

The MAPLE-B2 expect to find *((COLS+1)* x *(Rx+1))* input Y buffers successively placed in the system memory and ordered by one of the following two ways according to the *Y_MOD* field of the MEQYBMP parameter (see also **Figure 26-86**):

1. If *(Y_MOD=0)*: Columns 0 to *COLS* of Receive antenna #0 (after FFT processing) following by columns 0 to *COLS* of Receive antenna #1...
2. If *(Y_MOD=1)*: Columns 0 of receive antennas #0 to *Rx* following by columns 1 of receive antennas #0 to *Rx*...

1. In TS mode the Y samples are actually the vector $Q^H y$ where [Q,R]=qr(H).

Figure 26-86 describe the two optional modes:

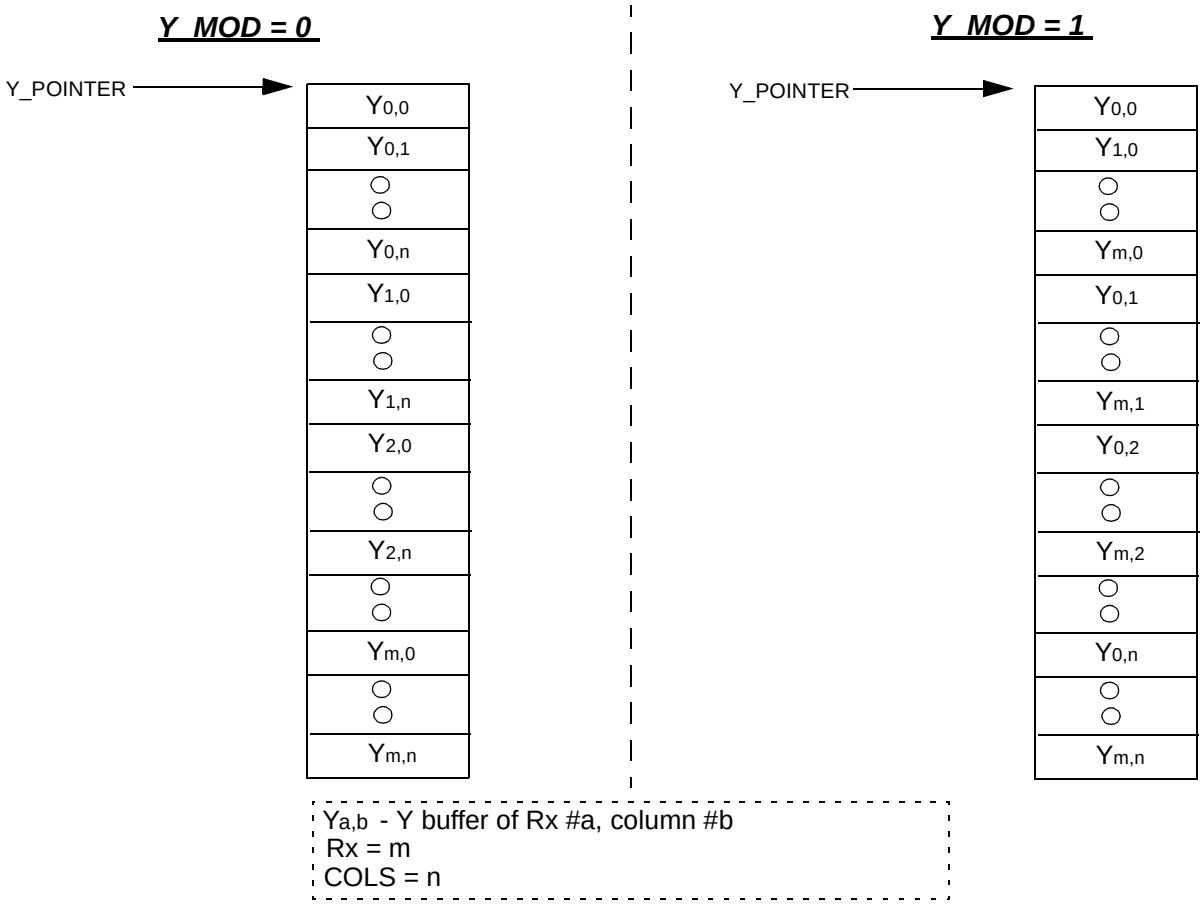

Figure 26-86. Y Buffers Order in System Memory with Respect to *MEQYBMP[Y_MOD]*

The MAPLE-B2 uses the following EQPE BD parameters to fetch the correct data for the current job:

1. *Y_POINTER* parameter - Points to the base address of all the Y buffers which includes data relevant for the current job.
2. *Y_GAP* parameter - Describe the size of each of the Y buffers located starting from *Y_POINTER.*
3. *Y_OFFSET* parameter - Describe the address offset of the relevant ***y*** samples within each Y buffer.

Following is an example which illustrates the usage of the above parameters. Assume an EQPE BD with the following parameters configuration (LNEQ): *Rx* = 3, *COLS* = 11, *ROWS* = 23, *Y_POINTER* = 0x10000000, *Y_GAP* = 1200, *Y_OFFSET* = 120. The current *Y_MOD* configuration is 0. From this configuration the MAPLE-B2 assume the following:

Table 26-34. Y Buffers address calculation example

$Y_{a,b}$	Absolute Address calculation	Size calculation (bytes)
$Y_{0,0}$	*Y_POINTER* + (4 bytes x *Y_OFFSET*) = 0x100001E0	(ROWS+1) x 4 = 96
$Y_{0,1}$	*Y_POINTER* + (4 bytes x Y_GAP) + (4 bytes x Y_OFFSET) = 0x100014A0	(ROWS+1) x 4 = 96
$Y_{0,2}$	*Y_POINTER* + (2 x 4 bytes x Y_GAP) + (4 bytes x Y_OFFSET) = 0x10002760	(ROWS+1) x 4 = 96
$Y_{0,11}$	*Y_POINTER* + (11 x 4 bytes x Y_GAP) + (4 bytes x Y_OFFSET) = 0x1000D020	(ROWS+1) x 4 = 96
$Y_{1,0}$	*Y_POINTER* + (12 x 4 bytes x Y_GAP) + (4 bytes x Y_OFFSET) = 0x1000E2E0	(ROWS+1) x 4 = 96
$Y_{1,11}$	*Y_POINTER* + (23 x 4 bytes x Y_GAP) + (4 bytes x Y_OFFSET) = 0x1001B120	(ROWS+1) x 4 = 96
$Y_{3,0}$	*Y_POINTER* + (36 x 4 bytes x Y_GAP) + (4 bytes x Y_OFFSET) = 0x1002A4E0	(ROWS+1) x 4 = 96
$Y_{3,11}$	*Y_POINTER* + (47 x 4 bytes x Y_GAP) + (4 bytes x Y_OFFSET) = 0x10037320	(ROWS+1) x 4 = 96

The expected internal data structure of each such Y buffer is described in **Figure 26-87**:

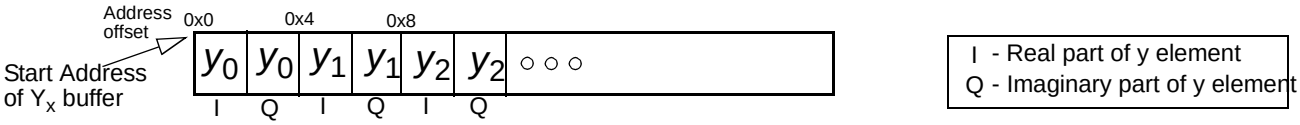

Figure 26-87. y Samples Data Structure

26.4.3.5.4.1.2 Y Scale Samples Input Data Structure

The EQPE supports a distinct Y scaling factor for each column of each Rx antenna. Therefore, there are (*Rx* + 1) x (*COLS* + 1) Y scale samples, each 1 Byte.

The expected order of the Y scale samples is as the following example (*Rx* = 3):

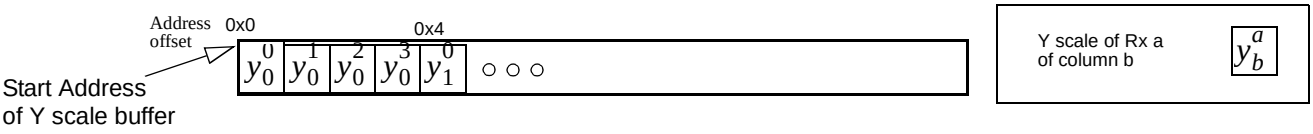

Figure 26-3. *Y* scale Samples Data Structure in Y Scale buffer for *LNEQ, MLEQ and TS Modes.*

The MAPLE-B2 expects to find the Y scale samples vector at the following address as calculated by the following EQPE BD parameters: Address = *SCL_PTR_BA* + (16 * *Y_SCL_OFFSET*).

26.4.3.5.4.2 H Samples

The ***H*** samples (for LNEQ and MLEQ) are the CE reference matrices (internal interpolation mode) or actual CE matrix (Non/External interpolation modes). Each of the ***H*** samples is

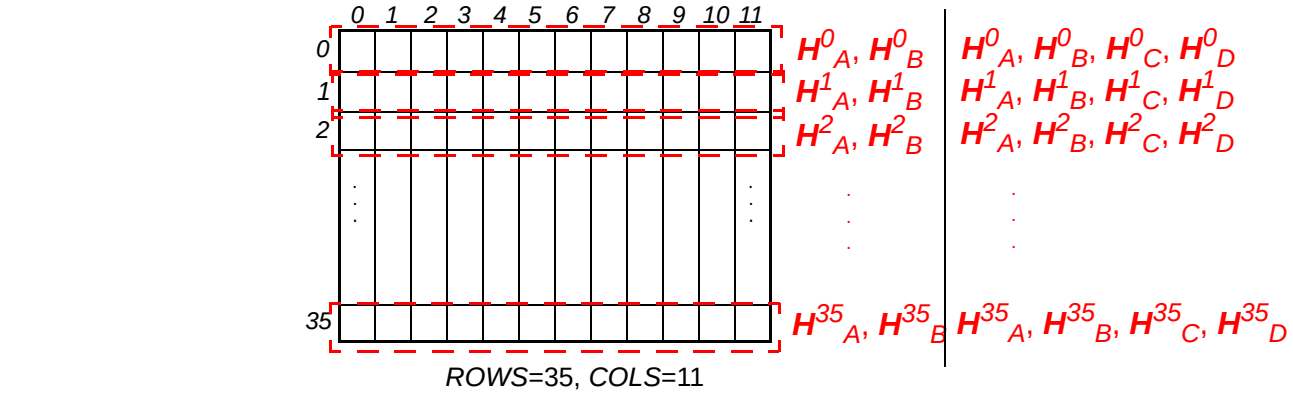
represented by a 16-bit fractional fixed point representation of 1q15 (*V*) real and imaginary parts (16I,16Q) and a scale factor (*SCL*) such that the actual value of the sample is: $V \times 2^{SCL}$.

26.4.3.5.4.2.1 H Matrices Arrangement on the Sub-Carrier Grid

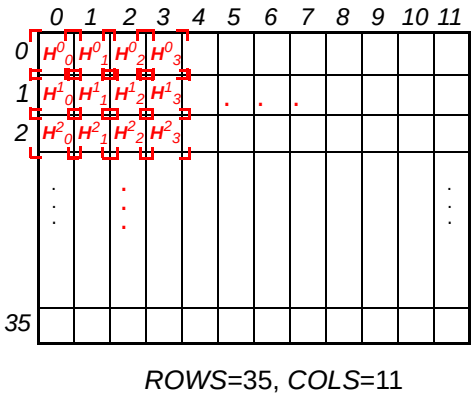
There are 4 interpolation modes supported by the EQPE that define the arrangement of the ***H*** matrices on the sub carrier grid. The interpolation mode is set in *INTRP* parameter of the EQPE BD:

- Internal Interpolation mode (II2 and II4) - In this mode there are two reference ***H*** matrices - $\boldsymbol{H}^{k}_{A}$ and $\boldsymbol{H}^{k}_{B}$ (II2) or 4 matrices $\boldsymbol{h}^{k}_{A}$,$\boldsymbol{h}^{k}_{B}$,$\boldsymbol{h}^{k}_{C}$,$\boldsymbol{h}^{k}_{D}$ (II4) shared by the entire row in the grid (*k* is the row index). The EQPE uses the matrices to calculate the interpolated CE matrices according to the interpolation weights (W samples). A distinct weight is applied for each layer for each column on the grid and may even be changed in the row dimension, thus achieving the desired interpolation strategy. For details see **Section 26.4.3.5.5.7**, *CE Matrix Interpolation*. A total of (*ROWS*+1)x2 and (*ROWS*+1)x4 ***H*** matrices are needed for II2 and II4 modes respectively.
- External Interpolation mode - In this mode there is one ***H*** matrix for each sub-carrier (it is assumed CE interpolation is done externally by the host), and no interpolation is performed by the EQPE. A total of (*ROWS*+1)x(*COLS*+1) ***H*** matrices are needed (one for each sub-carrier in the grid). The order of the matrices is according to the processing of the EQPE that is, *vertical order* (column by column).
- Non-Interpolated mode - In this mode a single ***H*** matrix is used for each row, no interpolation is performed by the EQPE. A total of (*ROWS*+1) ***H*** matrices are needed (one for each row).

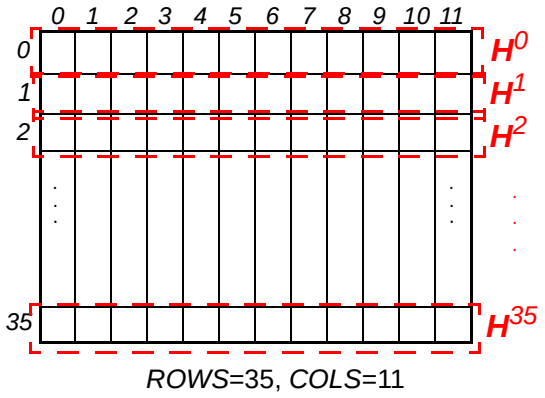
Figure 26-88 shows an example of the ***H*** matrices arrangement for all the interpolation modes.



(a) Internal Interpolation mode 2 | 4



(b) External Interpolation mode



(c) Non-Interpolated mode

Figure 26-88. *H* Matrices Arrangement on Sub-Carrier Grid

26.4.3.5.4.2.2 H Samples Input Data Structure

The H matrices input vectors number and size depends on the EQPE mode (LNEQ or MLEQ) and on the interpolation modes as described in **Table 26-33**. The H matrices arrangement on the Sub-Carrier grid is described in **Figure 26-88**.

Each H matrix dimensions is of ((*Rx+1)* * (*Lx+1)*) elements and the size of each element in the matrix is 32 bits (16I,16Q). The following table describe the total data size of ***H*** matrices input data expected with respect to the interpolation mode and other job's parameters:

Table 26-35. H Matrix Input Data Size

Interpolation Mode	H Matrix total input size calculations
Internal Interpolation 2 (II2)	((*Rx*+1) * (*Lx*+1) * 4_{bytes}) * (*ROWS*+1) * $2_{(2\ reference\ symbols\ per\ row)}$
Internal Interpolation 4 (II4)	((*Rx*+1) * (*Lx*+1) * 4_{bytes}) * (*ROWS*+1) * $4_{(4\ reference\ symbols\ per\ row)}$
External Interpolation	((*Rx*+1) * (*Lx*+1) * 4_{bytes}) * (*ROWS*+1) * (*COLS*+1)$_{(each\ column\ in\ row\ has\ CE\ symbol)}$
Non Interpolation	((*Rx*+1) * (*Lx*+1) * 4_{bytes}) * (*ROWS*+1) * $1_{(single\ reference\ symbols\ per\ row)}$

Note: In the case of *Lx*=2, the H matrix input data structure is identical to the case where *Lx*=3, therefore the above calculations should assume *Lx*=3 even if *Lx*=2.

The MAPLE-B2 expect to find each H matrix reference symbol in different vectors for the II2 and II4 interpolation modes (*H_POINTER0* to *H_POINTER3*), or in a single vector in case of external interpolation or non-interpolation modes (*H_POINTER0*).

The MAPLE-B2 uses the *CONS_H*, *H_OFFSET* and *H_GAP* fields of the EQPE BD to fetch the relevant input vectors into the EQPE: assuming $H_x{}^{i,j}$ is an element of H matrix #*x* (x = 0...*ROWS*) located in row *i* (*i* = 0...*Rx)* and column *j* (*j*=0...*Lx*) of the H matrix, the following describe the fetching order of the H matrix elements for the II2 and II4 interpolation modes (for II2 y=0,1 and for II4 y=0,1,2,3):

Table 26-36. H Elements Order in the H Vectors for II2 and II4 Interpolation Modes.

H pointer	Description	Index priority	H elements order
Hy_POINTER	Reference Symbol #y	for (*j* = 0, *j* <= *Lx*, *j*++) --for (*i* = 0, *i* <= *Rx*, *i*++) ----for (*x* = 0, *x* <= *ROWS*, *x*++) ------place $H_x{}^{i,j}$	$H_0{}^{0,0}$,$H_1{}^{0,0}$,...,$H_{ROWS}{}^{0,0}$,$H_0{}^{1,0}$,$H_1{}^{1,0}$,...,$H_{ROWS}{}^{1,0}$,...,$H_0{}^{Rx,0}$,$H_1{}^{Rx,0}$,...,$H_{ROWS}{}^{Rx,0}$,$H_0{}^{0,1}$,$H_1{}^{0,1}$,...,$H_{ROWS}{}^{0,1}$,$H_0{}^{1,1}$,$H_1{}^{1,1}$,...$H_{ROWS}{}^{1,1}$,...,$H_0{}^{Rx,Lx}$,$H_1{}^{Rx,Lx}$,...$H_{ROWS}{}^{Rx,Lx}$,

Figure 26-89 describe the expected location of each H element vector with respect to *H_CONS*, *H_GAP* and *H_OFFSET* values.

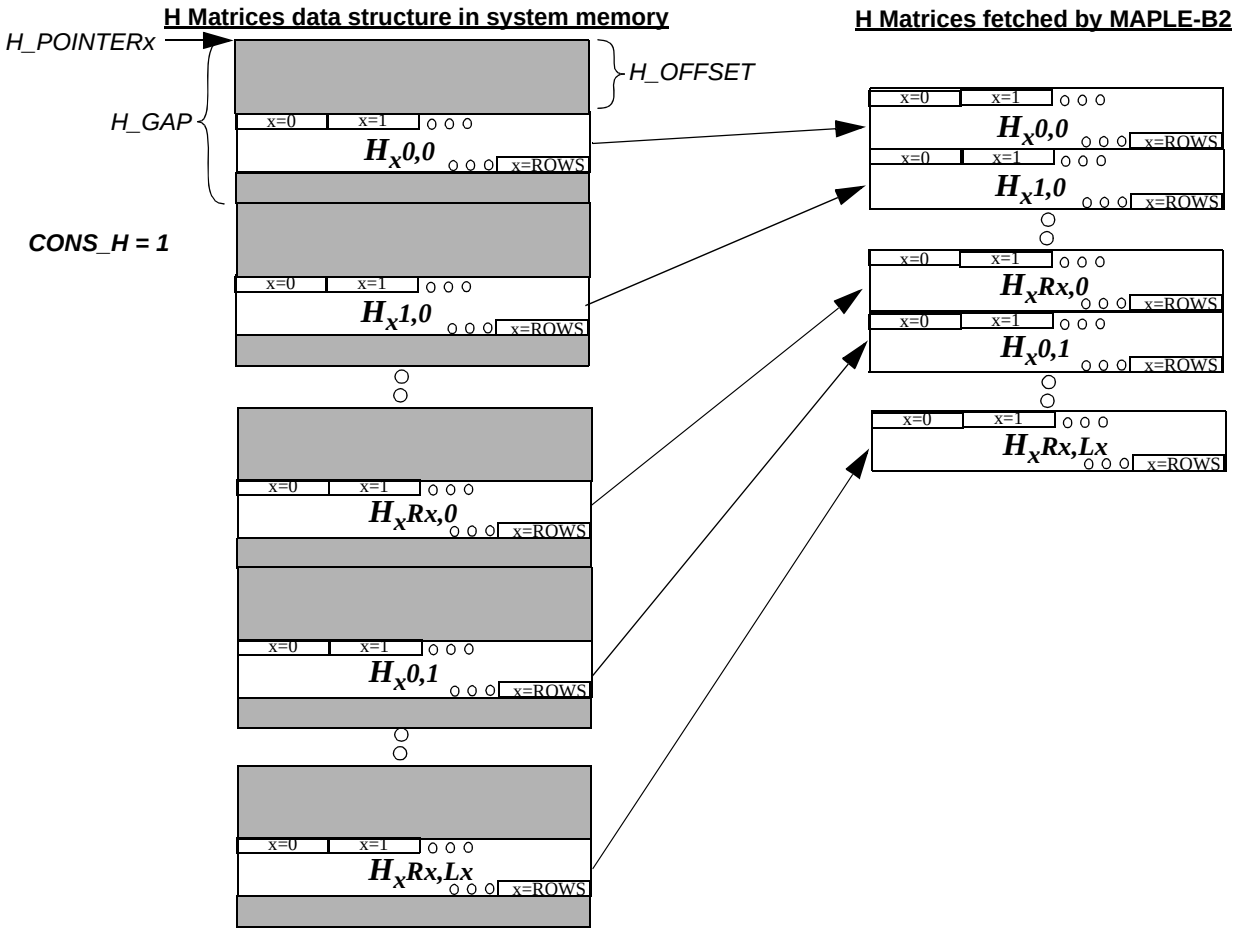


Figure 26-89. H input vectors address calculation using *H_OFFSET* and *H_GAP (CONS_H = 1)*

If the H input vectors are arranged in a consecutive manner for a given job (no gaps between the vectors), the *CONS_H* bit of the EQPE BD should be reset. In this case the MAPLE-B2 internally configures the *H_OFFSET* and *H_GAP* fields as follows:

— *H_OFFSET* = 0;
— *H_GAP = ROWS*;

Figure 26-90 describe the expected data structure in the system memory in case *CONS_H* = 0:

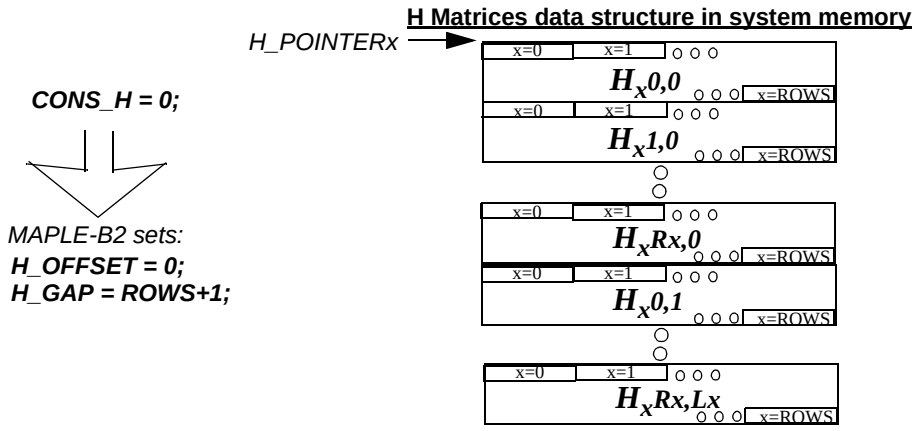

Figure 26-90. H input vectors in system memory in case *CONS_H* = 0

For the non interpolation mode there is only a single reference symbol of H matrices for the whole job. In that case the single input vector should be pointed by *H_POINTER0* and the order of the H matrix elements vectors are as described in **Table 26-36** and the expected location of each vector is the same as described in **Figure 26-89** or **Figure 26-90** (depends on *CONS_H*, *H_OFFSET* and *H_GAP* configuration).

For the external interpolation mode each column of the sub-carrier grid has a column of CE matrices. In that case, assuming $H^{y}_{x\,i,j}$ is an element of H matrix #*x* (x = 0...*ROWS*) of column #y (y= 0...*COLS*) located in row *i* (*i* = 0...*Rx)* and column *j* (*j*=0...*Lx*) of the H matrix, the following describe the fetching order of the H matrix elements vectors located in the single expected vector (*H_POINTER0*). The *CONS_H*, *H_OFFSET* and *H_GAP* fields are used to calculate the offset of the elements vectors as described in **Figure 26-89** or (depends on *CONS_H*, *H_OFFSET* and *H_GAP* configuration)

Table 26-37. H Elements Order in the H Vector for External Interpolation Mode.

H pointer	Description	Index priority	H elements order
H_POINTER0	Reference Symbols 0...*COLS*	for (*j* = 0, *j* <= *Lx*, *j*++) --for (*i* = 0, *i* <= *Rx*, *i*++) ----for (*y* = 0, *y* <= *COLS*, *y*++) ------for (*x* = 0, *x* <= *ROWS*, *x*++) --------place $H^{y}_{x\,i,j}$	$H^{0}_{0}{}^{0,0},H^{0}_{1}{}^{0,0},\ldots,H^{0}_{ROWS}{}^{0,0},H^{1}_{0}{}^{0,0},\ldots,H^{1}_{ROWS}{}^{0,0},\ldots,$ $H^{COLS}_{ROWS}{}^{0,0},H^{0}_{0}{}^{1,0},\ldots,H^{COLS}_{ROWS}{}^{Rx,0},H^{0}_{0}{}^{0,1},\ldots,$ $H^{COLS}_{ROWS}{}^{Rx,1},\ldots,H^{COLS}_{ROWS}{}^{Rx,Lx}$

Note: For external interpolation mode each new column of ***H*** samples must begin with a 16 bytes aligned address - therefore, if the current column do not end at the end of a 16 bytes line, the beginning address of the next column should jump to the next 16 bytes aligned address.

26.4.3.5.4.2.3 H Scales Input Data Structure

The number of H scale samples depends on the interpolation mode. In general, there is a distinct scaling factor for each element of the H matrix (*(Rx+1)* * (*Lx+1)* dimensions) and for each column/reference:

- For II2 there are 2*(*Rx*+1)*(*Lx*+1) H scale samples
- For II4 there are 4*(*Rx*+1)*(*Lx*+1) H scale samples
- For External Interpolation: (*COLS*+1)*(*Rx*+1)*(*Lx*+1) H scale samples
- For No-Interpolation: (*Rx*+1)*(*Lx*+1) H scale samples

All the ***H*** scale samples are of size of 1 byte each and their order in the input vector depends on the job's sub-carrier grid dimensions (*Rx*, *Lx*) and the interpolation mode. The following sections describe the vector structure for each of the relevant configurations.It is assumed that $h^{x}_{i,j}$ is the scale value of element *i,j* (*i* = 0...*Rx*, *j* = 0...*Lx*) in the H Matrix of reference symbol *x* (*x*=0,1 for *II2*, *x*=0...3 for *II4*, *x*=0...*COLS* for External Interpolation and *x* = 0 for Non-interpolation mode).

26.4.3.5.4.2.4 Internal Interpolation 2 (II2) H Scale Vector Structure

Table 26-38. *H* Scale Vector for *II2* and *Rx* x *Lx* Configuration Is 8x4[1]

26.4.3.5.4.2.7 Non Interpolation H Scale Vector Structure

The *H* scale vector structure for the non interpolation mode is identical to the data structure of the H scale vector for External interpolation mode (**Section 26.4.3.5.4.2.6**) with the only difference that for this case there is only a single column of CE matrices ($h^0_{i,j}$).

26.4.3.5.4.2.8 H Scale Vector Address

The MAPLE-B2 expects to find the H scale samples vector at the address as calculated by MAPLE-B2 using the following EQPE BD parameters:

— Address = *SCL_PTR_BA* + (16 * *H_SCL_OFFSET*).

26.4.3.5.4.3 R Samples

The ***R*** samples are the QR decomposition of H in TS mode. Each of the ***R*** samples is represented by a 16-bit fractional fixed point representation of 1q15 (*V*) real and imaginary parts (16I,16Q) and a scale factor (*SCL*) such that the actual value of the sample is: $V \times 2^{SCL}$.

R samples is relevant for the Tree Search (TS) mode only where the QR Decomposition is done externally by the host and QR results are the input for the EQPE. The MAPLE-B2 expects a single ***R*** matrix for each sub-carrier and a total of (*ROWS*+1)*(*COLS*+1) matrices are needed (one for each sub-carrier in the grid) for a TS mode job.

26.4.3.5.4.3.1 R Matrix Input Data Structure

For EQPE TS job, the MAPLE-B2 expect to find a single ***R*** matrix input vector consist of the ***R*** matrices ordered column by column starting from column #0 to column #*COLS (*defined in EQPE BD). The beginning of each ***R*** matrix column should start at 16 bytes aligned address. It means that if previous column of current job did not end at the end of line, the next column should begin at the end of next line. **Figure 26-91** describe an example of ***R*** matrix input:

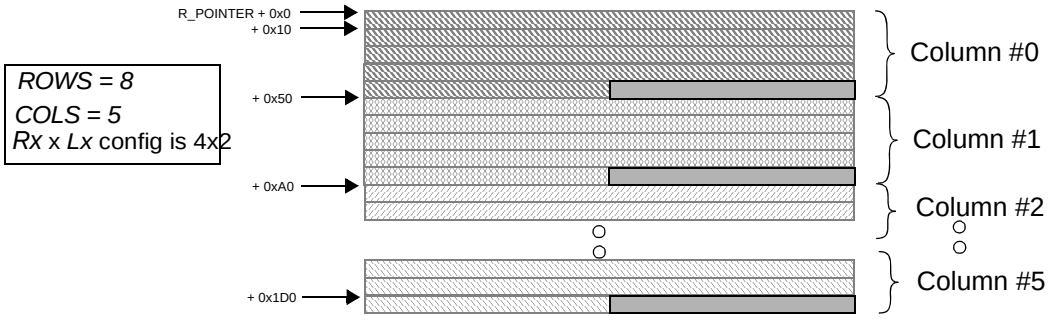

Figure 26-91. *R* Matrix Input Example

The size of each ***R*** matrix is: $(Lx+1)*(Lx+1)*4_{(bytes)}/2_{(upper\ right\ triangular\ matrix)}$.

The structure of the input ***R*** matrix column varies with respect to the *Lx* parameter of the EQPE BD. Assuming $Ry^{I}_{i,j}$ and $Ry^{Q}_{i,j}$ are the real value (*I*) and imaginary value (*Q*) of an ***R*** matrix element where:

- *y* is the index of the ***R*** matrix in the current column (y = 0...*ROWS*)
- *i/j* are the row/column indexes of the ***R*** matrix vertical/horizontal dimensions (*i* = 0...*Lx*, *j* = 0...*Lx*)

the following tables describe the ***R*** matrix structure of a single column in the vector with respect to the *Lx* parameter value:

Table 26-64. *R* Matrix Input Vector for *TS mode when Lx* = 3 (*R* Matrix Is of Size 4x4)

1.The location of the last R matrix in the column depends on the number of rows in the sub-carrier grid (*ROWS*)

26.4.3.5.4.3.2 R Scale Input Data Structure

There are 2 supported options for the R scaling factors, controlled by *RM_SCL_TYPE* field of the EQPE BD:

1. One shared scaling factor for all the ***R*** matrices (*RM_SCL_TYPE*=0).
2. A distinct scaling factor for each matrix. Therefore, there are (*ROWS*+1)*(*COLS*+1) ***R*** scale samples (*RM_SCL_TYPE*=1)[1].

The R scale samples are 1 Byte each and the order of the samples is as follows:

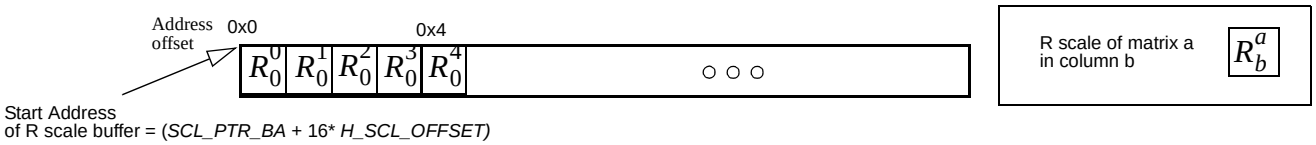

Figure 26-92. *R* Scale Samples Data Structure

The MAPLE-B2 expects to find the R scale samples vector at the following address as calculated by the following EQPE BD parameters: Address = *SCL_PTR_BA* + (16 * *H_SCL_OFFSET*).

26.4.3.5.4.4 M Samples

The ***M*** samples are the input matrix samples in MIV mode. Each of the ***M*** samples is represented by a 16-bit fractional fixed point representation of 1q15 (*V*) real and imaginary parts (16I,16Q) and a scale factor (*SCL*) such that the actual value of the sample is: $V \times 2^{SCL}$.

26.4.3.5.4.4.1 M Matrix Input Data Structure

The ***M*** matrix is relevant for the Matrix Inversion (MIV) mode only. The MAPLE-B2 expects a single vector consist of ***M*** matrices to be inverted by the EQPE. The number of matrices for a matrix inversion job is configured by the *ROWS* parameter of the EQPE BD. The dimensions of the input matrices are configured by the *Lx* parameter of the EQPE BD and the supported dimensions are: 4x4, 3x3, 2x2 and 1x1. The EQPE supports the following two types of input matrices inversion:

- Full Matrix Inversion processing - Both input and output matrices are full.
- Hermitian Matrix Inversion processing - Both input and output matrices are Hermitian

1. In this mode, the max grid size is limited to (ROW+1)*(COLS+1) ≤ 4096.

The control of the Matrix inversion type is done by the *FH* field of the EQPE BD. The size of each element in the matrix is 32 bits (16I, 16Q)[1] and the total size (in bytes) of each matrix depends on both the matrix type (full or hermitian) and its dimensions (as configured by the *Lx* parameter):

- Hermitian matrix (*FH*=0): Size = $(Lx + 1)^2 * 4_{bytes}/2$
- Full matrix (FH=1): Size = $(Lx + 1)^2 * 4_{bytes}$

The data structure of the input vector varies with respect to the matrix type and its dimensions. Assuming $M^I{}_x i,j$ and $M^Q{}_x i,j$ are the real (*I*) and imaginary (*Q*) parts of an element in the M matrix where:

- *x* is the index of the matrix (x = 0...*ROWS*).
- *i/j* are the row/column indexes of the ***M*** matrix vertical/horizontal dimensions (*i* = 0...*Lx*, *j* = 0...*Lx*)

The input data structure of the M matrix input vector is described as follows.

- Full Matrix Inversion. See **Table 26-68** through **Table 26-71**.

Table 26-68. *M* Matrix Input Vector for Full MIV *When Lx* = 3 (*M* matrix is of Size 4x4)

1.The last ***M*** matrix can be located in any of the 8 possible 16-bit structure of the last line (depending on the value of *ROWS*).

The MAPLE-B2 expects to find ***M*** matrix vector at the address pointed by *M_POINTER* during EQPE MIV jobs.

26.4.3.5.4.4.2 M Scale Input Data Structure

There are two supported options for the ***M*** scaling factors controlled by *RM_SCL_TYPE* field of the EQPE BD:

- One shared scaling factor for all the ***M*** matrices (*RM_SCL_TYPE*=0).
- A distinct scaling factor for each matrix. Therefore, there are (*ROWS*+1) ***M*** scale samples (*RM_SCL_TYPE*=1).

The ***M*** scale samples are 1 Byte each and the order of the samples is as follows:

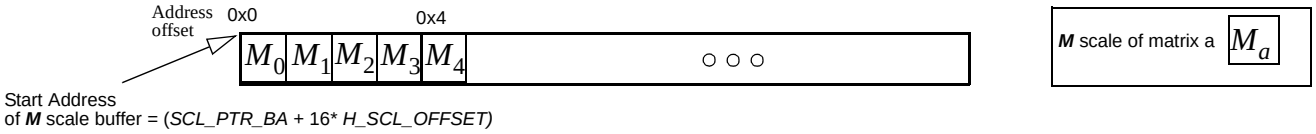

Figure 26-93. *M* Scale Samples Data Structure

If (*RM_SCL_TYPE*=0) then the M scale vector includes single scaling value only.

The MAPLE-B2 expects to find the ***M*** scale samples vector at the following address as calculated by the following EQPE BD parameters: Address = *SCL_PTR_BA* + (16 * *H_SCL_OFFSET*).

26.4.3.5.4.5 S Matrix

The S buffer contains the ***S*** matrices samples (***S*** = $\boldsymbol{C}_n^{-1}$). Each ***S*** sample is represented by a 16-bit fractional fixed point representation of 1q15 (*V*) either real (16I) or complex (16I,16Q) and a scale factor (*S_SCL*) such that the actual value of the sample is: $V \times 2^{S-SCL}$.

26.4.3.5.4.5.1 S matrices Arrangement on the Sub-Carrier Grid

2 parameters control the arrangement of the ***S*** matrices in the S buffer:

- *S_ROW*. The number of rows that share the same ***S*** matrix. If *S_ROW*=0 the all the rows in the job share the same ***S*** matrix.
- *S_COL*. The number of columns that share the same ***S*** matrix. If *S_COL*=0, then all the columns share the same ***S*** matrix.

Figure 26-94 illustrates few examples of using the S_ROW and S_COL on the sub-carrier grid:

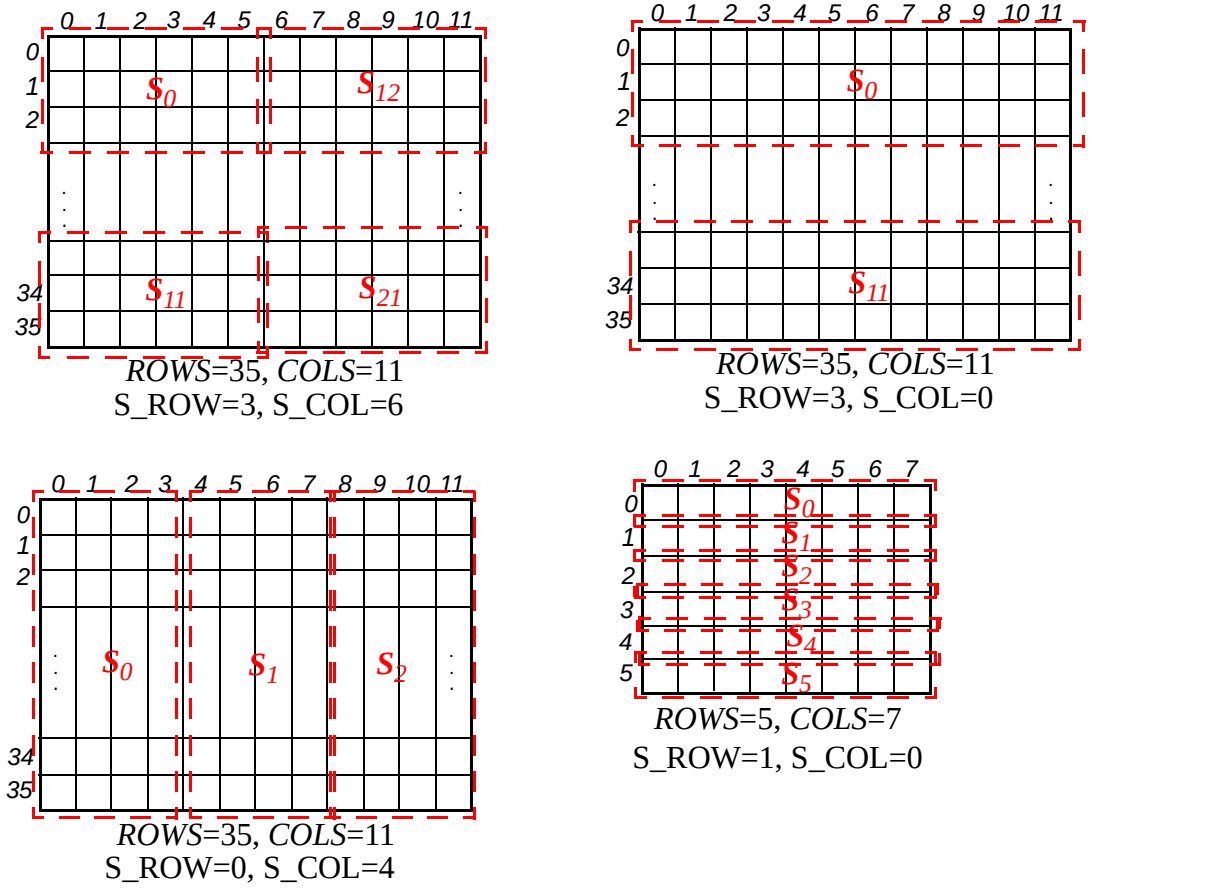

Figure 26-94. ***S*** Matrices Arrangement on the Sub-Carrier Grid

26.4.3.5.4.5.2 S Matrices Input Data Structure

For LNEQ mode, each ***S*** matrix is of *(Rx*+1) x (*Rx* +1) dimensions. There are two supported types of ***S*** matrices which are controlled by the *S_TYPE* parameter of the EQPE BD and affect the ***S*** matrix size:

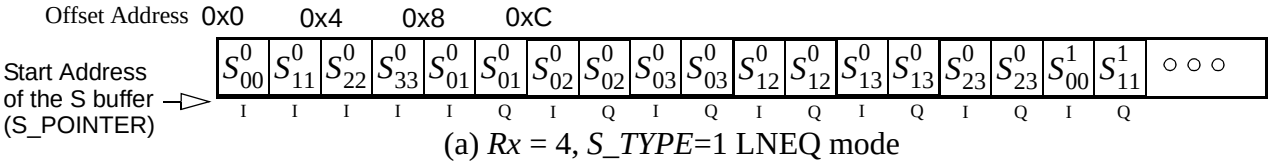
- *S_TYPE*=0: Real diagonal ***S*** matrix. In this case each S matrix is of size of (2 x *Rx)* Bytes

- *S_TYPE*=1: Hermitian ***S*** matrix. In this case each ***S*** matrix is of size of ((4 x *Rx* x *Rx)*/ 2*)* Bytes. The diagonal elements are real and written first followed by the upper-side off-diagonal elements which are complex and written row by row.

For MLEQ and TS mode the EQPE supports single scalar value (16I) per each ***S*** matrix (2 Bytes). For details see **Figure 26-95**.

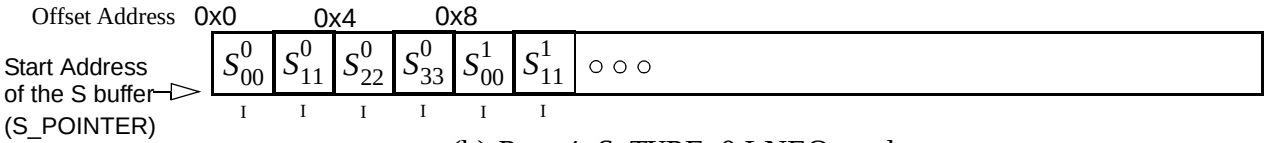
Figure 26-95 describes an example of the expected S matrix structure and the input vector structure for the different modes and types of S matrix:

$$S^0 = \begin{bmatrix} S_{00}^0 & S_{01}^0 & S_{02}^0 & S_{03}^0 \\ S_{01}^{0*} & S_{11}^0 & S_{12}^0 & S_{13}^0 \\ S_{02}^{0*} & S_{12}^{0*} & S_{22}^0 & S_{23}^0 \\ S_{03}^{0*} & S_{13}^{0*} & S_{23}^{0*} & S_{33}^0 \end{bmatrix} \quad \circ\circ\circ \quad S^N = \begin{bmatrix} S_{00}^0 & S_{01}^0 & S_{02}^0 & S_{03}^0 \\ S_{01}^{0*} & S_{11}^0 & S_{12}^0 & S_{13}^0 \\ S_{02}^{0*} & S_{12}^{0*} & S_{22}^0 & S_{23}^0 \\ S_{03}^{0*} & S_{13}^{0*} & S_{23}^{0*} & S_{33}^0 \end{bmatrix}$$



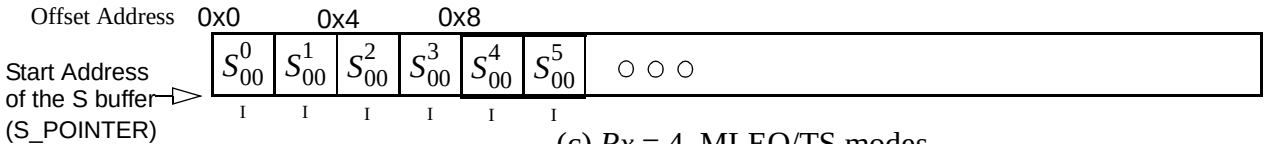
(a) *Rx* = 4, *S_TYPE*=1 LNEQ mode

$$S^0 = \begin{bmatrix} S_{00}^0 & 0 & 0 & 0 \\ 0 & S_{11}^0 & 0 & 0 \\ 0 & 0 & S_{22}^0 & 0 \\ 0 & 0 & 0 & S_{33}^0 \end{bmatrix} \quad \circ\circ\circ \quad S^N = \begin{bmatrix} S_{00}^0 & 0 & 0 & 0 \\ 0 & S_{11}^0 & 0 & 0 \\ 0 & 0 & S_{22}^0 & 0 \\ 0 & 0 & 0 & S_{33}^0 \end{bmatrix}$$



(b) *Rx* = 4, *S_TYPE*=0 LNEQ mode

$$S^0 = S_{00}^0 \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad \circ\circ\circ \quad S^N = S_{00}^N \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$



(c) *Rx* = 4, MLEQ/TS modes

Figure 26-95. S matrices Data Structure

The number of ***S*** matrices in the job is calculated as follows and also should be configured in the *S_SIZE* field of the EQPE BD:

if (*S_ROWS*=0 & *S_COLS* =0)

S_SIZE = 1

if (*S_ROW* ≠ 0 & *S_COLS*=0)

$$S\_SIZE = \left\lceil \frac{ROWS + 1}{SROWS} \right\rceil$$

if (*S_ROW* = 0 & *S_COLS* ≠0)

$$S\_SIZE = \left\lceil \frac{COLS + 1}{SCOLS} \right\rceil$$

if (*S_ROW* ≠ 0 & *S_COLS* ≠0)

$$S\_SIZE = \left\lceil \frac{COLS + 1}{SCOLS} \right\rceil \times \left\lceil \frac{ROWS + 1}{SROWS} \right\rceil$$

The MAPLE-B2 expect to find the ***S*** matrices vector at the address pointed by the *S_POINTER* field of the EQPE BD.

26.4.3.5.4.5.3 S Matrices Granularity Limitation

The S buffer size is 16KByte for LNEQ mode and 8KBytes for MLEQ and TS modes. It is prohibited to give a command that exceeds the S buffer size that is, the job includes more S matrices than the S buffer can contain. Calculating the S buffer size is done as follows:

if (*ALG* = 0 & *S_TYPE* = 0)

S_SIZE x (*Rx* + 1) x 2B ≤ 16KB

if (*ALG* = 0 & *S_TYPE* = 1)

S_SIZE x $(Rx + 1)^2$ x 2B ≤ 16KB

if (*ALG* = 1 or *ALG* = 2)

S_SIZE x 2B ≤ 16KB

For example, for an EQPE job in LNEQ mode of 1200x12 sub-carriers (*ROWS* = 1199, *COLS*=11) with 4 receive antennas (*Rx* = 3) and *S_TYPE*=1:

- if *S_COL*=0 then *S_ROW*>=3 are the legal values.
- if *S_COL*=6 then *S_ROW*>=5 are the legal values.

26.4.3.5.4.5.4 S Scale Samples Input Data Structure

The EQPE supports two types of scaling methods for the ***S*** matrix samples:

- Single shared scale value for all input matrices.
- Different scale value for each input S matrix.

Controlling which ***S*** scale method is used is done using the *S_SCL_TYPE* parameter of the EQPE BD. The size of each scaling sample is one byte and the size of the scale vector is either one byte

if single shared scale value is used (*S_SCL_TYPE*=0), or *S_SIZE* Bytes (see **Section 26.4.3.5.4.5.2**) if different scale value for each S matrix is used (*S_SCL_TYPE*=1).

The MAPLE-B2 expects to find the ***S*** scale samples vector at the following address as calculated by the following EQPE BD parameters: Address = *SCL_PTR_BA* + (16 * *S_SCL_OFFSET*).

Note: If *S_SCL_TYPE*=1, the total amount of ***S*** matrices is limited to 1600 for the job.

26.4.3.5.4.6 C Samples

The C vector contains the samples of $\boldsymbol{C}=\boldsymbol{C}_x^{-1}$. It is assumed that ***C*** is a real, diagonal *Lx* x *Lx* matrix. Each element in the ***C*** matrix is represented by 16-bit fractional (real-part only). The C samples are represented by a 16-bit mantissa in 1q15 (*V*). All ***C*** samples share a common scale factor written to the *C_SCL* parameter of the EQPE BD such that the actual value of each of the C samples is: $V \times 2^{C\_SCL}$.

The C vector is used only for LNEQ mode and only if the *C_EN* parameter of the EQPE BD is set. If *C_EN*=0 then the C vector is not used and the EQPE uses ***C* = *Identity* *Matrix*** in the calculation.

26.4.3.5.4.6.1 C Matrices Arrangement on the Sub-Carrier Grid

It is assumed that the ***C*** matrix is identical for all the sub-carriers in the same column in the grid. Therefore only one ***C*** matrix is inserted for each column. **Figure 26-96** shows an example of ***C*** matrices arrangement on the sub-carrier grid.

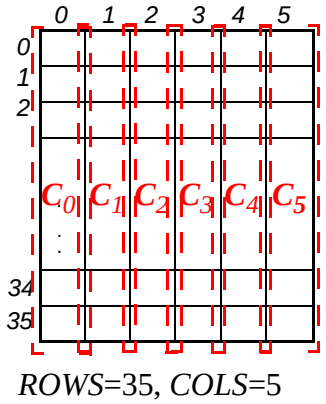


Figure 26-96. C Matrices Arrangement on Sub-Carrier Grid

26.4.3.5.4.6.2 C Samples Input Data Structure

Table 26-76 through **Table 26-79** describe the ***C*** samples vector input data structure. Assuming $C^x_{i,i}$ is the C matrix element where:

- *x* is the column index on the sub-carrier grid (*x* = 0...*COLS*)
- *i* is the column and row index of the element in the C matrix (*i* = 0...*Lx*)

Table 26-76. *C* Matrix Input Vector *When Lx* = 3 (*C* Matrix Is of Size 4x4)

1.The location of the last ***C*** matrix depends on the value of *COLS*.

Table 26-79. *C* Matrix Input Vector *When Lx* = 0 (*C* Matrix Is of Size 1x1)

Memory line	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
#1	C^0_{00}		C^1_{00}		C^2_{00}		C^3_{00}		...		...		...		...	

The MAPLE_B2 expect to find the ***C*** samples vector at the address pointed by the *C_POINTER* field of the EQPE BD.

All the ***C*** samples in the job share one common scale factor which should be written to *C_SCL* field of the EQPE BD hence no C scale vector is required. The *C_SCL* field is ignored if *C_EN* of the EQPE BD is reset (*C_EN* = 0).

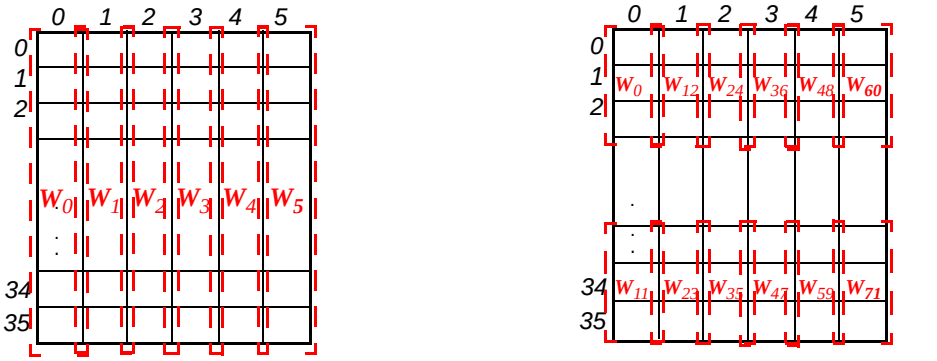
26.4.3.5.4.7 W Samples

The ***W*** samples are the interpolation weights. Each ***W*** sample is represented by a real 16-bit fractional fixed point representation of 2q14. The W samples are used only for LNEQ and MLEQ internal interpolations modes (*INTRP*=0,1).

26.4.3.5.4.7.1 W Samples Arrangement on the Sub-Carrier Grid

The parameter that controls the arrangement of the ***W*** samples on the sub-carrier grid is the *W_ROW* parameter of the EQPE BD. There is a distinct weight for every layer of every column for every reference symbol. The *W_ROW* parameter controls the number of rows that share the

same ***W*** samples. If *W_ROW*=0 then all the rows in the job share the same ***W*** samples. The following figure describe an example of the *W_ROW* usage:



(a) ROWS=35, *W_ROW*=0 *(b) ROWS*=35, *W_ROW*=3

Figure 26-97. W Matrices Arrangement on Sub-Carrier Grid

Note: if (*W_ROW* !=0) then the value of (*ROWS* + 1) must be a integer multiplication of *W_ROW*.

26.4.3.5.4.7.2 W Samples Input Data Structure

The ***W*** samples are of size of 2 bytes each. The total number of input ***W*** samples is:

if (*W_ROW* = 0)

II2: $2 \times 1 \times (Lx + 1) \times (COLS + 1) \times 2$ Bytes.

II4: $4 \times 1 \times (Lx + 1) \times (COLS + 1) \times 2$ Bytes.

else

II2: $2 \times \left\lceil \frac{ROWS + 1}{WROWS} \right\rceil \times (Lx + 1) \times (COLS + 1) \times 2$ Bytes

II4: $4 \times \left\lceil \frac{ROWS + 1}{WROWS} \right\rceil \times (Lx + 1) \times (COLS + 1) \times 2$ Bytes

The calculations above represent:

[references] x [weight per column] x [layers] x [columns] x [bytes per weight]

The total size of the ***W*** samples vector as calculated above is internally calculated by the MAPLE-B2 using the *W_SIZE* parameter of the EQPE BD which should be set as follows:

if ($W\_ROW = 0$)

$W\_SIZE = 1$

else

$W\_SIZE = \left\lceil \frac{ROWS + 1}{WROWS} \right\rceil$

The order to the ***W*** samples in the input vector is in correlation to the EQPE processing order of the sub-carriers as described in **Section 26.4.3.5.3**, *EQPE Sub-Carrier Grid*, that is, column by column.

If $W\_ROW = 0$, that is, all sub-carriers in each column share the same interpolation weight (see **Figure 26-97** (a)) then the expected order of the ***W*** samples in the input W vector would be:

For II2:

$W^0{}_0 0, W^0{}_0 1, W^0{}_1 0, W^0{}_1 1, \ldots, W^0{}_{Lx} 0, W^0{}_{Lx} 1, \backslash$
$W^1{}_0 0, W^1{}_0 1, W^1{}_1 0, W^1{}_1 1, \ldots, W^1{}_{Lx} 0, W^1{}_{Lx} 1, \backslash$
...
$W^{COLS}{}_0 0, W^{COLS}{}_0 1, W^{COLS}{}_1 0, W^{COLS}{}_1 1, \ldots, W^{COLS}{}_{Lx} 0, W^{COLS}{}_{Lx} 1.$

For II4:

$W^0{}_0 0, W^0{}_0 1, W^0{}_0 2, W^0{}_0 3, W^0{}_1 0, W^0{}_1 1, W^0{}_1 2, W^0{}_1 3, \ldots, W^0{}_{Lx} 0, W^0{}_{Lx} 1, W^0{}_{Lx} 2, W^0{}_{Lx} 3, \backslash$
$W^1{}_0 0, W^1{}_0 1, W^1{}_0 2, W^1{}_0 3, W^1{}_1 0, W^1{}_1 1, W^1{}_1 2, W^1{}_1 3, \ldots, W^1{}_{Lx} 0, W^1{}_{Lx} 1, W^1{}_{Lx} 2, W^1{}_{Lx} 3, \backslash$
...
$W^{COLS}{}_0 0, W^{COLS}{}_0 1, W^{COLS}{}_0 2, W^{COLS}{}_0 3, W^{COLS}{}_1 0, W^{COLS}{}_1 1, W^{COLS}{}_1 2, W^{COLS}{}_1 3, \ldots, W^{COLS}{}_{Lx} 0, \backslash$
$W^{COLS}{}_{Lx} 1, W^{COLS}{}_{Lx} 2, W^{COLS}{}_{lx} 3.$

Where:

— $W^x{}_y Z$ - *W* weight sample of column *x* ($x = 0 \ldots COLS$), with layer index *y* ($y = 0 \ldots Lx$). *Z* indicates it's the weight for reference input number *Z* (II2: $Z = 0,1$. II4: $Z = 0 \ldots 3$).

If $W\_ROW \neq 0$, that is, every number of rows equal to *W_ROW* the weights in the column change, the expected order of the ***W*** samples vector is as described in **Table 26-80**.

Table 26-80. *W* Samples Order in the *W* Vectors If $W\_ROW \neq 0$.

Interpolation Type	Index priority	W elements order
II2	for (x = 0, x <= *COLS*, x++) --for (i = 0, j <= J (= $\lceil (ROWS)/(WROWS) \rceil$), j++) ----for (y = 0, y <= *Lx*, y++) ------for (Z = 0, x <= *1*, x++) --------place $W^x{}_y Z$	$W^0{}_0 0, W^0{}_0 1, W^0{}_1 0, W^0{}_1 1, \ldots, W^0{}_{Lx} 0, W^0{}_{Lx} 1, W^0{}_1 0, \ldots,$ $W^0{}_{Lx} 0, W^0{}_{Lx} 1, \ldots, W^0{}_J 0, W^0{}_J 1, \ldots, W^0{}_{Lx} 1, W^1{}_0 0, \ldots,$ $W^1{}_{Lx} 1, \ldots, W^{COLS}{}_0 0, \ldots, W^{COLS}{}_{Lx} 1.$
II4	for (x = 0, x <= *COLS*, x++) --for (i = 0, j <= $\lceil (ROWS)/(WROWS) \rceil$, j++) ----for (y = 0, y <= *Lx*, y++) ------for (Z = 0, x <= *3*, x++) --------place $W^x{}_y Z$	$W^0{}_0 0, W^0{}_0 1, W^0{}_0 2, W^0{}_0 3, W^0{}_1 0, W^0{}_1 1, \ldots, W^0{}_{Lx} 0, W^0{}_{Lx} 1,$ $W^0{}_{Lx} 2, W^0{}_{Lx} 3, W^0{}_1 0, \ldots, W^0{}_{Lx} 0, W^0{}_{Lx} 1, W^0{}_{Lx} 2, W^0{}_{Lx} 3, \ldots,$ $W^0{}_J 0, W^0{}_J 1, W^0{}_J 2, W^0{}_J 3, \ldots, W^0{}_{Lx} 3, W^1{}_0 0, \ldots, W^1{}_{Lx} 3, \ldots,$ $W^{COLS}{}_0 0, \ldots, W^{COLS}{}_{Lx} 3.$

where for $W^x{}_y Z$:

- x is the sub-carrier grid column index (x = 0...*COLS*).
- i is the number of weight changes in each column (i = 0...$\lceil (ROWS)/(WROWS) \rceil$)
- y is the number of layers (y = 0...Lx)
- Z is the number of CE reference symbols (II2: Z = 0,1. II4: Z = 0...3)

The MAPLE-B2 expect to find the ***W*** samples vector at the address pointed by the *W_POINTER* field of the EQPE BD.

26.4.3.5.4.8 F Samples

The ***F*** samples are the feedback samples which are used in LNEQ mode for cancellation algorithms. The ***F*** samples are used only when cancellation is enabled, for details see **Section 26.4.3.5.6.3.1**, *Layer Cancellation*. Each feedback sample is represented by a 32-bit (16I,16Q) fractional mantissa in 1q15 (*V*). All ***F*** samples of the same column share the same scaling factor (F_SCL_{col}) such that the actual value of the sample is in: V x 2^{F_SCLcol}. The EQPE supports single layer cancellation only, therefore, the feedback samples of only one layer are expected as input to EQPE job.

26.4.3.5.4.8.1 F Samples Input Data Structure

The size of the F vector, which includes all ***F*** samples of a given layer to be cancelled, should include *(ROWS+1)* x *(COLS+1)* samples (each of size of 4 bytes). The order of the ***F*** samples input vector is column by column, that is, if F_x^y is a ***F*** sample of row index x (x = 0...*ROWS*) and of column index y (y = 0...*COLS*), then the expected order of the input vector is:

$$F^0_0, F^0_1, F^0_2,..., F^0_{ROWS}, F^1_0, F^1_1, F^1_2,..., F^1_{ROWS},..., F^{COLS}_0, F^{COLS}_1, F^{COLS}_2,..., F^{COLS}_{ROWS}.$$

The following figure illustrates such example:

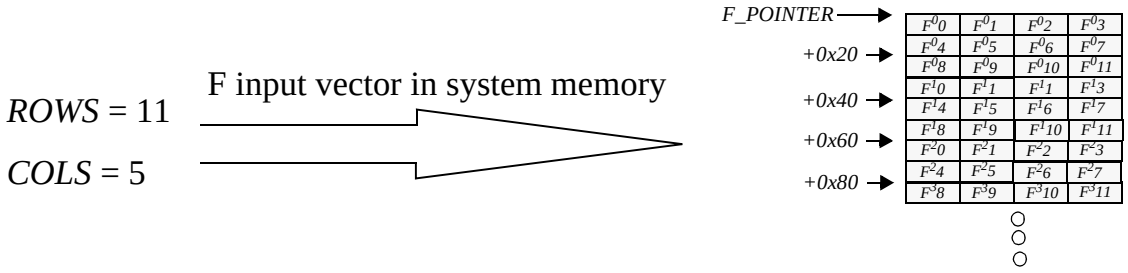


Figure 26-98. F Input Vector Example

The MAPLE-B2 expects to find the F input vector at the address pointed by the *F_POINTER* parameter of the EQPE BD.

26.4.3.5.4.8.2 F Scale Input Data Structure

The F scale input vector should include a single scale value, each of one byte, for each column as defined in the *COLS* field of the EQPE BD. The expected order of the scale values is:

$f_0, f_1, f_2, \ldots, f_{COLS}$.
where f_x is the scale value of column x (x = 0...*COLS*).

The MAPLE-B2 expects to find the ***F*** scale samples vector at the following address as calculated by the following EQPE BD parameters: Address = *SCL_PTR_BA* + (16 * *F_SCL_OFFSET*).

26.4.3.5.4.9 EQPE Input Data Structure - Summary

The following table summarize the EQPE input data vectors for each of its modes. The table summarize the sizes of each required vector in each mode.

Table 26-81. EQPE Input vectors sizes (in bytes)

Vector Type	LNEQ mode	MLEQ mode	TS mode	MIV mode

26.4.3.5.5 EQPE Processing

The following sections describe the different aspects of the EQPE processing.

26.4.3.5.5.1 EQPE Algorithm Description

The EQPE supports the following operations:

- Linear Equalization (MMSE or Zero Forcing)
- ML Equalization and Detection (using QRD-M algorithm)
- Tree-Search
- General purpose Matrix Inversion

26.4.3.5.5.2 Linear Equalization

Linear Equalization is the implementation of all the equalization schemes that include Zero-Forcing or MMSE with or without cancellation (SIC schemes).

The model assumptions are:

$$\boldsymbol{y} = \boldsymbol{Hx} + \boldsymbol{n}$$

where:

$\boldsymbol{y}$ is a N_Rx1 vector of the received samples from each *Rx* antenna.

$\boldsymbol{x}$ is a N_Tx1 the transmitted signal.

$\boldsymbol{H}$ is the N_RxN_T CE (Channel Estimation) matrix.

$$\boldsymbol{x} \sim CN\{\underline{\mathbf{0}}, \boldsymbol{C}_x\}\ , \quad \boldsymbol{n} \sim CN\{\underline{\mathbf{0}}, \boldsymbol{C}_n\}$$

where:

$\boldsymbol{C}_x$ is the N_TxN_T Covariance matrix of the transmitted signal.

$\boldsymbol{C}_n$ is the N_RxN_R Covariance matrix of the noise.

CN is complex Normal distribution.

The MMSE Estimation is:

$$\hat{\boldsymbol{x}} = (\boldsymbol{H}^H \boldsymbol{C}_n^{-1} \boldsymbol{H} + \boldsymbol{C}_x^{-1})^{-1} \boldsymbol{H}^H \boldsymbol{C}_n^{-1} \boldsymbol{y}$$

The notation of this document is that: $\boldsymbol{C} = \boldsymbol{C}_x^{-1}$, $\boldsymbol{S} = \boldsymbol{C}_n^{-1}$

In this notation the implemented output is:

$$\hat{\boldsymbol{x}} = (\boldsymbol{H}^H \boldsymbol{S} \boldsymbol{H} + \boldsymbol{C})^{-1} \boldsymbol{H}^H \boldsymbol{S} \tilde{\boldsymbol{y}} \quad , \qquad \textbf{Equation 1}$$

$\boldsymbol{H}$,$\boldsymbol{S}$,$\boldsymbol{C}$ and $\boldsymbol{y}$ are the inputs to the EQPE (see **Section 26.4.3.5.4**).

If cancellation is configured: $\tilde{\boldsymbol{y}} = \boldsymbol{y} - \boldsymbol{h}_i f_i$, otherwise $\tilde{\boldsymbol{y}} = \boldsymbol{y}$.

where:

$\boldsymbol{h}_i$ is the i[th] column of $\boldsymbol{H}$.

f_i is the estimation of layer i calculated from previous iterations (feedback layer).

Note: The EQPE supports only one internal layer cancellation. If more than one layer is required to be cancelled, then the host should perform the cancellation externally and give the EQPE the new $\boldsymbol{y}$ samples ($\boldsymbol{y}$ after cancellation) as the y samples.

Equation 1 is calculated in 3 main steps:

1. Matrix Multiplication:

$$\boldsymbol{D} = (\boldsymbol{H}^H \boldsymbol{S} \boldsymbol{H} + \boldsymbol{C})$$

$$\boldsymbol{z} = \boldsymbol{H}^H \boldsymbol{S} \tilde{\boldsymbol{y}}$$

2. QR Decomposition (using Given's-Rotation):

$$[\mathbf{Q},\mathbf{R}] = \mathrm{qr}(\mathbf{D})$$
$$\boldsymbol{q} = \boldsymbol{Q}^H \boldsymbol{z}$$

3. Back-Substitution:

solve $\boldsymbol{Rx}=\boldsymbol{q}$

Zero-Forcing algorithm uses the $\boldsymbol{H}$, $\boldsymbol{y}$, $\boldsymbol{C}=\boldsymbol{0}$, $\boldsymbol{S}=\boldsymbol{I}$ input such that

$$\hat{\boldsymbol{x}}_{ZF} = (\boldsymbol{H}^H\boldsymbol{H})^{-1}\boldsymbol{H}^H\tilde{\boldsymbol{y}} \qquad \textbf{Equation 2}$$

26.4.3.5.5.3 QRD-M Equalization (MLEQ)

QRD-M is a way to implement the Maximum Likelihood estimator or to approximate it.

For the model:

$$\boldsymbol{y} = \boldsymbol{Hx} + \boldsymbol{n}$$

$$\boldsymbol{n} \sim CN\{\boldsymbol{0}, \sigma^2\boldsymbol{I}\},\ \boldsymbol{x} \in QAM$$

The *ML* solution:

$$LLR(b) = \frac{1}{\sigma^2}[-\min_{\boldsymbol{x}:\ b=1}\{d(\boldsymbol{x})\} + \min_{\boldsymbol{x}:\ b=0}\{d(\boldsymbol{x})\}],\ d(\boldsymbol{x}) = \|\boldsymbol{y}-\boldsymbol{Hx}\|^2 \qquad \textbf{Equation 3}$$

where

$\boldsymbol{x}$ - the transmitted symbol vector $(N_T x1)$

$d(\boldsymbol{x})$ - the squared Euclidian distances between the received signal and constellation point $\boldsymbol{x}$.

$\boldsymbol{H}$ - the channel matrix $(N_R x N_T)$

$\boldsymbol{y}$ - the received signal vector $(N_R x1)$

σ^2 - the noise variance

The notation of this document is $\boldsymbol{S} = \boldsymbol{C}_n^{-1}$ and in MLEQ mode it is always a scaled identity matrix for example, $\boldsymbol{S} = \sigma^{-2}\boldsymbol{I}$

This solution has been shown to be optimal (without exploiting channel coding).

QRD-M:

First stage is to perform a QR Decomposition on the CE matrix $\boldsymbol{H}$, i.e $\boldsymbol{H}=\boldsymbol{QR}$.

The QRD has 2 properties:

- $\boldsymbol{Q}$ is a unitary matrix that is, $\boldsymbol{Q}^H\boldsymbol{Q}=\boldsymbol{I}$
- $\boldsymbol{R}$ is an upper-right triangular matrix.

This allows rewriting of the *ML* function:

$$d(\boldsymbol{x}) = \|\boldsymbol{y}-\boldsymbol{Hs}\|^2 = \|\boldsymbol{y}-\boldsymbol{QRx}\|^2 = \left\|Q^H\boldsymbol{y}-\boldsymbol{Rx}\right\|^2 = \|\tilde{\boldsymbol{y}}-\boldsymbol{Rx}\|^2$$

and the *ML* solution remains unchanged:

$$LLR(b) = \boldsymbol{S}[-\min_{\boldsymbol{x}:\,b=1}\{d(\boldsymbol{x})\} + \min_{\boldsymbol{x}:\,b=0}\{d(\boldsymbol{x})\}],\ d(\boldsymbol{x}) = \left\|\tilde{\boldsymbol{y}} - \boldsymbol{R}\boldsymbol{x}\right\|^2 \qquad \textbf{Equation 4}$$

The distances $d(\boldsymbol{x})$ in **Equation 4** can now be separated to N_T components, and the problem of finding the minimal d's can be illustrates as a tree-search.

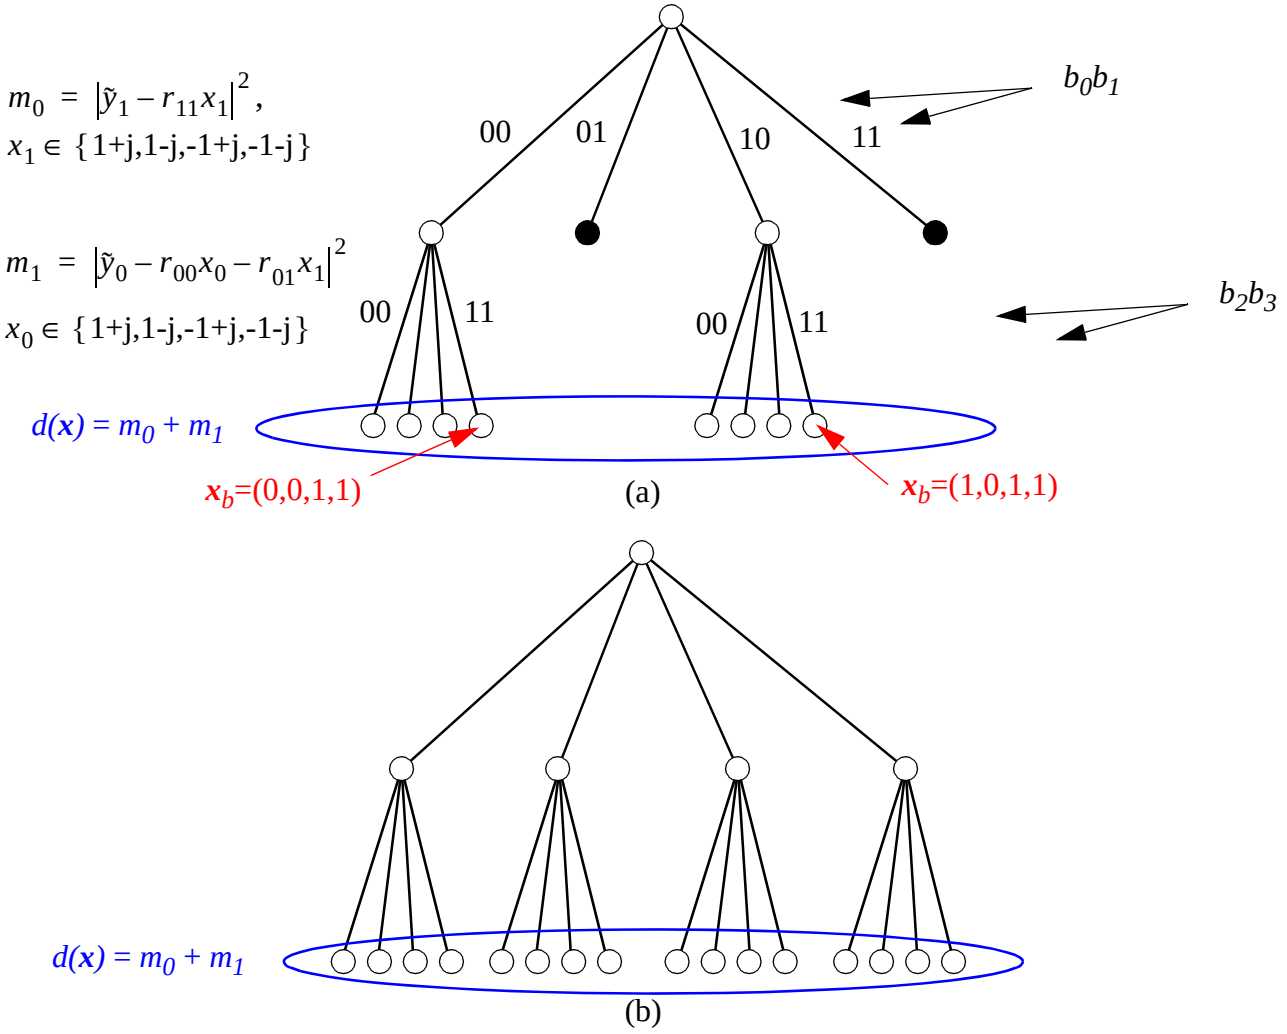

Figure 26-99. QRD-M Tree Search Example. QPSK, 2 Layers (a) M=2 (b) M=M_{max}=4

The *ML* solution can be obtained by calculating all the nodes of the tree. Each "leaf" of the tree (the nodes at the bottom level) represent the d's which are the sum of the first and second metrics. After calculating all of the *d*'s, the LLRs of the transmitted bits can be calculated according to **Equation 4**.

The *QRD-M* is a way to further reduce the complexity at the expense of the full performance, that is, it achieves sub-optimal performance with less operations. This is done by discarding parts of the tree that are less likely to be used by the LLR calculation **Equation 4**.

This is done by choosing the parameter $1<=M<=M_{max}$. At the first level of tree, all the nodes are calculated, and the *M* best nodes (the nodes with the minimal accumulated metric) are selected as survivors. At the next level, only the nodes coming from the surviving nodes are calculated. Again the M-best nodes are selected, and so on until the final level of the tree where the leaves represent the d's and the LLRs are calculated. At the final level of the tree, only (*Card* x *M*) *d*'s are available instead of $Card^{Nt}$. Because of this, we get an approximation of the LLRs and sub-optimal performance. (*Card* is the cardinality of the symbol constellation, for example, $Card_{QPSK}$=4,$Card_{16QAM}$=16...)

A greater problem might occur when one of the minimization problems solved in **Equation 4** to calculate the LLRs encounter an empty group (no *d*'s of that group survived), the method to deal with this problem are described in **Section 26.4.3.5.5.4**, *LLR Calculations*.

M provides a convenient trade-off control between performance and complexity. By choosing the maximal $M_{max}=Card^{(Nt-1)}$, we can obtain a full tree-search and the optimal performance. By reducing *M* we reduce complexity and narrow the tree-search.

26.4.3.5.5.4 LLR Calculations

The LLR of each bit is calculated according to **Equation 4**. When one of the minimization groups is empty, the EQPE takes maximal absolute value LLR from all the bits in the sub-carrier and assigns this value to the LLR with the proper sign.

26.4.3.5.5.5 Tree Search

The EQPE performs tree search only. The QR Decomposition is performed externally on the CE matrix ("H") and the EQPE is given R and Q^Hy (*Lx* x 1 vector) and performs tree search to produce LLRs of the transmitted bits as described in **Section 26.4.3.5.5.3**, *QRD-M Equalization (MLEQ)*.

26.4.3.5.5.6 Matrix Inversion

The EQPE performs matrix inversion for square matrices of size *Lx* x *Lx* using QR Decomposition:

$$[Q,R] = qr(M) \qquad \text{Equation 5}$$

The inversion is completed with Back-Substitution:

$$Rx_i = q_i \text{ , } i=1,...,Lx \qquad \text{Equation 6}$$

where:

$\boldsymbol{q}_i$ is the i^{th} column of $\boldsymbol{Q}^H$.

$\boldsymbol{x}_i$ is the i^{th} column of $\boldsymbol{M}^{-1}$ which are via Back-Substitution.

26.4.3.5.5.7 CE Matrix Interpolation

CE Matrix Interpolation is supported only for LNEQ and MLEQ modes (*ALG*=0,1). Interpolation is performed by using interpolation weights - "*W* samples" (see **Section 26.4.3.5.4.7**, *W Samples*) and the CE matrices samples - "*H* samples" (see **Section 26.4.3.5.4.2**, *H Samples*).

The EQPE supports 4 interpolation schemes:

- *Internal Interpolation 2* (II2)*:* (*INTRP*=0)
  In this mode the EQPE performs the interpolation internally using 2 references (A and B) for each sub-carrier. Only the reference H matrices are inserted and the EQPE performs weighted interpolation using them.
  Each row *k* has 2 CE reference matrices $\boldsymbol{H}^{A}_{k}$ and $\boldsymbol{H}^{B}_{k}$. By configuring $w^{A}_{i,j}$ and $w^{B}_{i,j}$ (*i*=0,1,...,*COLS* and *j*=0,...,*Lx*), Each column and layer can have a different weight for each reference matrix.
  The implemented interpolation for the sub-carrier in the k^{th} row in column *i* is (2 layers example):

$$H_{k,i} = [w^{A}_{i,0} \times h^{A}_{k,0} + w^{B}_{i,0} \times h^{B}_{k,0} \; ; \; w^{A}_{i,1} \times h^{A}_{k,1} + w^{B}_{i,1} \times h^{B}_{k,1}] \qquad \textbf{Equation 7}$$

  $\boldsymbol{h}^{A}_{k,0}$ is column 0 of reference matrix A of row k.

- *Internal Interpolation 4* (II4)[1]*:* (*INTRP*=1)
  In this mode the EQPE performs the interpolation internally using 4 reference matrices (A,B,C and D) for each sub-carrier. Only the reference H matrices are inserted and EQPE performs weight interpolation using them.
  Each row *k* has 4 CE reference matrices $\boldsymbol{H}^{A}_{k}$,$\boldsymbol{H}^{B}_{k}$,$\boldsymbol{H}^{C}_{k}$ and $\boldsymbol{H}^{D}_{k}$, and each Resource Element (RE) in the row can have a different weight for each reference vector or column in the reference matrix.
  The implemented interpolation for the sub-carrier in the k^{th} row in column *i* is:

$$h_{k,i} = [w^{A}_{i,0} \times h^{A}_{k} + w^{B}_{i,0} \times h^{B}_{k} + w^{C}_{i,0} \times h^{C}_{k} + w^{D}_{i,0} \times h^{D}_{k}] \qquad \textbf{Equation 8}$$

  $\boldsymbol{h}^{A}_{k}$ is reference vector A of row k.

- *External Interpolation:* (*INTRP*=2)
  In this mode, CE interpolation is performed by the host and the EQPE is given an explicit *H* matrix for each RE.
- *No Interpolation:* (*INTRP*=3)
  In this mode, no interpolation is performed and the EQPE is given one *H* matrix for each row. This matrix is used for each RE in the row.

1. This mode is not supported for 8x4, 8x3 jobs (*Rx*=7 and *Lx*=3,2).

Figure 26-100 shows an example of 3G-LTE and WiMAX allocations examples, and the translations of these jobs to the sub-carrier grid in internal interpolation 2 mode.

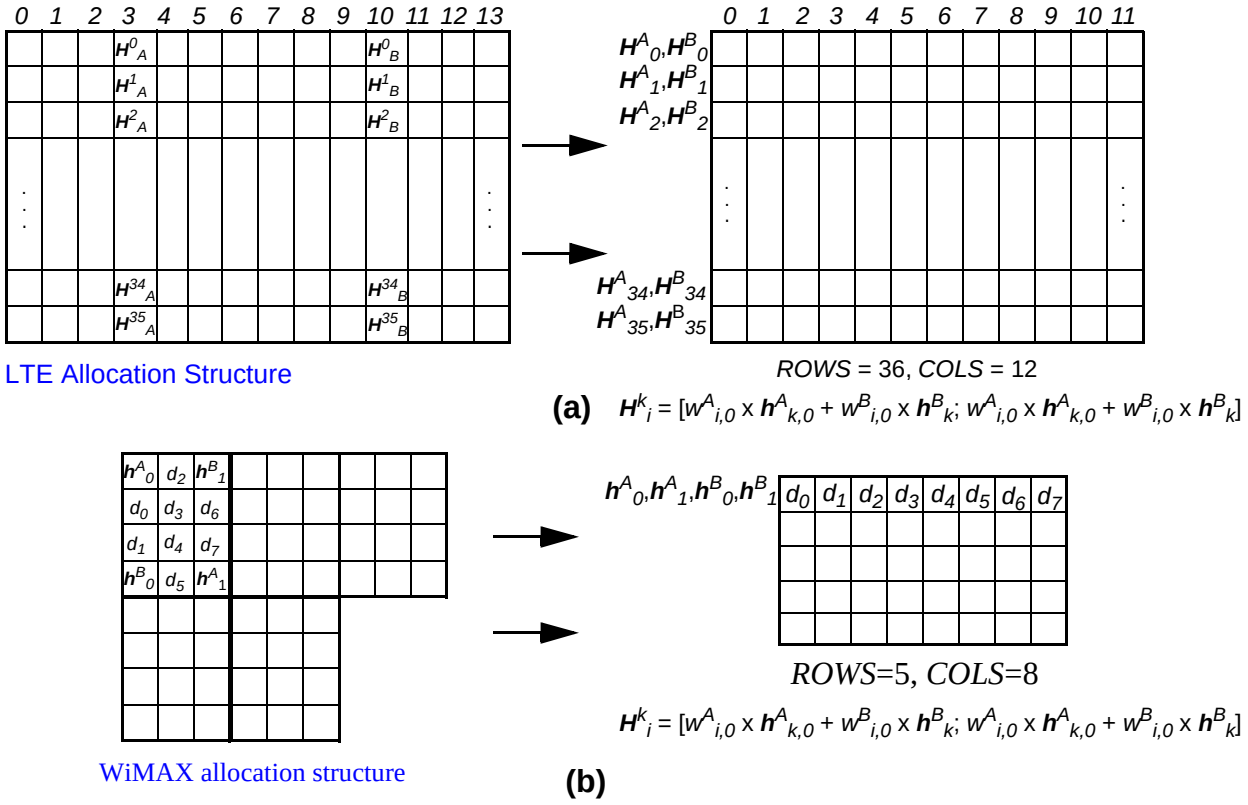

Figure 26-100. Internal Interpolation 2 (a) 3G-LTE Allocation (b) WiMAX Allocation

26.4.3.5.6 Scaling

The EQPE internal calculations are implemented with floating-point arithmetic. Each sample is represented by a mantissa of bits 20 (or more) and an 8-bit exponent factor.

26.4.3.5.6.1 Input Samples Scaling

The following subsections describe the scaling for various operating modes.

26.4.3.5.6.1.1 LNEQ, MLEQ. and TS Modes

Each of the input samples are represented in Block-Floating-Point representation (each data sample does not have a separate scaling factor rather there is one scaling factor shared for a group of samples depending on the input type). Each sample is composed by a mantissa (1q15 fraction) either real (16I) or complex (16I,16Q) and an 8-bit scale factor (*SCL*) such that the actual value of the sample is: $mantissa \times 2^{SCL}$.

26.4.3.5.6.1.2 MIV Mode

All input samples are in Block-Floating-Point representation. Each samples is composed by a mantissa (1q15 fraction) either real (16I) or complex (16I,16Q). There is one 8-bit scaling factor per matrix or one common scale factor for all matrices.

26.4.3.5.6.2 Output Samples Alignment (Scaling)

The EQPE supports several output alignment (scaling) configurations depending on its processing mode. The following sections describe the output alignment options for each mode.

26.4.3.5.6.2.1 Output Samples Alignment in LNEQ Mode

The output samples in LNEQ are initially (before alignment) in floating point representation with 32-bit (16I,16Q) mantissa and 8-bit exponent.

There are 3 supported output alignment modes in LNEQ which can be configured separately for each layer by configuring the *ALIGNx* field of the EQPE BD (x = 0...*Lx*):

- Max scale output alignment *(ALIGN<layer>*=0). In this mode each column and each layer is aligned separately to the maximal exponent in that column and layer. All the output samples for this column and layer shares the same exponent (the maximal) that is output by the MAPLE-B2 as described in **Section 26.4.3.5.8.1**, *EQPE Outputs for LNEQ*.
- User defined output alignment (*ALIGN<layer>*=1). In this mode, the host configures a scale value in the *ALIGN_VAL<layer>* field of the EQPE BD. The EQPE aligns all the output samples of the layer to that scale value. In case of overflow the EQPE saturates the sample, for example, assign the highest-positive/lowest-negative values according to sign of the sample.
- No Alignment (*ALIGN<layer>*=2). In this mode the EQPE does not align the output samples and they remain in floating point representation. The MAPLE-B2 outputs the scaling values for each symbol of each column of each layer as described in **Section 26.4.3.5.8.1**, *EQPE Outputs for LNEQ*.

Note: The User defined output alignment (*ALIGN<layer>*=1) may have a negative effect on the precision of the output samples due to discarding of LSB's (right shifts performed to reach *ALIGN_VAL<layer>*) and/or samples saturation (left shifts performed to reach *ALIGN_VAL<layer>*) that may occur due to the alignment.

26.4.3.5.6.2.2 Output Samples Alignment in MLEQ and TS Modes

The output samples (LLRs) in MLEQ and TS modes are initially (before alignment) in floating point representation 8-bit of 1q7 mantissa and 8 bit exponent for each LLR.

There are 2 supported alignment modes which can be configured separately for each layer by configuring *ALIGNx* field of the EQPE BD (x = 0...*Lx*):

- User defined output alignment (*ALIGN<layer>*=1). In this mode, the host configures a scale value in the *ALIGN_VAL<layer>* field of the EQPE BD. The EQPE aligns all the output samples of the layer to that scale value. In case of overflow the EQPE saturates the sample, for example, assign the highest-positive/lowest-negative values according to sign of the sample.
- No Alignment (*ALIGN<layer>*=2). In this mode the EQPE does not align the output samples and they remain in floating point representation. The MAPLE-B2 outputs the scaling values for each symbol of each column of each layer as described in **Section 26.4.3.5.8.2**, *EQPE Outputs for MLEQ and TS modes*.

26.4.3.5.6.2.3 Output Samples Alignment in MIV Mode

The output samples in MIV are initially (before alignment) in floating point representation with 32 bit (16I,16Q) of 1q15 mantissa and 8 bit exponent.

There are 4 supported alignment modes in MIV mode which can be configured in the *ALIGN0* field of the EQPE BD:

- Max scale output alignment (*ALIGN0*=0). In this mode each matrix is aligned separately to the maximal exponent in the matrix. All the output samples for the matrix shares the same exponent (the maximal). The maximal exponents (one for each matrix) is output by MAPLE-B2 as described in **Section 26.4.3.5.8.3**, *EQPE Outputs for MIV*.
- User Defined output alignment (*ALIGN0*=1). In this mode, the host configures a scale value in the *ALIGN_VAL0* field of the EQPE BD. The EQPE aligns all the output samples of all the matrices to that scale value, in case of overflow the EQPE saturates the sample, for example, assign the most highest positive/negative values according to sign of the sample.
- No Alignment (*ALIGN0*=2). In this mode the EQPE does not align the output samples and they remain in floating point representation. The MAPLE-B2 output the scale value of each element in each of the matrices as described in **Section 26.4.3.5.8.3**, *EQPE Outputs for MIV*.
- Global Max Alignment (*ALIGN0*=3). In this mode all output samples are aligned to an exponent value calculated by the first batch of EQPE MIV processing: due to limited EQPE output buffer size, the maximum alignment value of the first batch of processed matrices (which fills the output buffer), is used as an alignment value for the rest of the job processed matrices. Batch size varies according to matrix dimensions and type (full/hermitian). For example, for full 4×4 MIV job, batch size is 512 matrices. The single output scale value is output by MAPLE-B2 as described in **Section 26.4.3.5.8.3**, *EQPE Outputs for MIV*.

Note: The user-defined output alignment (*ALIGN0* = 1) may have a negative effect on precision of the output samples due to discarding of LSBs (right shifts performed to reach *ALIGN_VAL0*) and/or sample saturation (left shifts performed to reach *ALIGN_VAL0*) that may occur due to the alignment.

26.4.3.5.6.3 Layer Cancellation Rank Reduction and Layer Discarding

Layer Cancellation, Rank Reduction and Layer Discarding are optional features for LNEQ mode intended for Interference Cancellation (IC) schemes, where the equalization is performed in several iterations to improve the accuracy of the estimation. As from the second iteration, a-priory information is available in the form of improved estimations of some or all of the layers being estimated. These estimations is named feedback layers and is denoted as "f_i" for the i^{th} feedback layer.

26.4.3.5.6.3.1 Layer Cancellation

The EQPE supports layer cancellation by subtracting the feedback samples from the ***y*** samples. The EQPE supports single internal layer cancellation. If more than single layer cancellation is required, they may be performed by the host or one in the EQPE, and the rest by the host. For example, in 4x4 system where 3 cancellations are needed, the host may perform the first 2 cancellations, giving the EQPE a job with the updated ***y*** samples and layer cancellation of the third layer, alternatively the host may perform all 3 cancellations and give the EQPE a job with no internal cancellation.

The cancellation performed for each sub-carrier:

$$\tilde{\boldsymbol{y}}^k = \boldsymbol{y}^k - \boldsymbol{h}_i^k f_i^k \qquad \textbf{Equation 9}$$

where:

$\boldsymbol{h}^k_i$ is the i^{th} column of ***H*** in row k

f^k_i is row k of the estimation of layer i from a-priory knowledge.

This cancellation is performed before the equalization calculation.The cancellation performed is always a soft cancellation that is, the value subtracted from the ***y*** samples is always the "soft" values stored in the feedback buffer. Hard cancellation may be achieved by writing "hard" values to the feedback buffer.

Layer Cancellation is configured by setting *F_EN* bit and specifying the layer to be cancelled in *LTC* field of the EQPE BD. In addition to basic input samples, the feedback should also be written to the EQPE as described in **Section 26.4.3.5.4.8**, *F Samples*.

When performing cancellation (either internal or external) it is recommended to modify the MMSE calculation. This can be done in two ways:

1. Updating the signal covariance matrix to the new variance of the cancelled layers (it is assumed that the ***C*** matrices are calculated by the host). This is done by setting *C_EN* bit of the EQPE BD and preparing the ***C*** samples as described in **Section 26.4.3.5.4.6**, *C Samples*.
2. Rank reduction - see **Section 26.4.3.5.6.3.2**, *Rank Reduction*.

Note: There is no restriction on enabling both features in the same job, that is, the cancelled layer can also be reduced from the equalization calculations.

26.4.3.5.6.3.2 Rank Reduction

In some scenarios for example, Hard-IC or Soft-IC (when the feedback layers are estimated with high confidence), it is desirable to reduce the rank of the estimation problem (for example, reducing the equalization calculation from 4x2 to 4x1) after the cancellation by omitting one of the layers from the calculation. This is done by discarding the i^{th} column of ***H*** after the cancellation and reducing the problem to less layers equalization.

Rank reduction may be performed on all layers regardless of cancellation to support cases where the host performs the cancellation externally and requires rank reduction for those layers. The reduction is done on a column basis, so reduction for each column for each layer must be configured separately.

Enabling Rank Reduction is done by setting the *RRx*[15:0] bits of the EQPE BD (x = 0...3). Setting a bit in the *RRx* field reduces the matching column in the layer. For example, if *RR0*[3:0] bits are set then columns 0 to 3 of layer 0 are reduced from the calculations.

Note: Reducing all layers in a certain column is forbidden.

26.4.3.5.6.3.3 Layer Discarding

Layer Discarding is a feature intended for IC schemes that require the estimation of only some of the layers while still using them in the calculation of the other layers (in oppose to Rank Reduction). The MAPLE-B2 does not output these layers either for further iDFT processing (if the *POST_IDFT* bit of the EQPE BD is set) or to the system memory, thus saving redundant system data traffic or iDFT processing.

Layer Discarding is enabled by setting the *LD<layer>* bits of the EQPE BD. Discarding all layers in the job is forbidden.

26.4.3.5.7 CONVPE Support—FDU Processing

As part of CONVPE processing (see **Section 26.4.3.9**, *CONVPE Convolution and Correlation Processing Operation*), the EQPE includes a dedicated logic (FDU logic) which assists with vector multiplication processing. The FDU logic, which is not functional during EQPE processing (LNEQ, MLEQ, TS and MIV modes), is targeted for CONVPE processing assist only. Because both Equalization logic and FDU logic share the same EQPE internal resources (memories and logic), they cannot work in parallel, that is, the EQPE is either in FDU processing mode or Equalization processing mode. The FDU logic cannot be directly controlled by the host therefore has no programming model interface of its own. It can only be controlled by MAPLE-B2 firmware as part of the CONVPE processing. For functional details, see **Section 26.4.3.9.2.1**, *FDU Operation*.

26.4.3.5.8 EQPE Output Data Structure

The EQPE output data buffers varies with respect to the current processing mode (LNEQ, MLEQ, TS and MIV) and enabling/disabling additional features related to each processing mode. The following sections describe the output data buffers structures and type of the EQPE with respect to its processing modes.

26.4.3.5.8.1 EQPE Outputs for LNEQ

In LNEQ mode, the output samples are the estimation of the transmitted signals calculated according to **Equation 1** for each layer in the job. Each output sample is composed of a 32 bit mantissa (16I,16Q) in 1q15 representation (*V*) and an 8-bit signed exponent (*EXP*). The value of the sample is: $V \times 2^{EXP}$.

In the EQPE output buffer the mantissa is normalized, that is, for each sample at least one of the real or imaginary parts begins with 2’b01 (for positive value) or 2’b10 (for negative value). An exception is when both real and imaginary parts equal zero, in this case the exponent holds the most negative possible value 0x80 (-128). For LNEQ mode the EQPE supports 3 output alignment (scaling) types as described in **Section 26.4.3.5.6.2.1**, *Output Samples Alignment in LNEQ Mode*.

26.4.3.5.8.1.1 Data Samples (mantissa) Outputs for LNEQ

The valid output size in LNEQ mode depends upon the number of sub-carriers ((*ROWS+1)* x *(COLS + 1)*), the number of layers (*Lx*) and the cancellation options (layer discard *LDx* and rank reduction *RRx[y]*). In general, the output data structure size of each layer is (*ROWS*+1) x (*COLS*+1) x (4Byte mantissa), which is arranged column by column starting with column #0 to column #*COLS*. The output address pointer of each layer is pointed by the *OUT_POINTERx* field of the EQPE BD.

If the Layer Discard option (*LDx* field of the EQPE BD) is set for any of the layers, the MAPLE-B2 does not output any data related to that layer.

If the Rank Reduction option (*RRx[y]* field of the EQPE BD) is set for any of the columns in any of the layers, the MAPLE-B2 skip the reduced column outputs and continue outputting the following non reduced column while skipping the location of the reduced column in the system memory.

The following figure describe the MAPLE-B2 output mantissa structure for the different configurations:

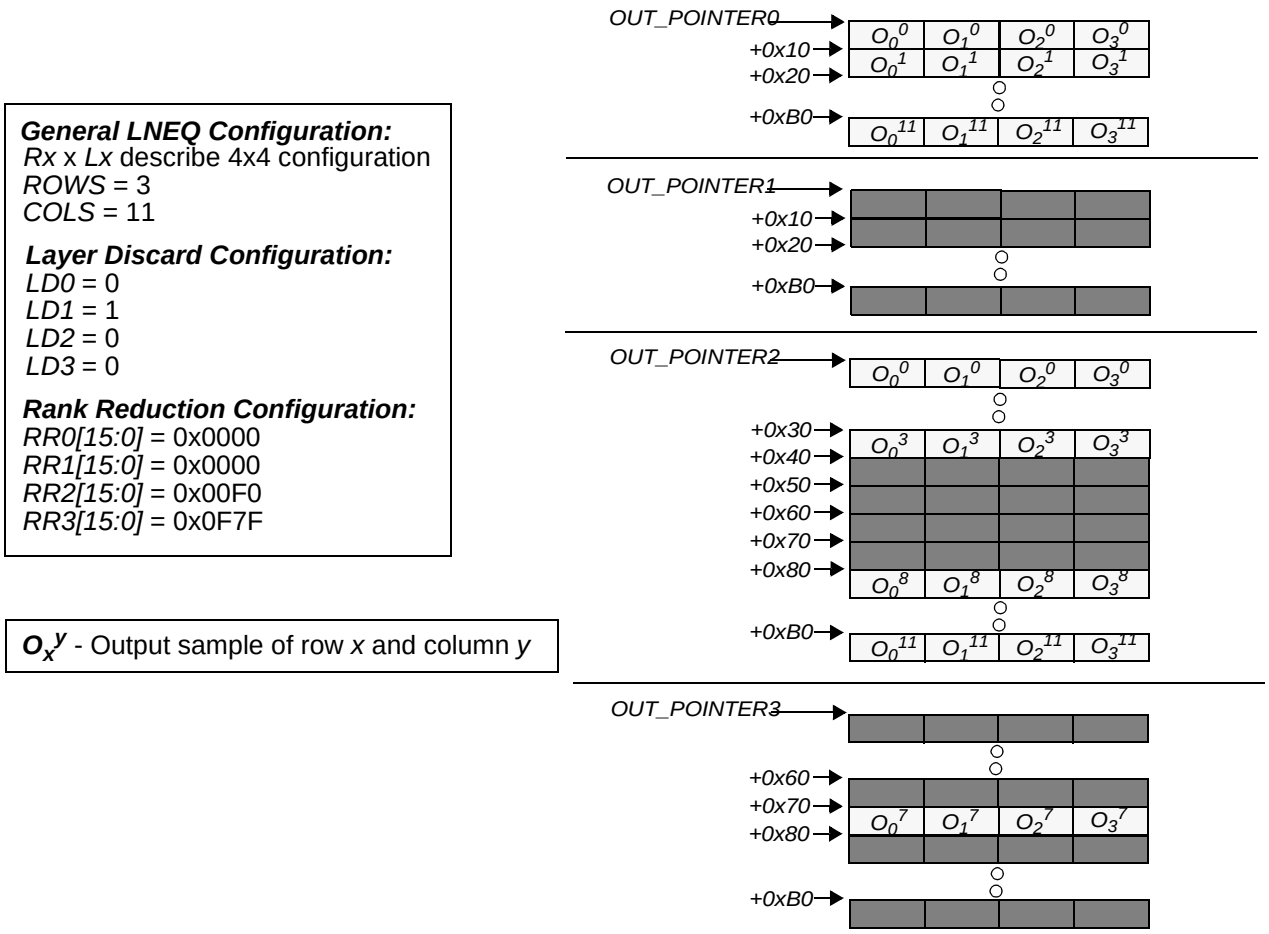

Figure 26-101. EQPE Output Data (mantissa) Structure for LNEQ Mode

The order of the data symbols in each column is starting from row #0 to row #ROWS where each sample contains the real part first following by the imaginary part as described in **Table 26-82**

Table 26-82. Output Samples Mantissas—LNEQ Mode

Memory line byte	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Sample	K				K + 1				K + 2				K + 3			
Value	*Real Part*		*Imaginary part*		*Real Part*		*Imaginary part*		*Real Part*		*Imaginary part*		*Real Part*		*Imaginary part*	

Each column of samples always starts on a new line. **Table 26-83** describe an example of output data in the system memory for the case of *ROWS* = 11

Table 26-83. Output samples arrangement example for *ROWS* = 11 (LNEQ mode)

Address	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
OUT_POINTERx	O_0^0				O_1^0				O_2^0				O_3^0			
+0x10	O_4^0				O_5^0				O_6^0				O_7^0			
+0x20	O_8^0				O_9^0				O_{10}^0				O_{11}^0			
+0x30	O_0^1				O_1^1				O_2^1				O_3^1			
...	...				...				...				...			
Value	*Real Part*		*Imaginary part*		*Real Part*		*Imaginary part*		*Real Part*		*Imaginary part*		*Real Part*		*Imaginary part*	

26.4.3.5.8.1.2 Scaled Samples Outputs for LNEQ

The MAPLE-B2 scales samples output data structure depends on the output alignment type as described in **Section 26.4.3.5.6.2.1**, *Output Samples Alignment in LNEQ Mode*.

26.4.3.5.8.1.3 Max Scale/User Defined Scale Output Alignment (LNEQ)

For Max Scale output alignment and User Defined output alignment (*ALIGNx* = 0,1), the output scale vector data structure is identical as in both cases the output scale vector for each layer includes a single scale sample for each column in the layer. In that case each layer's output scale vector structure is composed of single scale value (8 bits signed) for each column. The order of the scale values is starting from column #0 to column #*COLS*. If Rank Reduction feature is used (*RRx[y]*) then the reduced columns scale values is skipped in the same manner as the mantissa data (see **Section 26.4.3.5.8.1.1**), that is, the scale value location of the reduced column is skipped. If Layer Discard feature (*LDx*) is enabled for any of the layers, the MAPLE-B2 does not output the scale vector related to that layer.

The MAPLE-B2 outputs each of the layer's scale vector to the address calculated by EQPE BD parameters as follows:

Address<x> = *OUT_POINTER*<x>*16Bytes + *OUT_SCL_OFF*<x>*256Bytes

If (*OUT_SCL_OFF* = 0) the MAPLE-B2 output the scale vector at the next byte aligned address after the completion of writing the mantissa data as described above. **Table 26-84** describe an example the MAPLE-B2 output scale vectors structure for Max Scale and User Define output alignment with the Rank Reduction and Layer Discard parameters as described in **Figure 26-101**:

Table 26-84. Output Scale Vectors Example (Max Scale/ User Defined Scale in LNEQ Mode)

Address	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
*OUT_POINTER0**8B + *OUT_SCL_OFF0**256B	SCL_0	SCL_1	SCL_2	SCL_3	SCL_4	SCL_5	SCL_6	SCL_7	SCL_8	SCL_9	SCL_{10}	SCL_{11}				
*OUT_POINTER1**8B + *OUT_SCL_OFF1**256B																
*OUT_POINTER2**8B + *OUT_SCL_OFF2**256B	SCL_0	SCL_1	SCL_2	SCL_3					SCL_8	SCL_9	SCL_{10}	SCL_{11}				
*OUT_POINTER3**8B + *OUT_SCL_OFF3**256B								SCL_7								

26.4.3.5.8.1.4 No Output Alignment (LNEQ)

If No Alignment configuration (*ALIGNx* = 2) is used, the output scale vectors include scale value for each sample in each of the columns of each layer. The total number of scale values for each layer would be (*COLS*+1)x(*ROWS*+1). The order of the scale values in the scale vectors is identical to the order of the mantissa data as described above, that is, starting from the scale values of column #0 until the scale values of the last column (*#COLS*). The order of the scale values in each column is from index #0 to index *#ROWS*.

The scale values start address of each of the columns in the layer must be 4 bytes aligned. **Table 26-85** describe a scale vector example for *ROWS*=11:

Table 26-85. Output Scale Vector Example for *ROWS*=11 (No Alignment in LNEQ Mode)

Address	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
*OUT_POINTERx**8B + *OUT_SCL_OFFx**256B	SCL^0_0	SCL^0_1	SCL^0_2	SCL^0_3	SCL^0_4	SCL^0_5	SCL^0_6	SCL^0_7	SCL^0_8	SCL^0_9	SCL^0_{10}	SCL^0_{11}	SCL^1_0	SCL^1_1	SCL^1_2	SCL^1_3
*OUT_POINTERx**8B + *OUT_SCL_OFFx**256B + 0x10	SCL^1_4	SCL^1_5	SCL^1_6	SCL^1_7	SCL^1_8	SCL^1_9	SCL^1_{10}	SCL^1_{11}	SCL^2_0	SCL^2_1	SCL^2_2	SCL^2_3	SCL^2_4	SCL^2_5	SCL^2_6	SCL^2_7
...	...	...	...	...	...	...	...	...	...	...	...	...	...	...	...	...

The start address of the scale vector for each layer and the vector structure in case of Rank Reduction or Layer Discard features are enabled is to as described in **Section 26.4.3.5.8.1.3**.

26.4.3.5.8.2 EQPE Outputs for MLEQ and TS modes

In MLEQ and TS modes, the output samples are the LLRs (Log-Likelihood Ratios) of the transmitted bits calculated according to **Equation 3** (See **Section 26.4.3.5.5.3**) for each layer in the job. Each output sample is composed of a 8 bit mantissa in 1q7 representation (*V*) and an 8-bit signed exponent (*EXP*). The value of the sample is: $V \times 2^{EXP}$.

In the EQPE output buffer, the mantissa is normalized, that is, mantissa begins with 2'b01 (for positive value) or 2'b10 (for negative value). An exception is when the LLR equals zero, in this case the mantissa is all zeros and the exponent holds the most negative possible value 0x80 (-128). For MLEQ and TS modes the EQPE supports 2 output alignment (scaling) types as described in **Section 26.4.3.5.6.2.2**, *Output Samples Alignment in MLEQ and TS Modes*.

The output size in this mode depends upon the number of sub-carriers (*(ROWS+1)* x (*COLS+1)*), the number of layers (*Lx*) and the modulation of each layer (*MOD<x>*). The output size for each layer is calculated as follows:

Mantissa Size = *(ROWS+1)* x (*COLS+1)* x *MODULATION*[1] x (1Byte mantissa)

The scale vectors (exponent) size of each layer is either one byte size (if User Defined Alignment is used) or equals to "Mantissa Size" as calculated above (if No Alignment is used).

The structure of the vectors (both mantissa and scales) of each layer is column by column successively starting from column #0 to column *#COLS*. The order of the samples in each column is from index #0 to index *#ROWS*.

The MAPLE-B2 output the mantissa vectors of each layer to the address pointed by the *OUT_POINTERx* field of the EQPE BD, and the scale vectors to the address calculated as follows:

Address<x> = *OUT_POINTER*<x>*16Bytes + *OUT_SCL_OFF*<x>*256Bytes

26.4.3.5.8.3 EQPE Outputs for MIV

In Matrix Inversion Mode (MIV), the output samples are the entries of the inverted matrix, calculated according to **Equation 5** and **Equation 6** (see **Section 26.4.3.5.5.6**). Each output sample is composed of a 32 bit mantissa (16I,16Q) in 1q15 representation (*V*) and an 8-bit signed exponent (EXP). The value of the sample is: $V \times 2^{EXP}$.

In the EQPE output buffer the mantissa is normalized, that is, at least one of the real or imaginary parts begins with 2'b01 (for positive value) or 2'b10 (for negative value). An exception is when both real and imaginary parts equal zero, in this case the exponent holds the most negative possible value 0x80 (-128). For MIV mode the EQPE supports 4 output alignment (scaling) types as described in **Section 26.4.3.5.6.2.3**, *Output Samples Alignment in MIV Mode*.

1. The MODULATION is 2 for QPSK, 4 for 16QAM and 6 for 64QAM. Each layer may have a different modulation and thus the size of the output may differ between layers.

26.4.3.5.8.3.1 Data Samples (mantissa) Outputs for MIV

The EQPE inverted matrices output data structure depends on the Matrix type. If Full matrix inversion is required (*FH* = 1), then both the input and output matrix types are Full matrix. If Hermitian matrix inversion is required (*FH* = 0), then both the input and output matrix types are Hermitian. The output data structure of the mantissas (for both Full and Hermitian types of matrix) is identical to the input data structure of the matrices in MIV mode and is described in details in **Section 26.4.3.5.4.4.1**, *M Matrix Input Data Structure*.

26.4.3.5.8.3.2 Scale Samples (exponent) Outputs for MIV

The scale samples vector output data structure depends on the configuration of the output samples alignment used for the job. The following sections describe the scale vector output data structure for each of the supported alignments.

26.4.3.5.8.3.3 Max Scale Output Alignment for MIV

In this case the EQPE output single scale value (8 bits signed) for each matrix. The order of the values in the vector is from matrix #0 to matrix #*ROWS*. The address of the scale vector is calculated by MAPLE-B2 as follows:

Address = *OUT_POINTER*0*16Bytes + *OUT_SCL_OFF*0*256Bytes

If (*OUT_SCL_OFF0* = 0) the MAPLE-B2 output the scale vector at the next byte aligned address after the completion of writing the mantissa data of the last matrix as described above.

26.4.3.5.8.3.4 User Defined/Global Max Scale Output Alignment (MIV)

In this case the EQPE output single scale value for all the job. The address location of the 8 bits scale value is as described in the Max Scale Output Alignment case (see **Section 26.4.3.5.8.3.3**).

26.4.3.5.8.3.5 No Output Alignment (MIV)

In this case the EQPE output a scale value for each element of each of the inverted matrices. The scale vector address is calculated by MAPLE-B2 in the same manner as in **Section 26.4.3.5.8.3.3**, *Max Scale Output Alignment for MIV*. The structure of the output vector depend on both the matrices dimensions (*Lx*) and the matrices type, that is, Hermitian or Full (*FH*). Assuming $e^{i}_{x,y}$ is an element of matrix i (i = 0...*ROWS*), located in row *x* and column *y* (*x*,*y* = 0...Lx), the following tables describe the scale vectors structure for the different cases.

Table 26-86. Output Scale Vector Structure of Full MIV 1x1 (*FH*=1, *Lx*=0)

26.4.3.5.8.4 EQPE Output Data Structure - Summary

The following table summarize the EQPE output data vectors for each of its modes. The table summarize the sizes of each output vector in each mode.

Table 26-94. EQPE Output vectors sizes (in bytes)

Vector Type	LNEQ mode	MLEQ mode	TS mode	MIV mode
Output Samples	(*COLS*+1)*(*ROWS*+1)*(*Lx*+1)*4	per layer <*x*>=0,...,*Lx*: (*ROWS*+1)*(*COLS*+1)**MOD*<*x*> where *MOD*<*x*> = 2/4/6 for QPSK/16QAM/64QAM		if *FH*=0 (*ROWS*+1)*(*Lx*+1)*(*Lx*+1)*2 if *FH*=1 (*ROWS*+1)*(*Lx*+1)*(*Lx*+1)*4

Output Scale	per layer <x>=0,...,*Lx*:
	if *ALIGN*<*x*>=0:
	(*COLS*+1)
	if *ALIGN*<*x*>=1
	1 Byte
	if *ALIGN*<*x*>=2:
	(*COLS*+1)*(*ROWS*+1)
		per layer <*x*>=0,...,*Lx*:
		if *ALIGN*<*x*>=1
		1 Byte
		if *ALIGN*<*x*>=2:
		(*ROWS*+1)*(*COLS*+1)**MOD*<*x*>
		where *MOD*<*x*> = 2/4/6 for QPSK/16QAM/64QAM
				if *ALIGN0*=0:
				(*ROWS*+1)
				if *ALIGN0*=1:
				1 Byte
				if *ALIGN0*=2:
				(*ROWS*+1)*(*Lx*+1)*(*Lx*+1)
				if *ALIGN0*=3:
				1 Byte

26.4.3.5.9 Pre/Post DFT/iDFT Processing

For EQPE LNEQ mode, the MAPLE-B2 is capable of internally concatenating a DFT/iDFT processing to the EQPE processing thus significantly reduce the overall system latency and the required control interface towards the MAPLE-B2. The DFT/iDFT processing assist is executed using the eFTPE engines in the MAPLE-B2. For details on the eFTPE engines see **Section 26.4.3.3**, *eFTPE FFT/iFFT/DFT/iDFT Operation*.

There are two such concatenation options supported by the MAPLE-B2:

- iDFT processing of the EQPE outputs. In this flow every output column of the EQPE sub-carrier grid is being internally transferred into an eFTPE engine for iDFT processing. On iDFT processing completion, the MAPLE-B2 outputs the results into the system memory as defined by the EQPE BD parameters. Enabling this processing flow is done by setting the *POST_IDFT* bit of the EQPE BD.

- DFT processing of the EQPE feedback layer inputs. In this flow the MAPLE-B2 executes DFT processing on the input feedback layer to be cancelled by the EQPE. This processing is done prior to the EQPE processing. Each column of the input feedback layer is first being processed by an eFTPE engine (DFT processing) and only then internally transferred into the EQPE feedback buffer for EQPE processing. Enabling this processing flow is optional only if Feedback Cancellation is enabled (*F_EN*) and is done by setting the *F_DFT* bit of the EQPE BD.

Enabling both processing flows, that is, executing pre DFT processing on the input layer to cancel and post iDFT processing on the output layer is allowable.

The following sections describes in details the internal processing flow of these modes with respect to the EQPE BD parameters configurations.

26.4.3.5.9.1 Pre DFT Processing

When the pre DFT processing flow is enabled (by setting the *F_DFT* and *F_EN* bits of the EQPE BD), the MAPLE-B2 uses the following EQPE BD parameters to set an eFTPE engine to execute the pre DFT processing of the feedback layer:

- *COLS* - As each column of the input layer requires DFT processing, the *COLS* field is used by the MAPLE-B2 to determined the required number of DFT jobs to be processed.
- *ROWS* - The number of rows in each of the column is used to determine the DFT size to be processed for each of the columns in the layer.
- *F_DFT* - Indicates the MAPLE-B2 that the job type is DFT (and not iDFT).
- *SCL_PTR_BA* and *F_SCL_OFFSET* - Points to the address in the system memory where the scale value for each of the Feedback input columns is located. The scale value of each input column is used as the input exponent value of the eFTPE engine as described in **Section 26.4.3.3.9.4.5**, *Input Exponent*.

Additional settings for the eFTPE when executing pre EQPE processing are:

- Adaptive Scaling (see **Section 26.4.3.3.9.4.3**, *Adaptive Scaling*) - The eFTPE is always configured to work in Adaptive Scaling mode to maximize execution precision.
- Adaptive Input Scaling (see **Section 26.4.3.3.9.4.7**, *Adaptive Input Scaling*) - The eFTPE is always configured to work in Adaptive Input Scaling mode to maximize execution precision.

After EQPE BD parsing the MAPLE-B2 configure one of the eFTPE engines as described above and fetches the Feedback data from the address pointed by the *F_POINTER* field of the EQPE BD and into the chosen eFTPE engines' input buffer. For each of the processed columns in the eFTPE, when the DFT processing is completed the MAPLE-B2 transfer the output data out of the eFTPE output buffer and into the Feedback input buffer of the EQPE. The eFTPE Adaptive

Overall Scaling Status indication (see **Section 26.4.3.3.9.4.3**, *Adaptive Scaling*) is used as the Feedback input scale value of the EQPE.

26.4.3.5.9.2 Post iDFT Processing

When the post iDFT processing flow is enabled (by setting the *POST_IDFT* bit of the EQPE BD), the MAPLE-B2 uses the following EQPE BD parameters to set an eFTPE engine to execute the post iDFT processing of the EQPE output layers:

- *Lx and COLS* - Indicated the number of columns and number of layers to be output from the EQPE and requires iDFT post processing. As each column of each layer requires different iDFT processing the total number of iDFT processing is *Lx* x *COLS*. If Layer Discard (*LDx*) is enabled in the EQPE BD for any of the layers, then no iDFT processing occurs for this layer. If Rank Reduction (*RRx[y]*) is enabled for any of the columns of any of the output layers, then no iDFT processing occurs for the reduced column.
- *ROWS* - The number of rows in each of the column of the layers is used to determine the DFT size to be processed for each of the columns of the layers.
- *POST_IDFT* - Indicates the MAPLE-B2 that the job type is iDFT (and not DFT).
- *ALIGNx* - Indicates for each layer if the eFTPE is to work with configured Overall Scaling enabled or not (see **Section 26.4.3.3.9.4.4**, *Overall Scaling Amount Programming*). If the *ALIGNx* value is 0 (Max Scale Output Alignment) the Overall Scaling configuration in the eFTPE is disabled and the *OUT_SCL_OFFx* field of the EQPE BD points to the accumulated results of the EQPE + eFTPE scale values for each of the output columns of each layer. If the *ALIGNx* value is 1 (User Defined Output Alignment), the EQPE is activated with Max Scale Output Alignment mode (*ALIGNx*=0), but the eFTPE Overall Scaling configuration is enabled and the overall scaling value used for the eFTPE is the *ALIGN_VALx* field of the EQPE BD. Such flow assures maximum precision while the final EQPE+eFTPE processing results are as required in the EQPE BD.
- *PST_SCLR* - If set, the eFTPE Scalar Post Multiplication is enabled (see **Section 26.4.3.3.6**, *Scalar Post Multiplication in eFTPE*) for each iDFT result. The MAPLE-B2 supports a different scalar value for each iDFT job, that is, *Lx* x *COLS* different values. The scalar values used for the post multiplications are expected in the system memory as pointed by the *PST_SCLR_PTR* fields of the EQPE BD.
- *PST_SCLR_PTR* - The pointer to the system memory of the scalar values (*COLS* x *Lx* values) to be multiplied with the iDFT results if the *PST_SCLR* field of the EQPE BD is set. The *Lx* x *COLS* scalar values are expected successively hence the size of the data structure expected by MAPLE-B2 is:

  $4_{bytes} \times L_x \times COLS$

- *PST_VEC* - If set, the eFTPE vector post multiplication is enabled (see **Section 26.4.3.3.5.2**, *Post-Multiplication processing support in the eFTPE*). The MAPLE-B2 supports a different vector for each of the EQPE layers (*Lx*). It means that all iDFT jobs

related to the same layer uses the same vector. The Post Multiplication vectors are fetched by the MAPLE-B2 from the address detailed in the *PST_VEC_PTR* field of the EQPE BD.

- *PST_VEC_PTR* - Pointer in the system memory of the post multiplication vectors (*Lx* vectors) to be multiplied with the iDFT results if the *PST_VEC* field of the EQPE BD is set. The *Lx* post multiplication vectors are expected successively in the system memory hence the size of the data structure expected by MAPLE-B2 is:

  $4_{bytes} \times L_x \times ROWS$

Note: When Post iDFT Processing is enabled, the “No alignment” option (*ALIGNx*=2) must not be used as the eFTPE does not support floating point inputs.

Note: One addition setting for the eFTPE when executing post EQPE processing is Adaptive Scaling (see **Section 26.4.3.3.9.4.3**, *Adaptive Scaling*) - The eFTPE is always configured to work in Adaptive Scaling mode to maximize execution precision.

After EQPE BD parsing, the MAPLE-B2 configures the EQPE according to the BD parameters and launches the job into the EQPE. When the internal EQPE output_buffer_ready/job_done indication is received by MAPLE-B2, it configures an eFTPE engines as described above and transfer the EQPE output results into the eFTPE input buffer for iDFT processing. On eFTPE internal job done indication the MAPLE-B2 use the *OUT_POINTERx* parameter of the EQPE BD in order determined the output address of the results. The Scale values of each column of each layer after the iDFT processing are accumulated and are being output as described in **Section 26.4.3.5.8.1.3**, *Max Scale/User Defined Scale Output Alignment (LNEQ)*.

If the *INT_EN* bit of the EQPE BD is set, the MAPLE-B2 generates the relevant interrupt only after the completion of all the iDFT processing of all the layers.

26.4.3.5.10 EQPE Status Indications

The EQPE reports a matrix singularity indication. The report includes how many singular (or close to singular) matrices have been processed in the job.

The singularity check is done by configuring a threshold value in the EQPE Threshold Register (EQ_THRESH). If the ***R*** matrix (the upper-right matrix computed by the QRD) has one or more diagonal elements (the diagonal elements are positive real numbers) with exponents which are smaller than the threshold value, the matrix is considered to be singular (close to singular) and a dedicated counter in the EQPE is increment by 1. When the EQPE finishes the job, this counter, which holds the number of (close to) singular matrices processed in the job, is copied to the EQPE BD *SING* status field.

26.4.3.5.11 EQPE ECC Support

As part of the MAPLE-B2 ECC support (see **Section 26.4.3.1.1, *Memory Error Correction/Detection Support***), the EQPE include a status register which specify the exact memory module in which the ECC error has occurred.

If the general ECC error indication of the MAPLE-B2 is asserted, and by reading the PSIF PIC Event Register 2 (PSPICER2), the EQPE ECC indication bit is asserted, it means that the source of the ECC error is in the EQPE. Reading the EQPE ECC Event Register (EQ_ECCEVENT) gives indication as to which internal EQPE memory was the source of the ECC error. The EQ_ECCEVENT register includes a general ECC error bit ([31]) and a per memory indication bits ([21:0]). Resetting the EQPE general ECC error bit and relevant memory indication bits is done by writing ‘1’ to the relevant bits.

The following summarize the required actions to identify the source of the ECC interrupt:

1. Read the PSIF PIC Event Register 2 (PSPICER2) to detect which PE is the source of the ECC interrupt
2. If the EQ_ECC bit is asserted, then the source of the ECC interrupt is in the EQPE.
3. Read the EQ_ECCEVENT register to identify the exact memory module which was the source of the ECC interrupt.

To reset the ECC interrupt, the following action must occur:

1. Clear the general ECC error bit and the memory dedicated ECC error bit indications from the EQPE ECC Event Register (EQ_ECCEVENT) by writing ‘1’ to the relevant bits.
2. Clear the *EQ_ECC* error bit from the PSIF PIC Event Register 2 (PSPICER2) by writing ‘1’ to the bit.

26.4.3.6 CRPE Uplink/Downlink UMTS Chip Rate Processing Operation

The CRPE includes the following three processing units:

- CRPE Uplink Batch (CRPE-ULB). See **Section 26.4.3.6.1**.
- CRPE Uplink Fast (CRPE-ULF). See **Section 26.4.3.6.2**
- CRPE Downlink (CRPE-DL). See **Section 26.4.3.6.3**

The following subsections describe the functional operation of each of these units, and **Section 26.4.3.6.4** describe the CRPE internal reset flow which allows internal reset for the CRPE modules only in case of loosing synchronization with the Antenna I/F.

26.4.3.6.1 Chip Rate Uplink Batch Processing Element

The MAPLE-B2 supports UMTS (TS 25.211 and TS 25.213) Batch Chip Rate processing of data and control channels for Uplink as described in **Section 26.2**, *MAPLE-B2 Features*. These operations are executed using the Chip Rate- Uplink Batch Processing Element (CRPE-ULB).

26.4.3.6.1.1 CRPE-ULB Initialization

The CRPE-ULB initialization is composed of five stages:

1. CRPE-ULB Mode configuration parameter done by the API during the MAPLE-B2 initialization.
2. CRPE-ULB Parameters initialization done by the host after MAPLE-B2 initialization by API is completed and before the processing beginning of CRPE-ULB.
3. CRPE-ULB Core Descriptors initialization for each defined Group done by the host after the parameters initialization is completed.
4. CRPE-ULB Registers initialization done by the host after MAPLE-B2 initialization by API is completed and before the processing beginning of CRPE-ULB.
5. `Maple_crpe_ulb_init` routine activation which triggers the CRPE-ULB to start scanning the valid groups to process.

Note: It is recommended to follow the order of the above initialization steps to assure correct operation.

26.4.3.6.1.1.1 CRPE-ULB API Initialization

During the MAPLE-B2 initialization (see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)), the CRPE-ULB mode configuration parameter in the API must be initialized: See **Section 26.5.2.5**, *CRPE-ULB Mode Configuration Parameter (CRUBMCP)*, on page 26-328 for programming details.

26.4.3.6.1.1.2 CRPE-ULB Parameters Initialization

After the MAPLE-B2 initialization routine and before the beginning of the processing by the CRPE-ULB, the following CRPE-ULB parameters must be initialized:

- MAPLE CRPE-ULB Physical Channel <x> Base Address Parameter (MCUBPCHxBAP): Should be initialized for each active channel. Indicates the base address in the system memory where the MAPLE-B2 is to output the channels data. See **Section 26.5.3.5.2.1**, *MAPLE CRPE-ULB Physical Channel <x> Base Address Parameter (MCUBPCHxBAP)*, on page 26-351 for details.
- MAPLE CRPE-ULB Physical Channel <x> Size Parameter (MCUBPCHxSZP): Should be initialized for each active channel. Indicates the size of the output buffer in the system

memory. See **Section 26.5.3.5.2.2**, *MAPLE CRPE-ULB Physical Channel <x> Size Parameter (MCUBPCHxSZP)*, on page 26-352 for details.

- MAPLE CRPE-ULB Physical Channel <x> Write Pointer Parameter (MCUBPCHxWPP): Should be initialized with the value of *MCUBPCHxBAP[PCHxBA]* for each active channel. Maintained by MAPLE-B2 and points to the address where next data is to be written in the output buffer. See **Section 26.5.3.5.2.3**, *MAPLE CRPE-ULB Physical Channel <x> Write Pointer Parameter (MCUBPCHxWPP)*, on page 26-353 for details.
- MAPLE CRPE-ULB Physical Channel <x> Output Buffer Interrupt Configuration Parameter (MCUBPCHxOBICP): Should be initialized for each active channel. Indicates the interrupt methodology for each channel. See **Section 26.5.3.5.2.4**, *MAPLE CRPE-ULB Physical Channel <x> Output Buffer Interrupt Configuration Parameter (MCUBPCHxOBICP)*, on page 26-354 for details.
- MAPLE CRPE-ULB Group Configuration parameters: Should be initialized for each active group. Includes all relevant parameters for each of the defined groups. See **Section 26.5.3.5.2.5**, *MAPLE CRPE-ULB Group <x> Configuration 1 Parameter (MCUBGxC1P)*, on page 26-355, **Section 26.5.3.5.2.6**, *MAPLE CRPE-ULB Group <x> Configuration 2 Parameter (MCUBGxC2P)*, on page 26-356, **Section 26.5.3.5.2.7**, *MAPLE CRPE-ULB Group <x> Configuration 3 Parameter (MCUBGxC3P)*, on page 26-357, and **Section 26.5.3.5.2.8**, *MAPLE CRPE-ULB Group <x> Configuration 4 Parameter (MCUBGxC4P)*, on page 26-358 for details.
- MAPLE CRPE-ULB Antenna <x> Descriptor Parameter (MCUBANTxDP): Should be initialized for each active Antenna. Holds the base address in the system memory of each active antenna. See **Section 26.5.3.5.2.9**, *MAPLE CRPE-ULB Antenna <x> Descriptor Parameter (MCUBANTxDP)*, on page 26-359 for details.
- MAPLE CRPE-ULB Configuration Parameter (MCUBCP): Holds general configuration related to the CRPE-ULB operation mode. See **Section 26.5.3.5.2.10**, *MAPLE CRPE-ULB Configuration Parameter (MCUBCP)*, on page 26-360 for details.
- MAPLE CRPE-ULB Output Buffer Interrupt Configuration Parameter (MCUBOBICP): Describes the general output buffer interrupt configuration. See **Section 26.5.3.5.2.11**, *MAPLE CRPE-ULB Output Buffer Interrupt Configuration Parameter (MCUBOBICP)*, on page 26-361 for details.

26.4.3.6.1.1.3 CRPE-ULB Core Descriptors Initialization

After the Groups definition is completed during the parameters initialization, each Group's Core Descriptors should be initialized. The Core Descriptors data structure is detailed in **Section 26.5.4.6.1**, *CRPE-ULB Core Descriptors*. The number of Core Descriptors to be initialized for each defined Group is determined by the Group's number of Cores (*MCUBGxC1P[GxNOC]*).

26.4.3.6.1.1.4 CRPE-ULB Registers Initialization

After the MAPLE-B2 initialization routine and before the beginning of the processing by the CRPE-ULB, the following CRPE-ULB registers must be initialized:

- CRPE-ULB Interpolation Weights Configuration Registers: Holds the interpolation weights for CRPE-ULB Interpolation operation. See **Section 26.5.5.5.1**, *CRPE-ULB Interpolation Weights 1 Sample <x> Configuration Register (CRUBIW1SxCR)*, on page 26-525 and **Section 26.5.5.5.2**, *CRPE-ULB Interpolation Weights 2 Sample <x> Configuration Register (CRUBIW2SxCR)*, on page 26-526 for details.
- CRPE-ULB Group First Antenna <x> Configuration Register (CRUBGFAxCR): Holds the configuration values of the first antenna of each group. **Section 26.5.5.5.3**, *CRPE-ULB Group First Antenna <x> Configuration Register (CRUBGFAxCR)*, on page 26-527 for details.
- CRPE-ULB Group Number Of Antenna <x> Configuration Register (CRUBGNOAxCR): Holds the number of antennas for each group. See **Section 26.5.5.5.4**, *CRPE-ULB Group Number Of Antenna <x> Configuration Register (CRUBGNOAxCR)*, on page 26-528 for details.

26.4.3.6.1.1.5 Maple_crpe_ulb_init Routine Activation

Once all internal configuration is completed (as indicated in **Section 26.4.3.2.6.1.1** through **Section 26.4.3.2.6.1.4**), and the CRPE-ULB can start with data processing, the `Maple_crpe_ulb_init` routine must be initialized as described in **Section 26.4.5**, *MAPLE-B2 Internal Task Control*. This routine enable the CRPE-ULB internal interrupt assertion (towards the internal RISC engines), thus allowing them to start scanning for valid Groups for processing.

26.4.3.6.1.2 CRPE-ULB Modes of Operation

The CRPE-ULB supports the following modes of operation set during the initialization sequence as described in **Section 26.4.3.6.1.1**, *CRPE-ULB Initialization*:

26.4.3.6.1.2.1 Interpolation Mode

The CRPE-ULB allows 4 interpolation modes, depending on *INT_MODE* of the CRUBMCP initialization parameter:

Table 26-95. CRPE-ULB Interpolation Mode

CRUBMCP [INT_MODE]	MCUBCP [IIL]	Description	Number of Antennas supported if DBL_ANT_EN=0	Number of Antennas supported if DBL_ANT_EN=1
0	0	System memory contains OVSi (i=0,8) and no internal interpolation is performed	48	96
0	1	System memory contains OVSi (i=0,4,8,12) and no internal interpolation is performed	24	48

Table 26-95. CRPE-ULB Interpolation Mode (Continued)

CRUBMCP [INT_MODE]	MCUBCP [IIL]	Description	Number of Antennas supported if DBL_ANT_EN=0	Number of Antennas supported if DBL_ANT_EN=1
0	2	System memory contains OVSi (i=0,2,4,6,8,10,12,14) and no internal interpolation is performed	12	24
0	3	System memory contains OVSi (i=0...15) and no internal interpolation is performed	6	NA
1	X	System memory contains OVS0 and OVS8 and internal interpolation brings this to OVSi (i=0,8) or (i=0,4,8,12) or (i=0,2,4,6,8,10,12,14) or (i=0...15) depending on the fingers FOFFSET_L value.	48	96

26.4.3.6.1.2.2 Delay Spread Mode

The CRPE-ULB allows 2 modes of operation with regard to maximum delay spread between fingers as defined in the CRUBMCP initialization parameter:

- *DLY_SPRD* = 0; Delay spread up to 256 chips
- *DLY_SPRD* = 1; Delay spread up to 512 chips

The 2 modes differ in their performance, as described under **Section 26.4.3.6.1.5.2, *Finger Commands***.

Note: In case of larger than 512 chips delay between fingers, user should define multiple ULB processing channels for this specific PCH. THis is a typical case of RRH (Remote Radio Head) configurations.

26.4.3.6.1.2.3 Finger Combining Modes

The CRPE-ULB allows 3 finger combining modes determined by *FC_MODE* of the CRUBMCP initialization parameter:

- Finger combining bypass where each finger's resulting symbol is represented as a 32 bit (16I,16Q) value.
- Finger combining where resulting symbol is represented as 16-bit fixed point value with user defined scale.
- Finger combining where the resulting symbol is represented as a 6 bit exponent (extended to 16bits) with 16 bit mantissa with dynamic scaling.

For details on Finger combining see **Section 26.4.3.6.1.12**, *Finger Combining*.

26.4.3.6.1.2.4 One Output Buffer Mode

The CRPE-ULB supports two modes of operation with regard to its output buffer configuration as described in the CRUBMCP initialization parameter:

- *OOB* = 0; A job composed of a group of antennas should not exceed 4096 symbols.
- *OOB* = 1; A job composed of a group of antennas should not exceed 8192 symbols.

For details on the output data modes see **Section 26.4.3.6.1.13**, *Output Buffer Capacity*.

26.4.3.6.1.3 CRPE-ULB General Processing Flow

The CRPE Uplink Batch processing is fed by up to 96 antennas along with finger and physical channel commands from the system memory using MAPLE-B2 DMA, processes them, and outputs them to separate physical channel symbol rings.

Figure 26-102 illustrates the data structures used for the uplink batch processing:

Batch jobs are divided to groups. The commands belonging to the same group as well as their associated antennas are processed as one batch job on one single sub slot. That means that the VCOP is waiting till there’s enough data in all antennas belonging to the group to process their next sub slot and then reads the finger/physical channel commands from the system memory, process those commands followed by processing the antenna data.

Splitting the work into groups can be useful for example in the case where the same antenna is being processed more than once (cancellation schemes), and on different time points. In that case two antenna numbers shall be used for processing the same antenna data.

As shall be described in **Section 26.4.3.6.1.13**, *Output Buffer Capacity* the output buffer of the CRPE-ULB accelerator is limited. Splitting the work into several groups allows the MAPLE-B2 to empty the internal output buffer into the system before continuing to the job of the next group.

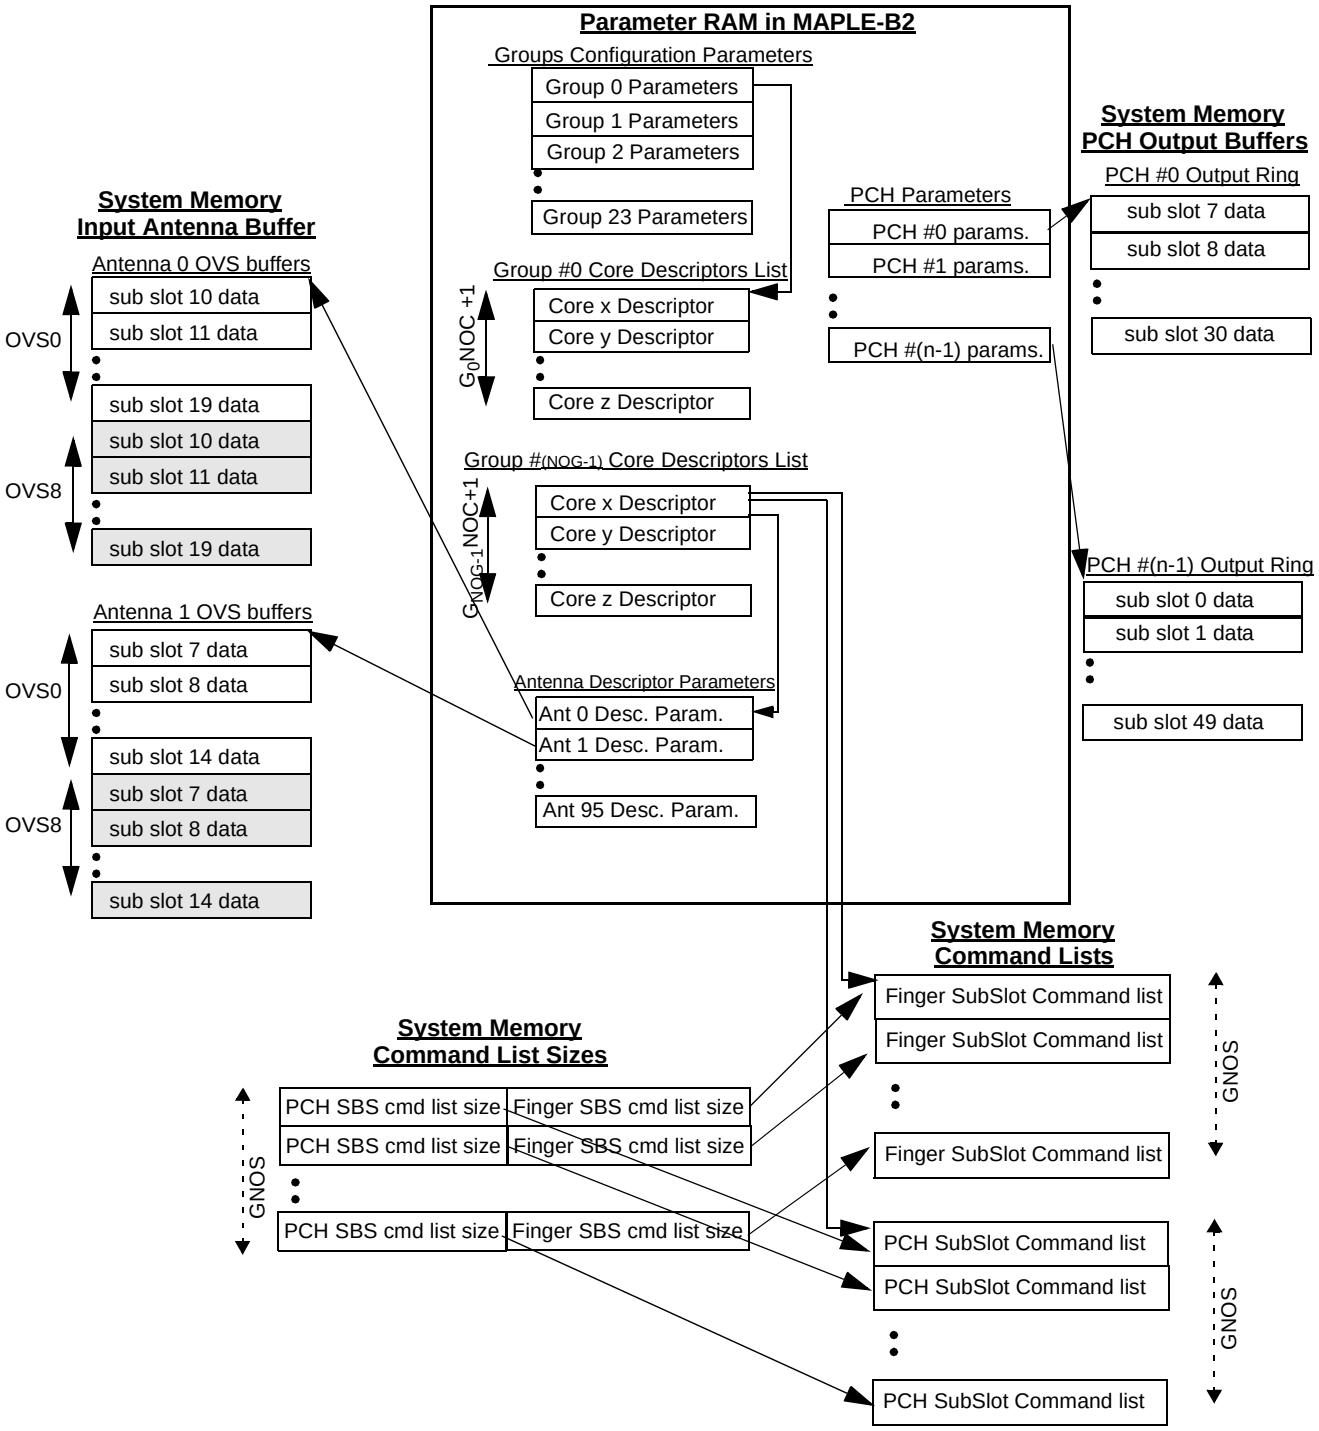

Figure 26-102. Uplink Batch Data Structure Map

26.4.3.6.1.4 CRPE-ULB Data Organization

The CRPE Uplink Batch processing uses the following data organization which supports the following:

- **Groups**: up to 24 groups. Each group is associated with up to 8 cores. The cores in the group are organized in a list inside the MAPLE-B2 parameter memory starting at address *MCUBGxCP1[CDLBA]*. All cores belonging to a group are processed by the CRPE-ULB as a single batch (per Sub-Slot).
- **Core:** each core manages the availability of the input stream (PCH commands, Fingers commands and Antenna data) towards the CRPE-ULB using its own antenna input data structure and commands lists. For details see **Section 26.4.3.6.1.5**, *CRPE-ULB Command Processing Flow*, on page 26-204
- **Antennas**: Antennas are allocated to Groups using the following configurations:
  - Antennas base address are defined in the *MCUBANTxDP[ABA]* parameter fields.
  - Antennas size is defined in the *GANTSZ* field of the *MCUBGxC3P* parameter.
  - Antennas allocated to a Group index start from the Group's first antenna index: *CRUBGFAxCR[GxFANT]*, and to antenna index: *CRUBGFAxCR[GxFANT] + CRUBGNOAxCR[GxNOA] - 1*

Note: An antenna index can be allocated to a single Group only, that is, no overlapping of antennas across Groups.

Configuration example:

- Group #0 contains antennas 0–1 and a single core handling all PCHs of the antennas.
- Group #1 contains antennas 2–9 and two cores. Each Core is responsible for different PCHs allocated to this group.

26.4.3.6.1.5 CRPE-ULB Command Processing Flow

In order for the MAPLE-B2 to start with Sub-Slot processing of a certain Group (Group x), all the Sub-Slot Write Pointers of the Cores related to this Group (*CSWP* fields of the Group's Core Descriptors) must have a different value from the Group Sub-Slot Read Pointer (*MCUBGxC2P[GSRP]*). This indication implies that the PCH/Finger Commands (of all the Cores of the Group) for the next Sub-Slot to be processed are already updated by the Cores in the system memory. Once the above is met, the following is executed by the MAPLE-B2:

1. Read from the Core Command Size Table of each Core (pointed by the *CCLSTBA* field of each Core Descriptor) the size of the PCH command list for the current Sub-Slot. The

Sub-Slot offset within the Core Command Size Table is indicated by the Group x Sub-Slot Command Read Pointer: *MCUBGxC2P[GSCRP]*.

2. Once PCH Command size is available: Fetch the PCH commands (of each Core) from the Core Command List. The Sub-Slot offset within the PCH Command List is indicated by the Group x Sub-Slot Command Read Pointer: *MCUBGxC2P[GSCRP]*.
3. Read from the Core Command Size Table of each Core (pointed by the *CCLSTBA* field of each Core Descriptor) the size of the Finger command list for the current Sub-Slot. The Sub-Slot offset within the Core Command Size Table is indicated by the Group x Sub-Slot Command Read Pointer: *MCUBGxC2P[GSCRP]*.
4. Once Finger Command size is available: Fetch the Finger commands (of each Core) from the Core Command List. The Sub-Slot offset within the Finger Command List is indicated by the Group x Sub-Slot Command Read Pointer: *MCUBGxC2P[GSCRP]*.
5. Once PCH/Finger Commands of all Cores are fetched into the CRPE -ULB, the MAPLE-B2 resets the sizes of the PCH/Finger Commands (of each Core) in the Core Command Size Table indicating that this Sub-Slot Commands are already fetched and can be over-run.
6. The MAPLE-B2 increment by one the *MCUBGxC2P[GSCRP]* field indicating that this Sub-Slot index is under processing.
7. Pending internal CRPE-ULB input buffer availability, the MAPLE-B2 fetches Antenna data relevant for this Sub-Slot processing from the Antenna System buffers as described in **Section 26.4.3.6.1.7**, *Antenna Input Sub Slot Data Structure (All modes)*.

Note: Incrementing *MCUBGxC2P[GSRP] and MCUBGxC2P[GSCRP]* does not guarantee data coherency - i.e the associated data transfers have not necessarily completed. Only incrementing *MCUBGxC4P[GOBSWP]* implies that all input data for the job has been used hence can be overwritten

When the CRPE-ULB Output buffer is ready with a Group's Sub-Slot processed data, the MAPLE-B2 performs the following:

1. Check if the current Sub-Slot Completion drives Finished Channels Buffer update and potential interrupt assertion (for details see **Section 26.4.3.6.1.15**, *Output Interrupt and Finished Channels Buffer Maintenance.*)
2. For each PCH related to the Group, the following is executed:
   - PCH output data is transferred to system memory as described in **Section 26.4.3.6.1.14**, *Output Buffer Data Structure*.
   - If Finished Channels Buffer update check point is reached, checks the PCH needs based on Finished Channel definition and acts accordingly (see **Section 26.4.3.6.1.15.1**, *Finished Channel Definition*).
3. Increment *MCUBGxC4P[GOBSWP]* by one, indicating the last Sub-Slot results are available in the system memory.

26.4.3.6.1.5.1 Core Descriptors and Command List Size Table

The Core Descriptor that describes a core within a Group (see **Section 26.5.4.6.1**, *CRPE-ULB Core Descriptors*, on page 26-475 for details) includes several fields describing the commands data base:

- *CCLSTBA* points to a cyclic table which holds the actual size of the PCH command list in bytes and the actual size of the Finger command list in bytes for each Sub-Slot entry (*GNOS* entries) of a core in a specific Group. The size of each command list must be aligned to 16 bytes (the 3 LSB are ignored by MAPLE-B2).The following figure describe the expected Command List Size Data Structure:

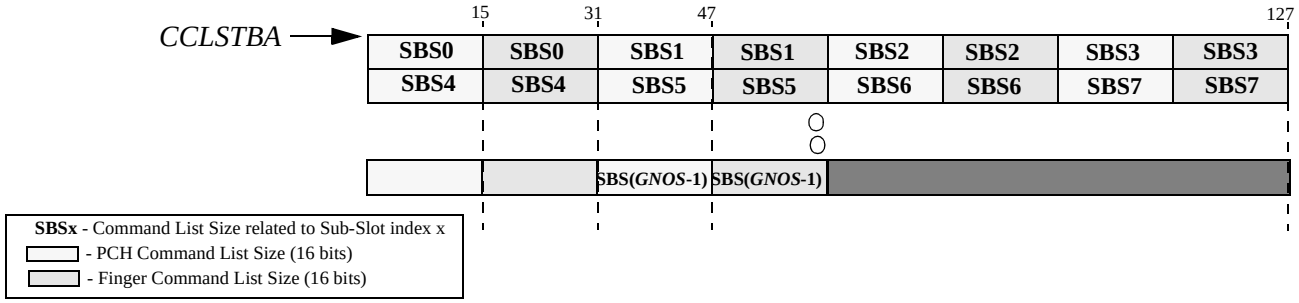

Figure 26-103. Command List Size Data Structure

- *CPBA*/*CFBA* is a base address to the PCH/Finger Command List of the Core associated with Sub-Slot index #0. The PCH/Finger Command Lists of the following Sub-Slot indexes are concatenated to this Command List. The MAPLE-B2 uses this base address to calculate the location of the PCH/Finger Command Lists.
- *CMAXP*/*CMAXF* (in 16 bytes multiplication). The maximum potential size of the PCH/Finger Command List of a Core per Sub-Slot. The VCOP uses this size to calculate the start address of the PCH/Finger Command List associated with each Sub-Slot index. **Figure 26-104** describe an example of PCH Command List Data Structure and Address calculation:

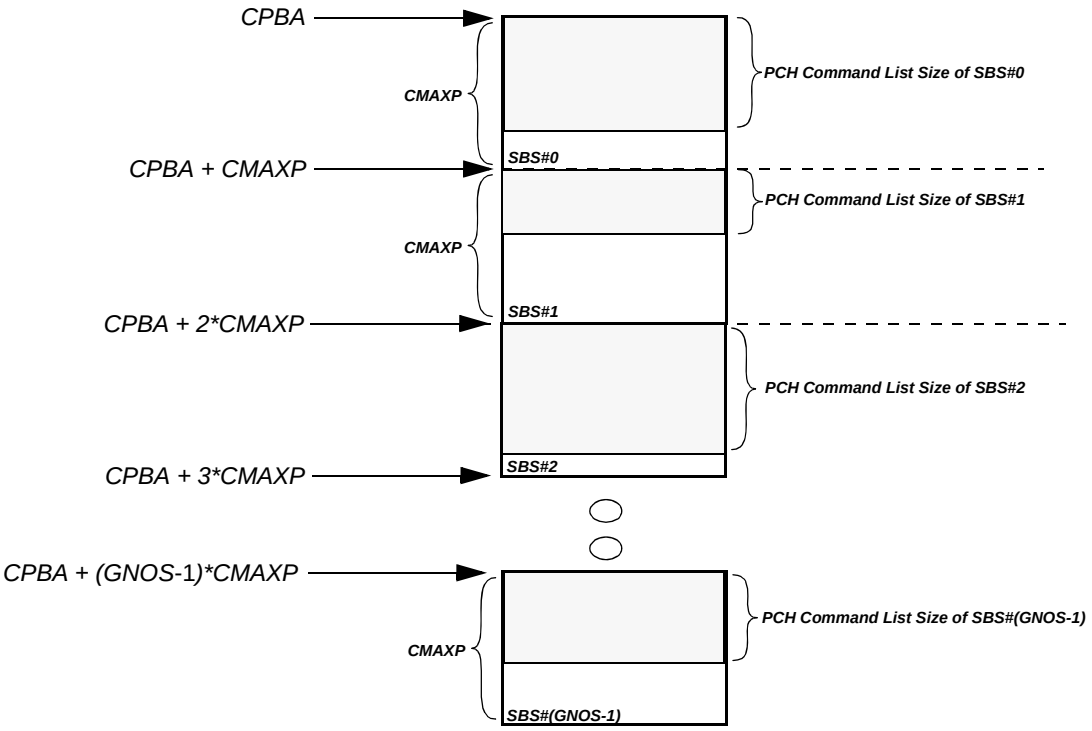

Figure 26-104. PCH Command List Data Structure

26.4.3.6.1.5.2 Finger Commands

The Finger Command data structure defines fingers attributes and allows performing operations on Fingers associated with a PCH. The Finger Command data structure is described in **Section 26.5.4.6.2**, *CRPE-ULB Finger Command Structure*.

The following describe the parameter fields in the Finger Command:

- *FMO* is the Finger Memory Offset of the CRPE-ULB operation result. Valid when Finger Combining mode is disabled (*CRUBMCP[FC_MODE]*=0). For details see **Section 26.4.3.6.1.14.1**, *Finger Combining Bypass (FC_MODE = 0)*.
- *AID* is the Antenna ID number (0 to 95).
- *PCH_ID*. The value of this field should be identical to the PCH_ID field of the PCH Command related to the PCH it is associated with.
- *GAIN_I*, *GAIN_Q* represent the gain complex value to be multiplied with the generated symbol after chip combining.
- *FOFFSET_H* is the offset (in chips) of the finger from the beginning of the Sub-Slot.
- *FOFFSET_L* is the offset of the start of the finger within a chip.
- *CMD* describe which type of Finger command is required. **Table 26-96** describe the command type options:

Table 26-96. Finger Commands Types Options

[CMD] Value	Command Meaning	Required Valid Fields In Command
0	NULL	None.
1	Modify Finger - Gain	CMD, FID, GAIN_I, GAIN_Q
2	Add new Finger	All field
3	Remove finger	CMD,FID, AID, FOFFSET_L
5	modify finger - all	All fields

- *FID* is the unique Finger ID for each existing finger.

The MAPLE-B2 supports two optional Finger command sizes : 16 bytes command size and 8 bytes command size.

16 Bytes Finger Command size

The following figure describe the structure of a 16 bytes Finger command:

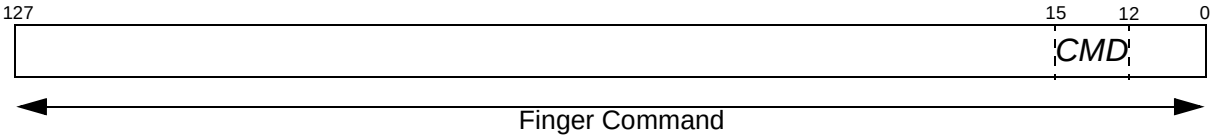

Figure 26-105. 16 bytes Finger command

For the 16 bytes command size all *CMD* values described in **Table 26-96** are valid.

8 Bytes Finger Command size

In case the required Finger command type is “Modify Finger - Gain” (*CMD* = 1 as per **Table 26-96**), it is possible to place two such Finger commands in a 16 bytes data structure as follows:

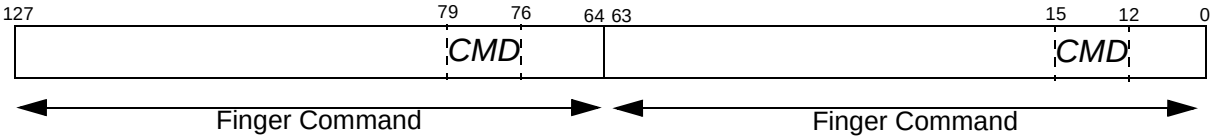

Figure 26-106. 8 bytes Finger command

Note: A 16 bytes command size start address must be aligned to 16 bytes address. Also, if single 8 bytes command is required in a 16 bytes aligned address, the other 8 bytes command field must get a NULL value (*CMD* = 0).

26.4.3.6.1.5.3 PCH Commands

The PCH Command data structure defines PCH attributes and allows performing operations on the PCH. The PCH Command data structure is described in **Section 26.5.4.6.3**, *CRPE-ULB PCH Command Structure*.

The following describe the parameter fields in the PCH Command:

- *NOF* defines the maximum Number Of Fingers for this PCH. It it used only in the case of Finger Combining is disabled (*CRUBMCP[FC_MODE]*=0).
- *ODT* is the Output Data Type for this PCH. It can be either the real portion only, the imaginary portion only, the complex number (both portions) or out data is disabled (compress PCH). For details see **Section 26.4.3.6.1.13**, *Output Buffer Capacity*
- *CS* indicates the Code type for this PCH (long/short Code). for details see **Section 26.4.3.6.1.9**, *Descrambling*
- *GRP_ID* indicates to which Group this PCH is related.There are up to 24 Groups supported.
- *EXP* represent the scale value used in the output buffer during Finger combining. For details see **Section 26.4.3.6.1.12**, *Finger Combining*.
- *FCOR_I*, *FCOR_Q* represent the real and imaginary portions of the frequency correction factor to be multiplied (each Sub-Slot) with the previous frequency correction factor. for details see **Section 26.4.3.6.1.12**, *Finger Combining*.
- *OVSF* indicates the PCH Orthogonal Variable Spreading Factor for this PCH.
- *SCRI* is the initial code value for the Descrambling processing. For details see **Section 26.4.3.6.1.9**, *Descrambling*.
- *PCH_ID* is the PCH ID number this PCH command is targeted for.
- *CMD* describe which type of PCH command is required. **Table 26-97** describe the command type options:

Table 26-97. PCH Commands Types Options

[CMD] Value	Command Meaning	Required Valid Fields In Command
6	add / modify PCH	All Fields
7	Remove PCH	PCH_ID
8	Reset FCOR_I_VAR, FCOR_Q_VAL values	PCH_ID

- *SF* indicates the PCH Spreading Factor.
- *SCBO* indicates the offset (in Sub-Slot units) between the PCH scrambling code and its first Sub-Slot.

26.4.3.6.1.6 Interpolation Modes

The following subsections describe the operation of the various interpolation modes (*CRUBMCP[INT_MODE]*) as defined by the programmed input interpolation level (*MCUBCP[IIL]*)

26.4.3.6.1.6.1 Internal Interpolation Antenna Input Data Structure (*INT_MODE* = 1)

For the case of *CRUBMCP[INT_MODE]* = 1, the interpolation processing is done inside the CRPE-ULB and the expected input data buffers from each antenna are:

1. Antenna Over Sampling #0 input buffer (OVS0).
2. Antenna Over Sampling #8 input buffer (OVS8).

Figure 26-107 illustrates an example of a single antenna input data structure for the case where the number of input sub slots in the ring is 5 (*MCUBGxC3P[GANTSZ]* = 5). The antenna data structure is located in the system in address pointed to by *MCUBANTxDP[ABA]*. The VCOP reads the next 256 chips data from the location pointed to by *MCUBGxC3P[GARP]* for all antennas belonging to the group.

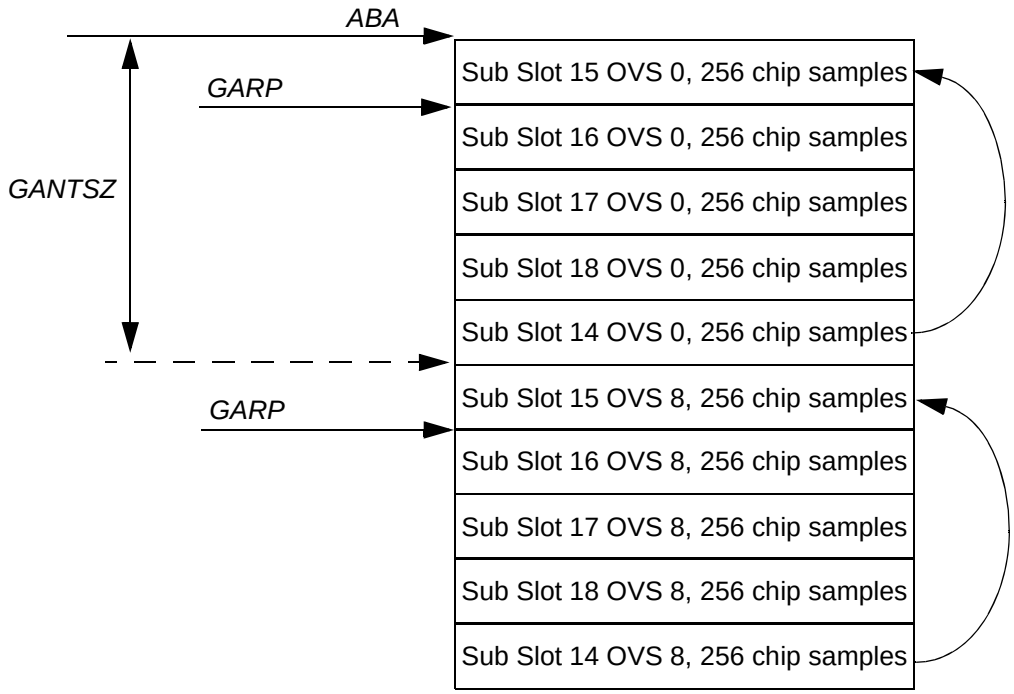

Figure 26-107. Single Antenna input Data Structure Where *GANTSZ* = 5 and *INT_MODE* = 1

26.4.3.6.1.6.2 External Interpolation 2x Antenna Input Data Structure (*INT_MODE*=0, *IIL*=0)

For the case of *CRUBMCP[INT_MODE]* = 0, the antenna input data structure is assumed to be interpolated already. With Input Interpolation Level 2 (*MCUBCP[IIL]*=0) the input antenna data contains two over-samples per chip.

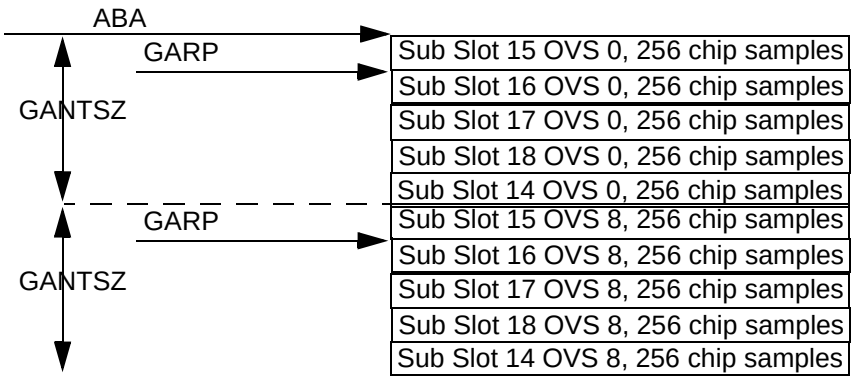

Figure 26-108. Single Antenna Input Data Structure Where *GANTSZ*=5, *INT_MODE* = 0, *IIL*=0

26.4.3.6.1.6.3 External Interpolation 4x Antenna Input Data Structure (*INT_MODE*=0, *IIL*=1)

For the case of *CRUBMCP[INT_MODE]* = 0, the antenna input data structure is assumed to be interpolated already. With Input Interpolation Level 4 (*MCUBCP[IIL]*=1) the input antenna data contains four over-samples per chip.

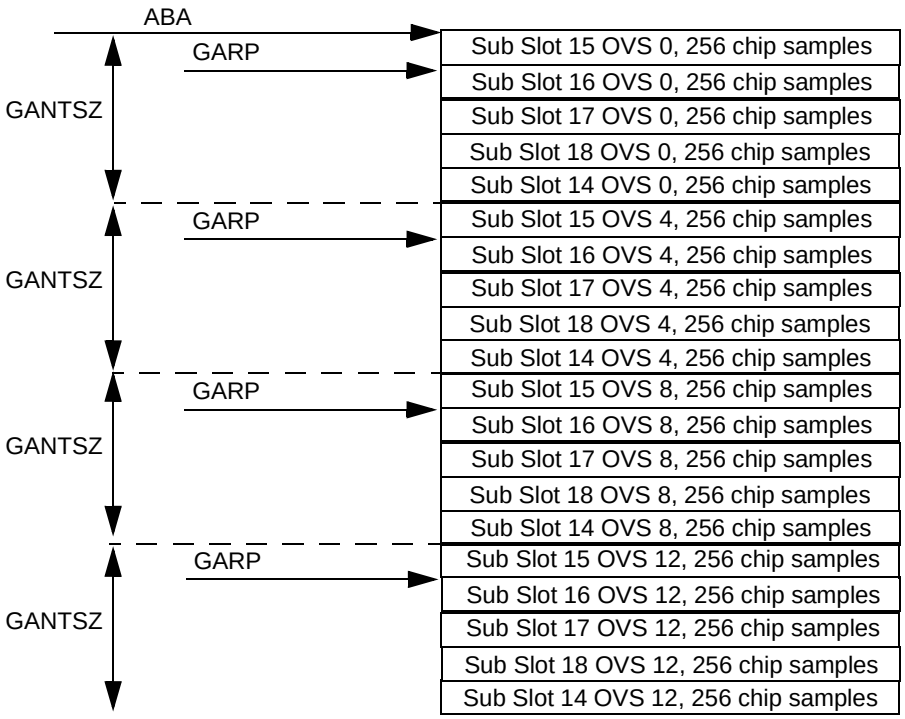

Figure 26-109. Single Antenna Input Data Structure Where *GANTSZ*=5, *INT_MODE* = 0, *IIL*=1

26.4.3.6.1.6.4 External Interpolation 8x Antenna Input Data Structure (*INT_MODE*=0, *IIL*=2)

For the case of *CRUBMCP[INT_MODE]* = 0, the antenna input data structure is assumed to be interpolated already. With Input Interpolation Level 8 (*MCUBCP[IIL]*=2) the input antenna data contains eight over-samples per chip.

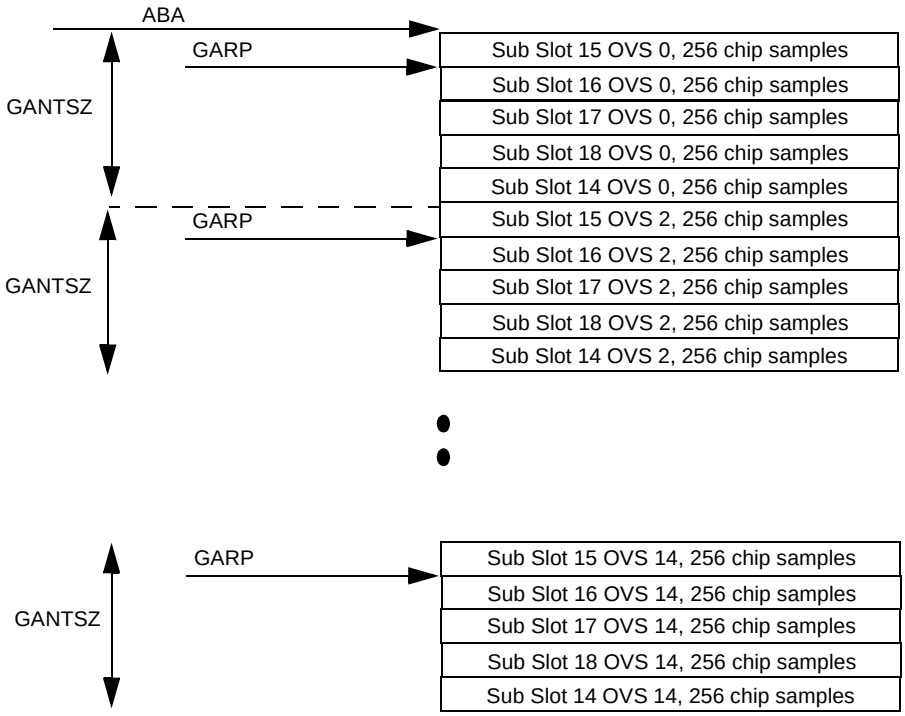

Figure 26-110. Single Antenna Input Data Structure Where *GANTSZ*=5, *INT_MODE* = 0, *IIL*=2

26.4.3.6.1.6.5 External Interpolation 16x Antenna Input Data Structure (*INT_MODE*=0, *IIL*=3)

For the case of *CRUBMCP[INT_MODE]* = 0, the antenna input data structure is assumed to be interpolated already. With Input Interpolation Level 8 (*MCUBCP[IIL]*=3) the input antenna data contains sixteen over-samples per chip.

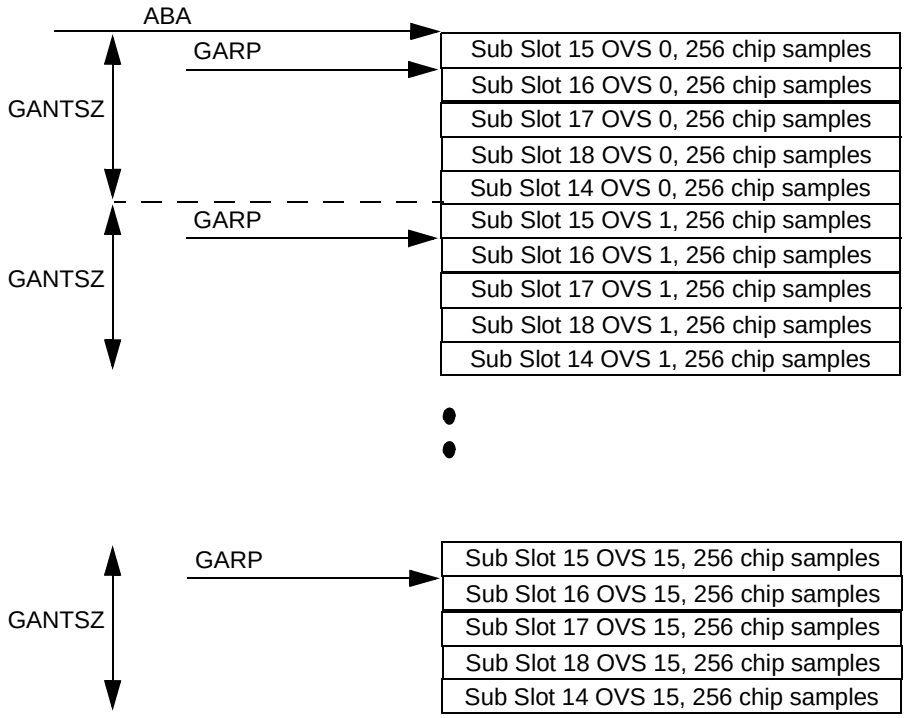

Figure 26-111. Single Antenna Input Data Structure Where *GANTSZ*=5, *INT_MODE* = 0, *IIL*=3

26.4.3.6.1.7 Antenna Input Sub Slot Data Structure (All modes)

Figure 26-112 illustrates one sub slot input data structure

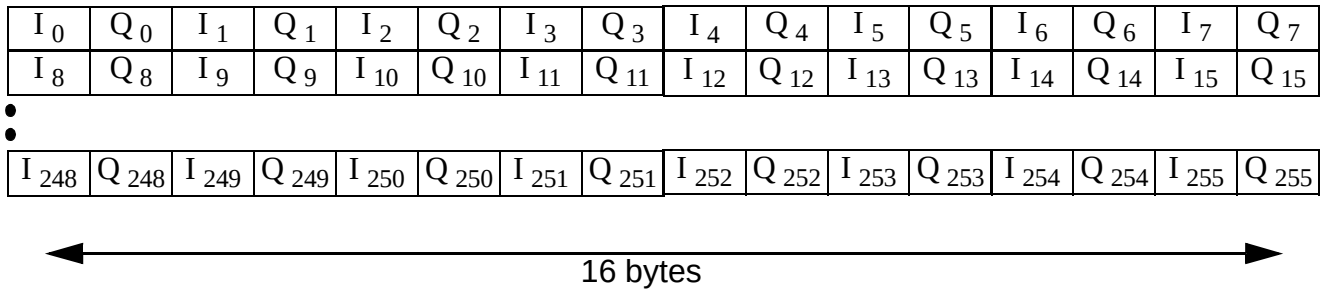

Figure 26-112. Sub Slot Data Structure

Figure 26-113 illustrates another example: Group #1 which is composed of 3 antennas. Antenna 2,3 and 4 which base address is located in *MCUBANT2DP[ABA]*, *MCUBANT3DP[ABA]* and *MCUBANT4DP[ABA]* correspondingly. All 3 antennas share the same group antenna size: *MCUBG1C3P[GANTSZ]* = 10 sub slots and the same read pointer *MCUBG1C3P[GARP]* = 2. Antenna #2 is managed by core #0 and antennas #3 and #4 by core #1. The figure illustrates the pointers values with respect to current memory structure of a single oversampled buffer per antenna. Using the *ABA* and *GANTSZ* value, the MAPLE-B2 internally calculates the relevant pointers for the other oversampled buffers.

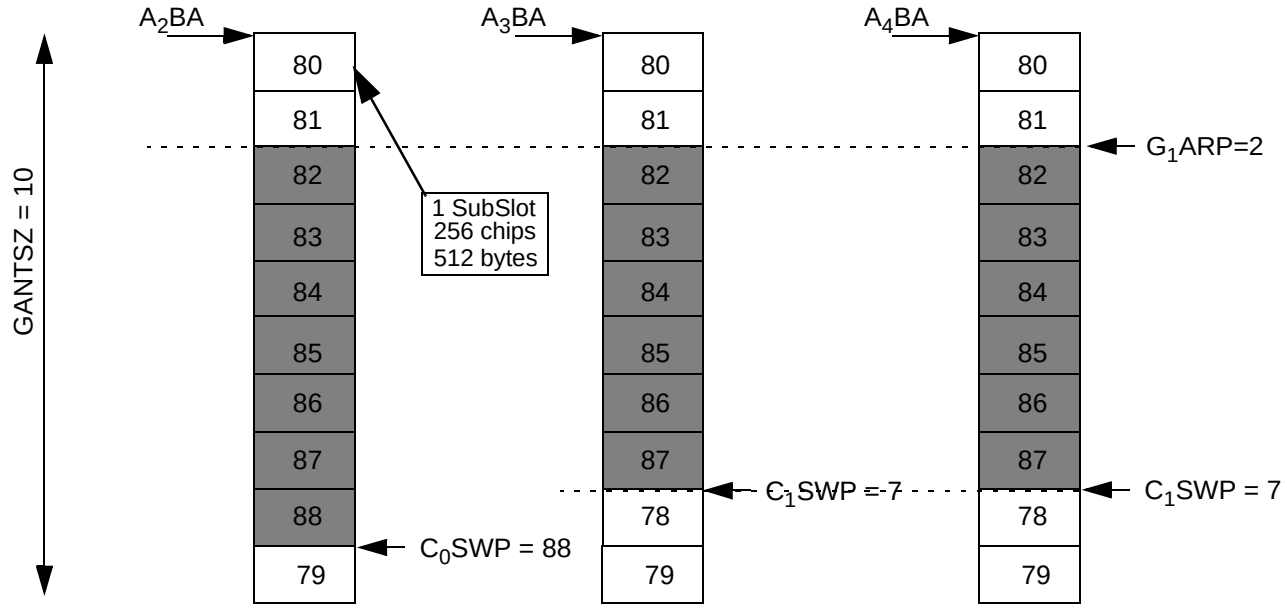

Figure 26-113. Input Buffer Structure of Single Oversampled Buffer for the Group's Antennas

VCOP processes sub slot k for all antennas in a group only if all the group's cores Write Pointers (C_xSWP) >= (k + 4)[1] and only after reading all commands belonging to sub slot k (refer to **Section 26.4.3.6.1.5**).

26.4.3.6.1.8 Internal Interpolation Processing implementation

The internal interpolation operation uses one set of 8 weights to create a single interpolated samples. The 8 nearest over-samples (4 past and 4 future samples) are used to generate the interpolated sample using the 8 relevant weights (*CRUBIW$_x$S$_y$CR[IW$_z$S$_y$]*, x = 0,1, y = 0...7, z = 0...7).

1. In case *CRUBMCP[DLY_SPRD]* = 1, then sub slot k can be processed only if (C_xSWP) >= (k+5)

26.4.3.6.1.8.1 Interpolation x16: *INT_MODE* = 1

Figure 26-114 illustrates how over-Samples are created for Interpolation x 16 for S_{n+1}:

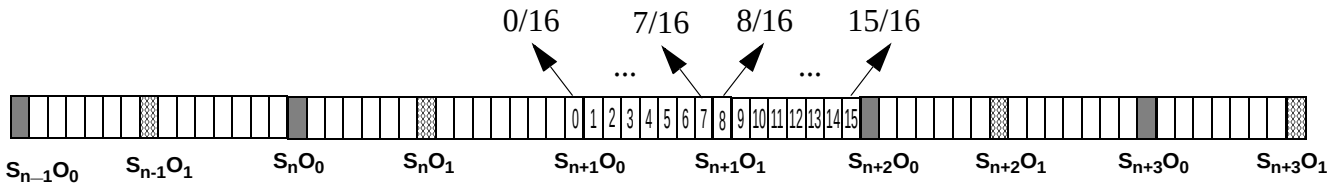

Figure 26-114. 8 Phase, 8 Tap, x16 Interpolation

For (x = 0 ; x = 7; x++):

$$S_{n+1;x/16} = IW0S_x * S_{n-1}O_1 + IW1S_x * S_nO_0 + IW2S_x * S_nO_1 + IW3S_x * S_{n+1}O_0 + IW4S_x * S_{n+1}O_1 + IW5S_x * S_{n+2}O_0 + IW6S_x * S_{n+2}O_1 + IW7S_x * S_{n+3}O_0$$

For (x = 8 ; x = 15; x++):

$$S_{n+1;x/16} = IW0S_x * S_nO_0 + IW1S_x * S_nO_1 + IW2S_x * S_{n+1}O_0 + IW3S_x * S_{n+1}O_1 + IW4S_x * S_{n+2}O_0 + IW5S_x * S_{n+2}O_1 + IW6S_x * S_{n+3}O_0 + IW7S_x * S_{n+3}O_1$$

26.4.3.6.1.8.2 Interpolation x8: *INT_MODE* = 1

Figure 26-115 illustrates how Over-Samples are created for Interpolation x 8 for S_{n+1}:

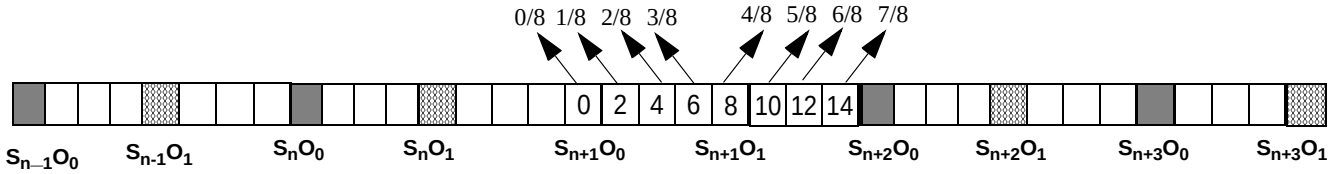

Figure 26-115. 8 Phase,8 Tap, x8 Interpolation

For (x = 0,2,4,6):

$$S_{n+1;x/8} = IW0S_x * S_{n-1}O_1 + IW1S_x * S_nO_0 + IW2S_x * S_nO_1 + IW3S_x * S_{n+1}O_0 + IW4S_x * S_{n+1}O_1 + IW5S_x * S_{n+2}O_0 + IW6S_x * S_{n+2}O_1 + IW7S_x * S_{n+3}O_0$$

For (x = 8,10,12,14):

$$S_{n+1;x/8} = IW0S_x * S_nO_0 + IW1S_x * S_nO_1 + IW2S_x * S_{n+1}O_0 + IW3S_x * S_{n+1}O_1 + IW4S_x * S_{n+2}O_0 + IW5S_x * S_{n+2}O_1 + IW6S_x * S_{n+3}O_0 + IW7S_x * S_{n+3}O_1$$

26.4.3.6.1.8.3 Interpolation x4: *INT_MODE* = 1

Figure 26-116 illustrates how Over-Samples are created for Interpolation x 4 for S_{n+1}:

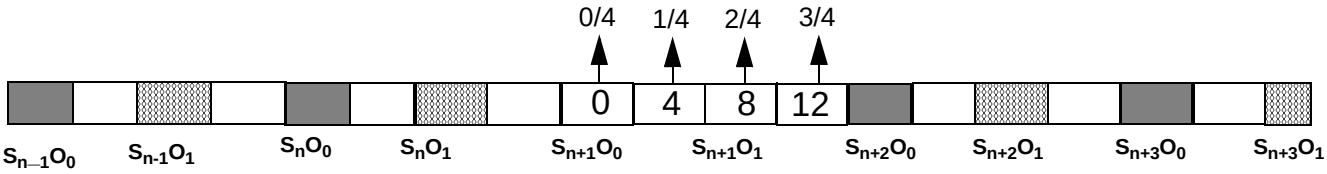

Figure 26-116. 8 Phase, 8 Tap, x4 Interpolation

For (x = 0,4):

$$S_{n+1;x/4} = IW0S_x * S_{n-1}O_1 + IW1S_x * S_nO_0 + IW2S_x * S_nO_1 + IW3S_x * S_{n+1}O_0 + IW4S_x * S_{n+1}O_1 + IW5S_x * S_{n+2}O_0 + IW6S_x * S_{n+2}O_1 + IW7S_x * S_{n+3}O_0$$

For (x = 8,12):

$$S_{n+1;x/4} = IW0S_x * S_nO_0 + IW1S_x * S_nO_1 + IW2S_x * S_{n+1}O_0 + IW3S_x * S_{n+1}O_1 + IW4S_x * S_{n+2}O_0 + IW5S_x * S_{n+2}O_1 + IW6S_x * S_{n+3}O_0 + IW7S_x * S_{n+3}O_1$$

26.4.3.6.1.8.4 Interpolation x2: *INT_MODE* = 1

Figure 26-117 illustrates how Over-Samples are created for Interpolation x 2 for S_{n+1}:

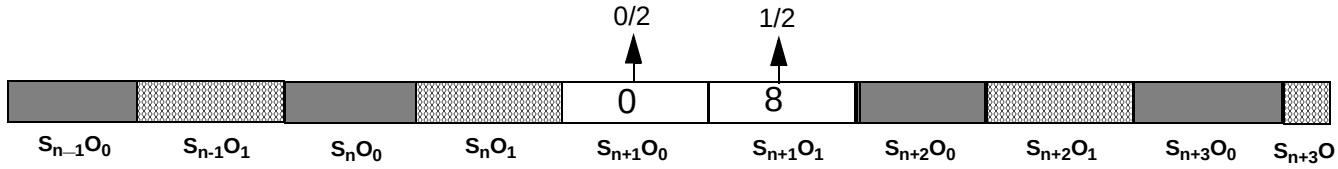

Figure 26-117. 8 Phase, 8 Tap, x2 Interpolation

$$S_{n+1;0/2} = IW0S_0 * S_{n-1}O_1 + IW1S_0 * S_nO_0 + IW2S_0 * S_nO_1 + IW3S_0 * S_{n+1}O_0 + IW4S_0 * S_{n+1}O_1 + IW5S_0 * S_{n+2}O_0 + IW6S_0 * S_{n+2}O_1 + IW7S_0 * S_{n+3}O_0$$

$$S_{n+1;1/2} = IW0S_0 * S_nO_0 + IW1S_0 * S_nO_1 + IW2S_0 * S_{n+1}O_0 + IW3S_0 * S_{n+1}O_1 + IW4S_0 * S_{n+2}O_0 + IW5S_0 * S_{n+2}O_1 + IW6S_0 * S_{n+3}O_0 + IW7S_0 * S_{n+3}O_1$$

26.4.3.6.1.8.5 Internal Interpolation Control

When working in Internal Interpolation mode (*CRUBMCP[INT_MODE]*=1), the internal interpolation processing is executed per finger according to the *FOFFSET_L* field of the Finger command (see **Section 26.4.3.6.1.5.2**, *Finger Commands*). This parameter describe the Finger offset between two chips and hence dictate the required internal interpolation executed for this chip. The range of values for the *FOFFSET_L* parameter is 0 to 15 and the internal interpolation executed for the finger is described in **Table 26-98**:

Table 26-98. Internal Interpolation Type with Respect to *FOFFSET_L*

FOFFSET_L	Internal Interpolation execution
1,3,5,7,9,11,13,15	x16
2,6,10,14	x8
4,8,12	x4
0,8	x2

Note: When working in Double Antenna mode (*CRUBMCP[DOUBLE_ANT_EN]*), x16 internal interpolation is not supported hence allowed values for the *FOFFSET_L* are: 0, 2, 4, 6, 8, 10, 12 and 14.

26.4.3.6.1.8.6 Interpolation Saturation During Internal Interpolation

Each interpolated chip is the results of adding 8 multiplications results, each multiplication between an input chip sample (8 bits) and its corresponding weight (8 bits). Because each multiplication result can potentially be as large a 16 bits, their sum may be as large as 19 bits. This intermediate result is then divided (shifted right) by the value of *CRUBMCP[ISHA]*, and if the remaining result is greater than (+127) or smaller than (-128) then it is considered as a saturated result, else the result is truncated to 8 bits representation. If the result is saturated the *CRUBISCSR[IS_COUNT]* is increment by one and the 8 bits result get the value of (+127) or (-128) depend on saturation direction. **Figure 26-118** describe the internal interpolation calculations implementation:

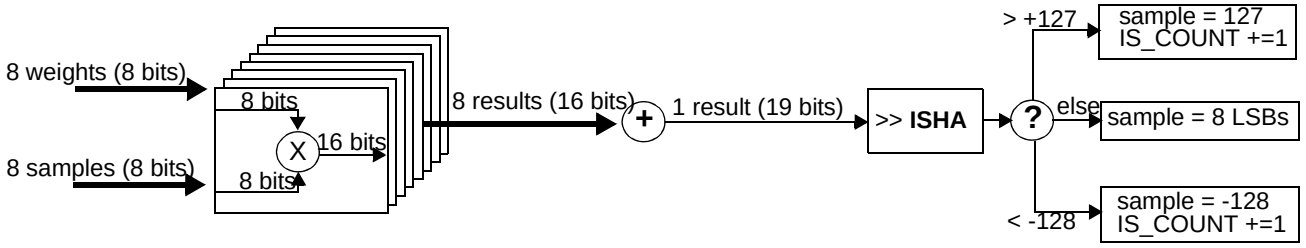

Figure 26-118. Internal Interpolation Calculation Flow

26.4.3.6.1.9 Descrambling

The CRPE-ULB performs the descrambling operation in accordance with the 3GPP standard (section 4.3.2). The complex-value sequence of interpolated chips is multiplied by a complex-value scrambling code that is internally generated. The scrambling code may either be a long code or a short code, depending on the value of the *CS* field of the PCH command associated with the currently processed finger.

Figure 26-119 illustrates the descrambling process. A scrambled chip is multiplied by the conjugate of the i^{th} element of the scrambling code $C_n[i]$, and a descrambled chip is generated.

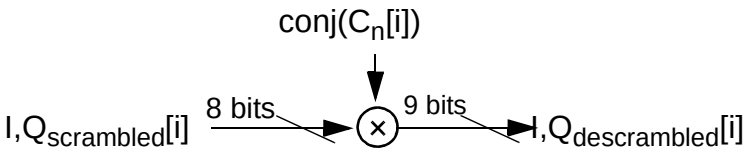

Figure 26-119. Chip Descrambling Illustration

The scrambling operation can potentially increase the I,Q data dynamic range from 8 bits to 10 bits. However, as we treat the temporary result: -(-256) as +255, rather than +256, 9 bits suffice.

26.4.3.6.1.9.1 Scrambling Data Offset

Prior to the descrambling operation, the *CSBO* value of the PCH command - which is PCH specific, and the *MCUBGxC2P[GxSRP]* value - which is common to all currently processed PCHs, needs to be properly initialized.

Figure 26-120 illustrates the relationship between *CSBO* and *GxSRP*:

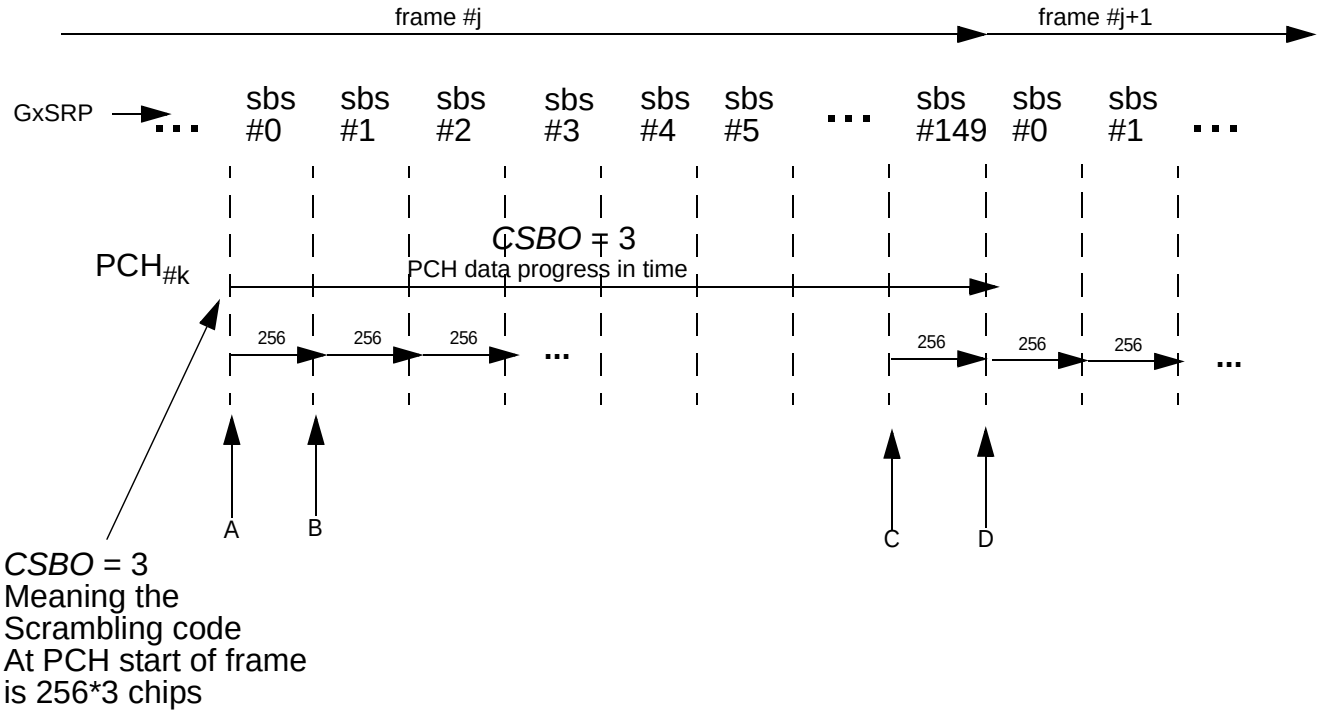

Figure 26-120. Scrambling Code Init Per PCH

The *CSBO* value, indicates, in units of sub-slots (256 chips), the time period between the PCH scrambling code initialization, when it started generating one complex value each chip-period, and the time in which the PCH transmission of its first chip. In the example, *CSBO* = 3 for PCH #k, since 3 sub-slots pass between the scrambling code initialization, and the beginning of transmission.

The *GxSRP* value, indicates the currently processed sub-slot by CRPE-ULB. It is common to all PCHs.

As a result, for each 256 chips job, the scrambling initial value for each PCH, is calculated as follows:

1. The scrambling code generator is initialized using the *SCRI* value of the PCH command (PCH specific).
2. The scrambling code generator is 'advanced' in time for an amount of chips equals to: (*GxSRP* + *CSBO*)%150[1] * 256;

In the example above (**Figure 26-120**), the scrambling code initial chip starting points are:

— Point A: (0+3)%150 *256 = 768 chips
— Point B: (1+3)%150 * 256 = 1,024 chips
— Point C: (149+3)%150 * 256 = 2 * 256 = 512 chips
— Point D: (0+3)%150 * 256 = 768 chips

26.4.3.6.1.9.2 Descrambling Using Long Codes

If the value of *CS* for a PCH is '0' (long code indication) - the descrambling code that is generated internally is a long code. This section provides the definition of descrambling code $C_{long,n}[i]$ for n=0,..., $2^{\wedge 24} - 1$ and i=0,..., 38399. The descrambling code is a complex sequence consisting of any of the following complex numbers: 1+j, 1-j, -1+j, -1-j. Hence every complex element of the scrambling pattern can be generally represented as follows:

$C_{long,n}[i] = I_n[i] + (j*Q_n[i])$

where $I_n[i]$ = 1 or –1, and $Q_n[i]$= 1 or –1.

Let X(i) denote the i^{th} symbol of sequence X.

Initial condition for sequence X is:

$X(0)=SCRI[0],\ X(1)=SCRI[1],\ldots\ X(23)=SCRI[23]$

where *SCRI* is initialized in the PCH command.

Recursive definition of subsequent X symbols is:

$X_n(i+24) = X_n(i+3)\ \text{xor}\ X_n(i).$

Let Y(i) denote the i^{th} symbol of sequence Y.

Initial condition for sequence Y is:

$Y(0)=Y(1)=Y(2)=\ldots=Y(22)=Y(23)=1.$

Recursive definition of subsequent Y symbols is:

$Y(i+24) = Y(i+3)\ \text{xor}\ Y(i+2)\ \text{xor}\ Y(i+1)\ \text{xor}\ Y(i).$

Let $z_n(i)$ denote the i^{th} symbol of sequence z_n.

The n_{th} sequence z_n is defined as:

$z_n(i) = X_n(i)\ \text{xor}\ Y(i).$

1. 150 is the number of sub-slots in a frame - the scrambling code is initialized every frame.

Let $Z_n(i)$ denote the i^{th} symbol of sequence Z_n.

The n_{th} sequence Z_n is defined as:

$$Z_n(i) = \begin{cases} +1 \text{ if } x_n(i) = 0 \\ -1 \text{ if } x_n(i) = 1 \end{cases}$$

Finally, the n_{th} complex descrambling code sequence $C_{long,n}$ is defined as:

$$C_{long,n}[i] = I_n[i] + j*Q_n[i]$$

$$I_n[i] = C_{long,1,n}[i] = Z_n(i)$$

$$Q_n[i] = C_{long,1,n}[i] * C_{long,2,n}[2*floor(i/2)] * (-1)^i$$
$$= Z_n(i) * Z_n(2*floor(i/2)+16777232) * (-1)^i$$

26.4.3.6.1.9.3 Descrambling Using Short Codes

If the value of *CS* for a PCH is '1' (short code indication) - the descrambling code that is generated internally is a short code. This section provides the definition of descrambling code $C_{short,n}[i]$ for n=0,..., $2^{\wedge}24 - 1$ and i=0,..., 255. The code is repeated cyclically by setting $C_{short,n}[255] = C_{short,n}[0]$. The descrambling code is a complex sequence consisting of any of the following complex numbers: 1+j, 1-j, -1+j, -1-j. Hence every complex element of the descrambling pattern can be generally represented as follows:

$$C_{short,n}[i] = I_n[i] - j*Q_n[i]$$

where $I_n[i]$ = 1 or -1, and $Q_n[i]$= 1 or -1.

Let a(i) denote the i^{th} symbol of sequence a.

Initial condition for sequence a is:

$$a(0)=2*SCRI[0]+1,\ a(1)=2*SCRI[1],\ldots\ a(7)=2*SCRI[7]$$

where *SCRI* is initialized in the PCH command.

Recursive definition of subsequent a symbols is:

$$a(i) = \{3*a(i-3) + a(i-5) + 3*a(i-6) + 2*a(i-7) + 3*a(i-8)\} \% 4$$

Let b(i) denote the i^{th} symbol of sequence b.

Initial condition for sequence a is:

$$b(0)=2*SCRI[8],\ \ldots\ b(7)=2*SCRI[15]$$

Recursive definition of subsequent b symbols is:

$$b(i) = \{ b(i-1) + b(i-3) + b(i-7) + b(i-8) \} \% 2$$

Let d(i) denote the i^{th} symbol of sequence d.

Initial condition for sequence a is:

$$d(0)=2*[SCRI_{16}]\ ,\ \ldots\ d(7)=2*[SCRI_{23}]$$

Recursive definition of subsequent b symbols is:

$$d(i) = \{ d(i-1) + d(i-3) + d(i-4) + d(i-8) \} \% 2$$

Let $z_n(i)$ denote the i^{th} symbol of sequence z_n.

The n_{th} sequence z_n is defined as:

$$z_n(i) = \{ a(i) + 2b(i) + 2d(i) \} \% 4$$

For all sequences, i = 0...254 , where $z_n(255) = z_n(0)$, which extends the sequence to 256 chips.

Let $Z_n(i)$ denote the i^{th} symbol of sequence Z_n.

The n_{th} sequences $C_{short,1,n}(i)$ and $C_{short,2,n}(i)$ are defined as listed in **Table 26-99**.

Table 26-99. Short Codes Sequences Definitions

$Z_n(i)$	$C_{short,1,n}(i)$	$C_{short,2,n}(i)$
0	+1	+1
1	-1	+1
2	-1	-1
3	+1	-1

Finally, the n_{th} complex descrambling code sequence $C_{short,n}$ is defined as:

$$C_{short,n}[i] = I_n[i] + (j \times Q_n[i]).$$

$$I_n[i] = C_{short,1,n}[i]$$

$$Q_n[i] = C_{short,1,n}[i] * C_{short,2,n}[2*floor(i/2)] * (-1)^i$$

26.4.3.6.1.10 Despreading

The CRPE-ULB performs despreading by correlating the finger chips with their matching elements from the channelization code. The channelization code $C_{ch,SF,OVSF}$ pattern, as it is defined in the 3GPP standard, is generated internally in accordance with section 4.3.1.1 of the standard. The parameters *SF* and *OVSF* from the PCH Command parameters, govern which channelization code is generated.

26.4.3.6.1.11 Combining

The descrambled and despreaded chips of a symbol, are accumulated to form a soft-symbol. The sum of up to 256 chips (9 bits each) generates an intermediate 17 bits result.

26.4.3.6.1.12 Finger Combining

The CRPE-ULB support Finger Combining for symbols of all fingers associated with a PCH. Finger Combining output mode, internal precision, and whether it is used are all determined by the *CRUBMCP[FC_MODE]*, as summarized in **Table 26-100**:

Table 26-100. CRPE-ULB Fingers Combining Modes

FC_MODE value	Description	Supported Output data types: *PCH[ODT]*	Data Output Format with respect to *PCH[ODT]*	Saturation
0	- FC bypass. - Output all fingers as-is per PCH	[2] - Complex I,Q	Each symbol: I (16 bits) + Q (16 bits) , fixed point, unscaled	If *DDS*[1] = '0' it may occur
1	FC enabled with Fixed scale per PCH	[0] - Real only [1] - Imaginary only	[0] - Each symbol: 16 bit fixed point (real portion), with fixed scale [EXP] per PCH. [1] - Each symbol: 16bit fixed point (imaginary portion), with fixed scale [EXP] per PCH.	May occur (depending on [EXP]
2	Reserved			
3	FC enabled. Dynamic scale Floating point format	[0] - Real only [1] - Imaginary only	[0] - Each symbol : 16bit floating point + 6bit exponent , sign extended to16bit (real portion) [1] - each symbol : 16bit floating point + 6bit exponent , sign extended to 16bit (imaginary portion)	Does not occur.

1. DDS is defined in the CRUBMCP parameter.

The Finger Combining operation functionality is illustrated in **Figure 26-121**:

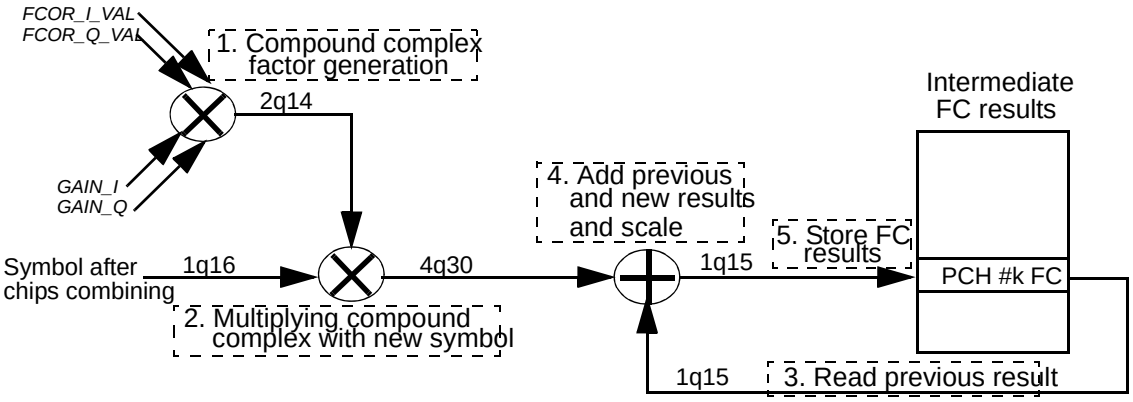

Figure 26-121. Finger Combining Operation

The following list describes the details of the stages shown in **Figure 26-121**:

1. Compound Complex Factor (CCF) is generated by a complex multiplication of the internal complex frequency correction I and Q factors (*FCOR_I_VAL* and *FCOR_Q_VAL* parameters generated by multiplying previous *FCOR_I_VAL* and *FCOR_Q_VAL* with the *FCOR_I* and *FCOR_Q* once per Sub-Slot) with the fingers specific gain factors (*GAIN_I* and *GAIN_Q* parameters of the Finger Command. For details, see **Section 26.4.3.6.1.12.2**, *Frequency Correction Factor*, **Section 26.5.4.6.2**, *CRPE-ULB Finger Command Structure*, and **Section 26.5.4.6.3**, *CRPE-ULB PCH Command Structure*.
2. The CCF is multiplied (complex multiplication) by the symbol generated from the Chips combine unit (see **Section 26.4.3.6.1.12**, *Finger Combining*).
3. The previous intermediate Finger Combining result is read from the output buffer.
4. The previous result and the new result are combined and scaled.

5. The combined result is written to the output buffer.

26.4.3.6.1.12.1 FC Bypass Mode

When *FC_MODE* = 0, the CRPE-ULB does not perform Finger Combining to the symbols associated with any of the PCH. Instead, the PCH related fingers are output by MAPLE-B2 as described in **Section 26.4.3.6.1.14.1**, *Finger Combining Bypass (FC_MODE = 0)*

26.4.3.6.1.12.2 Frequency Correction Factor

The CRPE-ULB supports frequency correction for the purpose of Finger Combining calculation, as described in **Section 26.4.3.6.1.12**, *Finger Combining*. The *FCOR_I* and *FCOR_Q* parameter of the PCH Command represent the expression: '*FCOR_I* + j**FCOR_Q*' or e^{j*b}:

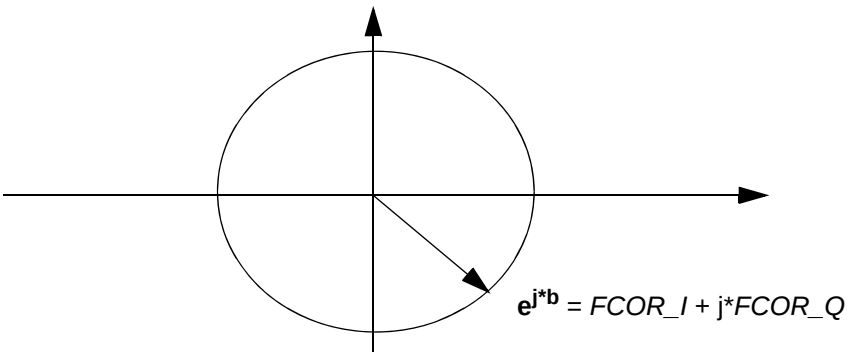

Figure 26-122. Frequency Correction—Representation of Phase

These parameters express the angle by which the phase of the internal *FCOR_I_VAL* and *FCOR_Q_VAL* is rotated (multiplied) once per sub-slot . After adding / modifying a PCH, the value of the *FCOR_I_VAL* and *FCOR_Q_VAL* is set to 0x4000 + 0x0*j , which is equivalent to "1+0*j" in 2q14 format. The *FCOR_I_VAL* and *FCOR_Q_VAL* values may be reset by applying *CMD* opcode of '8' to the PCH command.

In **Figure 26-123**, *FCOR_I* and *FCOR_Q* are set so they represent $e^{j*(pi/8)}$, so each sub-slot, the *FCOR_I_VAL* and *FCOR_Q_VAL* for this PCH is rotated by pi/8. The initial phase for *FCOR_I_VAL* and *FCOR_Q_VAL* (base) is '0x4000+0*j'

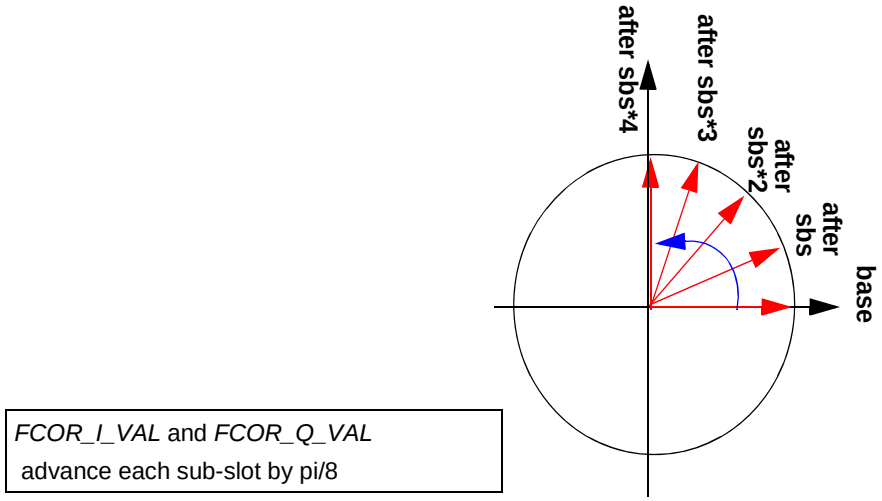

Figure 26-123. Frequency Correction Example

Note: The value '*FCOR_I* + j**FCOR_Q*', which is represented in fixed point format of 2q14, must be bounded by the unit circle, that is, ($FCOR\_I^{\wedge 2} + FCOR\_Q^{\wedge 2}$) <= 1 for correct operation.

26.4.3.6.1.13 Output Buffer Capacity

The CRPE-ULB output buffer supports for up to 4,096 I or Q (real) symbols, in *OOB* = 0 mode, or 8,192 in *OOB* = 1 mode, per group[1]. In general, when possible, it is preferable to work with *OOB* = 0 as it means internal double output buffer implementation hence better performance. **Table 26-101** summarizes the 'cost', in units of symbols, per user, depending on PCH *SF*, *FC_MODE* and *ODT*:

Table 26-101. Number of Real Symbols Per PCH

PCH [SF] value	[FC_MODE] = 0 PCH [ODT] = 2 (Cost in unit of symbols per sub-slot)	[FC_MODE] = 1/3 PCH [ODT] = 0/1 (Cost in unit of symbols per sub-slot)
256	2 * [NOF+1]	1
128	4 * [NOF+1]	2
64	8 * [NOF+1]	4
32	16 * [NOF+1]	8
16	32 * [NOF+1]	16
8	64 * [NOF+1]	32
4	128 * [NOF+1]	64
2	256 * [NOF+1]	128
Note: When FC_MODE = 0, PCH[ODT] must equal 2.		

1. See **Section 26.4.3.6.1.4**, *CRPE-ULB Data Organization* for the definition of a group

However, due to internal implementation, the maximal achieved utilization may be less than 100%. This is due to the required alignment per PCH, according to its *SF*, as described in the table below: (for the *FC_MODE* = 0 case, the effective size, which is *NOF* * (number of symbols) determines the alignment).

Table 26-102. Alignment of PCH According to SF

PCH [SF] Value	Size [units of symbols]	Required Alignment [units of symbols]
256	1	May start at alignments: 0,1,2,3,4,5,6,7
128	2	May start at alignments: 0,2,4,6
64	4	May start at alignments: 0,2,4
32 / 16 / 8 / 4 / 2	8 / 16 / 32 / 64 / 128	May start at alignment 0
Note: A memory line holds 8 symbols, so for all of these cases, they take multiples of one line.		

Using the values in **Table 26-101** and **Table 26-102**, it is possible to calculate the maximum number of PCH supported per required scenario, using the following pseudo code:

```
Alignment = 0;
For (i=0; i < LAST_PCH_NUM; i++)
{
     pch_min_size = func(SF,NOF); // calculate number of symbols according to Table 26-101
     pch_effective_size = pch_min_size + func(Alligment,pch_min_size); according to Table
     26-102
     Alignment = (Alignment + pch_effective_size) % 8 ; // up to 8 symbols per line; update
     alignment

}
```

The effective PCH size, therefore, depends on whether the PCH previous to it (previous PCH_ID) ended in an allowed alignment. If not - an unused space is between the end of the previous PCH and the beginning of the current one.

The following bulleted items provide several use cases as examples:

- Use Case #1. Two sectors AMR without FC (*FC_MODE*=0)
  - 268 PCH with *SF* = 256 and *ODT* = 0
  - Assuming 8 fingers per PCH
  - 268 x 1 symbols per PCH × 8 fingers= 2,144 symbols

  Conclusion: Use case #1 can be supported with *OOB* = 0 (<4,096 symbols)
- Use Case #2. Three sectors, high bit rate AMR, with FC (*FC_MODE*=1/3)
  - 384 PCH with *SF* = 128 and *ODT* = 0
  - 384 × 2 symbols per PCH = 768 symbols

  Conclusion: Use case #2 can be supported with *OOB* = 0 (<4,096 symbols)

- Use Case #3. Two sectors, High Speed, with FC (*FC_MODE*=1/3)
  - 8 PCH × SF8 with VoiP, per sector.
  - 16 PCH × SF4 with High speed data PCH, per sector.
  - 4 PCH × SF256 with Control, per sector
  - Total per sector: 8 × 32 symbols + 16 × 64 symbols + 4 × 1 symbol = 1,284 symbols.
  - Total per device = 1,284 × 2 = 2,568 symbols

  Conclusion: Use case #3 can be supported with *OOB* = 0 (<4,096 symbols)
- Use Case #4. Two sectors, High Speed, without FC (*FC_MODE* =0)
  - 4 PCH × SF2 × 3 fingers
  - 4 PCH × SF4 × 4 fingers
  - Total: 4 × 256 symbols x 3 fingers + 4 × 128 symbols × 4 fingers = 5,120 symbols

  Conclusion: Use case #4 can be supported with *OOB* = 1 only (<8,192 symbols).

26.4.3.6.1.14 Output Buffer Data Structure

Each physical channel has its own output buffer in system memory. (see *MCUBPCHx* parameters in **Section 26.5.3.5.2.1** to **Section 26.5.3.5.2.4**). The output buffer is a cyclical buffer of Sub-Slot data entries. The structure of Sub-Slot data depends on the value of *CRUBMCP[FC_MODE]*. The following subsections describe the Sub-Slot data entry structure depending on *FC_MODE*.

26.4.3.6.1.14.1 Finger Combining Bypass (*FC_MODE* = 0)

In this mode, the MAPLE-B2 does not perform FC to the symbols generated by each finger. As a result the output data buffer of each PCH contains all the fingers related to this PCH. The output buffer structure in this case is arranged as follows: each Finger Command (see **Section 26.5.4.6.2**) includes a Finger Memory Offset (*FMO*) indicating the Finger offset index in the output memory. All of the symbols of finger i are followed by the symbols of finger i+1. The order of the symbols/fingers can also be described as follows:

- The Finger with *FMO*=0 containing symbols 0 to n–1
- The Finger with *FMO*=1 containing symbols 0 to n–1
- ...
- The Finger with *FMO=NOF* containing symbols 0 to n–1.

  where:

  FMO - Finger Memory Offset index (see Finger Command in **Section 26.5.4.6.2**.)

  NOF - Number of Fingers for each PCH see PCH Command in **Section 26.5.4.6.3**.)

  n - Number of symbols in Sub-Slot.

The number of symbols ‘n’ depends on the Spreading Factor (*SF)* of the PCH (see PCH Command in **Section 26.5.4.6.3**), as described in **Table 26-103**:

Table 26-103. Number of Symbols Per Finger

PCH [SF] Value	Value of 'n'
256	1
128	2
64	4
32	8
16	16
8	32
4	64
2	128

Figure 26-124 shows an example of the output data structure of a Sub-Slot with the following properties:

- *SF* = 6 (Spreading factor is: 128)
- *NOF* = 5

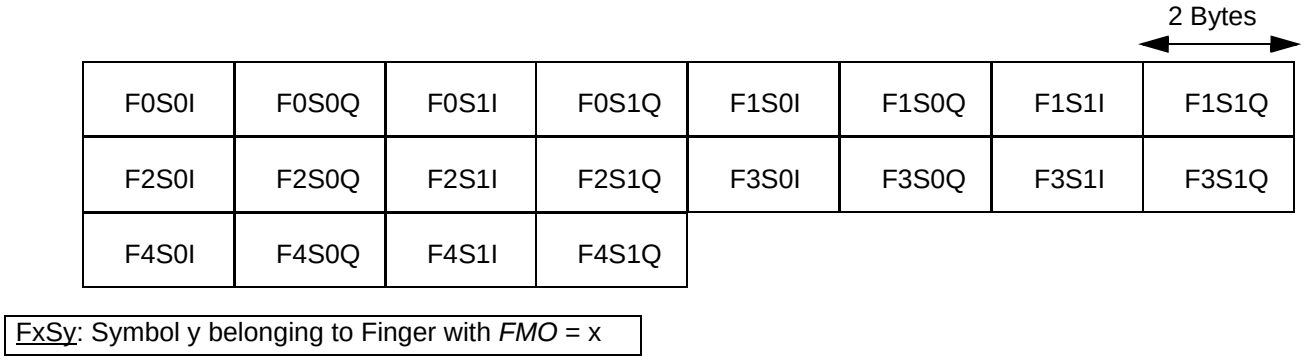

Figure 26-124. Sub-Slot Output Data Structure for *FC_MODE* = 0 Example

Note that *FMO* determines the exact offset in which the finger is located, regardless if there are fingers with *FMO* index smaller than the current *FMO*. For example: If in the above example (**Figure 26-124**) currently only 2 fingers are associated with this PCH, with *FMO* of '3' and '4' - the Sub-Slot data entry contains 'place-holders' in offsets 0,1 and 2, and the fingers data is located in offsets 3 and 4, respectively:

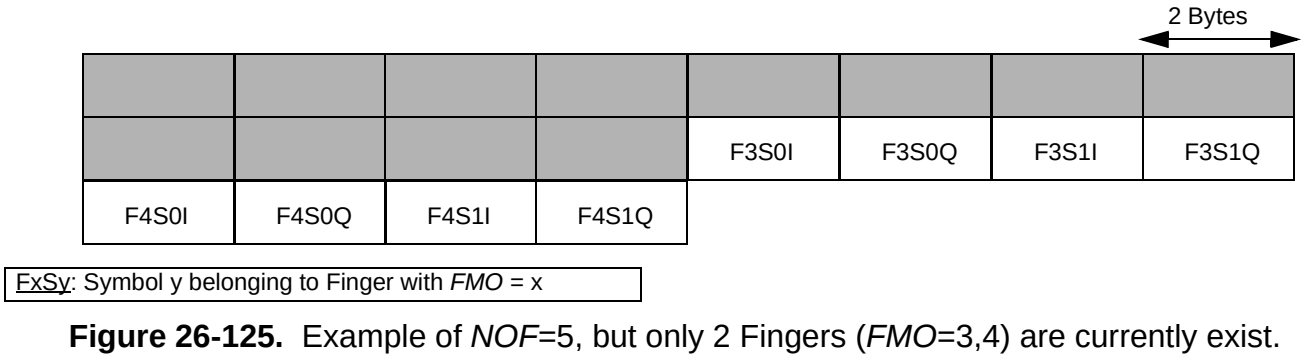

Figure 26-125. Example of *NOF*=5, but only 2 Fingers (*FMO*=3,4) are currently exist.

26.4.3.6.1.14.2 Finger Combining Enabled 16 bits Fixed Point Outputs (*FC_MODE* = 1)

In this mode, MAPLE-B2 performs FC to the symbols generated by each finger. The result of the FC is a 16-bit fixed point symbol, not normalized, with a scale of $2^{\wedge EXP}$ (*EXP* is described in the PCH command - **Section 26.5.4.6.3**). The symbols may become saturated if the user defined scale is smaller from the internally calculated scale. The Sub-Slot output data entry structure is:

Symbol 0 ; Symbol 1 ; ... ; Symbol ‘n-1’

where ‘n’ is defined as per **Table 26-103**.

Each symbol may contain an ‘I’ portion only or ‘Q’ portion only, depending on the *ODT* field of the PCH Command. **Figure 26-126** provides an example for the output data structure of a Sub-Slot, with the following properties:

- *SF* = 2 (Spreading Factor is 8)
- *ODT* = 0

2 Bytes

S0	S1	S2	S3	S4	S5	S6	S7
S8	S9	S10	S11	S12	S13	S14	S15

Figure 26-126. *Sub-Slot Output Data Structure for FC_MODE* = 1 Example

26.4.3.6.1.14.3 Finger Combining Enabled 32 bits Floating Point Outputs (*FC_MODE* = 3)

In this mode, MAPLE-B2 performs FC to the symbols generated by each finger. The result of the FC is a 32-bit floating point symbol composed of:

- 16 bits sign extended exponent generated as follows: *exponent*={10{*EXP[5]*},*EXP[5:0]*} where *EXP* is described in the PCH command - **Section 26.5.4.6.3**. The number represented by the exponent is $2^{exponent}$.
- 16 bits normalized mantissa.

The Sub-Slot output data entry structure is:

Symbol 0 mantissa; Symbol 0 exponent; Symbol 1 mantissa; Symbol 1 exponent;... ;
Symbol ‘n-1’ mantissa; Symbol ‘n-1’ exponent

where ‘n’ is defined as per **Table 26-103**.

Each symbol may contain an ‘I’ portion only or ‘Q’ portion only, depending on the *ODT* field of the PCH Command. **Figure 26-126** provides an example for the output data structure of a Sub-Slot, with the following properties:

- *SF* = 3 (Spreading Factor is 16)
- *ODT* = 0

2 Bytes

Figure 26-127. *Sub-Slot Output Data Structure for FC_MODE* = 3 Example

26.4.3.6.1.14.4 System Output Buffers Structure

Each PCH has a cyclic buffer of multiple Sub-Slots data entries with parametrized base address, and size (see *PCHxBA* and *PCHxSZ* fields in **Section 26.5.3.5.2.1** and **Section 26.5.3.5.2.2**). MAPLE-B2 writes symbols to the output buffer while updating a write pointer to the buffer (see *PCHxWP* field in **Section 26.5.3.5.2.3**). When all PCH processing related to a certain Group in a certain Sub-Slot is completed, and the MAPLE-B2 got indication that all output data for this Sub-Slot is placed in external system buffers, it updates the Group Sub-Slot Write-Pointer (*MCUBGxC4P[GOBSWP]*). This pointer points to the index of the completed Sub-Slot within 2 frames time window (0...299).

26.4.3.6.1.14.5 Compressed Mode (*ODT* = 0x3)

Each PCH, regardless of the FC operating mode, may receive the *ODT* value of 0x3, which stands for compressed mode. While the PCH is compressed mode, it is considered as being processed for the purpose of Group Sub-Slot write pointer update, and output interrupt, but the PCH write pointer (*PCHxWP* field in **Section 26.5.3.5.2.3**) is not updated. A PCH may enter/exit compressed mode every Sub-Slot, using a PCH command.

26.4.3.6.1.15 Output Interrupt and Finished Channels Buffer Maintenance.

MAPLE-B2 uses a single interrupt as indication of finished channels. A finished channel is a channel for which MAPLE-B2 has processed a specified amount of Sub-Slots. It does not mean that the processing of that channel stops.

There is a single interrupt dedicated for all Groups/channels. Finished channel IDs are stored in a cyclic buffer, which once the interrupt is asserted, can be read by the host to identify the finished channels. For details see **Section 26.4.3.6.1.15.2**, *Finished Channel Buffer*, on page 26-230.

The host can define how often to perform a search for finished channels using the *OB_INT_CHK_STEP* field of the MCUBOBICP parameter. This field indicates the number of Sub-Slots between each such search and interrupt assertion. For details see **Section 26.4.3.6.1.15.3**, *Finished Channel Search.*

26.4.3.6.1.15.1 Finished Channel Definition

Finished Channels definition is done by configuring a pair of parameters for each PCH:

1. *MARK* - determines the next Sub-Slot index (0...1199) were the channel is considered finished.
2. *STEP* - determines the value by which *MARK* is increment once current *MARK* value has reached, that is, if *MARK* index is reached *MARK = MARK + STEP*.

The *MARK* and *STEP* fields can be configured in the *MCUBPCHxOBICP* parameter.

26.4.3.6.1.15.2 Finished Channel Buffer

Once a check point for a Group is reached (that is, *#OB_INT_CHK_STEP* Sub-Slots have passed for this Group from last check), the MAPLE-B2 searches for all the finished channels in the Group (see **Section 26.4.3.6.1.15.1**, *Finished Channel Definition*). Each finished channel ID is added to the finished channel IDs buffer (*MCUBFCBxP*) by writing its PCH ID (*PCH_ID* field in the PCH Command - **Section 26.5.3.5.2.3**), and the write pointer to the finished channel IDs buffer (*MCUBOBICP[FCWP]*) is updated accordingly. The MAPLE-B2 asserts the output interrupt only if finished channel IDs were added to the buffer during this search for this Group. When the host receives the output interrupt, it looks in the *MCUBFCBxP* for all the channels that were added since the last interrupt was serviced. The MAPLE-B2 uses the bd_done[31] interrupt line (see **Section 26.4.3.1.2**, *MAPLE-B2 Interrupts*) as the ULB_DONE output interrupt[1].

Note: The ULB_DONE interrupt must be initialized and enabled as described in **Section 26.4.3.1.2**, *MAPLE-B2 Interrupts*.

The finished channels buffer (*MCUBFCBxP*) is a cyclical buffer with 512 entries. The MAPLE-B2 adds finished buffers to this channel and updates the associated write pointer (*FCWP*) without checking for possible buffer overrun. It is up to the host to make sure no overrun occur in this buffer.

26.4.3.6.1.15.3 Finished Channel Search

When MAPLE-B2 processing reaches a check point for a Group (*#OB_INT_CHK_STEP* Sub-Slots have passed for this Group from last check), it then searches for all the PCH of the Group for which the current Group processed Sub-Slot index is greater (or equal) to the *MARK* value. Each such channel is added to the finished channels buffer and its *MARK* value is increment by *STEP*. An internal *MASK* bit (defined in the *MCUBPCHxOBICP* parameter*)* is used by MAPLE-B2 to overcome modulo calculations; it should be initialized to 1 when the channel opens.

Note: The above flow suggest that a finished channel is reported only during check points and on the same Sub-Slot index indicated by the *MARK* field. For example, if for certain PCH_X configuration MARK=430, Current Sub-Slot index for this Group is 400, *OB_INT_CHK_STEP* field is set to 50 and this Sub-Slot index for this Group is a check point. The next check point for this Group is only when Sub-Slot index gets to 450, and at that point only the PCH_X is identified as finished channel and the ULB_DONE interrupt is asserted.

In order for the finished channels buffer and interrupt assertion mechanism to work correctly the following limitations must apply:

1. The *STEP* fields of all PCH must be greater (or equal) than the *OB_INT_CHK_STEP* parameter definition.
2. The *MASK* bit must be set to ‘1’ during PCH initialization.
3. The *OB_INT_CHK_STEP* value must be configured according to the limitations as described in **Section 26.4.3.6.1.15.4**, *Finished Channel Search Limitations.*

1. If the CRPE-ULB functionality is enabled, the BD_DONE interrupt [31] should not be allocated to any of the other’s PE rings.

26.4.3.6.1.15.4 Finished Channel Search Limitations.

Each finished channels search check point invokes the internal RISC engine to perform a search as described above for all valid PCH in the group. Such a search, if performed in frequent check-points for each group (small value for the *OB_INT_CHK_STEP* parameter) and on high number of valid PCH per group may degrade the whole MAPLE-B2 performance as it utilizes the RISC on the expanse of other PEs. To avoid such degradations, the following equation describe the recommended *OB_INT_CHK_STEP* and *STEP* parameters configurations with respect to the total number of active PCH defined:

$$\frac{\sum_{\forall(x \in \{\text{active channels}\})} \left(10 + \frac{20}{\text{MCUBPCHxOBICP[STEP]}}\right)}{\text{MCUOBICP[OB\_INT\_CHK\_STEP]}} < 3001$$

Examples:

- If there are 100 active channels, each with *STEP* value of 1 (check every Sub-Slot) and the *OB_INT_CHK_STEP* is also set to 1, the result of the left side of the equation is 3000.
- If all channels are active (512 channels), each with *STEP* value of 2 and the *OB_INT_CHK_STEP* is set to 4, the result of the left side of the equation is 2560.

26.4.3.6.1.16 CRPE-ULB Performance

The CRPE-ULB performance is dictated by 3 main components :

- *Interpolation*. Affected by the number of Input antennas and the Interpolation over-sample.
- *Descrambling and Despreading*. Affected by the total number of fingers and their Spreading Factor
- *Maintenance*. Affected by the number of Finger commands, and a minimal amount of maintenance time where maintenance is the period between two successive Sub-Slots processing periods.

These components share the same ‘budget’ of 33,300 cycles per Sub-Slot, or 333,000 cycles per slot according to the following calculations (and assuming 500MHz clock frequency):

$$256_{\text{chips in sbs}} * 1/(3.84e6)_{\text{single chip time (sec.)}} * 500e6_{\text{cycles/sec.}} =\sim 33{,}300 \text{ cycles.}$$

Table 26-104 details how many cycles each ULB operation requires:

Table 26-104. CRPE-ULB Operations Performance (in cycles)

Operation	Operation Configuration	Cycles per Operation
Interpolation	*DLY_SPRD* = 0	36 cycles per ANT per OVS
	DLY_SPRD = 1	48 cycles per ANT per OVS
Descrambling and Despreading (DD)	Spreading Factor 2 (*SF* = 0)	32 cycles per Finger
	Spreading Factor 4 (*SF* = 1)	16 cycles per Finger
	Spreading Factor 8 (*SF* = 2)	8 cycles per Finger
	Spreading Factor 16 to 256 (*SF* = 2...7)	4 cycles per Finger
Maintenance	Minimal maintenance period per Group per Sub-Slot	1550 cycles
	'Modify Gain' Finger command	1 cycle per Finger
	'Add New' Finger command	4 cycles per Finger
	'Remove' Finger command	4 cycles per Finger
	'Modify' Finger command	6 cycles per Finger

The following equation calculates the amount of cycles required for the CRPE-ULB to perform its tasks per Sub-Slot:

ULB SBS Cycles =
*MAX(Interolation , DD)*1.25 +*
*MAX(minimal Maintenance,Fingers Commands execution)*1.1*

The following illustrates the CRPE-ULB performance calculations for an example use-case. The example assumes two Groups configuration where each Group includes:

- 24 Antennas
- Internal Interpolation with Delay Spread of up to 256 chips (*DLY_SPRD* = 0)
- Number of OVS is 8.
- Number of PCHs is 64
- Spreading Factor of PCHs is 4
- Number of Fingers per PCH is 8
- In 2 Sub-Slots (of the Slot) all fingers are modified ('Finger Modify' command).
- In 8 Sub-slots (of the Slot) no fingers command are executed.

As per the above configuration assumptions the CRPE-ULB performance (average calculation per Sub-Slot per Group):

Interpolation cycles = $24_{Ant.}$ * 8_{OVS} * 36_{cycles} = 6912 cycles.

DD cycles = 64_{PCH} * $8_{Fingers}$ * 16_{cycles} = 8192 cycles.

Finger Commands execution and Maintenance period (average per Sub-Slot) = $2/10_{SBS/Slot}$ * 64_{PCH} * $8_{Fingers}$ * 6_{cycles} + $8/10_{SBS/Slot}$ * 1550_{cycles} = 1855 cycles.

and the total Sub-Slot cycles of the CRPE-ULB per Group are:

ULB SBS Cycles = 8192*1.25 + 1855*1.1 = 12280 cycles.

Assuming the CRPE-ULB work on two such Groups, its utilization is estimated as:

CRPE-ULB utilization = (12280*2)/33300 = **~73%**

26.4.3.6.2 Chip Rate Uplink Fast Operation

The MAPLE-B2 supports UMTS (TS 25.211 and TS25.213) up-link Chip Rate processing for low latency Physical channels such as DPCCH, E-DPCCH, RACH and HS-DPCCH as described in **Section 26.2**, *MAPLE-B2 Features*. These operations are executed using the Chip Rate- Up-Link Fast Processing Elements (CRPE-ULF).

26.4.3.6.2.1 CRPE-ULF Initialization

The CRPE-ULF initialization is composed of:

- CRPE-ULF Parameters initialization done by the host after MAPLE-B2 initialization by API is completed and before the processing beginning of CRPE-ULF.
- CRPE-ULF Configuration Registers initialization done by the host after MAPLE-B2 initialization by API is completed and before the processing beginning of CRPE-ULF.

26.4.3.6.2.1.1 CRPE-ULF Parameters Initialization

After the MAPLE-B2 initialization routine and before the beginning of the processing by the CRPE-ULF, the following CRPE-ULF parameters must be initialized:

- MAPLE CRPE-ULF Command Input Buffer Address <x> Parameter (MCUFCIBAxP): This set of parameters holds the base address and the size of the command input buffers of the CRPE-ULF. See **Section 26.5.3.5.3.1**, *MAPLE CRPE-ULF Command Input Buffer Address <x> Parameter (MCUFCIBAxP)*, on page 26-364 for detail.
- MAPLE CRPE-ULF Command Input Buffer Write Pointer <x> Parameter (MCUFCIBWPxP): Holds the command input buffer write pointer. Should be set to zero during initialization. See **Section 26.5.3.5.3.2**, *MAPLE CRPE-ULF Command Input Buffer Write Pointer <x> Parameter (MCUFCIBWPxP)*, on page 26-365 for details.
- MAPLE CRPE-ULF Command Input Buffer Read Pointer <x> Parameter (MCUFCIBRPxP): Holds the command input buffer read pointer. Should be set to zero during initialization. See **Section 26.5.3.5.3.3**, *MAPLE CRPE-ULF Command Input Buffer Read Pointer <x> Parameter (MCUFCIBRPxP)*, on page 26-366 for details.

- MAPLE CRPE-ULF Interpolation Bypass General Configuration Parameter (MCUFIBGCP): This parameter holds the general configuration parameters for interpolation bypass mode. See **Section 26.5.3.5.3.4**, *MAPLE CRPE-ULF Interpolation Bypass General Configuration Parameter (MCUFIBGCP)*, on page 26-367 for details.
- MAPLE CRPE-ULF Interpolation Bypass Group Attributes <x> Parameter (MCUFIBGAxP): This set of parameters holds the group attributes for interpolation bypass mode. **Section 26.5.3.5.3.6**, *MAPLE CRPE-ULF Interpolation Bypass Group Attributes <x> Parameter (MCUFIBGAxP)*, on page 26-369 for details.
- MAPLE CRPE-ULF Interpolation Bypass Antenna Address <x> Parameter (MCUFIBAAxP): This set of parameters holds the base address of the antenna input buffers in system memory. See **Section 26.5.3.5.3.7**, *MAPLE CRPE-ULF Interpolation Bypass Antenna Address <x> Parameter (MCUFIBAAxP)*, on page 26-370 for details.

26.4.3.6.2.1.2 CRPE-ULF Configuration Registers Initialization

After the MAPLE-B2 initialization routine (see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)) and before the beginning of the processing by the CRPE-ULF, the following CRPE-ULF configuration registers must be initialized:

- ULF General Configuration Register (ULFGCR): Includes general configuration parameters for the CRPE-ULF. See **Section 26.5.5.6.1**, *ULF General Configuration Register (ULFGCR)*, on page 26-532 for details.
- ULF Interpolation Configuration Register <x> (ULFICRx): This set of registers defines the interpolation weights of the CRPE-ULF. See **Section 26.5.5.6.3**, *ULF Interpolation Configuration Register <x> (ULFICRx)*, on page 26-534 for details.
- ULF Output Buffer <x> Base Configuration Register (ULFOBxBCR): This set of registers holds the base address of the output buffers of the CRPE-ULF. See **Section 26.5.5.6.4**, *ULF Output Buffer <x> Base Configuration Register (ULFOBxBCR)*, on page 26-536 for details.
- ULF Output Buffer <x> Attributes Configuration Register (ULFOBxACR): This set of registers hold the attributes parameters of the output buffers of the CRPE-ULF. See **Section 26.5.5.6.5**, *ULF Output Buffer <x> Attributes Configuration Register (ULFOBxACR)*, on page 26-537 for details.

26.4.3.6.2.2 CRPE-ULF Modes of Operation

The CRPE-ULF supports the following modes of operation set during the initialization sequence as described in **Section 26.4.3.6.2.1**, *CRPE-ULF Initialization*:

26.4.3.6.2.2.1 CRPE-ULF Interpolation Modes

The interpolation modes are set by writing to *ULFGCR[INB]* and *ULFGCR[OVS]*. The interpolation modes are summarized in **Table 26-105**:

Table 26-105. Interpolation Modes

INB	*OVS*	Description
0	0	Data is written to IB by Antenna I/F with OVS_2 and interpolated internally to OVS_2
0	1	Data is written to IB by Antenna I/F with OVS_2 and interpolated internally to OVS_4
0	2	Data is written to IB by Antenna I/F with OVS_2 and interpolated internally to OVS_8
0	3	Data is written to IB by Antenna I/F with OVS_2 and interpolated internally to OVS_{16}
1	0	non interpolated R_X data with OVS_2 is fetched from system memory by MAPLE-B2
1	1	Interpolated R_X data with OVS_4 is fetched from system memory by MAPLE-B2
1	2	Interpolated R_X data with OVS_8 is fetched from system memory by MAPLE-B2
1	3	Interpolated R_X data with OVS_{16} is fetched from system memory by MAPLE-B2

26.4.3.6.2.2.2 CRPE-ULF Delay Spread Modes

The delay spread mode is set by writing to *ULFGCR[MDS]*. The delay spread modes are described in **Table 26-106**

Table 26-106. Delay Spread Modes

MDS	Maximum Delay Spread	Max Number of PCHs
0	256 chips	512
1	512 chips	341

26.4.3.6.2.2.3 CRPE-ULF Pilot Correlation Modes

The PILOT correlation mode is set by writing to *ULFGCR[PCE]*. The PILOT correlation modes are described in **Table 26-107**

Table 26-107. Pilot Correlation Modes

DS	Description
0	Correlation with PILOT bits is disabled
1	Correlation with PILOT bits is enabled

26.4.3.6.2.2.4 CRPE-ULF Early/Late Modes

The Early-Late (EL) mode is set by writing to *ULFGCR[ELDx]*. The EL modes are described in **Table 26-108**

Table 26-108. EL Modes

ELD7	ELD6	ELD5	ELD4	ELD3	ELD2	ELD1	ELD0	Description
x	x	x	x	x	x	x	0	EL processing is enabled for PILOT Soft Symbol
x	x	x	x	x	x	0	x	EL processing is enabled for TFCI Soft Symbol
x	x	x	x	x	0	x	x	EL processing is enabled for FBI Soft Symbol

Table 26-108. EL Modes

ELD7	ELD6	ELD5	ELD4	ELD3	ELD2	ELD1	ELD0	Description
x	x	x	x	0	x	x	x	EL processing is enabled for TPC Soft Symbol
x	x	x	0	x	x	x	x	EL processing is enabled for E-DPCCH Soft Symbol
x	x	0	x	x	x	x	x	EL processing is enabled for HS-DPCCH Soft Symbol
x	0	x	x	x	x	x	x	EL processing is enabled for general purpose #0 Soft Symbol
0	x	x	x	x	x	x	x	EL processing is enabled for general purpose #1 Soft Symbol

26.4.3.6.2.3 CRPE-ULF Functional Description

The CRPE Uplink Fast processing receives up to 24 antennas data along with finger and physical channel commands from the system memory, process the data, and outputs it to symbol rings located within the system memory. The input data can be written to the MAPLE-B2 MBus Slave1 port (see **Figure 26-3**) by the CPRI or to be read from system memory for modes in which the interpolation is bypassed. The commands describe the physical channels and the fingers. The output data is written to system memory and calculated for the following three cases:

- Early
- On-time
- Late

Figure 26-128 describes data structures used for the CRPE-ULF processing

26.4.3.6.2.4 CRPE-ULF Data Organization

The MAPLE-B2 is programmed with information about up-to 3200 fingers belong to up to 512 Physical Channels. The CRPE-ULF correlate interpolated version of input data with the Spreading and Scrambling code of each finger. The accumulation results of all the fingers belong to the same PCH are packed and written to up-to 18 queues in system memory. The default mode to input data is by writing to the slave port of MAPLE-B2. Additional input data mode is the Interpolation Bypass mode in which data from system memory is being fetched by MAPLE-B2.

The IB data structure and memory map is configured by the following:

- *ULFGCR[IBM]* which selects the access mode to IB.
- *ULFGCR[INB]* which enables or disables interpolation logic.
- *ULFGCR[NOA]* which set the number of active antennas.
- *ULFGCR[OVS]* which set the over-sampling rate.

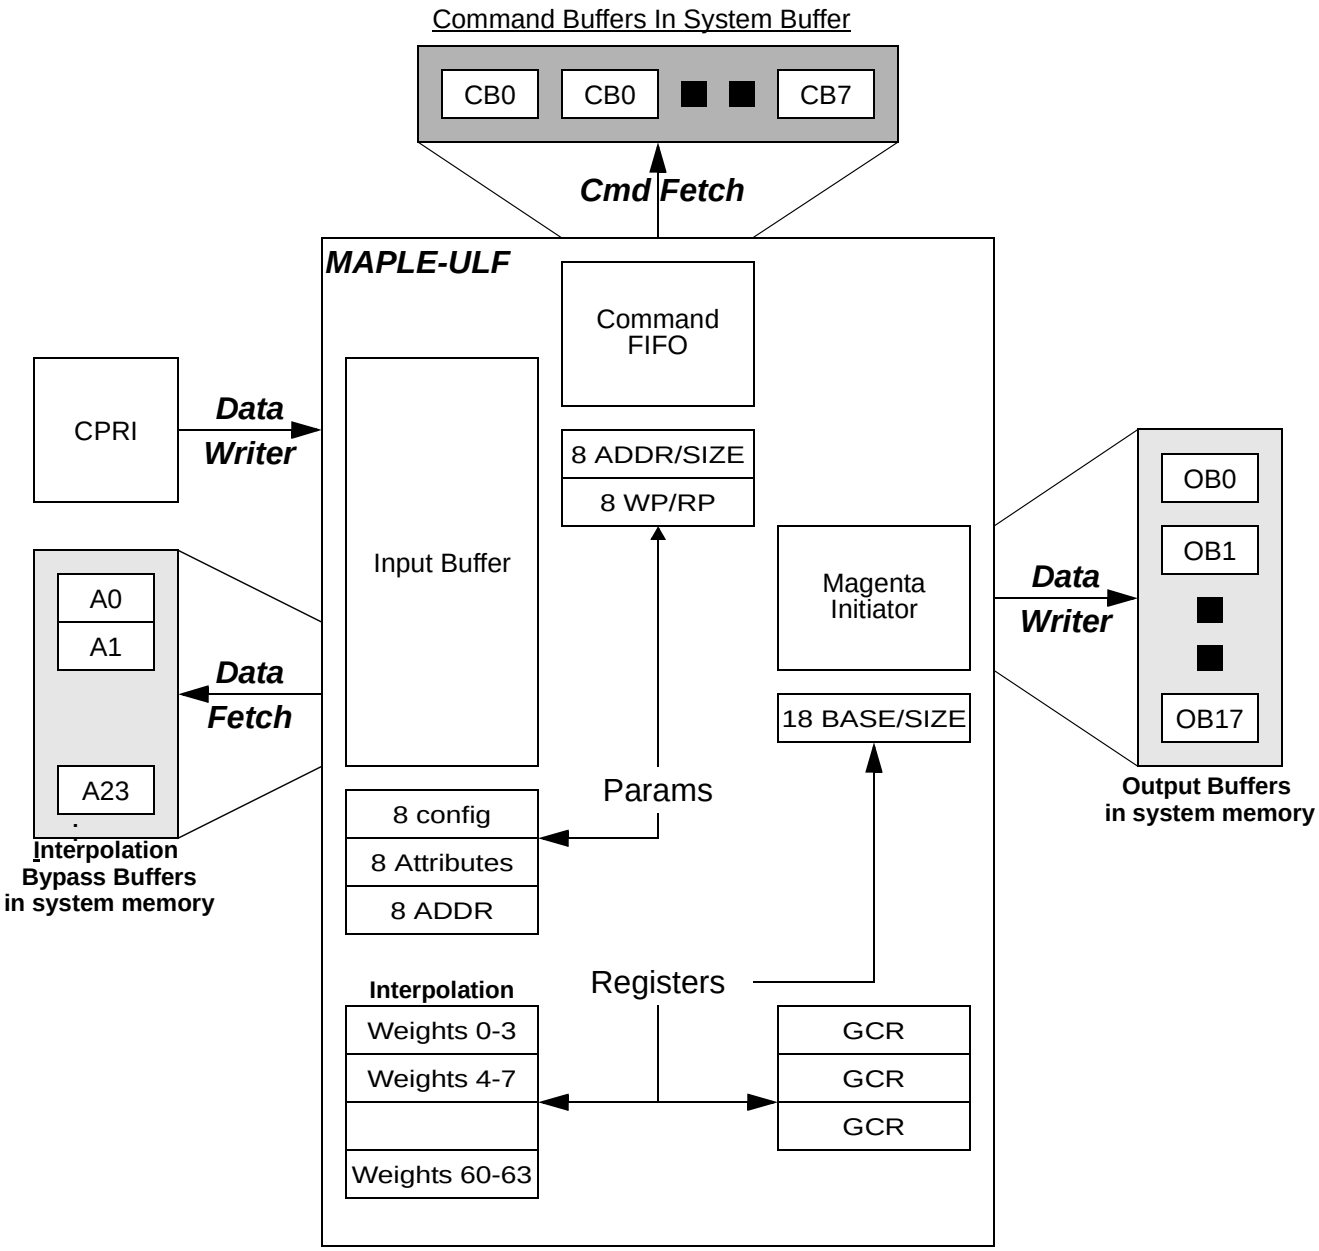

Figure 26-128. ULF Data Structure

26.4.3.6.2.5 Time Synchronization

ULF synchronizes to the system time by counting the 32 chip processing period logic. The time synchronization logic consists of a Global Chip Counter. The reset value of the counter is 76797, it's increment by 32 for each completed processing period and it's wrapped around on 2 frames boundary.

SBS	299								0			
PP	0	1	2	3	4	5	6	7	0	1	2	3
GCC	76573	76605	76637	76669	76669	76701	76733	76765	76797	29	61	93

SBS - Sub-Slot
PP - Processing Period
GCC - Global Chip Counter

Figure 26-129. Global Chip Counter implementation

26.4.3.6.2.6 Input Data Structures

The following subsections described the input data structures based on the interpolation modes selected.

26.4.3.6.2.6.1 Input Data Structure—Interpolation Enabled

In interpolation enabled mode, the Input Buffer (IB) is divided to up-to 24 pairs of cyclic buffer (up to a total 48 cyclic buffers). Each such pair of cyclic buffers contains data of single antenna such that the first cyclic buffer contains first samples of the chips and the second buffer contains the second sample of the chips. The size of each such cyclic buffer is 288 bytes and it can be accessed with write transactions granularity of 16 bytes. A pair of buffers is able to store up-to 144 chips such that the first sample of each chip is written to the first buffer and the second sample of each chip is written to the second buffer.

A chip is written to successive 2 bytes such that the most significant Byte stores the Real part and the least significant Byte stores the Imaginary part. **Figure 26-130** describes the data structure of a chip:

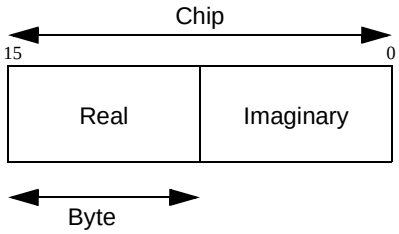

Figure 26-130. Data Structure of a Chip

There are 2 active buffers per active antenna. The number of active buffers is 2x(*ULFGCR[NOA]*+1). In interpolation enable mode, there are 2 modes to write the data to the

IB: Direct Mode and Window Mode. Choosing the input buffer mode is done by configuring the *ULFGCR[IBM]* bit.

Direct Mode

The data is written with real addresses of the IB in a cyclic order. which means that after writing chip to address 143, the next chip is written to address chip 0 and so on. **Figure 26-131** Describes the IB data structure with Interpolation in Direct mode:

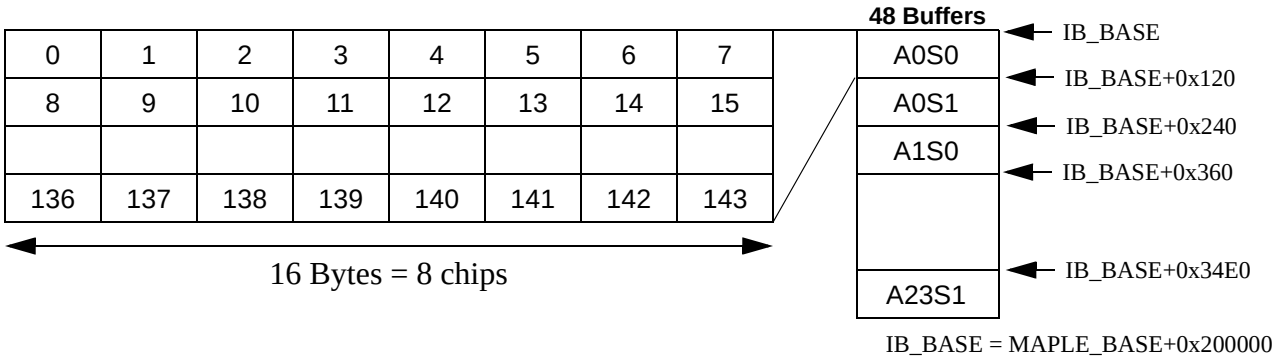

Figure 26-131. IB Data Structure Interpolation Enable - Direct Mode

Window Mode

The data is written to 4 virtual addresses of the buffer. Each buffer, that represent antenna and OVS, has access space for 32 chips. After writing the 32 chip, the next is written to chip 0. **Figure 26-132** describes the IB data structure with Interpolation in window mode:

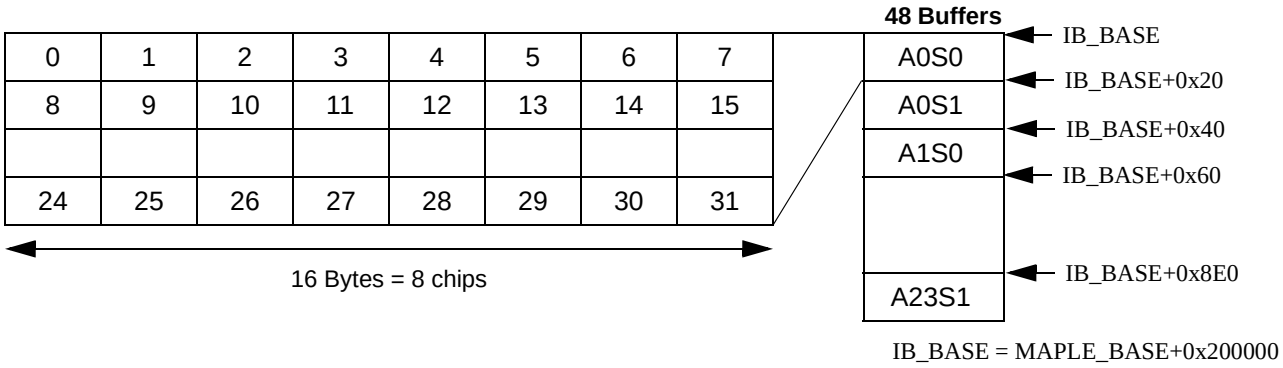

Figure 26-132. IB Data Structure Interpolation Enable

Note: The IB mode required when working in CPRI streaming mode or in interpolation bypass mode is the Window Mode (*ULFGCR[IBM]*=1*)*.

26.4.3.6.2.6.2 Input Data Structure—interpolation Bypass Mode

The IB is divided to buffers such that each buffer is a cyclic buffer which stores data of one antenna. The maximum number of antennas allowed and the number of chips in a buffer depend

on the Over Sampling rate. Interpolation bypass mode is set by setting the *ULFGCR[INB]* bit. The over sampling rate of x2, x4, x8 or x16 is set by setting *ULFGCR[OVS]* to 0, 1, 2 or 3 respectively.

Table 26-109 lists the number of maximum active antennas allowed (set by *ULFGCR[NOA]*) with respect to the over sampling rate (set by *ULFGCR[OVS]*):

Table 26-109. Maximum Number of Antennas in Interpolation Bypass Mode

OVS	Maximum NOA	Number of Bytes Per Chip	Size of IB per OVS per Ant
2	24	4	144 chips
4	24	8	72 chips
8	12	16	72 chips
16	6	32	72 chips

Note: When working with interpolation bypass mode, only IB Window Mode is supported (*ULFGCR[IBM]*=0). For details see **Section** , *Window Mode*, on page 26-240.

26.4.3.6.2.6.3 Input Data interface—Interpolation Bypass Mode

When the CRPE-ULF is working in Bypass mode the IB contains interpolated data and the interpolation filter is bypassed. The data is fetched by MAPLE-B2 from up-to 24 antenna cyclic buffers that located in system memory. The 24 Antenna cyclic buffers can be divided to up to 8 groups. Each group share the same write pointer which describe the buffer state of all group's antenna buffers.

The amount of groups, their size and the shared read pointer for all the groups are set in the *MCUFIBGCP* parameter (**Section 26.5.3.5.3.4**, *MAPLE CRPE-ULF Interpolation Bypass General Configuration Parameter (MCUFIBGCP)*). Each group is responsible for number of antennas according to the configuration of the *MCUFIBGAxP* parameter (**Section 26.5.3.5.3.6**, *MAPLE CRPE-ULF Interpolation Bypass Group Attributes <x> Parameter (MCUFIBGAxP)*). This parameter also includes the shared write pointer for the group.

Figure 26-133 illustrate 2 core groups that manage 2 antenna buffers. Each core group has its own write pointer and a mutual read pointer.

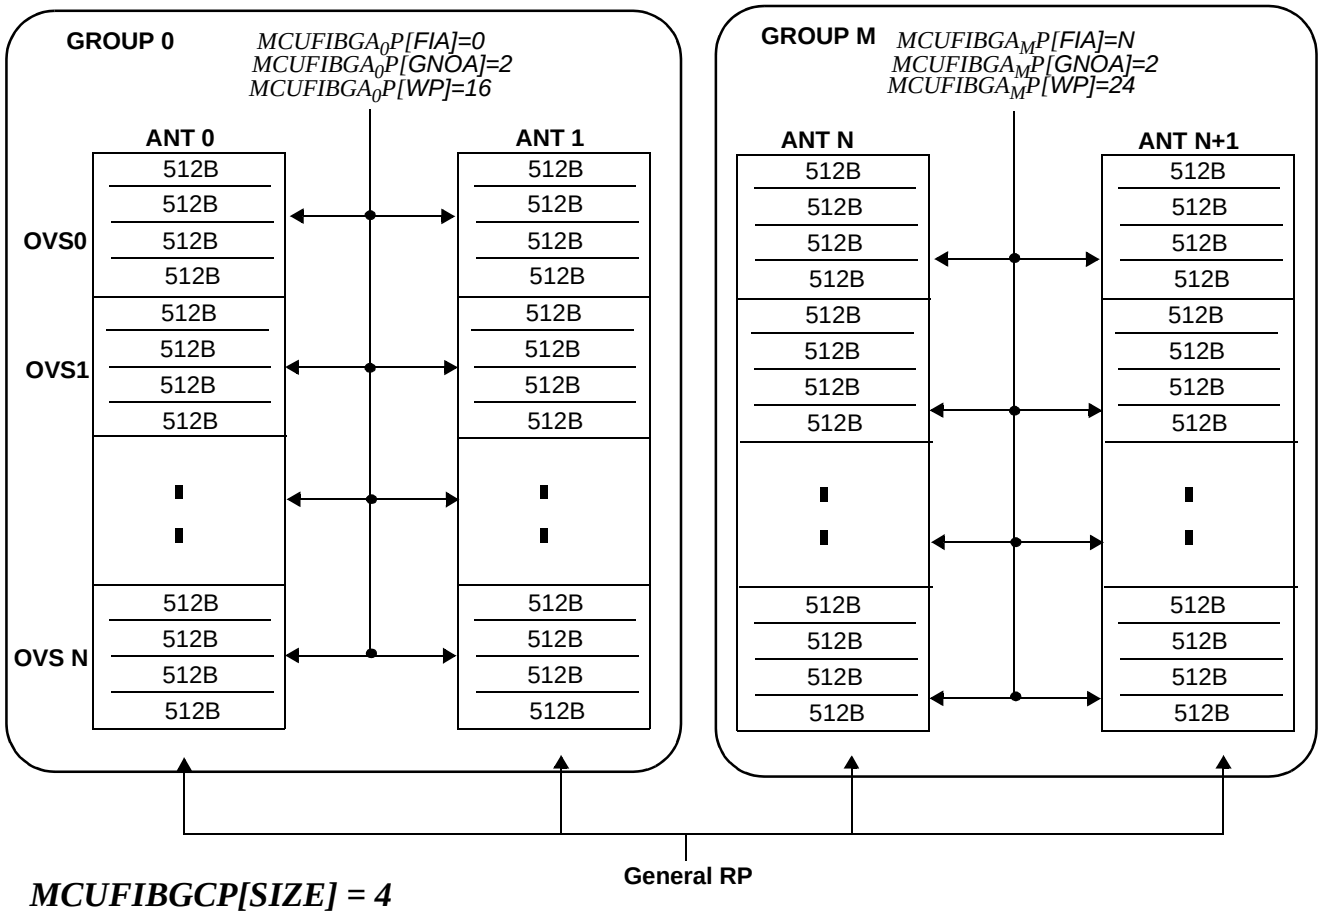

Figure 26-133. Antennas Group Input Data Structure

VCOP processes the next 64 bytes chunk of data for all antennas of all groups only if all the group's write pointers (*MCUFIBGAxP[WP]*) are bigger (cyclic pointers) than the global Read Pointer (*MCUFIBGCP[RP]*) and only after the previous data have been processed.

The MAPLE-B2 initiates the write/read pointers status check on the following internal events:

1. CRPE-ULF initiates an internal "Done" indication for processing the previous 32 chip data.
2. The CRPE-ULF timer indication event occur. The initial value of the timer is being configured in the *MCUFIBGCP[TMR]* field.

On every internal "Done" indication from the CRPE-ULF, the MAPLE-B2 check the pointers status. If there is no data to fetch, the MAPLE-B2 initiates the internal timer indicating the next time point to check the pointers. If in the next time point to check there is no data to fetch, the MAPLE-B2 continues with initiating the timer until data is valid to fetch.

Interpolation Bypass initialization

After MAPLE-B2 initialization, when configuring the CRPE-ULF to interpolation bypass mode and setting all relevant parameters, the host should trigger the `Maple_crpe_ulf_init` routine (see **Section 26.4.5**, *MAPLE-B2 Internal Task Control*, on page 26-312) to indicate the internal firmware to start fetching the data into the CRPE-ULF. Initiating this routine should be done once after initialization and only for Interpolation bypass mode.

26.4.3.6.2.7 Interpolation Processing

The interpolation logic is enabled if *ULFGCR[INB]* is cleared. Interpolation is implemented by an eight taps polyphase filter with programmable weights.

The interpolation logic calculates 8 phases for each sample. Each phase is calculated by eight programmable weights. Each weight is 8 bit Real which is multiplied by one of 4 predecessor or 4 successor samples. The phases are numbered from 0 to 7 such that interpolated phase 0 replaces a sample, phase 1 is closest to the four predecessor samples and phase 7 is closest to the 4 successor samples. **Figure 26-134** describes the interpolation of phase 4:

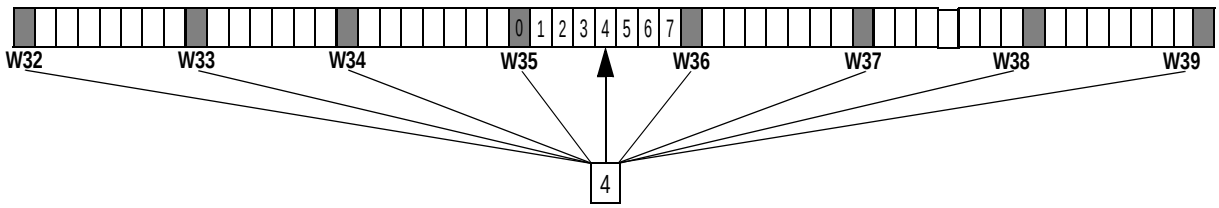

Figure 26-134. Interpolation of Sample 4

Table 26-110 describes the relation between the programmable weights and the interpolated sample:

Table 26-110. Interpolation Weights

Sample	Most far predecessor	Second Most far predecessor	Second closest predecessor	closest predecessor	closest successor	second closest successor	second most far successor	most far successor
0	ULFICR0[W0]	ULFICR0[W1]	ULFICR0[W2]	ULFICR0[W3]	ULFICR1[W4]	ULFICR1[W5]	ULFICR1[W6]	ULFICR1[W7]
1	ULFICR2[W8]	ULFICR2[W9]	ULFICR2[W10]	ULFICR2[W11]	ULFICR3[W12]	ULFICR3[W13]	ULFICR3[W14]	ULFICR3[W15]
2	ULFICR4[W16]	ULFICR4[W17]	ULFICR4[W18]	ULFICR4[W19]	ULFICR5[W20]	ULFICR5[W21]	ULFICR5[W22]	ULFICR5[W23]
3	ULFICR6[W24]	ULFICR6[W25]	ULFICR6[W26]	ULFICR6[W27]	ULFICR7[W28]	ULFICR7[W29]	ULFICR7[W30]	ULFICR5[W31]
4	ULFICR8[W32]	ULFICR8[W33]	ULFICR8[W34]	ULFICR8[W35]	ULFICR9[W36]	ULFICR9[W37]	ULFICR9[W38]	ULFICR9[W39]
5	ULFICR10[W40]	ULFICR10[W41]	ULFICR10[W42]	ULFICR10[W43]	ULFICR11[W44]	ULFICR11[W45]	ULFICR11[W46]	ULFICR11[W47]
6	ULFICR12[W48]	ULFICR12[W49]	ULFICR12[W50]	ULFICR12[W51]	ULFICR13[W52]	ULFICR13[W53]	ULFICR13[W54]	ULFICR13[W55]
7	ULFICR12[W56]	ULFICR12[W57]	ULFICR12[W58]	ULFICR12[W59]	ULFICR13[W60]	ULFICR13[W61]	ULFICR13[W62]	ULFICR13[W63]

Given 8 complex samples with 8 bits Real and 8 bits Imaginary, and given 8 corresponding weights (8 bit width) the interpolation is done according the following pseudo code:

```
Let R0,R1 ... R7 be the Real part of the complex samples
Let I0,I1 ... I7 be the Imaginary part of the complex samples
Let W0,W1 ... W7 be the corresponding weights
Let R be the real part of the interpolated sample
Let I be the Imaginary part of the interpolated sample
         R = (R0xW0 + R1xW1 + R2xW2 + R3xW3 + R4xW4 + R5xW5 + R6xW6 + R7xW7)>> ULFGCR[IS]
         I = (I0xW0 + I1XW1 + I2xW2 + I3xW3 + I4xW4 + I5xW5 + I6xW6 + I7XW7)>> ULFGCR[IS]
// Saturation:
         If R>127 then R=127
         If R<-128 then R = -128

         If I>127 then I=127
         If I<-128 then I= -128
```

26.4.3.6.2.8 Despreading and Descrambling (DD)

The DD operation refers to extracting a Soft Symbol of a specific finger out of a stream of chips. For E-/DPCCH which are spread with SF=256, the DD operation produces one Soft Symbol for each 256 chips. The DD is done by selecting 256 samples chips belong to the same Soft Symbol and correlating them with the PCH's scrambling code and OVSF. If the PILOT Soft Symbol is expected and *ULFGCR[PCE]* = 1, the chips are correlated with the expected pilot bit too.

26.4.3.6.2.8.1 Antenna Selection

The antenna interpolated input is selected by the *AID* field of the Finger Command (*FIC[AID]*) such that if *FIC[AID]*=0, correlation is done on antenna #0 data, if *FIC[AID]*=1, correlation is done on antenna #1 data,..., and if *IFC[AID]* = 23, correlation is done on antenna #23 data. *FIC[AID]* must be less than or equal to *ULFGCR[NOA]*. For details on the Finger Command data structure see **Section 26.4.3.6.2.11.1**, *Finger Command (FIC) Structure*.

26.4.3.6.2.8.2 Chip Selection.

The DD operation is done on the 256 chips. The selection of the chips depends on the internal Global Chip Counter (GCC), the PCH Command sub-slot start attribute (*PCHC[SBS]*) and the finger offset (*FIC[FOF]*). For details on the PCH Command data structure see **Section 26.4.3.6.2.11.2**, *Physical Channel Command Structure (PCHC)*

Figure 26-135 describes the chips selection for two fingers belong to the same PCH. The first finger is with offset FOF0 chips relative to *PCH[SBS]* and the second finger is with offset FOF1 chips relative to *PCH[SBS]*.

- For processing its first Soft Symbol (F0SS0), the first finger selects the chips (SBS*256 + FOF0) to (SBS*256 + FOF0 + 255)
- For processing its second Soft Symbol (F0SS1), the first finger selects the chips ((SBS+1)*256 + FOF0) to ((SBS+1)*256 + FOF0 + 255)
- For processing its first Soft Symbol (F1SS0), the second finger selects the chips (SBS*256 + FOF1) to (SBS*256 + FOF1 + 255).

- For processing its second Soft Symbol (F1SS1), the second finger selects the chips ((SBS+1)*256 + FOF1) to ((SBS+1)*256 + FOF1 + 255).

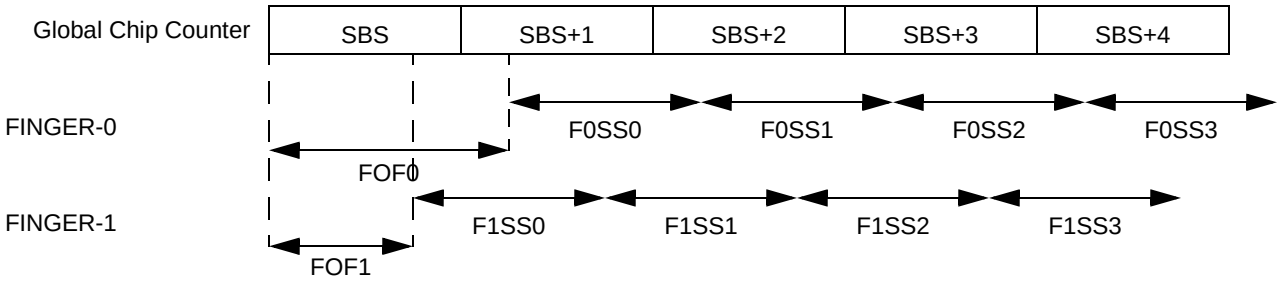

Figure 26-135. Chip Selection

26.4.3.6.2.8.3 Physical Channel (PCH) and Slot Format (SLF) Selection

DD processing supports 4 physical channel types: DPCCH, E-DPCCH, HS-DPCCH and PRACH.

- DPCCH produced 10 bits of data with the following structure:
  - 3 to 8 PILOT bits
  - 0, 2, 3 or 4 Transport Format Combination Indicator bits (TFCI)
  - 0 or 1 Feedback Information bits (FBI)
  - 2 or 4 Transport Power Control bits (TPC)
- E-DPCCH and HS-DPCCH produced 10 bits of data with no division to groups.
- RACH produces 8 PILOT bits and 2 TFCI bits.

The *PCHC[SLF]* field selects the Physical Channel type and the Slot Format as described in **Table 26-111**.

Table 26-111. ULF Supported Slot Formats

SLF	PCH	SBS0	SBS1	SBS2	SBS3	SBS4	SBS5	SBS6	SBS7	SBS8	SBS9
0	DPCCH	PILOT#0	PILOT#1	PILOT#2	PILOT#3	PILOT#4	PILOT#5	TFCI#0	TFCI#1	TPC#0	TPC#1

26.4.3.6.2.8.4 Scrambling Sequence Generation

The DD logic correlates the Rx buffer data with a complex-valued scrambling sequences. The scrambling sequence may be either a short scrambling sequence or a long scrambling sequence. The short and long scrambling sequences supported by DD logic complies with the long and short scrambling codes defines in *3GPP TS 25.211 v9.0.0 (2009-09)* sub clause 4.3.2.

A scrambling sequence is a series of 38400 complex numbers such that each complex number is either 1+j, 1-j, -1+j or -1 -j. There are 2^{24} different short scrambling sequences and 2^{24} different long scrambling sequences.

The DD logic uses the PCH Command (*PCHC*) attributes to select the PCH unique scrambling sequence, and together with the Finger Command (*FIC*) attributes and the Global Chip Counter, adjusts the scrambling sequence to the finger's offset.

The DD logic uses the Long/Short Scrambling sequence indication (*PCHC[LSS]*) and the Scrambling Sequence Number (*PCHC[SSN]*) to select the scrambling sequence:

- If *PCHC[LSS]* = 0, the DD logic uses *PCHC[SSN]* to select one of 2^{24} long scrambling sequences.
- If *PCHC[LSS]* = 1, the DD logic uses *PCHC[SSN]* to select one of 2^{24} short scrambling sequences.

In each processing period and for each finger the DD logic calculates 32 complex values which are correlated with the Rx data buffer. The complex values are calculated as followed:

```
Let S[i] be the i^th complex value of the selected scrambling sequence (i=0 to 38399)
Let S_pp[j] be the complex value to be correlate with the j^th chip of the PP. (j = 0 to 31)
Parameters:
GCC - internal Global Chip Counter
SBO - offset of the scrambling sequence in resolution of sub-slot and relative to GCC.
To be defined in the PCH Command (PCHC)
FOF - the finger's offset. To be defined in the Finger Command (FIC)
for(i=0 to 31)
        Spp[i] = S[(GCC+ i + SBO*256 - FOF)%38400]
```

Note: The scrambling sequence is shifted one chip to the left to support Early/On-time/Late (EOL) processing.

Figure 26-136 describes an example of scrambling sequences calculations with the following parameters:

- S1 is calculated with *PCHC[SBS]* = 63, *PCHC[SBO]* = 0 and *PCHC[FOF]*=0
- S2 is calculated with *PCHC[SBS]* = 63, *PCHC[SBO]* = 1 and *PCHC[FOF]*=0
- S3 is calculated with *PCHC[SBS]* = 63, *PCHC[SBO]* = 1 and *PCHC[FOF]*= 270

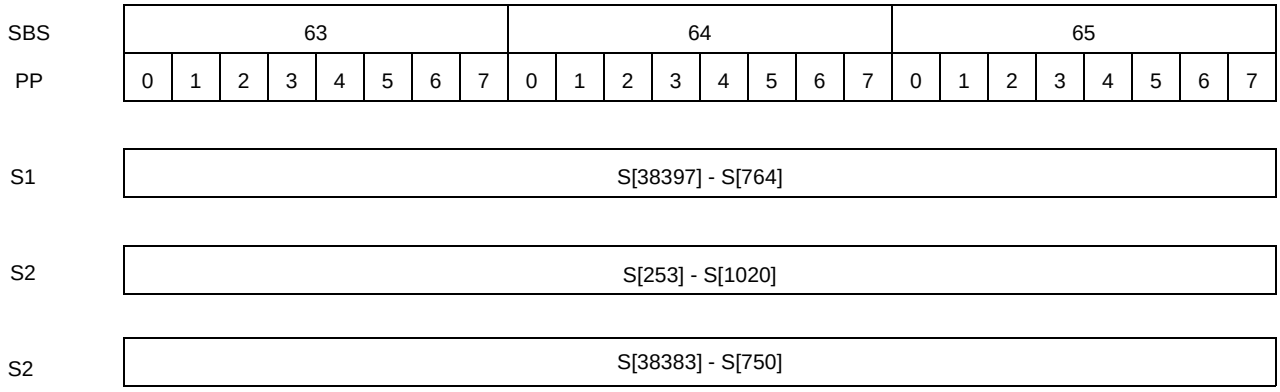

Figure 26-136. Scrambling Sequences Calculation Example

26.4.3.6.2.8.5 OVSF Code Generation

The **O**rthogonal **V**ariable **S**preading **F**actor (OVSF) code is a series of 256 real values which can be 1 or -1. CRPE-ULF supports the following OVSF codes:

- OVSF 256,0 for DPCCH.
- OVSF 256,1 for E-DPCCH.
- OVSF 256,16i+15 (i=0 to 15) for PRACH control part.
- OVSF 256,1, 256,31, 256,32 and 256,64 for HS-DPCCH

26.4.3.6.2.8.6 Pilot Code Generation

The DD logic correlates the Rx Buffer data with the pilot code when: *ULFGCR[PCE]* = 1, the PCH is DPCCH and during sub-slot when a pilot Soft Symbol is expected (as describes in **Table 26-111**). When *PCHC[SLF]*=0 or *PCHC[SLF]*= 8, there are 6 pilot bits per slot and total of 90 pilot bits in a frame. **Table 26-112** describes the pilot code when *PCHC[SLF]*=0 or *PCHC[SLF]*=8:

Table 26-112. PILOT Bits for *PCHC[SLF]*=0 or *PCHC[SLF]*=8

sub-slot/slot	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
1	1	0	0	0	1	1	1	1	0	1	0	1	1	0	0
2	1	0	1	0	0	1	1	0	1	1	1	0	0	0	0

Table 26-112. PILOT Bits for *PCHC[SLF]*=0 or *PCHC[SLF]*=8

sub-slot/slot	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
3	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
4	1	1	0	0	0	1	0	0	1	1	0	1	0	1	1

8-9	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

When *PCHC[SLF]* =6, there are 3 pilot bits per slot and total of 45 pilot bits in a frame. **Table 26-116** describes the pilot code when *PCHC[SLF]*=6:

Table 26-116. PILOT Bits for *PCHC[SLF]*=6

sub-slot/slot	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
0	1	0	0	0	1	1	1	1	0	1	0	1	1	0	0
1	1	0	1	0	0	1	1	0	1	1	1	0	0	0	0
2	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
3-9	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

When *PCHC[SLF]* =7, there are 7 pilot bits per slot and total of 105 pilot bits in a frame. **Table 26-117** describes the pilot code when *PCHC[SLF]*=7:

Table 26-117. PILOT Bits for *PCHC[SLF]*=7

sub-slot/slot	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14
0	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
1	1	0	0	0	1	1	1	1	0	1	0	1	1	0	0
2	1	0	1	0	0	1	1	0	1	1	1	0	0	0	0
3	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
4	1	1	0	0	0	1	0	0	1	1	0	1	0	1	1
5	0	0	1	0	1	0	0	0	0	1	1	1	0	1	1
6	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1
7-9	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

In each processing period and for each finger the DD logic calculates 32 real values which are correlated with Rx Buffer data. The real value are calculated as followed:

```
Let PILOT[s][j][k] be the pilot bit for SLF=s, for the j^th slot and the k^th sub-slot.
Let P[i] be the real value correlate with the i^th chip of the processing period (i=0 to 31)
Parameters:
        GCC - Global Chip Counter
        SLF - Slot Format of the PCH
        FOF - Finger Offset
```

```
for(i=0 to 31)
        j = FLOOR((GCC + i - FOF)/2560)
        k = FLOOR((GCC + i - FOF)/256)
        if(PILOT[SLF][j][k] == 1)
           P[i] = 1;
        else
           P[i] = -1
```

Note: The Pilot sequence is shifted one chip to the left to support Early/On-time/Late (EOL) processing.

26.4.3.6.2.8.7 DPCCH/PRACH PILOT Correlation

The DPCCH PILOT correlation is a function which produces a 16 bits Real and 16 bits Imaginary complex-valued soft symbol. The DPCCH PILOT correlation is used when the PCH is DPCCH, the current Soft Symbol is pilot and *ULFGCR[PCE]* = 1. The correlation function gets as an input the following parameters:

- 256 chips represented by a complex number with 8 bits Real part and 8 bits Imaginary part.
- 256 scrambling complex numbers which may be 1+j, 1-j, -1+j or -1-j.
- 256 spreading numbers which can be either 1 or -1
- A pilot number which can be either 1 or -1

The correlation function is described in the following pseudo code:

```
Let A[i] + B[i]j be the i^th chip
Let C[i] + D[i]j be the i^th scrambling number
Let E[i] be the i^th spreading number
Let P be the pilot number
Let S_I be the Real part of the output soft symbol
Let S_Q be the Imaginary part of the output soft symbol

S_I = 0;
S_Q = 0;

# Real part and Imaginary part of (A[i]+B[i]j)*(C[i]-D[i]j)*E[i]*(-Pj)
for(i=0;i<256;i++){
        S_I += P*E[i]*B[i]*C[i] - P*E[i]*A[i]*D[i];
        S_Q += -P*E[i]*A[i]*C[i] -P*E[i]*B[i]*D[i];
}
S_I = S_I>>ULFGCR[DDS];
S_Q = S_Q>>ULFGCR[DDS];

if(S_I > 32767)
        S_I = 32767;
if(S_I < -32768)
        S_I = -32768;
if(S_Q > 32767)
        S_Q - 32767;
if(S_Q < -32768)
        S_Q = -32768;
```

26.4.3.6.2.8.8 E-DPCCH and HS-DPCCH Data Correlation.

The E/HS-DPCCH data correlation is a function which produces a 16 bits Real and 16 bits Imaginary complex-valued soft symbol. The correlation function gets as an input the following parameters:

- 256 chips represented by a complex number with 8 bits Real part and 8 bits Imaginary part.
- 256 scrambling complex numbers which may be 1+j, 1-j, -1+j or -1-j.
- 256 spreading numbers which can be either 1 or -1

The correlation function is described in the following pseudo code:

```
Let A[i] + B[i]j be the i^th chip
Let C[i] + D[i]j be the i^th scrambling number
Let E[i] be the i^th spreading number

Let S_I be the Real part of the output soft symbol
Let S_Q be the Imaginary part of the output soft symbol

S_I = 0;
S_Q = 0;

for(i=0;i<256'i++){
    S_I += E[i]*A[i]*C[i] + E[i]*B[i]*D[i]; # Real part of (A[i]+B[i]j)*(C[i]-D[i]j)*E[i]
    S_Q += E[i]*B[i]*C[i] - E[i]*A[i]*D[i]; # Imaginary of (A[i]+B[i]j)*(C[i]-D[i]j)*E[i]
}
S_I = S_I>>ULFGCR[DDS];
S_Q = S_Q>>ULFGCR[DDS];

if(S_I > 32767)
    S_I = 32767;
if(S_I < -32768)
    S_I = -32768;
if(S_Q > 32767)
    S_Q - 32767;
if(S_Q < -32768)
    S_Q = -32768;
```

26.4.3.6.2.8.9 Early/On-time/Late (EOL) Processing

EOL processing refers to processing a finger three times with fixed offset forward and backward relative to the offset set by *FIC[FOF]*. The EOL is enabled depending on the type of the soft symbol and on the corresponding *ULFGCR[ELDx]* bit:

- For PILOT Soft Symbol, EOL is enabled only if *ULFGCR[ELD0]* is reset.
- For TFCI Soft Symbol, EOL is enabled only if *ULFGCR[ELD1]* is reset.
- For FBI Soft Symbol, EOL is enabled only if *ULFGCR[ELD2]* is reset.
- For TPC Soft Symbol, EOL is enabled only if *ULFGCR[ELD3]* is reset.
- For ED-DPCCH Soft Symbol, EOL is enabled only if *ULFSCR[ELD4]* is reset.
- For HS-DPCCH Soft Symbol, EOL is enabled only if *ULFSCR[ELD5]* is reset.

- For General Purpose #0 Soft Symbol, EOL is enabled only if *ULFSCR[ELD6]* is reset.
- For General Purpose #1 Soft Symbol, EOL is enabled only if *ULFSCR[ELD7]* is reset.

When EOL is enabled DD processing is done on three fingers: Early finger, On-Time finger and Late finger. These three fingers produces three Soft Symbol respectively: Early Soft Symbol, On-Time Soft Symbol and Late-Soft Symbol.

The offset of the EOL fingers, in resolution of 1/16 chips, is set by *FIC[FOF]*, *FIC[SID]* and *PCHC[ELO]* as follows:

- The offset of the Early finger is *FIC[FOF]**16 + *FIC[SID]* - *PCHC[ELO]* - 1.
- The offset of the On-Time finger is *FIC[FOF]**16 + *FIC[SID]*.
- The offset of the Late finger is *FIC[FOF]**16 + *FIC[SID]* + *PCHC[ELO]* + 1.

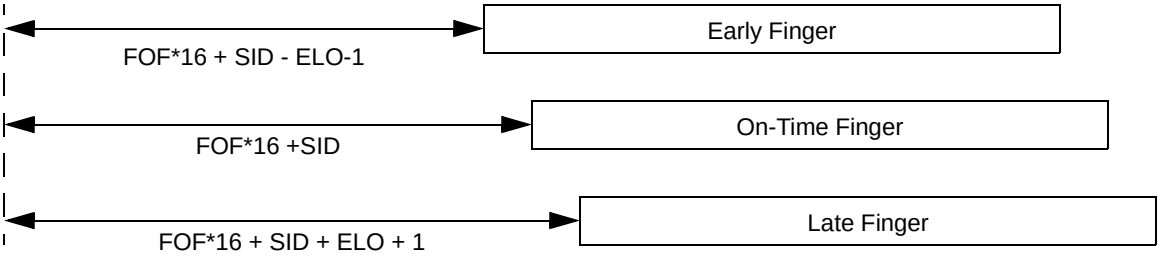

Figure 26-137. EOL Offset

Some notes:

- Due to EL offset the DD processing requires 34 chips during each processing periods.
- During the very first Processing Period (PP), the DD logic uses chips number –2 to chips number 31 such that chips –2 and –1 are zeroes.
- The On-Time finger is shifted one chip to the left, that is, in the very first PP, when ignoring *FIC[FOF]* it aligned to chips –1 to 30. The Early and Late fingers are with offset of *PCHC[ELO]* relative to the On-Time Finger.
- In each processing period the EOL fingers are progressed 32 chips forward.

Figure 26-138 describes the EOL fingers during the very first PP.

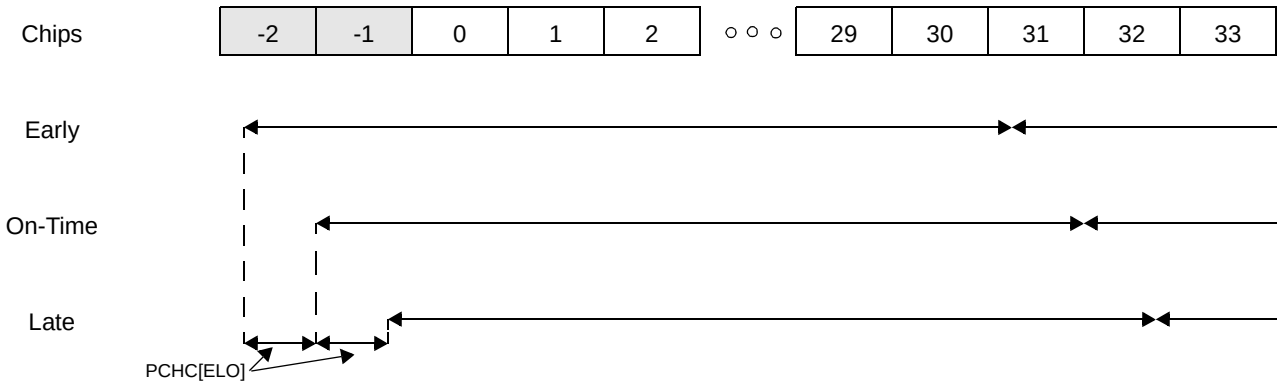

Figure 26-138. EOL Fingers in the Very First PP

26.4.3.6.2.8.10 Updating Finger Offset

The finger offset can be reprogrammed by issuing a Finger Command (FIC) with new Finger Offset (*FIC[FOF]*) and/or Sample ID (*FIC[SID]*) fields while preserving the old PCH ID (*FIC[PCHID]*), Antenna ID (*FIC[AID]*) and Finger Number (*FIC[FIN]*) values. The new offset applies in the sub-slot number set by *FIC[SBS]* field. When moving a finger forward, the DD logic produces the last Soft Symbol of the old finger (for sub-slot *FIC[SBS]*-1), stops processing during the gap between the old finger and the new finger, and restarts processing at the new start position of the new finger.

When moving a finger backward, the DD logic prematurely produces the last Soft Symbol of the old finger in the start position of the new finger. As a result the last Soft Symbol of the old finger (for sub-slot *FIC[SBS]*-1) would be less accurate. An alternative for moving a finger backward is killing the old finger after it produces the Soft Symbol for sub-slot SBS-1 and open a new finger with new offset to replace it from *FIC[SBS]* sub-slot index and on. In this case, the new finger must have new *FID*, may have new *FOF* and *SID*, and must have old *PCHID* and *FIN*.

Note: Eliminating a finger is done by setting its Antenna ID (*FIC[AID]*) to *ULFGCR[NOA]*.

Moving fingers options are described in **Figure 26-139**:

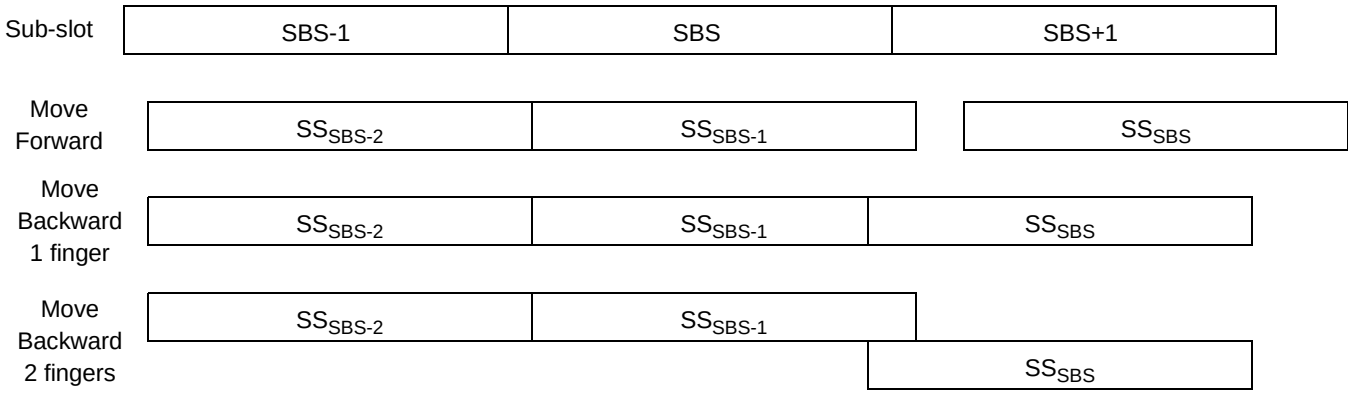

Figure 26-139. Moving Fingers options

If the finger Antenna ID (*FIC[AID]*) is changed on the fly the DD logic does not calculate the tail of the old Soft Symbol on the PP it starts the new Soft Symbol. Instead, the DD logic outputs the last intermediate result calculated in the previous PP.

The following example describes changing Finger's Antenna ID on the fly. The DD logic calculates SS0 and SS1 using data received on antenna #0 and calculates SS2 on data received on antenna #1. During SBS0 PP1, the DD logic calculates the tail of SS0 and outputs the symbol. It also starts to calculate SS1 and output the first intermediate result. During SBS1 PP1, the DD logic does not calculate the tail of SS1; instead, it outputs the last intermediate result for SS1 (which is calculated during SBS1 PP0). It also starts calculating SS2 and outputs its first intermediate result.

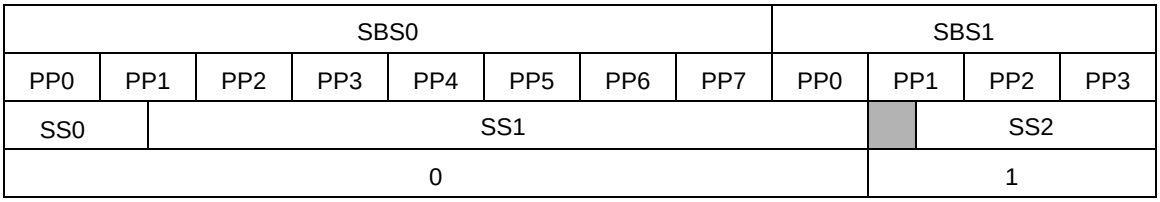

Figure 26-140. Changing AID On-the-Fly

26.4.3.6.2.9 Compressed PCHs

Compressed PCHs are transmitted on selected slots of a frame as indicated by *PCHC[SEx]*. The DD logic is activated only for a slot for which its corresponding *PCHC[SEx]* bit is set. The index of the slot is calculated with regard to the Global Clock Counter (GCC), the Sub-Slot Offset (*PCHC[SBO]*), the Sub-Slot Start indication (*PCHC[SBS]*), and the Finger Offset (*FIC[FOF]*) as described in the following pseudo code:

```
Let SI[i] be the SLOT index for the i^th chip of the processing period (i=0 to 31)
Parameters:
        GCC - Global chip counting.
        SBO - Sub-slot offset of the PCH
        SBS - Sub-slot when the PCH is activated
        FOF - Finger offset

for(i=0;i<32;i++)
        SI[i]= Floor((GCC + i - (SBS%150)*256 +SBO*256 - FOF)%38400/2560)
```

26.4.3.6.2.10 CRPE-ULF Output Data

The following subsections describe the output data structure for CRPE-ULF processing.

26.4.3.6.2.10.1 Soft Symbol Packet Structure

The Soft Symbol of all fingers belong to the same PCH are packed and written to system memory. There are two types of packet, the first type of packet (Type-0) is used when Aery/Late processing is disabled and the second type of packet (Type-1) is used when the EL is enabled.

- Type-0 packet consists of 64 bits header followed by On-Time Soft Symbols (SSs).
- Type-1 packet consists of 64 bits header followed by On-Time SSs, followed by Early SSs, followed by Late SSs.

The packets have the following characteristics:

- In both types of packets, a Soft Symbol is a complex number with 16 bits Real part and 16 bits Imaginary part.
- In both types of packets the Soft Symbol are ordered with respect to the finger number (*FIC[FIN]*) such that the first soft symbol belongs to the finger with *FIC[FIN]*=0, the second Soft Symbol belong to the finger with *FIC[FIN]*=1 and the last Soft Symbol belong to the finger with *FIC[FIN]* value equals to the *NOF* field of the Soft Symbol Packet Header (see **Section 26.4.3.6.2.10.2**, *Soft Symbol Packet Header*, on page 26-256).
- In both types of packets zero soft symbols are added after the last Soft Symbol such that the size of the packets is integer multiplication of 16 Bytes.

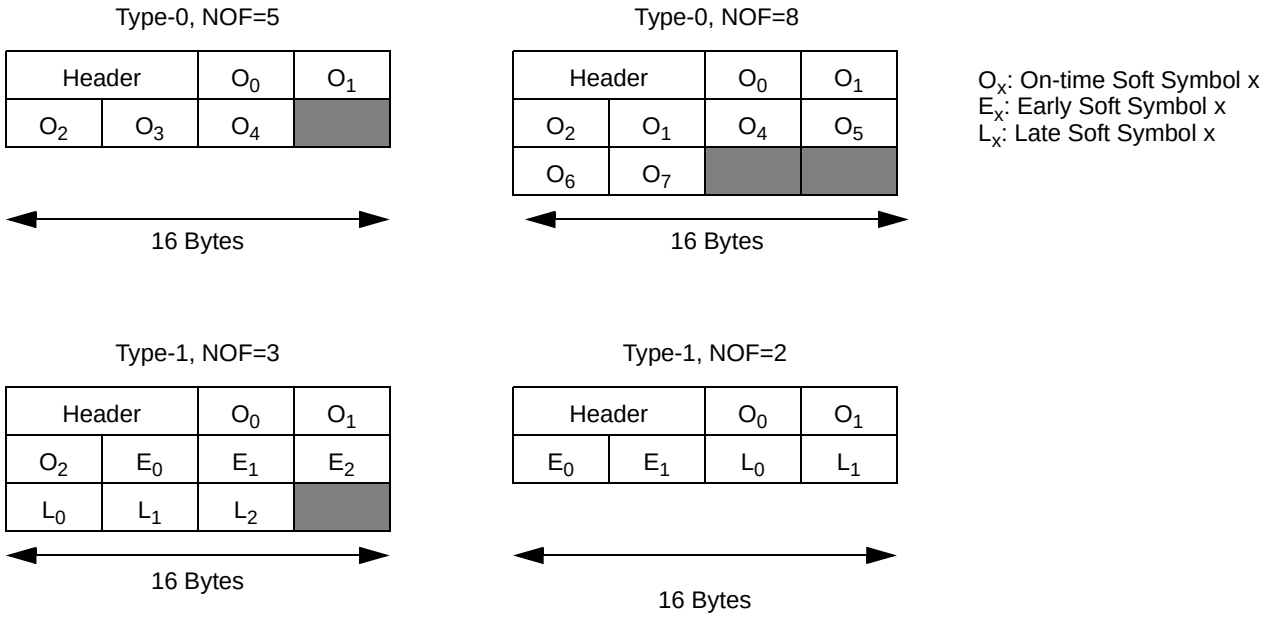

Figure 26-141. Type-0 and Type-1 Packets examples

26.4.3.6.2.10.2 Soft Symbol Packet Header

Figure 26-142 Describes the Soft Symbol Packet Header

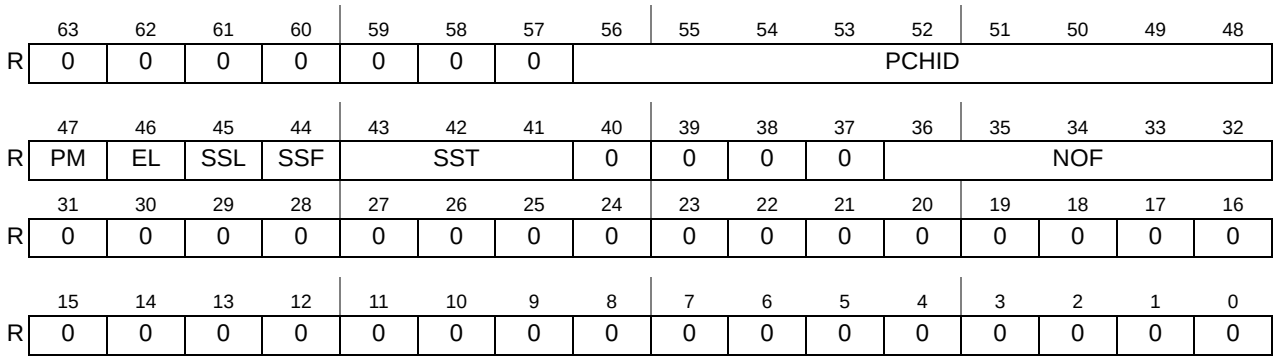

Figure 26-142. Soft Symbol Packet Header structure

Table 26-118 Describes the Soft Symbol Packet Header fields description:

Table 26-118. Soft Symbol Packet Header Field Descriptions

Field	Bits	Description
—	63–57	Reserved
PCHID	56–48	**PCHID**. The PCH ID to which this packet belong to.
PM	47	**Pilot Mark**. This bit is set if the current Soft Symbol type is PILOT and the index of the PILOT bit is equal to the *PMS* field in the PCH Command (PCHC).
EL	46	**Early Late**. Early/Late Indication. 0 - The packet does not contain Early/Late Soft Symbols 1 - The packet contains Early/Late Soft Symbols

Table 26-118. Soft Symbol Packet Header Field Descriptions (Continued)

Field	Bits	Description
SSL	45	**Soft Symbol Last**. Last soft symbol of a Type indication. 0 - The packet does not contain a last Soft Symbol of a Type 1 - The packet contains a last Soft Symbol of a Type
SSF	44	**Soft Symbol First**. First soft symbol of a Type indication. 0 - The packet does not contain a first Soft Symbol of a Soft Symbol Type 1 - The packet contains a first Soft Symbol of a Type
SST	43–41	**Soft Symbol Type**. 0: the packet contains DPCCH/PRACH PILOT Soft Symbol 1: the packet contains DPCCH/PRACH TFCI Soft Symbol 2: the packet contains DPCCH FBI Soft Symbol 3: the packet contains DPCCH TPC Soft Symbol 4: the packet contains E-DPCCH Soft Symbol 5: the packet contains HS-DPCCH Soft Symbol 6: the packet contains General Purpose #0 symbol 7: the packet contains General Purpose #1 symbol
—	40–37	Reserved
NOF	36–32	**Number Of Fingers**. The number of finger in the packet. 0 - The packet includes single finger. 1 - The packet includes 2 fingers. ... 31 - The packet includes 32 fingers.
—	31–0	Reserved

26.4.3.6.2.10.3 System Memory Output Buffers Structure

The Soft Symbol packets are written to up-to 18 cyclic buffers in the system memory. Each buffer has a programmable base address set by its corresponding *ULFOBxBCR[BASE]*. The base address must be 16 bytes aligned. The Size the buffers, are set by *ULFOBxACR[SIZE]* with granularity of 16 bytes. The first 16 bytes of a buffer stores the buffer's status information: Write Pointer (WP) and Time Stamp (TIME). The Write Pointer is initialized to *ULFOBxBCR[BASE]*+16 and it wraps back to *ULFOBxBCR[BASE]*+16 address when it reaches *ULFOBxBCR[BASE]+ULFOBxACR[SIZE]* address.

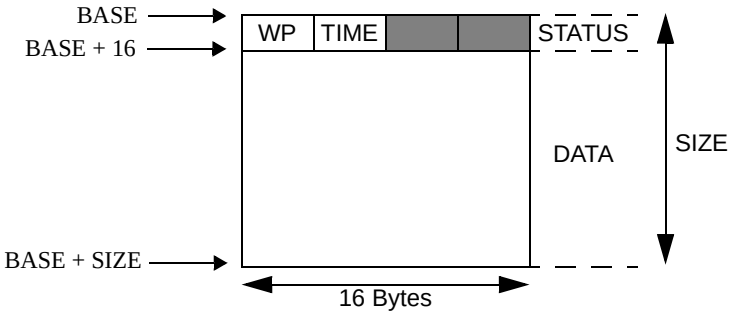

Figure 26-143. Output Buffer Structure

Each buffer includes a Group ID (*GID*) and Type Enable (*TEx*) configuration. A packet is directed to one of the buffers according to its Group ID and Type (*GID* and *SST* fields of the Packet Header), that is, a packet is directed to a certain buffer only if the packet and the buffer

share the same Group ID (*GID*) and if the type of the packet (as indicated by header's *SST* field) is enabled for this buffer (as indicated by *ULFOBxACR[TEx]*).

Note: It is the responsibility of the host to configure the CRPE-ULF output buffer such that a packet is directed to no less and no more than single output buffer.

Table 26-119 shows an example in which the PCHs are divided between 6 cores such that each core uses three output buffers. The first output buffer is used to store PILOT Soft Symbol, the second is used to store low latency Soft Symbol such as FBI and TPC and the third output buffer is used to store high latency Soft Symbol such as TFCI and E-DPCCH and HS-DPCCH.

Table 26-119. Output Buffer Programming, 6 groups, Fast/Slow

Buffer	GID	TE0 (PILOT)	TE1 (TFCI)	TE2 (FBI)	TE3 (TPC)	TE4 (E-DPCCH)	TE5 (HS-DPCCH)
0	0	1	0	0	0	0	0
1	0	0	0	1	1	0	0
2	0	0	1	0	0	1	1
3	1	1	0	0	0	0	0
4	1	0	0	1	1	0	0

26.4.3.6.2.10.4 Writing the Output Data Results

The CRPE-ULF uses a dedicated MBus Initiator (MI) interface (sharing MBus Master 3 with internal DMA engine) to write packets toward system memory. The transactions priority is set by configuring the *ULFGCR[MP]*.

The MI updates the Output Buffers (OB) status once, twice, four times or eight times in a processing period (32 chips) by writing the new Write Pointer (WP) and the new Time Stamp (TIME) to the base address of the OB as defined in *ULFOBxBCR[BASE]*. Controlling the update of the output buffers is done by setting the *ULFGCR[OBUR]*.

26.4.3.6.2.11 CRPE-ULF Command Flow

The CRPE-ULF is controlled by two types of commands:

- Physical Channel Commands (PCHC)
- Finger Commands (FIC).

A PCHC sets attributes which are common to all the fingers belong to the same PCH. A FIC set attributes which are specific to a finger. MAPLE-B2 is able to receive up-to 3200 FICs and up-to 512 PCHCs in time frame of a sub-slot. It can receive FIC commands to an already activated fingers and PCHC command to an already activated PCHs.

The new commands is activated according to the command's *SBS* (sub-slot start) field. MAPLE-B2 is able to receive one command for a Finger or PCH at a time, i.e writing a new command to a Finger/PCH while a previous command to the same Finger/PCH is pending is not allowed. The Commands are generated by the host (or multiple hosts) and written to dedicated queues in system memory as defined in the *MCUFCIBAxP[BASE]* fields. The size of each such queue is defined in *MCUFCIBAxP[SIZE]*. The MAPLE-B2 is responsible to fetch the commands from system memory queues as per CRPE-ULF internal requests. For details on the command fetching see **Section 26.4.3.6.2.11.3**, *Command Fetching Description*.

26.4.3.6.2.11.1 Finger Command (FIC) Structure

Figure 26-144 Describes the Finger Command (FIC) structure:

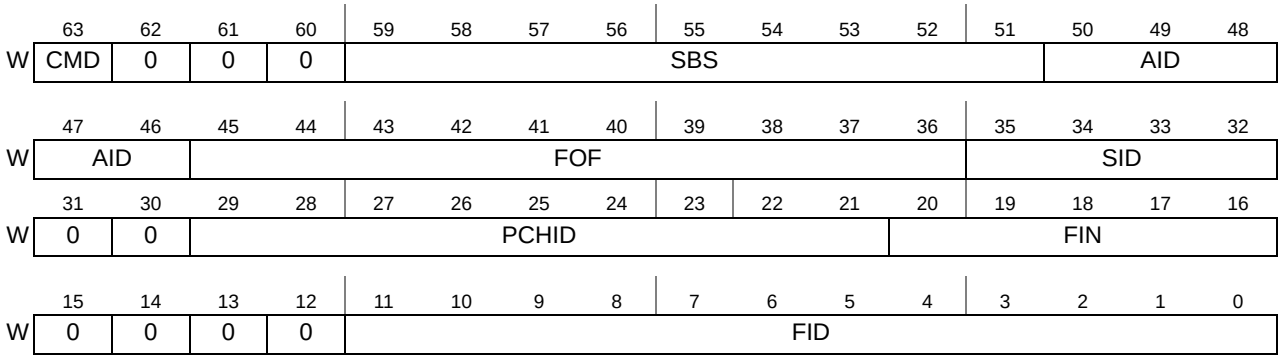

Figure 26-144. Finger Command Structure

Table 26-120 Describes the Finger Command field description:

Table 26-120. Finger Command Fields

Field	Bits	Description
CMD	63	**Command**. This bit should be set to 0 to indicate it's a Finger Command.
	62-60	Reserved
SBS	59–51	**Sub-Slot Start.** Indicates the activation time of the command in resolution of sub-slot. Valid range: 0 to 299
AID	50–46	**Antenna ID**. Selects the antenna input buffer. To disable the finger, AID should be set to *ULFGCR[NOA]*
FOF	45–36	**Finger Offset**. The finger's offset with regard to PCH start point and with resolution of 1 chip. If *ULFGCR[MDS]*=1, maximum offset allowed is 767. If *ULFGCR[MDS]*=0, maximum offset allowed is 511.

Table 26-120. Finger Command Fields

Field	Bits	Description
SID	35–32	**Sample ID**. Selects one sample out of 16 samples of a chip. If *ULFGCR[OVS]*=0, SID can be either 0 or 8. If *ULFGCR[OVS]*=1, SID can be either 0, 4, 8 or 12. If *ULFGCR[OVS]*=2, SID can be either 0, 2, 4, 6, 8, 10, 12 or 14. If *ULFGCR[OVS]*=3, SID can be any number between 0 to 15.
	31–30	Reserved.
PCHID	29–21	**PCH ID**. The ID of the PCH to which the finger belongs to. ***Note***: Once a PCHID is set it can't be reconfigure as long as the finger is active.
FIN	20–16	**Finger Number.** The index of the finger in the PCH packet. Valid Range: 0 to 31
	15–12	Reserved.
FID	11:0]	**Finger ID**. The ID of the finger to which the command refers to.

26.4.3.6.2.11.2 Physical Channel Command Structure (PCHC)

Figure 26-145 Describes the PCHC structure

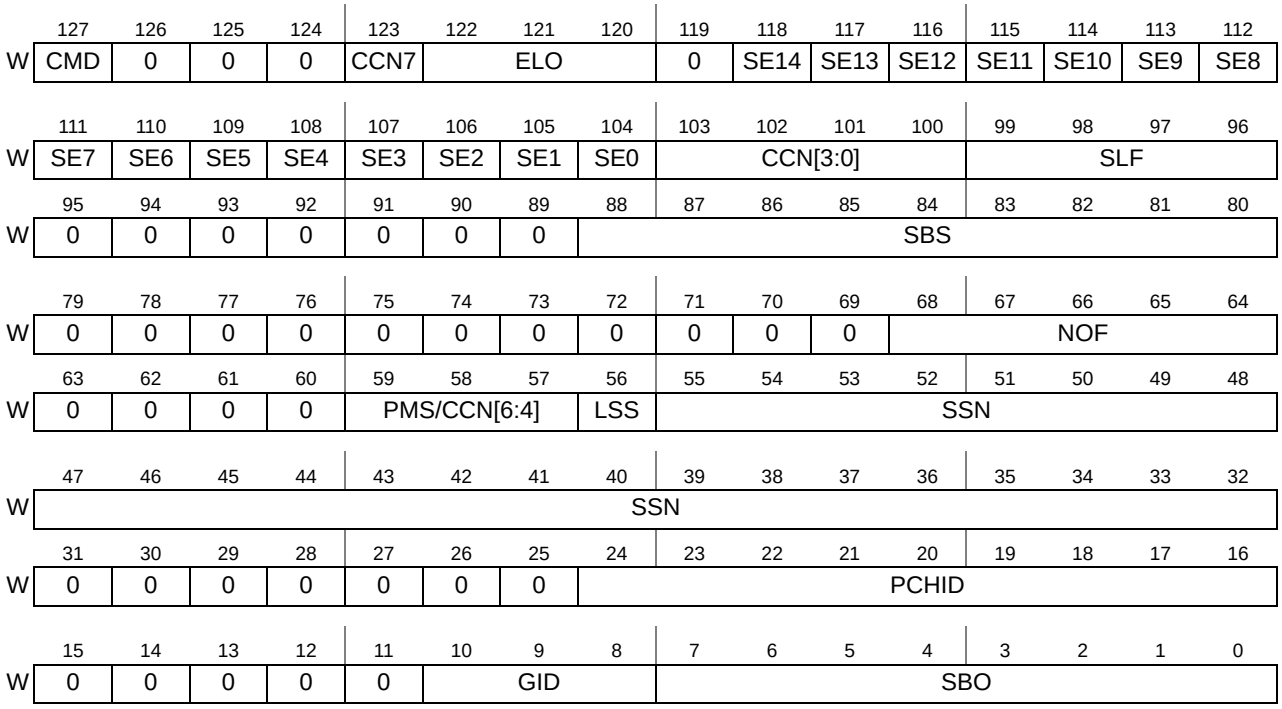

Figure 26-145. PCHC Structure

Table 26-121 Describes the PCH command field description:

Table 26-121. PCHC Field Descriptions

Field	Bits	Description
CMD	127	**Command ID**. Should be set to 1 to indicate PCH Command.
	126–124	Reserved.

Field	Bits	Description
CCN7	123	**Channelization Code Number bit 7**. This field together with *CCN[6:4]* and *CCN[3:0]* explicitly selects the channelization code number when using general purpose slot format (SLF=12 or SLF=13). For details see CCN[3:0] definition
ELO	122–120	**Early Late Offset**. 0: EL offset is 1/16, this value is allowed when *ULFGCR[OVS]* = 3. 1: EL offset is 2/16, this value is allowed when *ULFGCR[OVS]* > 1. 2: EL offset is 3/16, this value is allowed when *ULFGCR[OVS]* = 3. 3: EL offset is 4/16, this value is allowed when *ULFGCR[OVS]* > 0. 4: EL offset is 5/16, this value is allowed when *ULFGCR[OVS]* = 3. 5: EL offset is 6/16, this value is allowed when *ULFGCR[OVS]* > 1. 6: EL offset is 7/16, this value is allowed when *ULFGCR[OVS]* = 3. 7: EL offset is 8/16 ***Note:*** Once ELO is set it can't be reconfigure as long as the PCH is active (that is, as long as there are active fingers belong to this PCH).
	119	Reserved.
SE14	118	**Slot Enable 14**. 0 - The PCH is not transmitted on slot #14 1 - The PCH is transmitted during on slot #14
SE13	117	**Slot Enable 13**. 0 - The PCH is not transmitted on slot #13 1 - The PCH is transmitted during on slot #13
SE12	116	**Slot Enable 12**. 0 - The PCH is not transmitted on slot #12 1 - The PCH is transmitted during on slot #12
SE11	115	**Slot Enable 11**. 0 - The PCH is not transmitted on slot #11 1 - The PCH is transmitted during on slot #11
SE10	114	**Slot Enable 10**. 0 - The PCH is not transmitted on slot #10 1 - The PCH is transmitted during on slot #10
SE9	113	**Slot Enable 9**. 0 - The PCH is not transmitted on slot #9 1 - The PCH is transmitted during on slot #9
SE8	112	**Slot Enable 8**. 0 - The PCH is not transmitted on slot #8 1 - The PCH is transmitted during on slot #8
SE7	111	**Slot Enable 7**. 0 - The PCH is not transmitted on slot #7 1 - The PCH is transmitted during on slot #7
SE6	110	**Slot Enable 6**. 0 - The PCH is not transmitted on slot #6 1 - The PCH is transmitted during on slot #6
SE5	109	**Slot Enable 5**. 0 - The PCH is not transmitted on slot #5 1 - The PCH is transmitted during on slot #5
SE4	108	**Slot Enable 4**. 0 - The PCH is not transmitted on slot #4 1 - The PCH is transmitted during on slot #4
SE3	107	**Slot Enable 3.** 0 - The PCH is not transmitted on slot #3 1 - The PCH is transmitted during on slot #3
SE2	106	**Slot Enable 2**. 0 - The PCH is not transmitted on slot #2 1 - The PCH is transmitted during on slot #2

Field	Bits	Description
SE1	105	**Slot Enable 1**. 0 - The PCH is not transmitted on slot #1 1 - The PCH is transmitted during on slot #1
SE0	104	**Slot Enable 0.** 0 - The PCH is not transmitted on slot #0 1 - The PCH is transmitted during on slot #0
CCN[3:0]	103–100	**Channelization Code Number bits [3:0]**. – For slot format 0 to 9 this field is ignored. – For slot format 10 this field selects the channelization code number as follows: 0: channelization code number is 256,15 1: channelization code number is 256,31 2: channelization code number is 256,47 3: channelization code number is 256,63 4: channelization code number is 256,79 5: channelization code number is 256,95 6: channelization code number is 256,111 7: channelization code number is 256,127 8: channelization code number is 256,143 9: channelization code number is 256,159 10: channelization code number is 256,175 11: channelization code number is 256,191 12: channelization code number is 256,207 13: channelization code number is 256,223 14: channelization code number is 256,239 15: channelization code number is 256,255 – For slot format 11 this field selects the channelization code number as follows 0: channelization code number is 256,1 1: channelization code number is 256,31 2: channelization code number is 256,32 3: channelization code number is 256,64 – For slot format 12 and slot format 13 this field, together with *CCN[7]* and *CCN[6:4]*, explicitly selects the channelization code number.
SLF	99–96	**Slot Format**. This field sets the slot format and the PCH: 0: DPCCH Slot Format #0 1: DPCCH Slot Format #0A 2: DPCCH Slot Format #0B 3: DPCCH Slot Format #1 4: DPCCH Slot Format #2 5: DPCCH Slot Format #2A 6: DPCCH Slot Format #2B 7: DPCCH Slot Format 3 8: DPCCH Slot Format 4 9: E-DPCCH 10: PRACH control part 11: HS-DPCCH 12: General purpose slot format #0 13: General purpose slot format #1 14–15: Reserved.
	95–89	Reserved
SBS	88–80	**Sub-Slot Start**. Indicates the activation time of the command in resolution of sub-slot. Valid range: 0 to 299
	79–69	Reserved

Field	Bits	Description
NOF	68–64	**Number of Fingers**. The number of fingers belong to the PCH. 0 - The PCH include single finger 1 - The PCH include 2 fingers. ... 31 - The PCH include 32 fingers
	63–60	Reserved
PMS/ CCN[6:4]	59–57	**Pilot Mark Select** For slot formats 0 to 8 and for slot format 10, this field set the index of the pilot bit to which the PM bit in the packet header is set: 0: The Pilot Mark bit is set for PILOT #0 1: The Pilot Mark bit is set for PILOT #1 2: The Pilot Mark bit is set for PILOT #2 3: The Pilot Mark bit is set for PILOT #3 4: The Pilot Mark bit is set for PILOT #4 5: The Pilot Mark bit is set for PILOT #5 6: The Pilot Mark bit is set for PILOT #6 7: The Pilot Mark bit is set for PILOT #7 For slot formats 9, 11, 12 and 13, the PMS field is ignored. **Channelization Code Number bits [6:4]** For slot formats 12 and 13, this field together with CCN7 and CCN[3:0] explicitly selects the channelization code number.
LSS	56	**Long Short Select**. Selects between long and short scrambling sequences: 0 - A long scrambling code is selected for the PCH. 1 - A short scrambling code is selected for the PCH.
SSN	55–32	**Scrambling Sequence Number**. Indicates the PCH's scrambling sequence number.
	31–25	Reserved
PCHID	24–16	**PCH ID**. The ID of the PCH to which this command refers to. Valid range: 0 to 511
	15–11	Reserved
GID	10–8	**Group ID**. This field set the group ID to which this PCH belong to 0: The PCH belongs to group 0 1: The PCH belongs to group 1 2: The PCH belongs to group 2 3: The PCH belongs to group 3 4: The PCH belongs to group 4 5: The PCH belongs to group 5 6–7: Reserved
SBO	7–0	**Sub-Slot Offset**. Indicates index of the sub-slot where the command is activated. 0–149: Sub-Slot index. 150–255: Reserved.

26.4.3.6.2.11.3 Command Fetching Description

The MAPLE-B2 gets Finger and Physical channel commands by reading from up to 8 cyclic buffers in system memory. The buffers address and size are configured in the *MCUFCIBAxP* parameters (**Section 26.5.3.5.3.1**, *MAPLE CRPE-ULF Command Input Buffer Address <x> Parameter (MCUFCIBAxP)*, on page 26-364). The buffer defined by this address space is cyclic, which means that when the pointer equal to the size, it is set to zero.

The MAPLE-B2 fetches up to 1919 commands from the command buffers (up to 8) on every Processing Period (32 chips time), depend on the internal CRPE-ULF command fifo. The

MAPLE-B2 scan the external command buffers in a cyclic manner, that is, it starts by fetching all available commands from the first buffer, moving on to the next buffer and so on. After the last buffer is reached, it starts from the first buffer again. An external buffer is valid when its size (*MCUFCIBAxP[SIZE]*) is larger than zero and its Write Pointer (*MCUFCIBWPxP[WP]*) is greater (cyclic manner) than the Read Pointer (*MCUFCIBRPxP[RP]*). The host should update the Write Pointer when adding new commands in the system buffer, and the MAPLE-B2 update the Read Pointer when fetching the new commands. For details on the Write/Read Pointers see **Section 26.5.3.5.3.2**, *MAPLE CRPE-ULF Command Input Buffer Write Pointer <x> Parameter (MCUFCIBWPxP)*, on page 26-365 and **Section 26.5.3.5.3.3**, *MAPLE CRPE-ULF Command Input Buffer Read Pointer <x> Parameter (MCUFCIBRPxP)*, on page 26-366

26.4.3.6.2.11.4 Command Generation Restrictions

The following restrictions apply when issuing commands:

- The host should write a new PCH/Finger Command with a given sub-slot activation index (*SBS*) no later than 2 full sub-slots prior to its activation index, that is, *SBS* ≥ *ULFTSR[SSI]* +3. See example in **Figure 26-146**.
- The maximum pending time for a new command in the external system buffers is 146 sub-slots, that is, *SBS* ≤ *ULFTSR[SSI]*+146. See example in **Figure 26-146**.
- Command activation takes 2 or 3 sub-slots if *ULFGCR[MDS]* = 0 or 1 respectively. A new PCHC/FIC with a certain *PCHID*/*FID* can be issued only after the activation completion of the previous command with the same *PCHID*/*FID*. See example in **Figure 26-146**.

For example, if *ULFGCR[MDS]* = 0 and the command is set with *SBS* = 87, then the host can write the command to system memory no earlier than *ULFTSR[SSI]* = 241 and no later than *ULFTSR[SSI]* = 84. The earliest time the user can issue the next command (to the same PCH or FInger) is in sub-slot 89 with earliest activation time SBS = 92.

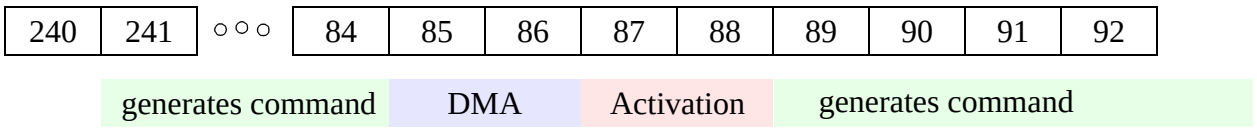

Figure 26-146. Setting a Command with SBS = *87 (ULFGCR[MDS]=0)*

26.4.3.6.2.11.5 Command Setting Rules

Use the following guidelines to issue commands:

- A PCH is active when there is at least one active finger with PCHID equal to the PCH ID. All PCH attributes except ELO can be set while a PCH is active. Fingers can be add to and remove from PCH while it is active.

- When *ULFGCR[MDS]* = 0, the finger belonging to a PCH must comply with maximum delay spread of 256 chips, that is, the difference between the latest finger offset and the earliest finger offset must not exceed 256 chips. In this mode, the maximum finger offset allowed is $255_{\text{(last chip index in current sub-slot)}}+256_{\text{(max delay spread)}} = 511$.
- When MDS = 0, the finger belonging to a PCH must comply with maximum delay spread of 512 chips, that is, the difference between the latest finger offset and the earliest finger offset must not exceed 512 chips. In this mode, the maximum finger offset allowed is $255_{\text{(last chip index in current sub-slot)}}+512_{\text{(max delay spread)}} = 767$.
- A finger is active when its *FIC[AID]* is less then *ULFGCR[NOA]*. All the finger attributes, except for the *FIC[PCHID]*, can be re-configured while the finger is active. To change the finger *FIC[PCHID]*, the finger must be removed and regenerated using a new *FIC[PCHID]*.
- Removing a finger is done by generating a finger command where *FID* is set to the ID of the finger that shall be removed, *AID* is set to *ULFGCR[NOA]*, SBS is set to the sub-slot index in which the finger shall be removed and other parameters (*SID*, *FOF*, *FIN* and *PCHID*) are set to the last value configured by the last finger command for this finger.
- A finger is moved forward when the new *FIC[FOF]* is greater than the old *FIC[FOF]*. The finger is moved backward when the new *FIC[FOF]* is less than the old *FIC[FOF]*. The finger can be moved forward and backward on the fly. There is no limit on moving a finger forward on the fly; however, when moving a finger backward on the fly it can only be moved up to 223 chips.
- To move a finger backward more than 223 chips, remove the finger and then regenerate it with a new offset.

26.4.3.6.2.12 CRPE-ULF Errors

The CRPE-ULF reports the following error types:

- **Command Error**: If a PCH/Finger Command is received and the command *SBS* field indicates that the command is early or late (see **Section 26.4.3.6.2.11.4**, *Command Generation Restrictions*), the *ULFESR[CE]* is set and the command attributes (PCH/Finger Command Type and Command ID) are written to *ULFCFSR*. Upon receiving a Command Error indication, the CRPE-ULF should be reset as described in **Section 26.4.3.6.4**, *CRPE Reset*.
- **Input Buffer Overflow Error**: If the input buffer overflows, the *ULFESR[IBO]* is set and the address of the transaction that caused the error is written to the Input Buffer Status Register (*ULFIBSR[ADDR]*). Upon receiving a Input Buffer Overflow indication, the CRPE-ULF should be reset as described in **Section 26.4.3.6.4**, *CRPE Reset*.

Upon assertion of any of the above events, the MAPLE-B2 asserts the general error interrupt (see **Section 26.4.3.1.2.2**, *General Error Event Interrupt*), indicating a CRPE-ULF error. Indication

as to the error type (Command Error or Input Buffer Overflow Error) is achieved by reading the *ULFESR*.

26.4.3.6.2.13 CRPE-ULF Initialization

The following steps describe the CRPE-ULF initialization (or re-initialized) flow :

1. MAPLE-B2 completes with its API initialization.
2. Host configure CRPE-ULF logic by writing to *ULFGCR* and *ULFSCR*.
3. Host (optionally) configure interpolation logic by writing to *ULFICRx*
4. Host configure at least one output buffers by writing to *ULFOBxBCR* and *ULFOBxACR*.
5. Host configure MAPLE CRPE ULF parameters indicating commands buffers.
6. Host generates MAPLE-B2 PCR Command (`Maple_crpe_ulf_init`) if Interpolation bypass is enabled.
7. Host wait for Antenna I/F synchronization.
8. Host enables the data stream from antenna I/F directly to CRPE-ULF in case of interpolation enabled mode or indirectly in case of interpolation bypass mode.
9. Host generates PCHCs and FICs and write them to system memory.

26.4.3.6.3 Chip Rate Downlink Processing Operation

The MAPLE-B2 supports UMTS (TS 25.211 and TS25.213) Chip Rate processing for Downlink as described in **Section 26.2**, *MAPLE-B2 Features*. These operations are executed using the Chip Rate- Downlink Processing Elements (CRPE-DL).

26.4.3.6.3.1 CRPE-DL Initialization Parameter

During the MAPLE-B2 initialization (see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)), the CDOMCP parameter in the API must be initialized: See **Section 26.5.2.4**, *CRPE-DL Output Mode Configuration Parameter (CDOMCP)*, on page 26-326 for details.

26.4.3.6.3.2 CRPE Chip-Rate Downlink Processing

The Chip Rate Downlink processing is divided into the following areas of discussion:

- CRPE Downlink operation overview
- Channels Activation and Maintenance
- Input data
- Internal CRPE operation
  - TPC override
  - STTD encoding
  - Spreading operation

- Scrambling operation
- Gain operation
- Physical channels (PCHs) Combine operation
- Beam-forming operation

- Output data
- Initialization and Synchronization

26.4.3.6.3.3 CRPE Downlink Operation Overview

The CRPE Downlink PE operation is described schematically in **Figure 26-147**:

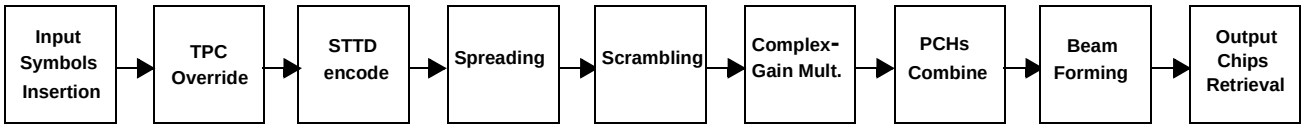

Figure 26-147. CRPE Downlink operation

The CRPE Downlink PE (CRPE-DL) accepts mapped I/Q symbols (optionally STTD encoded, see **Section 26.4.3.6.3.6.4**, *STTD Encoding*, on page 26-274) arranged in 1 or up to 1024 cyclic buffers of physical channels, and performs a set of operations on them:

- TPC override. See **Section 26.4.3.6.3.6.1**, *TPC Override*, on page 26-272.
- STTD encoding. See **Section 26.4.3.6.3.6.4**, *STTD Encoding*, on page 26-274.
- Spreading operation. See **Section 26.4.3.6.3.6.5**, *Spreading Operation*, on page 26-274.
- Scrambling operation. See **Section 26.4.3.6.3.6.6**, *Scrambling Operation*, on page 26-275.
- Multiplication by a complex gain operation. See **Section 26.4.3.6.3.6.7**, *Gain Operation.*, on page 26-275.
- Physical channels (PCHs) Combine operation. See **Section 26.4.3.6.3.6.8**, *Combine Operation*, on page 26-277.
- Beam-forming operation. See **Section 26.4.3.6.3.6.9**, *Beam Forming Operation*, on page 26-278.

The result are output of chips, arranged in a form of 16 antenna buffers, as described under **Section 26.4.3.6.3.7**, *Output Modes Of Operation*, on page 26-280.

26.4.3.6.3.4 Channels Activation and Maintenance

Prior to channel's processing by CRPE-DL, the host is required to program channel's parameters at MAPLE-B2 and CRPE-DL, and fill associated input buffer with input stream symbols of at least a single slot (at least 2 first channel's slots for fast channels).

Out of the 512 supported channels, up to 200 channels can be treated as fast channels. Out of the 200 channels, up to 100 channels are allowed to be active in the same sub-slot. The difference

between fast channels and the rest of the channels is that fast channels activation can be performed at a latency of a single sub-slot before required processing time (see **Figure 26-149**), while the rest of the channels are activated at a latency of at least slot before required processing time (see **Figure 26-148**). Note that all channels (including fast channels) require termination or compressed mode change programming at a latency of at least slot before processing time. All channels can be programmed up to a single frame before actual processing time.

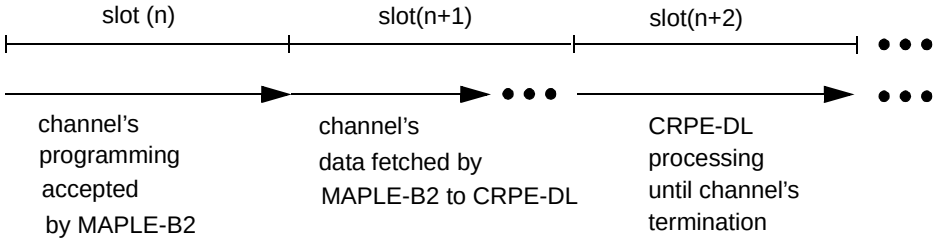

Figure 26-148. Channel Programming Latency Illustration

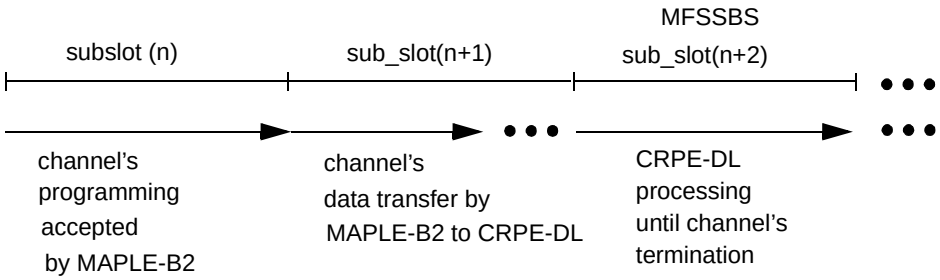

Figure 26-149. Sub-Slot Latency Channel Programming Illustration

For normal channels, MAPLE-B2 fetches channel data that requires processing in the next slot at the current slot time. For fast channels, during the slot of fast channel activation, MAPLE-B2 fetch channel's data that require processing at current slot and next slots.

Channels activation, termination, and compressed status update is programmed using *MCDLFCxP0*, *MCDLFCxP1* and *MCDLFCxP2* parameters for fast channels and *MCDLSCxP0*, *MCDLSCxP1* and *MCDLSCxP2* parameters for the rest of the channels. It is not allowed to activate the same channel using both sets of registers. The *MCDLNOCLP* parameter defines a limit to the maximum number of used slot channels, and a limit to the maximum number of used fast channels. The limit numbers are used as MAPLE-B2's configuration information that is used to reduce MAPLE-B2 processing time by indicating the maximum number of channel's parameters which requires attending.

The processing of a slot channel starts at slot number and sub-slot number as defined by *MCDLSCxP0[MSSL]* and *MCDLSCxP1[MSSBS]*, or *MCDLFCxP0[MFSSL]* and *MCDLFCxP1[MFSSBS]* for fast channels, respectively. The same fields also determine compressed mode status change points.

MCDLSCxP1[MCMPC] and *MCDLFCxP1[MFCMPC]* defines the compressed mode status up until the current slot and sub-slot (but does not include the current slot and sub-slot) for the slot/fast channels, and *MCDLSCxP1[MCMPN]* and *MCDLFCxP1[MFCMPN]* defines the compressed mode status starting from the current slot and sub-slot (including the current slot and sub-slot) for the slot/fast channels.

When *MCDLSCxP1[MCONT]* (or *MCDLFCxP1[MFCONT]* for fast channels) is cleared, the processing of a channel terminates at the slot and sub-slot defined by *MCDLSCxP0[MESL]* and *MCDLSCxP1[MESBS]*, or *MCDLFCxP0[MFESL]* and *MCDLFCxP1[MFESBS]* for fast channels, respectively. Otherwise, channel processing continues from one frame to the next.

Other parameters that are programmed in these registers, apart from system buffer parameters, indicate whether the channel is a synchronization channel (spreading and scrambling bypass) by using *MCDLSCxP1[MSYNC]* (or *MCDLFCxP1[MFSYNC]* for fast channel) and defines the channel spreading factor and spreading factor reduction in compressed mode, using *MCDLSCxP1[MSF]* and *MCDLSCxP1[MSFR]*, or *MCDLFCxP1[MFSF]* and *MCDLFCxP1[MFSFR]* for fast channels, respectively.

When these parameters are updated by the host, the host should set the *MCDLSCxP0[MVALID]* (or *MCDLFCxP0[MFVALID]* for fast channels), indicating to MAPLE-B2 that parameters are updated. Upon channel activation, the host also must clear the *MCDLSCxP0[MSTARTED]* (or *MCDLFCxP0[MFSTARTED]* for fast channel).

Each of the *MCDLSCxP(0–2)* parameters has a dedicated address per channel ID #x. *MCDLFCxP(0–2)*, however, is a joint and limited pool of parameters for all channels where the *MCDLFCxP1[MFCID]* defines to which of the possible 1024 channels (512 channels plus 512 associated external STTD channels) this set of parameters is associated. When a couple of channels are used as STTD pair (channel IDs #x and #(x+512)), the channel of external STTD (channel #x+512) must be programmed at *MCDLFCxP(0-2)* entry that is greater than its coupled channel’s entry.

Figure 26-150 illustrates concatenation of channel termination, channel parameters reprogramming and new channel activation. Since same channel index is used for both old and new parameters, a pipe cleaning period of 2 slots is required from the slot of channel termination by the host, until the slot of new channel activation by the host.

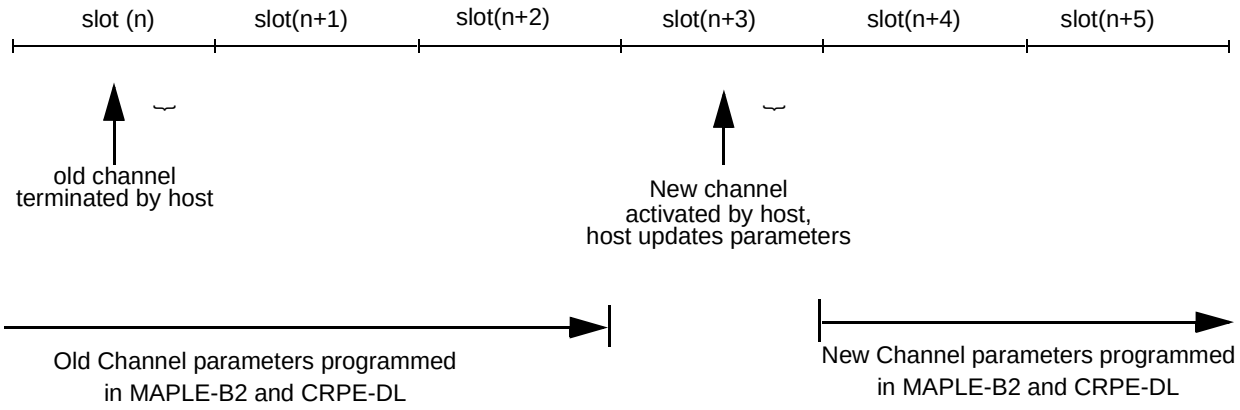

Figure 26-150. Channel Reprogramming Illustration

The following items describe the sequence of actions required for CRPE-DL Physical Channels (PCHs) activation and maintenance:

1. Initial Configuration:
   - Update Scrambling Initialization LUT Memory. See **Section 26.4.3.6.3.6.6**, *Scrambling Operation*
   - Update Slot Format LUT Memory. See **Section 26.5.5.7.2**, *CRPE-DL Slot Format Look-Up Table (SFLUT)*
   - Update CRPE-DL Beam Forming Coefficients Values Control Registers (*CDBFCVLRx*).
   - Update CRPE-DL Beam Forming Coefficients Timing Command Control Registers (*CDBFCTCRLx*).
   - Activate CRPE-DL by writing to CRPE-DL Start Control Register (*CDSLR*)
2. Channel Activation and Termination:
   - Update CRPE-DL General Command Control Register (*CDGCLR*).
   - Activate channel at MAPLE-B2's CRPE-DL Slot/Fast Channel Parameters (*MCDLSCxP(0-2)/MCDLFCxP(0-2)*)
   - Update compressed status change in the Slot/Fast Channel Parameters (*MCDLSCxP(0-2)/MCDLFCxP(0-2)*) upon every change of compressed mode.
   - Terminate channel at in the Slot/Fast Channel Parameters (*MCDLSCxP(0-2)/MCDLFCxP(0-2)*).
3. Channel Maintenance:
   - Update CRPE-DL TPC Command Control Register (*CDTCLR*). It can be updated up to once per slot.
   - Update CRPE-DL Virtual Antenna Gains Control Registers (*CDVAGLR(0-1)*). It can be updated up to once per slot.
   - Update CRPE-DL Virtual Antennas Gain Command Control Register (*CDVAGCLR*). It can be updated up to once per slot.

— Update CRPE-DL Idle Period Control Registers (*CDIPLRx*). It can be updated once per idle period per virtual antenna.
— Update CRPE-DL Beam Forming Coefficients Values Control Registers (*CDBFCVLRx*). This operation is optional
— Update CRPE-DL Beam Forming Coefficients Timing Command Control Register (*CDBFCTCRLx*). This operation is optional.

26.4.3.6.3.5 CRPE-DL Input Data Structure

The number of supported input streams is up to 1024, each potentially sourced from a different system buffer. An input stream is associated with a single Physical Channel (PCH). If STTD operation is performed externally, 2 input streams are associated with the same PCH. Channels indexes 512–1023 are reserved to input streams of external STTD operation. In the case of external STTD operation, channel #x and channel #x+512 (x=0,1...,511) are coupled, where channel #x+512 is the external STTD channel.

Figure 26-151 illustrates the CRPE-DL supported input data structure:

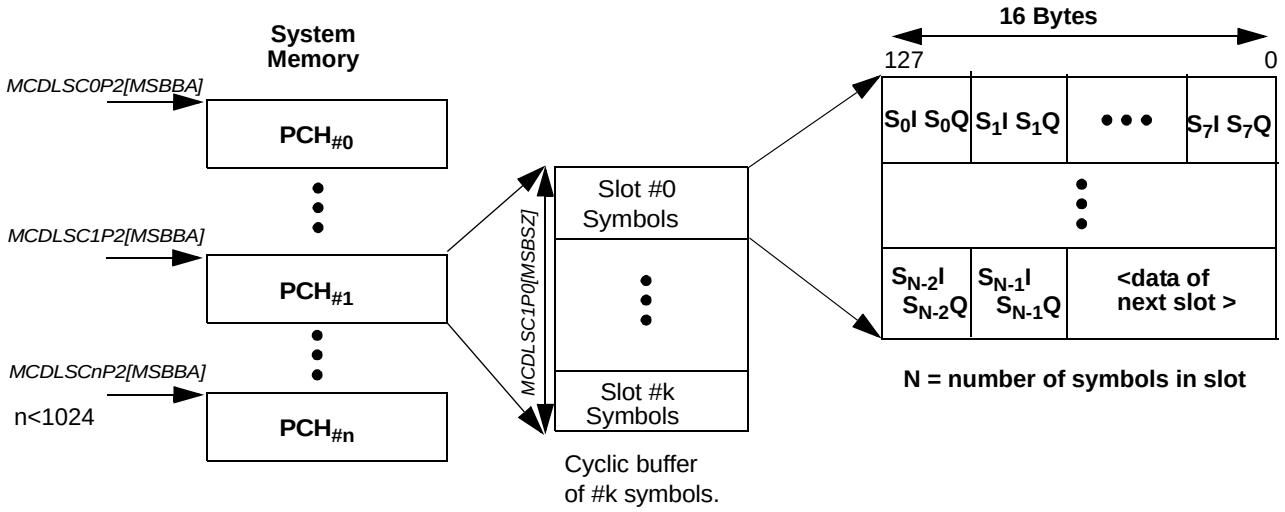

Figure 26-151. CRPE-DL input buffer

Each cyclic buffers contains complex symbols (8 bits I and 8 bits Q pair), 8 complex symbols per 16 bytes address, as illustrated in **Figure 26-151**.

Each buffer contains a number of slots, and each slot contains a number of bytes, depending on the Spreading Factor of the $PCH_{\#x}$, as detailed in **Table 26-122**. The total number of bytes per buffer is defined by *MCDLSCxP0[MSBSZ]* (or *MCDLFCxP0[MFSBSZ]* for fast channels). The base address of the buffer is defined by *MCDLSCxP2[MSBBA]* (or *MCDLFCxP2[MFSBBA]* for fast channels).

Table 26-122. Slots Size with respect to Spreading Factor of $PCH_{\#x}$

SF of PCHx value	Slot Size (bytes)
4	1280
8	640
16	320
32	160
64	80
128	40
256	20

Slots that belong to compressed frame with Spreading Factor (SF) reduction contain the number of bytes as indicated by **Table 26-122** according to the reduced SF. Zero valued complex symbols in the buffer represent symbols that need not be transmitted due to compressed mode. In addition, synchronization channel slots are supported with 256 complex symbols per slot at SF = 1 (512 bytes per slot).

The base address of each input buffer at 256 bytes unit is defined by *MCDLSCxP2[MSBBA]* (or *MCDLFCxP2[MFSBBA]* for fast channel), while the size at 2 bytes unit is defined by *MCDLSCxP0[MSBSZ]* (or *MCDLFCxP0[MFSBSZ]* for fast channel). The slots in each buffer are placed in subsequent addresses. All symbols in the buffer are sequential. First symbol of slot #k is placed in the address that immediately follows last symbol of slot #k-1.

Each input buffer is associated with internal read-pointer: *MCDLSCxRPP* (or *MCDLFCxRPP*, for fast channel) which is updated by MAPLE-B2, indicating the last address that have been fetched by the MAPLE-B2 and can be used by the host to monitor CRPE-DL processing progress and to prevent buffer overruns while adding new data into the buffer. Typically, the host is synchronized to global ‘frame’, ‘slot’ and ‘sub-slot’ timing of the system and is not required to monitor read-pointer to avoid buffer overrun or under-run.

26.4.3.6.3.6 Internal CRPE Operation

This section describes the required details on how to setup a PCH to perform the various CRPE-DL operations.

26.4.3.6.3.6.1 TPC Override

The CRPE-DL is capable of overriding DPCCH TPC fields with updated TPC input symbol generated by the host prior to slot transmission. The following section describes the process details.

26.4.3.6.3.6.2 Slot Format Look Up Table

Before setting up a PCH, the host must create/update the entry in the *Slot Format LUT memory* to which the PCH is associated with. This entry is used for the TPC commands, as specified in **Section 26.4.3.6.3.6.3**, *TPC Value Override*. Each Slot Format LUT entry contains information

that defines the distribution of input symbols to up to five different fields in a slot, and may identify one of the fields as TPC. **Section 26.5.5.7.2**, *CRPE-DL Slot Format Look-Up Table (SFLUT)* describes the SFLUT information.

The settings listed in the SFLUT are constant throughout the entire usage of the PCH. Changing an entry is only possible after tearing down the PCHs associated with it. The Slot Format LUT memory allows up to 90 concurrent different slot formats.

26.4.3.6.3.6.3 TPC Value Override

During CRPE-DL operation, TPC override of a PCH#x and it STTD pair (PCH#x+512) is done by direct accessing to the CRPE-DL TCP Command Control Register (*CDTCLR*). TPC override is turned on by setting *CDTCLR[TPCOV]*. The updated TPC complex symbol is defined by the *CDTCLR[TPCSI]* and *CDTCLR[TPCSQ]* fields. This symbol may override correlating input symbols. The TPC field may contain more than a single symbol, but all TPC symbols of TPC field in a single slot have the same value. The overriding symbol value assumes no STTD operation. CRPE-DL manipulates the overriding symbol value in case an STTD operation affects the input stream. In this case, CRPE-DL changes the overriding TPC value to match post STTD operation prior to overriding the associated input buffer symbols.

The TPC override programming event is allowed to occur anytime during the PCH#x and PCH#x+512 transmission period. Its value takes effect at the following event of processing first symbol of TPC field by CRPE-DL.

Figure 26-152 illustrates a 5 field slot in which the second field is a TPC field. TPC update takes affect for the current slot only if it arrives before processing any TPC symbol of the PCH at the current slot.

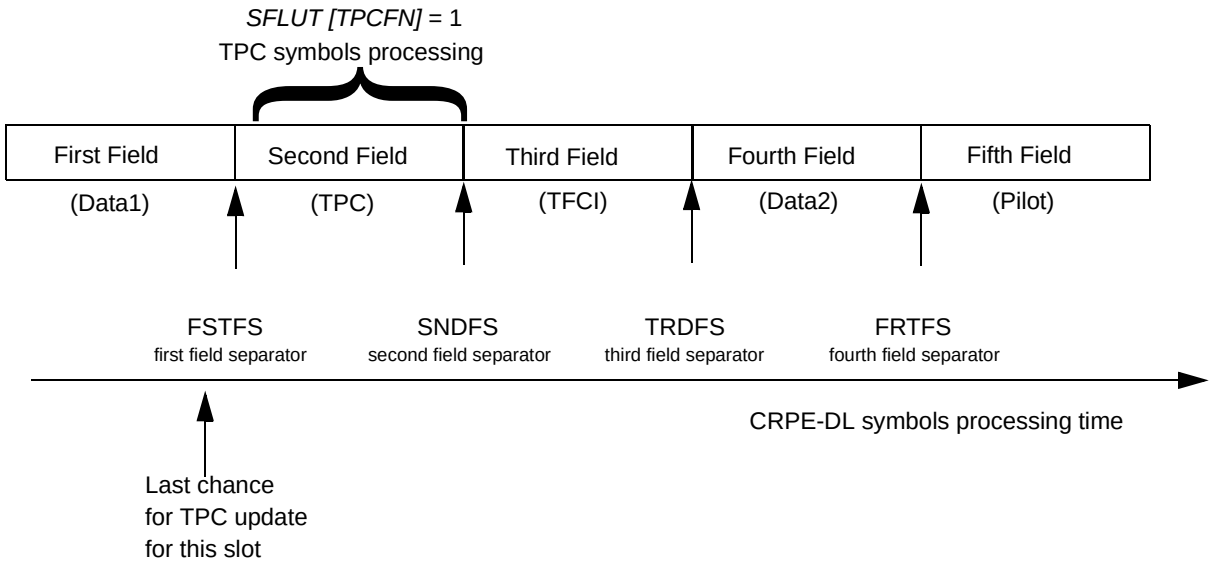

Figure 26-152. TPC update timing

A TPC update command that occurs at least 16 chips (about 4.17 µs) prior to the start of TPC field processing, affects current slot. TPC commands that occur 15 or less chips prior to the start of the TPC field processing may affect the current or the next slot.

26.4.3.6.3.6.4 STTD Encoding

When the *CDGCLR[STTD]* field is set with the value of 2, indicating internal STTD calculations, the CRPE-DL performs STTD operation internally on relevant channel. The input stream involved with such a channel is processed twice. First time data is processed without STTD operation and targeted to virtual antenna as pointed by *CDGCLR[VANTA]*. Second time data is encoded as illustrated by **Figure 26-153**, processed and targeted to virtual antenna as pointed by *CDGCLR[VANTAB]*. When working with internal STTD enable (*CDGCLR[STTD]*=2) the *CDGCLR[VANTABEN]* value should be 1.Otherwise CRPE-DL does not perform STTD operation on the associated channel.

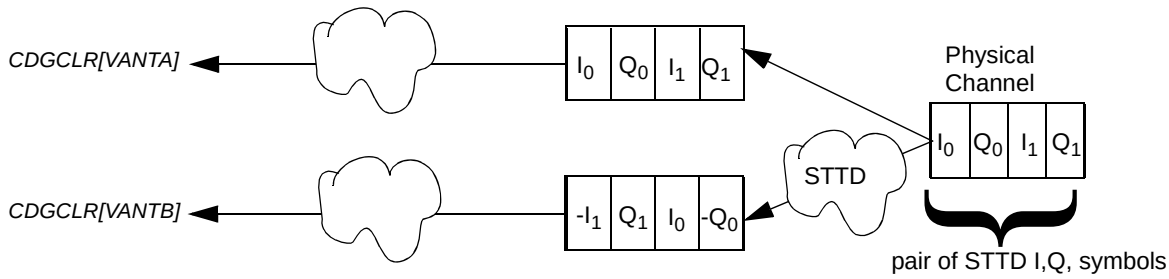

Figure 26-153. CRPE-DL STTD Diversity Operation

CRPE-DL can perform STTD encoding only for channels for which uniform operation for all symbols of the slot (as illustrated in **Figure 26-153**) is suitable for the channel. In addition, CRPE-DL does not support internal STTD operation for channels with a Spreading Factor of 256.

Channels which require STTD encoding which is not supported by CRPE-DL should be encoded externally. In this case, two input streams must be assigned as two separate CRPE-DL PCHs: one original assigned to channel #x (x=0,1,...,511), and a second coupled external STTD with diversity assigned to channel #x+512. The *CDGCLR[STTD]* field associated with the STTD diversity stream that was encoded externally should get the value 3.

26.4.3.6.3.6.5 Spreading Operation

CRPE-DL performs channelization as specified in 3GPP TS version 9.9.0 (release 9) 25.213 standard section 5.1.2.

I and Q branches of the physical channel (except in case of synchronization channel, identified by setting *CDGCLR[SCH]*) are separated to chip rate by the same real-valued channelization code. The channelization code of compressed/non-compressed frames is defined by the

CDGCLR[OVSF]/CDGCLR[CMOVSF] fields respectively, and by the *MCDLSCxP1[MSF]* field (or *MCDLFCxP1[MFSF]* for fast channels).

The channelization code pattern is generated internally by CRPE-DL, in accordance with the standard. **Figure 26-154** illustrates the repeating channelization code patterns $C_{ch,MSF,OVSF}$ of several selected *OVSF* and *MSF* values. Note that Spreading Factor value must always be greater than correlating OVSF value.

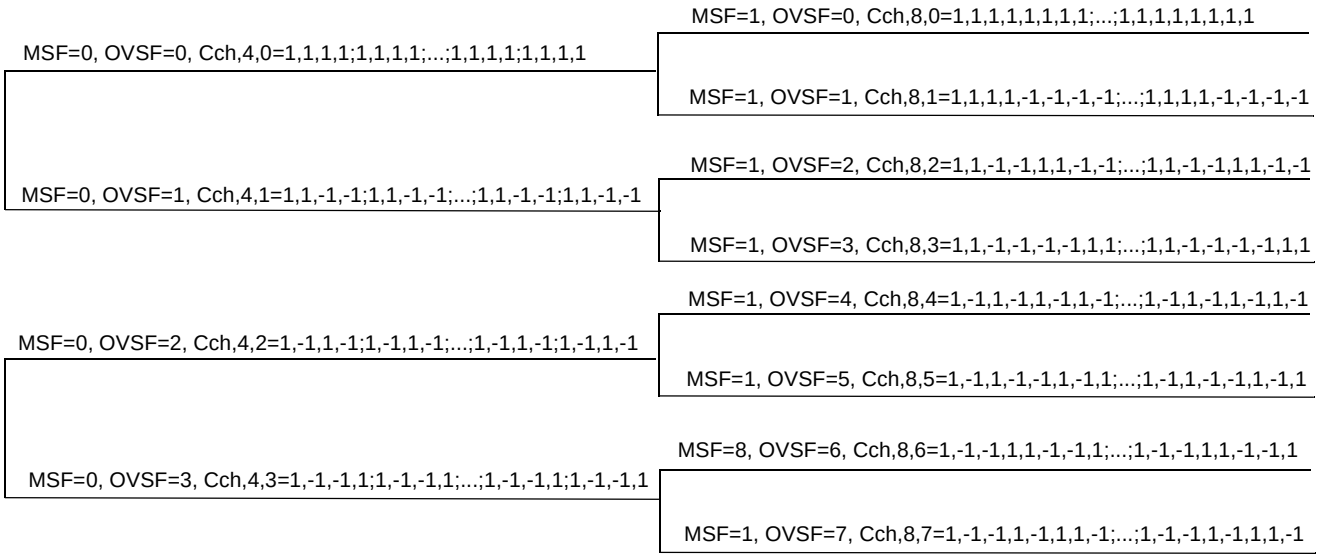

Figure 26-154. Channelization Code Patterns for MSF = 4,8 Illustration

26.4.3.6.3.6.6 Scrambling Operation

The CRPE-DL supports up to 32 different simultaneous scrambling codes, associated with non compressed frames. Scrambling is performed according to 3GPP TS 25.213 section 5.2.2. The CRPE-DL is generating the spreading code internally using an internal Scrambling Initialization Look-Up Table (*SCRILUT*). Each entry in the *SCRILUT* contains the parameter SN_x. This parameter, 13 bits wide, selects a single scrambling code, ranging from 0 to 8191 and associated with non compressed frames. Each PCH contains a pointer to one of the 32 possible entries in the LUT, identified by the *CDGCLR[SCRIX]* field. In addition, the *CDGCLR[CMSCR]* field selects the scrambling code of compressed frames to be either the same as the scrambling code of non compressed frames, or associated left or right alternative scrambling code.

The *SCRILUT* description is detailed in **Section 26.5.5.7.3**, *CRPE-DL Scrambling Initialization Look-Up Table (SCRILUT)* and should be initialized during CRPE-DL initial configuration phase.

26.4.3.6.3.6.7 Gain Operation.

Performing Gain operation and Phase shift adjustments to the output chips is done by controlling each PCH parameters as follows:

Each field out of five possible fields in a slot, as defined by Slot Format LUT (see **Figure 26-152**), is associated with a single 16 bit real gain factor out of four possible real gain factors per channel. The *SFLUT[FSTGF]* (in the Slot Format LUT) associates the first, second, third or forth real gain factor with first field; while *SFLUT[SNDGF]*, *SFLUT[TRDGF]*, *SFLUT[FRTGF]* and *SFLUT[FFTGF]* associate real gain factors with second, third, fourth and fifth fields respectively.

The real gain factors are 2 bytes signed real numbers. In addition to the real gain factors, *CDVAGLR1[IGA]* and *CDVAGLR1[QGA]* represent a complex factor for antenna A; while *CDVAGLR1[IGB]* and *CDVAGLR1[QGB]* represent a complex factor for antenna B. The complex factors are 4 bits each, 2 bits are assigned for the real part of the complex factor and 2 bits are assigned for the imaginary part of the complex factor. Each 2 bits may represent signed values from the range of 1, 0 or –1. The real gain factors along with the complex factors are used for gain and phase shift of each channel separately.

The values of the four real factors of a channel are associated with both virtual antennas A and B, and programmed at the *CDVAGLR0* register fields per PCH. Complex factors are programmed at *CDVAGLR1* registers (also per PCH). Each PCH has a dedicated registers' address space for the programming of its gains.

Gains Usage synchronization

The *CDVAGLR(0-1)* registers, containing the actual gain factors per channel, are treated as shadow registers and do not necessarily become effective immediately. The *CDVAGCLR[GUS]* and *CDVAGCLR[GUN]* fields, as programmed in the CRPE-DL Virtual Antennas Gain Command Control Register, point to the slot from which programmed gains become effective. The *CDVAGCLR[GUS]* points to a specific slot, while *CDVAGCLR[GUN]* indicates that new gains should be used at the earliest slot in the channel frame.

CRPE-DL uses previously programmed gain factors for all slots preceding the slot pointed by *CDVAGCLR[GUS]* or *CDVAGCLR[GUN]*. For the programming of *CDVAGCLR[GUS]* value, the user need not take into account channel sub-slot offset. The actual update is performed automatically when processing the first symbol of a field pointed by *SFLUT[GUF]* at the Slot Format LUT. Gain is also updated when the first symbol of a new channel is processed.

If gain weights are re-programmed before becoming effective, the overridden weights are lost and never used. If *CDVAGCLR[GUS]* or *CDVAGCLR[GUN]* are re-programmed before CRPE-DL reaches the slot pointed by them, the overridden *CDVAGCLR[GUS]* or *CDVAGCLR[GUN]* are lost and never used. **Figure 26-155** illustrates the usage of updated gains.

Gain update latency is allowed to be as low as 16 chips chunk before the affected slot processing starts. An update of gain weights values, indicating the required usage of a new gain, must occur before CRPE-DL started processing the first IQ symbol of the slot pointed by *CDVAGCLR[GUS]*.

The processing state of CRPE-DL, indicating progress of chips processing, is accessible to the system by reading CRPE-DL Processing State Status Register. *CDPSSR[FI]*, *CDPSSR[SI]*, *CDPSSR[BI]* and *CDPSSR[CI]* indicate the index of currently processed frame, slot, sub-slot and chunk respectively.

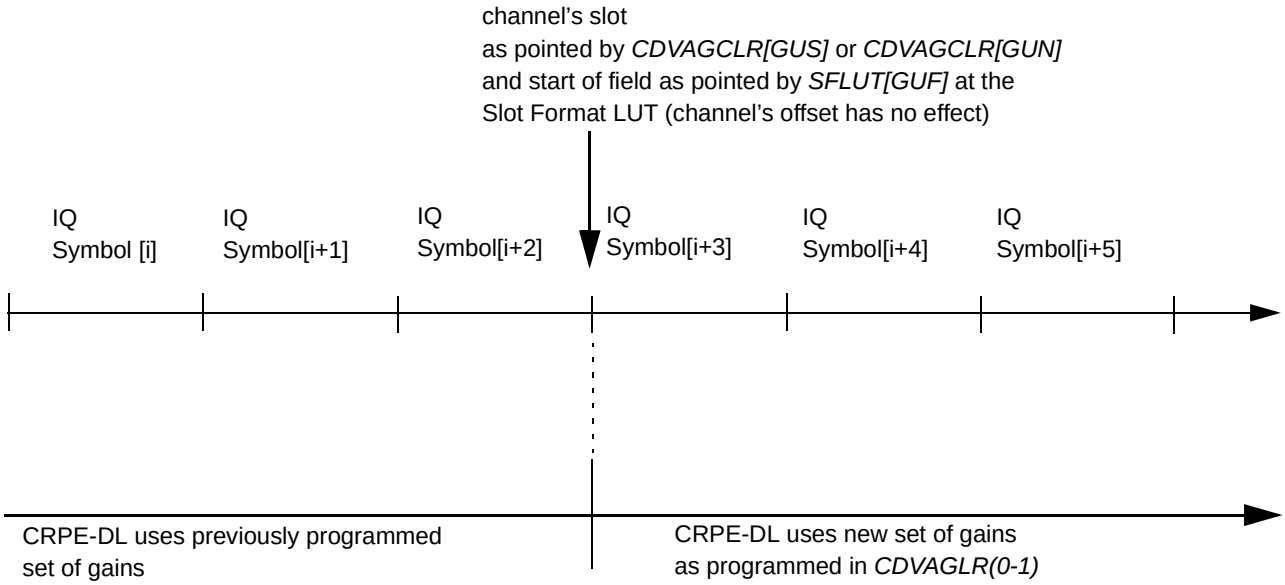

Figure 26-155. Usage Of Updated Gains Illustration

26.4.3.6.3.6.8 Combine Operation

CRPE-DL processes 16-chip chunks from all active channels (one channel after the other) and accumulates the channels chips at the combine stage. Sixteen chips per virtual antenna are accumulated at the combine stage. A complex chip in the combine stage is represented by real and imaginary parts of 32 bits each. Chip values are limited between the upper and lower saturation values. Each virtual antenna has its own entry in the combine stage.

After accumulating the chips at the combine stage, the representation of the chip is reduced from 64 bits (32 real and 32 imaginary) to 32 bits (16 real and 16 imaginary). The *CDCCSCLRx[CCSNUM]* field determines the number of shift right operations to perform for the combined chips. The *CDCCSCLRx[CCSNUM]* is a shadow parameter that takes effect at the slot and sub-slot indicated by *CDCCSCLRx[CCSUSL]* and *CDCCSCLRx[CCSUSS]*, respectively, or at the next earliest sub-slot if *CDCCSCLRx[CCSUN]* is set to 1.

Each channel is targeted to up to 2 virtual antennas out of 16 virtual antennas, indicated by *VANTA* and *VANTB* as programmed in the *CDGCLR* register. The *CDGCLR[VANTABEN]* field, when set, enables virtual antenna B in addition to virtual antenna A. Otherwise, the processed chips of the channel are targeted only to virtual antenna A. When *CDGCLR[STTD]* equals 2, the channel should be directed to both antennas, while the STTD diversity stream, which is generated internally by CRPE-DL, is targeted to virtual antenna B.

26.4.3.6.3.6.9 Beam Forming Operation

The CRPE-DL is capable of performing beam forming operations. The output of beam forming operations are 16 beam output antennas. Each beam antenna is a unique complex linear combination of 4 virtual antennas associated with the beam antenna.

Each beam is formed independently. The virtual antennas are separated to 4 groups of 4 virtual antennas, and the beam antennas are also separated to 4 groups of 4 beam antennas. The groups are coupled to pairs such that each group of virtual antennas forms beams at a single group of beam antennas. **Figure 26-156** illustrates the correlation between virtual antennas and beam antennas. The figure illustrates 4 groups of 4 virtual antennas each group, generating 4 groups of 4 beams. The following objects are shown:

- VA_i represents 4 bytes chips of virtual antennas i at the combine stage.
- BF_{mn} is a complex coefficient, used for the multiplication of virtual antenna m while forming beam antenna n.
- BA_i represents 4 bytes chip of beam antenna i at the CRPE-DL output buffer.

The values of the complex coefficients BF_{mn} are programmed in the CRPE-DL Beam Forming Control Registers (*CDBFCVLR(0-7)*) using the following equation:

$$BF_{mn} = (BF_{mn}I) + j \times (BF_{mn}Q)$$

The BF_{mn} coefficients are written to shadow registers. The latest programmed coefficients take effect starting from the slot and sub-slot as specified in *CDBFCTCLRx[BFUSL]* and *CDBFCTCLRx[BFUSS]* fields respectively. *CDBFCTCLRx[BFUN]* may be used instead of *CDBFCTCLRx[BFUSL]* and *CDBFCTCLRx[BFUSS]*, indicating that coefficients should take effect at the next earliest sub-slot.

The *CDBFCTCLR0* register correlates with *CDBFCVLR(0–1)* registers, *CDBFCTCLR1* register correlates with *CDBFCVLR(2–3)* registers, *CDBFCTCLR2* register correlates with *CDBFCVLR(4–5)* registers and *CDBFCTCLR3* register correlates with *CDBFCVLR(4–5)* registers.

The most basic case of beam forming is the one at which each virtual antenna is directly mapped to the correlating output antenna (virtual antenna *n* to output antenna *n*, where *n* = 0 to 15). The beam forming coefficients need to be programmed for the basic case as well as more complex case prior to CRPE-DL operation.

After beam-forming operation, the chips are internally represented by 54 bits (27 real and 27 imaginary). Final output chips are reduced to representation of 32 bits (16 real and 16 imaginary). The *BFSNUM* field in *CDBFCTCLR(0-3)* determines the number of shift right operations to perform for the chips after beam forming operation. The *BFSNUM* is a shadow field that takes affect at slot and sub-slot as pointed by *CDBFCTCLRx[BFSUSL]* and *CDBFCTCLRx[BFSUSS]* respectively, or at the next earliest sub-slot if *CDBFCTCLRx[BFSUN]* is set to 1.

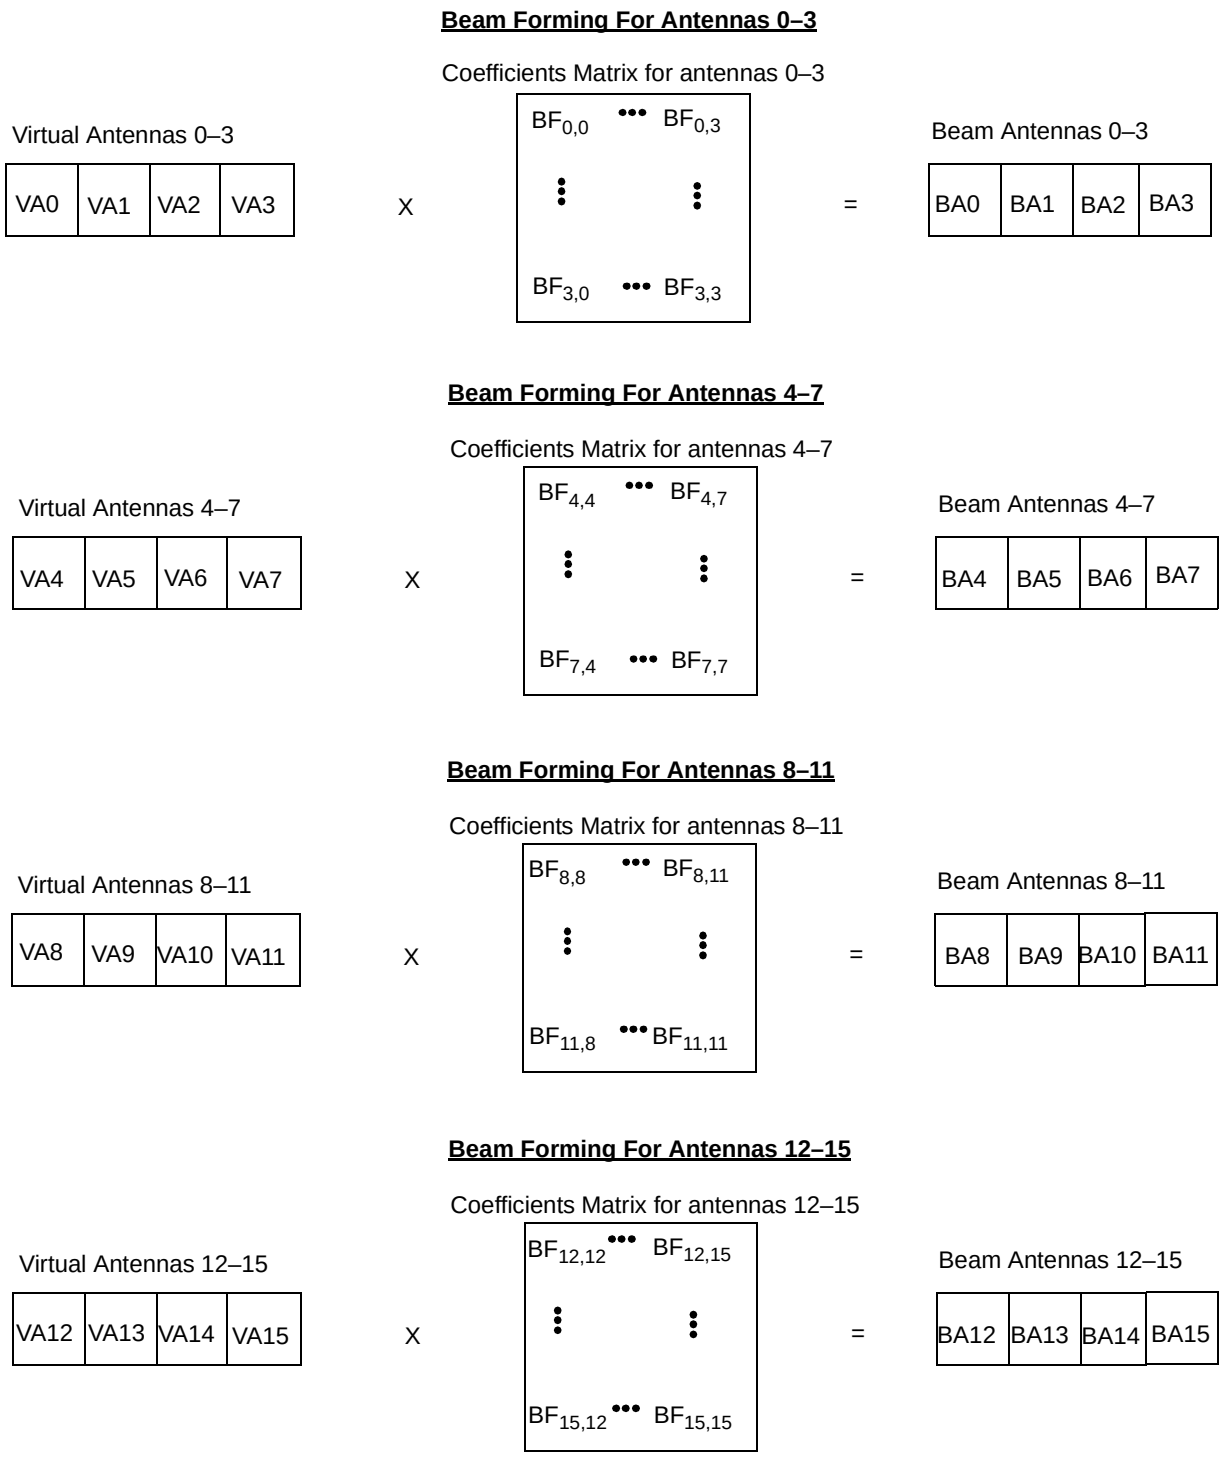

Figure 26-156. Virtual Antennas And Beam Antennas Correlation Illustration

26.4.3.6.3.6.10 Virtual Antennas Idle Period

Each virtual antenna is associated with its own Idle Period Control Register (*CDIPLR*). This register defines periods of time in which all coefficients associated with the virtual antenna are considered as zero, regardless their actual values in *CDBFCVLR(0-7)* registers.

The first slot and sub-slot of the idle period of virtual antenna i are defined by *CDIPLR[IPSSL$_i$]* and *CDIPLR[IPSSBS$_i$]* respectively. Start time is included in the idle period.

The last slot and sub-slot of the idle period of virtual antenna i are defined by *CDIPLR[IPESL$_i$]* and *CDIPLR[IPESBS$_i$]* respectively. End time is not included in the idle period.

The programming of *CDIPLR* register takes affect for a single idle period. When programming the register, the host should set *IPV$_i$* bit and CRPE-DL clears the bit once an idle period is performed from start to end.

26.4.3.6.3.7 Output Modes Of Operation

The MAPLE-B2 supports the following two operation modes with respect to CRPE-DL outputs:

- CPRI output mode in which output stream is accessible at the output buffer of the CRPE-DL through the MBus slave port for CPRI direct access.
- MAPLE-B2 output mode in which MAPLE-B2 actively transfers output stream to external system buffers.

During MAPLE-B2 output mode, MAPLE-B2 transfers data from CRPE-DL output buffer to system buffers each time a new processing chunk (16 chips per antenna) is available. In CPRI output mode data is fetched from CRPE-DL output buffer by an external master (CPRI) independently.

26.4.3.6.3.7.1 MAPLE-B2 Output Mode

MAPLE-B2 output mode is selected when *CDOMCP[MOM]* field in the CRPE-DL Output Mode Parameter is set. The *MCDLOBxBAP* parameters along with *MCDLOBxSP* parameters define the system output cyclic buffers to which MAPLE-B2 transfers the output chips. The *MCDLOBxBAP[MOBBA]* field defines the base address of the antenna's output system buffer at granularity of 128 bytes. The *MCDLOBxSP[MOBSZ]* field defines the size of the antenna's output system buffer at granularity of 128 bytes. The MAPLE-B2 transfers 256 chips per antenna at time period of a single sub-slot.

The MAPLE-B2 maintains an output buffer write pointer for each output buffer in the *MOWR_PTR* field of the *MCDLOBxWPP* parameter. Each antenna is associated with its own dedicated write pointer parameter. This parameter can be monitored to verify MAPLE-B2 transfer progress; however it is not required to do so, because it can be assumed that MAPLE-B2 transfer rate is sufficient for real time requirements. The write pointer parameter can also be used to identify the completion of first data chunk transfer after system initialization.

The system output buffers are filled by MAPLE-B2 cyclically; when MAPLE-B2 reaches the end of a buffer, it wraps back to the base address of the buffer. **Figure 26-157** illustrates output system buffer example of antenna #0.

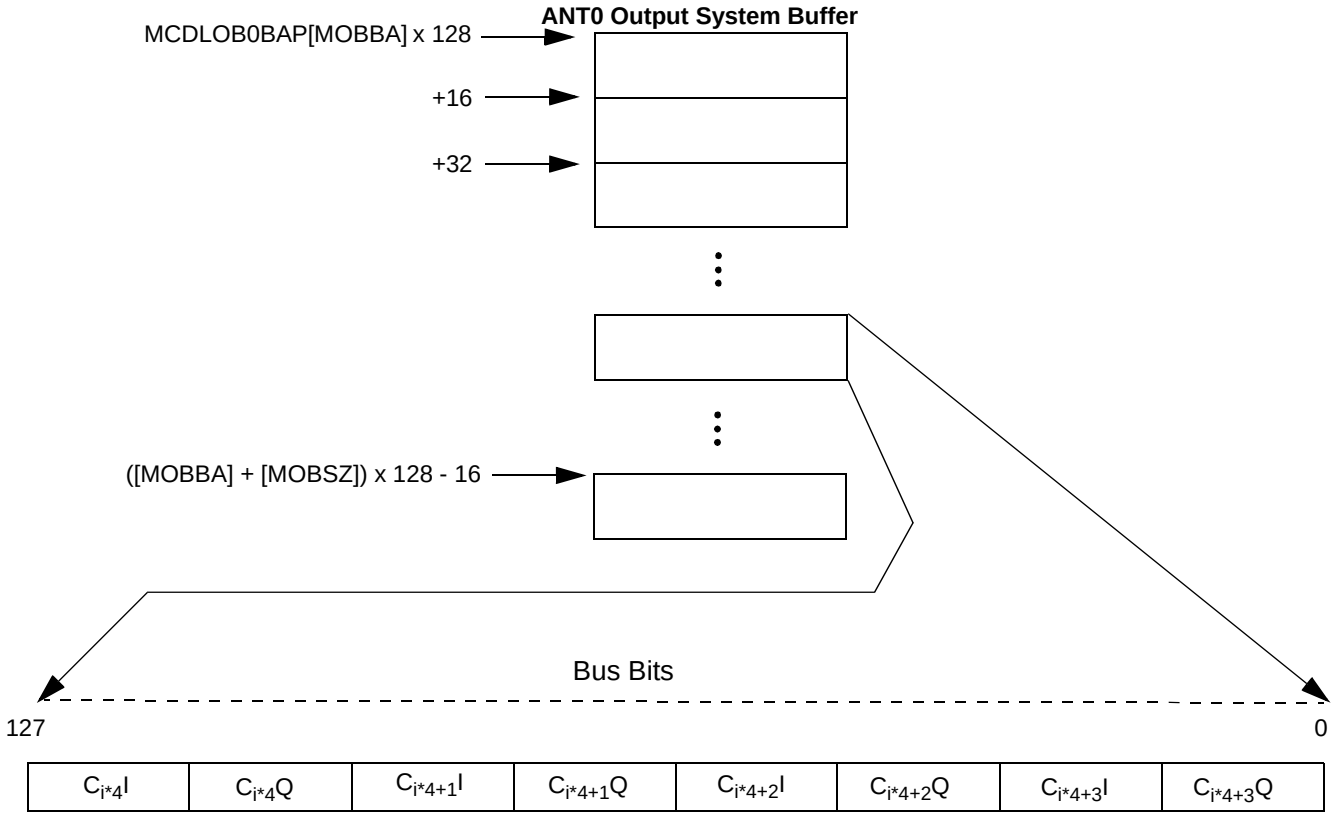

Figure 26-157. Output System Buffers Illustration

26.4.3.6.3.7.2 CPRI Output Mode

CPRI output mode is selected when the *CDOMCP[MOM]* field is cleared. In this mode, MAPLE-B2 expects that CRPE-DL output buffer is read directly by an external host such as CPRI DMA. The data structure of the CRPE-DL output buffer is illustrated at **Figure 26-158** and is detailed in **Section 26.5.5.7.1**, *CRPE-DL Chips Output Data Table (CDCODT)*

The CRPE-DL output buffer contains 2 entries per antenna. Each entry contains 16 chips data of a single antenna. An output chip is a complex number, represented by 2 bytes of real part and 2 bytes of imaginary part.

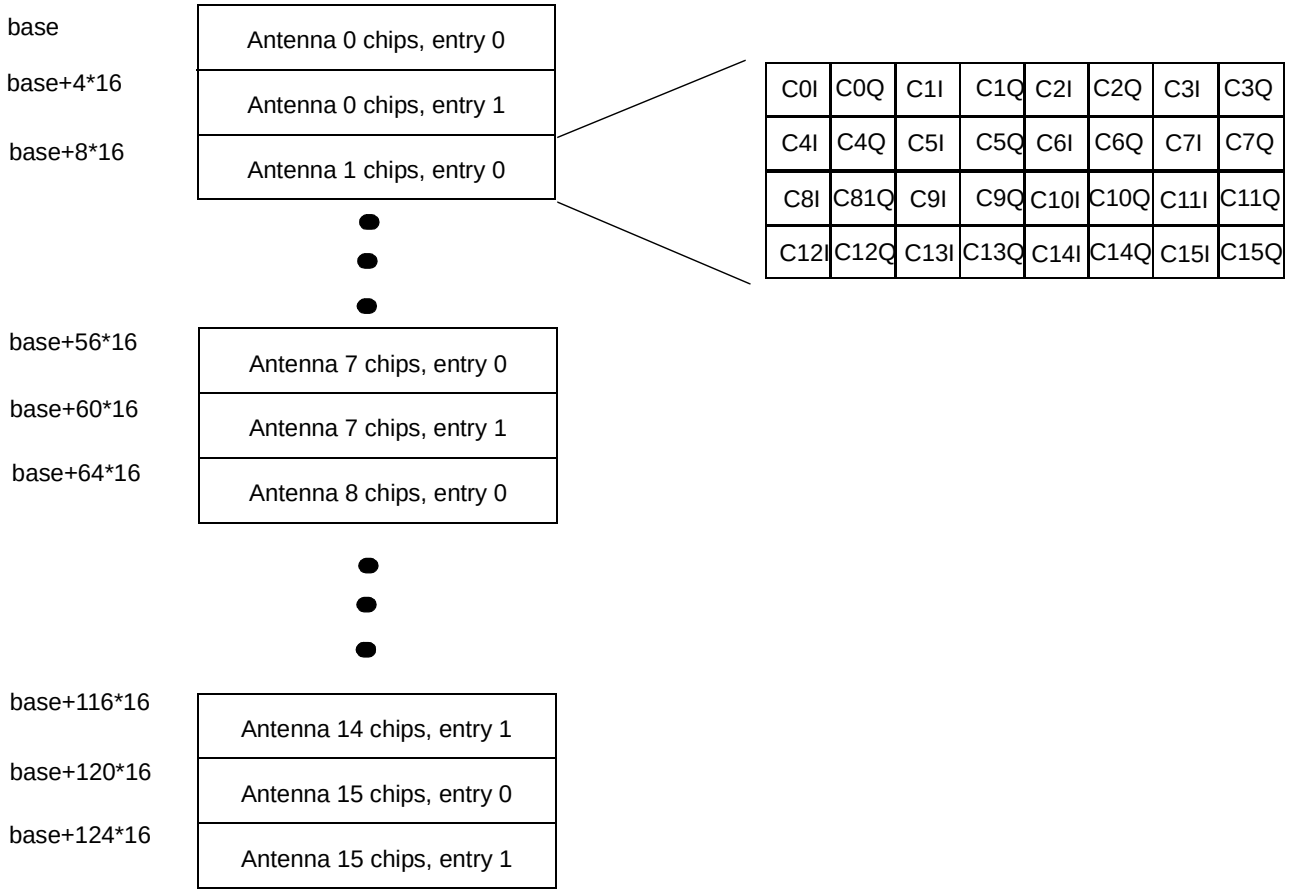

Figure 26-158. CRPE-DL Output Buffer Entry Data Organization Illustration

26.4.3.6.3.7.3 Output Buffer Accesses Constraints

The following is a list of required assumptions and constraints needed to maintain proper use of the CRPE-DL output buffer:

- For Output Buffer Overrun Prevention the following must be maintained:
  - Accesses to CRPE-DL output buffer are monitored for the purpose of CRPE-DL rate control and overrun prevention. Chips of all enabled antennas at current buffer entry should be read before chips from next entry are accessed.
  - Enabling *A0EN* to *A15EN* bits of the *CDOMCP* parameter enables the activation of output antennas 0 to 15 respectively.
  - Every chip should be read a single time.
  - The size of any CRPE-DL output buffer access is a multiple of 16 bytes.
  - Addresses of all CRPE-DL accesses are aligned to 16 bytes.
  - Output buffer reads are at a rate of 3.84 Mega chips per second per antenna. Since each buffer entry includes 16 chips per antenna, chips of all activated antenna must be read from buffer entry at time period of no longer than 4.166 µs.

- For Output Buffer Under-Run Prevention, the following must be maintained:
  - The 2 buffer entries shell accessed in a cyclic manner: read all chips of enabled antennas from first entry, then read all chips of enabled antennas from second entry, then read all chips of enabled antennas from first entry an so on.
  - Output buffer reads are at a rate of 3.84 Mega chips per second per antenna. Since each buffer entry includes 16 chips per antenna, an attempt to accesses more than one buffer entry at the same 4.166 µs time period by an external master is forbidden. During MAPLE-B2 Output Mode the rate of buffer entry change is triggered by an internal CRPE-DL event; in this case there is no restriction of 4.166 µs period.

26.4.3.6.3.8 Initialization of CPRI Output Mode

The following describes the initialization sequence of the CRPE-DL assuming CPRI Output Mode:

1. Host activates CPRI module.
2. CPRI start synchronization period:
   a. Providing frame and sub-slot synchronization events periodically.
   b. Sending zeros to antenna without reading CRPE-DL output buffer.
3. Host writes channels' symbols to system buffers.
4. Host starts polling CPRI synchronization status, until CPRI is synchronized.
5. Host initializes channels at MAPLE-B2 parameters and CRPE-DL registers:
   a. Initialization of LUT Memories.
   b. Initialization of beam forming coefficients.
   c. Initialization of channel activation and parameters.
   d. Initialization of frame, slot and sub-slot counters by performing a write access to CRPE-DL Start Control Register (*CDSLR*).
6. Host start polling the *CDESR[OBS]* status indication, waiting for completion of processing of two chunks.
7. CRPE-DL starts processing when receiving new sub-slot event that follows *CDSLR* write. CRPE-DL fills first 2 chunks of all antennas at output buffer.
8. CRPE-DL sets Output Buffer Status event (*CDESR[OBS]*) to indicate that first 2 chunks of CRPE-DL output buffer are ready to be fetched since *CDSLR* was written.
9. Host can configures CPRI to start fetching data.
10. CPRI fetches first chunk of CRPE output data and then second chunk of output data. CPRI continues to fetch CRPE output chunks at steady state synchronized to the frame start.
11. CRPE-DL continue to fill output buffer at steady state. CRPE-DL monitors CPRI accesses to output buffer to prevents internal output buffer data override.

26.4.3.6.3.9 CRPE-DL Rate Control

CRPE-DL is designed to work at a rate that is faster than real-time requirements. The actual processing rate of CRPE-DL, therefore, requires external control. CRPE-DL rate control is based on two mechanisms: output chip override prevention and controlled processing task per processing period.

26.4.3.6.3.9.1 Output Chip Override Prevention

CRPE-DL writes its output chips to an internal output buffer. At CPRI output mode (*CDOMCP[MOM]*=0) the chips from the output buffer are directly read by an external host such as CPRI, while at MAPLE-B2 output mode (*CDOMCP[MOM]*=1) chips are transferred by MAPLE-B2 to a system buffer.

CRPE-DL monitors the read accesses from its internal output buffer, and prevents overrun of chips that are still not read from the buffer. If a risk of chips overrun at CRPE-DL output buffer occurs, the CRPE-DL halts its processing until relevant chips are read from the output buffer.

The output buffer is a 16 chips double buffer per antenna. At a steady state, CRPE-DL writes chips to one buffer per antenna while chips are read from the other buffer.

26.4.3.6.3.9.2 Controlled Processing Task Per Processing Period

CRPE-DL performs a defined task according to the selected processing period. The processing period can be a 16 chips chunk period or a 256 chips sub-slot period according to the configuration of the *RSEL* field in the *CDOMCP* parameter. Once the defined task processing is complete, CRPE-DL automatically halts its operation and waits for an external event, indicating that a new processing period has just started.

The external event source is selected to be an interrupt if *CDOMCP[RCS]* = 1, or write access to the CDRLR register if *CDOMCP[RCS]* = 0. In the latter case, writing 1 to *CDRLR[CSE]* is used to represent new chunk event, while writing 1 to *CDRLR[BSE]* is used to represent new sub-slot. *CDRLR* is cleared automatically by the CRPE-DL.

CRPE-DL uses new sub-slot event to begin its initial operation after *CDSLR* is written.
CRPE-DL uses new sub-slot event to start execution of a new sub-slot if *CDOMCP[RSEL]* = 1.

CRPE-DL uses a new chunk event to start execution of a new 16 chips if *CDOMCP[RSEL]* = 0.

26.4.3.6.4 CRPE Reset

The MAPLE-B2 supports internal reset assertion for the CRPE modules only (CRPE-ULF, CRPE-DL and CRPE-ULB). Such internal reset assertion may be required in the case the Antenna I/F (CPRI) and the CRPE modules loose synchronization hence should be reset. Reset assertion for the CRPE modules is done by initiating the `Maple_reset_crpe` routine as

described in **Section 26.4.5**, *MAPLE-B2 Internal Task Control*. Once initiated, the MAPLE-B2 performs the following:

1. Set the *MCRRCIP[CR_RST]* (see **Section 26.5.3.5.1.1**) bit indicating that the CRPE reset routine is initiated.
2. Disable all CRPE modules internal interrupts and related routines.
3. Wait to the completion of all running CRPE modules related routines which were initiated prior to reset routine assertion.
4. Assert the internal CRPE hard reset input.
5. Start with CRPE configuration initialization as described in the API parameters.
6. Reset the *MCRRCIP[CR_RST]* bit indicating the internal CRPE reset is completed.

Once internal reset is completed, each of the CRPE modules should be initialized as described in each module's initialization explanation. Note that the initialization part which is executed in the API during MAPLE-B2 initialization is already executed during the `Maple_reset_crpe` routine as described above.

26.4.3.7 CRC Operation

The MAPLE-B2 supports CRC checks and CRC calculations for block sizes of up to 16 KBytes and with eight optional CRC polynomials. These operation are executed using internal CRCPE instantiated in PSIF2.

Note: The CRC processing executed by the CRC Processing Elements is not standard related and, therefore, is not affected by the MAPLE-B2 operation mode.

26.4.3.7.1 CRCPE Buffer Descriptor Structure

A detailed description of the CRC Buffer Descriptor structure expected by the host for the CRCPE BD rings is provided in **Section 26.5.4.7**, *CRCPE Buffer Descriptor Structure*, on page 26-481.

26.4.3.7.2 CRC Input Data Structure

After parsing the CRC Buffer Descriptor, MAPLE-B2 starts fetching the input buffer into its internal memories for the CRC calculations/checks. The address of the input buffer should be specified in the [CRC_IB] field of the CRC BD. The CRC input buffer must be of size which is aligned to 8 bits. The CRC input buffer size must be specified in the [CRC_BS] field of the CRC

BD. **Figure 26-159** shows an example of a 1224 bits block and how it should be placed in the system memory to be input for the MAPLE-B2 CRC processing:

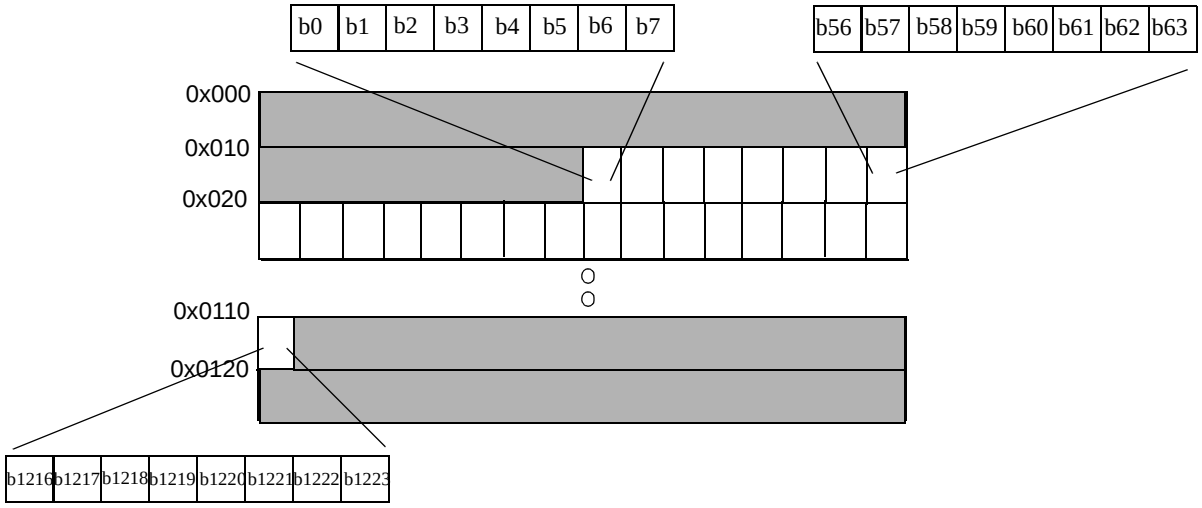

Figure 26-159. Example of Placing a Block of 1224 Bits in the System Memory for CRC Calculation

If CRC calculations are required to be executed on blocks which are not 8 bits aligned, zero padding bits must be added at the beginning of the input buffer, before the first data bit. **Figure 26-160** shows an example of a 1220 bits block and how it should be placed in the system memory to be input for the MAPLE-B2 CRC processing:

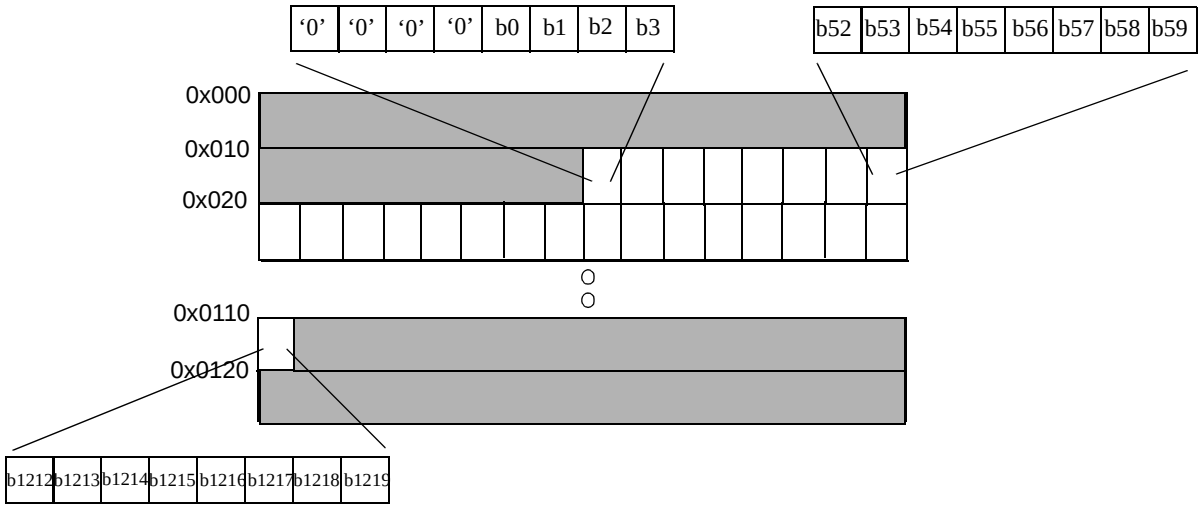

Figure 26-160. Example of Placing a Block of 1220 Bits in the System Memory for CRC Calculation

The MAPLE-B2 CRCPE performs the following two types of CRC processing:

- *CRC calculations*: If the [CHECK] bit in the CRC BD is reset, the MAPLE-B2 performs CRC calculation on the input buffer and place the CRC calculation result in the [CRC_RSLT] field of the CRC BD.
- *CRC checks*: If the [CHECK] bit in the CRC BD is set, the MAPLE-B2 performs CRC check on the input buffer and updates the [FAIL] status bit in the CRC BD with the CRC check result. If the [FAIL] bit is set by the MAPLE-B2, the CRC check failed. If the [FAIL] bit reset, the CRC check passed.

26.4.3.7.3 Byte Reverse CRC Processing

The CRCPE is capable of performing byte reverse CRC processing for both CRC calculations and CRC checks. By resetting the [RVRS_IN] bit in the CRC BD, the MAPLE-B2 performs byte reverse CRC processing on the input data. **Figure 26-161** describe the CRC processing of a 64 bits vector with respect to the [RVRS_IN] bit configuration:

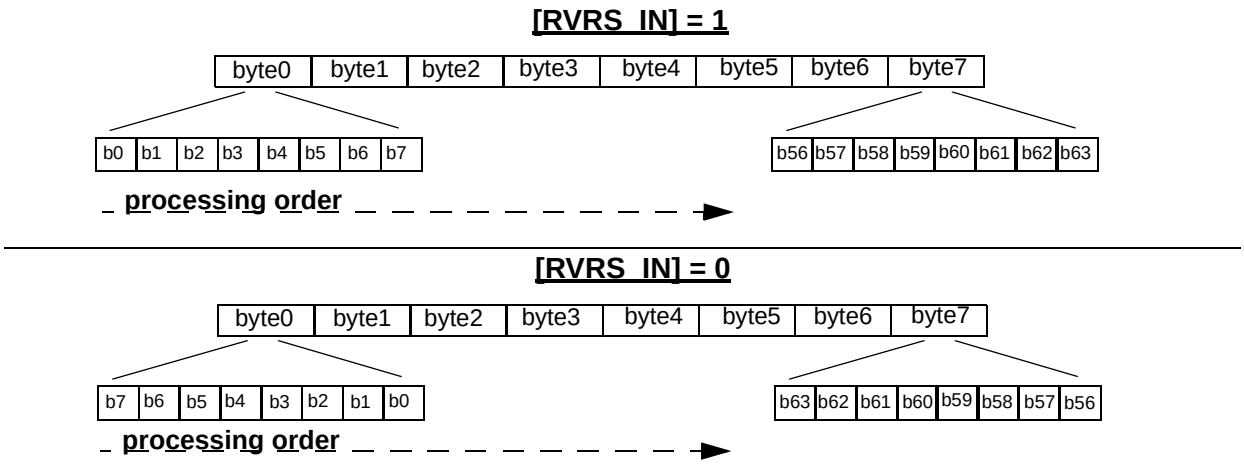

Figure 26-161. CRC Processing Order with Respect to [RVRS_IN] Bit

26.4.3.7.4 CRC Initial Value

The CRCPE is capable of initializing its CRC initial value with any configurable value. By configuring the [CRC_INIT] field of the CRCPE BD, MAPLE-B2 copies the value into the CRCPE machine before the beginning of the CRC processing.

The configured value of the [CRC_INIT] field must be with the same size as the CRC polynomial. For example, if the configured polynomial is CRC16-CCITT or CRC16 [CRC_POLY] = 010 or 011 respectively), the valid bit which is copied by MAPLE-B2 into the CRCPE is CRC_INIT[15:0] only. In this case, bits 31–16 of the [CRC_INIT] files remain not valid.

26.4.3.7.5 CRC Polynomials

The CRCPE supports eight types of CRC polynomials. The control of the CRC processing polynomial is done using the [CRC_POLY] field of the CRC BD according to **Table 26-123**:

Table 26-123. Supported CRC Polynomials with respect to [CRC_POLY] Field

[CRC_POLY]	CRC Type	CRC Polynomial
'000'	CRC24	$D^{24} + D^{23} + D^6 + D^5 + D + 1$
'001'	CRC24	$D^{24} + D^{23} + D^{18} + D^{17} + D^{14} + D^{11} + D^{10} + D^7 + D^6 + D^5 + D^4 + D^3 + D + 1$
'010'	CRC16-CCITT	$D^{16} + D^{12} + D^5 + 1$
'011'	CRC16	$D^{16} + D^{15} + D^2 + 1$
'100'	CRC32	$D^{32} + D^{26} + D^{23} + D^{22} + D^{16} + D^{12} + D^{11} + D^{10} + D^8 + D^7 + D^5 + D^4 + D^2 + D + 1$
'101'	CRC18	$D^{18} + D^{17} + D^{14} + D^{13} + D^{11} + D^{10} + D^8 + D^7 + D^6 + D^3 + D^2 + 1$
'110'	CRC12	$D^{12} + D^{11} + D^{10} + D^8 + D^5 + D^4 + 1$
'111'	CRC6	$D^6 + D^5 + D^3 + D^2 + D^1 + 1$

26.4.3.7.6 CRC Processing Results

The MAPLE-B2 is capable of performing the following processing of the CRC results:

26.4.3.7.6.1 Reverse Output Operation

When resetting the [RVRS_OUT] bit of the CRCPE BD, the MAPLE-B2 performs reverse operation on the CRC result. The reverse operation means reflecting the result such as the Most Significant Bit (MSB) becomes the Least Significant Bit (LSB) and vice versa. **Figure 26-162** describe the output reverse operation on a 16 bits CRC result:

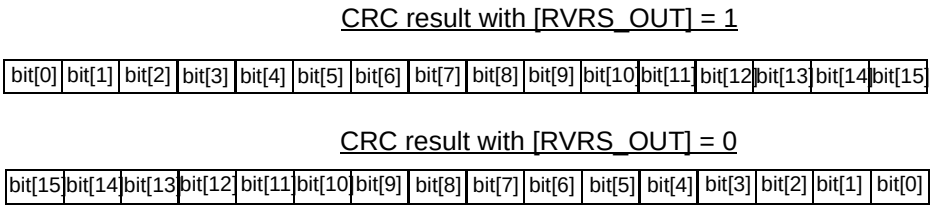

Figure 26-162. Reverse Output operation description

26.4.3.7.6.2 Inverse Output Operation

When setting the [INV_OUT] bit of the CRCPE BD, the MAPLE-B2 performs bit wise inverse operation on the CRC result. **Figure 26-163** describes the output Inverse operation on a 16-bit CRC result:

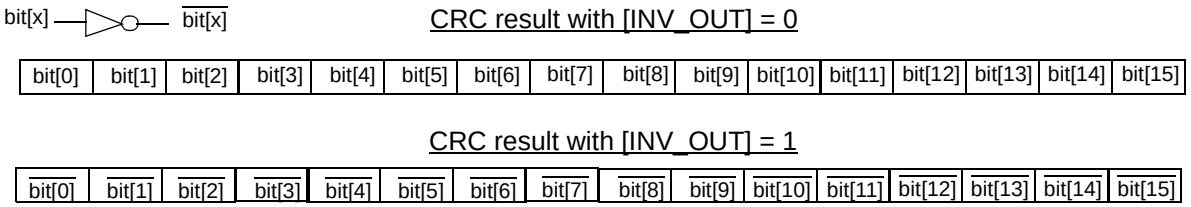

Figure 26-163. Inverse Output Operation Description

26.4.3.7.6.3 CRC Result Check/Calculate

If CRC check is required ([CHECK] = 1), MAPLE-B2 returns the CRC check PASS/FAIL indication using the [FAIL] status field of the CRC BD. If, after the [OWNER] bit is cleared, the [FAIL] status bit indication is set, the CRC check has failed. If it is reset, the CRC check has passed.

If CRC calculation is required ([CHECK] = 0), MAPLE-B2 returns the CRC calculation result in the [CRC_RSLT] field of the CRC BD. By setting the [UPDATE] bit in the CRC BD, MAPLE-B2 also updates the CRC result at the end of the input buffer in the system memory. **Figure 26-164** describes an example of input buffer after the CRC BD completion when the [UPDATE] bit is set:

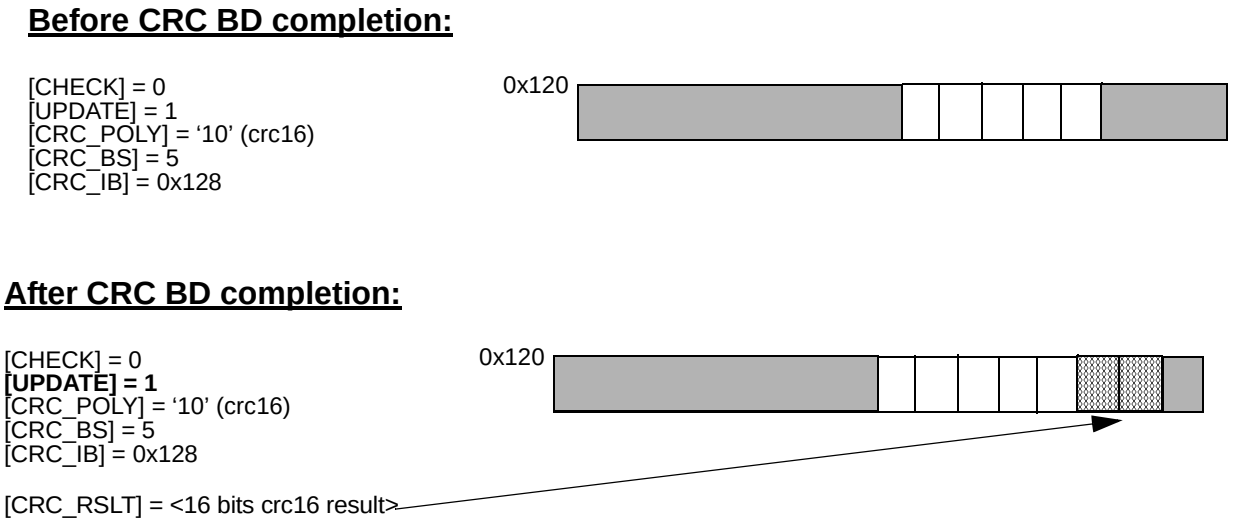

Figure 26-164. System Memory Update with CRC Result When [UPDATE] Bit is Set

26.4.3.8 Code Generation Operation

The MAPLE-B2 supports WCDMA Scrambling Code Generation acceleration. It is design to generate Uplink and Downlink scrambling and Hadamard codes, and to calculate their multiplication results. These calculation are executed using the CGPE instantiated in the Chip-Rate processing Element (CRPE).

26.4.3.8.1 CGPE Buffer Descriptor Structure

A detailed description of the Code generation Buffer Descriptor structure expected by the host for the CGPE BD rings is provided in **Section 26.5.4.8**, *CGPE Buffer Descriptor Structure*, on page 26-486.

26.4.3.8.2 CGPE Processing

The Codes Generator is responsible of generating uplink or downlink complex-valued scrambling codes and dedicated OVSF codes to be scrambled with uplink physical channels, as defined in 3GPP TS 25.213 (release 9):

- clause 4.3 - “Uplink spreading and modulation”
- clause 5 - “Downlink spreading and modulation”

The following sub-sections details its functionality.

26.4.3.8.2.1 OVSF Codes Generation

The **O**rthogonal **V**ariable **S**preading **F**actor (**OVSF**) codes are used as channelisation codes to preserve the orthogonality between a user’s different physical channels.

Figure 26-165 illustrates OVSF codes generation. Each level in the code tree defines OVSF codes of length SF, corresponding to a spreading factor of SF.

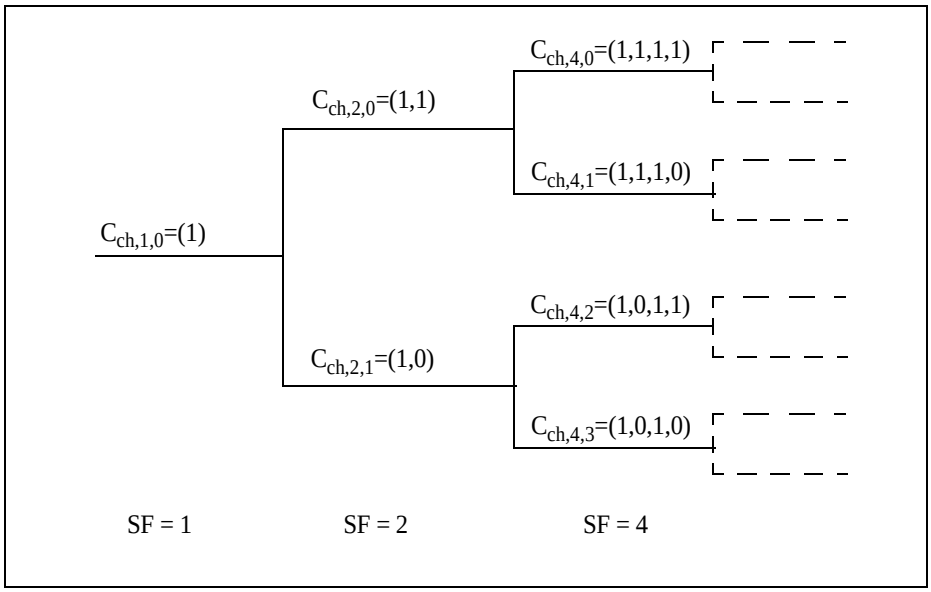

Figure 26-165. Code Tree for generation of Orthogonal Variable Spreading Factor codes

The OVSF codes are uniquely described as $C_{ch,SF,k}$, where SF is the Spreading Factor of the code and k is the code number, $0 \leq k \leq$ (Spreading Factor - 1). Controlling the OVSF value in the CGPE is done by the *OVSF_NUM* value of the CGPE BD.

The CG supports the following subset of Spreading Factor values: 1, 2, 4, 8, 16, 32, 64, 128 and 256 and is controlled in the CGPE by the *SF* field of the CGPE BD. The generation method for the channelisation code is defined in *3GPP TS 25.213 V9.1.0 (release 9) - clause 4.3.1 - "Channelisation codes"*

26.4.3.8.2.2 Uplink Scrambling Codes Generation

All uplink physical channels are subjected to scrambling with a complex-valued scrambling code. In WCDMA uplink transmissions, the scrambling code can either be short or long. Configuring the CGPE to generate uplink code is by setting the *UL_CODE* field of the CGPE BD (*UL_CODE* = 1) and controlling whether this generated code is long or short is done by setting the *LONG_MODE* field of the CGPE BD.

26.4.3.8.2.2.1 Long Complex Scrambling Codes Generation

The long scrambling sequences $C_{long,1,n}$ and $C_{long,2,n}$ are constructed from position wise modulo 2 sum of 38400 chip segments of two binary m-sequences generated by means of two generator polynomials of degree 25.

Let x, and y be the two m-sequences respectively.

The x sequence is constructed using the primitive (over GF(2)) polynomial $X^{25}+X^3+1$.

The y sequence is constructed using the polynomial $X^{25}+X^3+X^2+X+1$.

The sequence $C_{long,2,n}$ is a 16,777,232 chip shifted version of the sequence $C_{long,1,n}$. *PN_NUM[23:0]* (of the CGPE BD) is the 24 bit binary representation of the scrambling sequence number n.

The x sequence depends on the chosen scrambling sequence number n and is denoted x_n, in the sequel. Furthermore, let $x_n(i)$ and y(i) denote the i_{th} symbol of the sequence x_n and y, respectively.

The m-sequences xn and y are constructed as:

Initial conditions:

$x_n(0)=PN\_NUM[0]$, $x_n(1)= PN\_NUM[1]$, ... ,$x_n(23)= PN\_NUM[23]$, $x_n(24)=1$.
$y(0)=y(1)=...=y(23)= y(24)=1$.

Recursive definition of subsequent symbols:

$x_n(i+25) =x_n(i+3) + x_n(i)$ modulo 2, $i=0,..., 2^{25}-27$.
$y(i+25) = y(i+3)+y(i+2) +y(i+1) +y(i)$ modulo 2, $i=0,..., 225-27$.

Define the binary Gold sequence Z_n by:

$z_n(i) = x_n(i) + y(i)$ modulo 2, $(i = 0, 1, 2, ..., 2^{25}-2)$.

The real valued Gold sequence Z_n is defined by:

$$Z_n(i) = \begin{cases} +1 \text{ if } Z_n(i) = 0 \\ \\ -1 \text{ if } Z_n(i) = 1 \end{cases} \qquad \text{for } i = 0,1,...,2^{25}-2$$

Now, the real-valued long scrambling sequences $C_{long,1,n}$ and $C_{long,2,n}$ are defined as follows:

$C_{long,1,n}(i) = Z_n(i)$, $(i = 0, 1, 2, ..., 2^{25}-2)$
$C_{long,2,n}(i) = Z_n((i + 16777232)$ modulo $(2^{25}-1))$, $i = 0, 1, 2, ..., 2^{25}-2$.

Finally, the complex-valued long scrambling sequence $C_{long,\,n}$, is defined as:

$$C_{long,n}(i) = Z_{long.1,n}(i)\ (1 + j(-1)^i\ C_{long,2,n}(2\lfloor \frac{i}{2} \rfloor))\ ,\quad i = 0, 1,..., 2^{25}-2$$

Figure 26-166 illustrates the Uplink scrambling sequence generator:

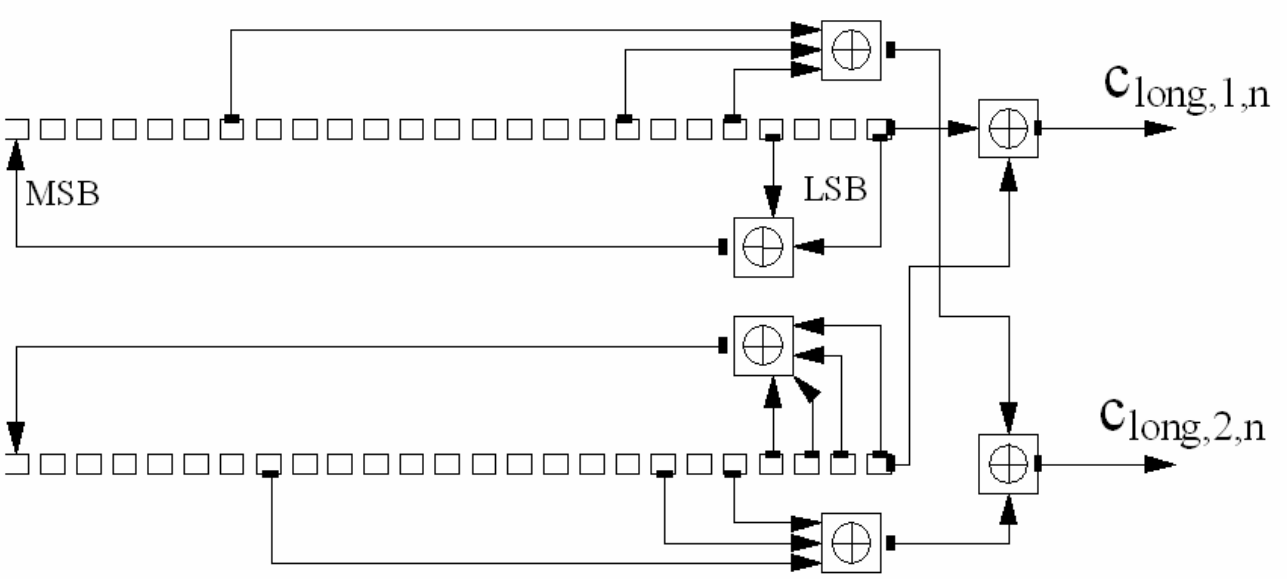

Figure 26-166. Configuration of the Uplink Long Scrambling Sequence Generator

26.4.3.8.2.2.2 Short Complex Scrambling Codes Generation

The short scrambling sequences $C_{short,1,n}(i)$ and $C_{short,2,n}(i)$ are defined from a sequence from the family of periodically extended *S(2)* codes.

PN_NUM[23:0] is the 24 bit binary representation of the code number n.

The n_{th} quaternary *S(2)* sequence $Z_n(i)$, 0 <= n <= 16777215, is obtained by modulo 4 addition of three sequences, a quaternary sequence *a(i)* and two binary sequences *b(i)* and *d(i)*, where the initial loading of the three sequences is determined from the code number n.

The sequence $Z_n(i)$ of length 255 is generated according to the following relation:

$$Z_n(i) = a(i) + 2b(i) + 2d(i)\ \text{modulo}\ 4,\ i = 0, 1,..., 254$$

The quaternary sequence *a(i)* is generated recursively by the polynomial

$$g0(x) = x^8+3x^5+x^3+3x^2+2x+3$$

as:

$$a(0) = 2 * PN\_NUM[0] + 1\ \text{modulo}\ 4$$
$$a(i) = 2 * PN\_NUM[i]\ \text{modulo}\ 4,\ i = 1, 2,..., 7$$
$$a(i) = 3a(i-3) + a(i-5) + 3a(i-6) + 2a(i-7) + 3a(i-8)\ \text{modulo}\ 4,\ i = 8, 9,..., 254$$

The binary sequence *b(i)* is generated recursively by the polynomial

$$g1(x) = x^8+x^7+x^5+x+1$$

as:

```
b(i) = PN_NUM[8+i] modulo 2, i = 0, 1,..., 7
b(i) = b(i-1) + b(i-3) + b(i-7) + b(i-8) modulo 2, i = 8, 9,..., 254
```

The binary sequence *d(i)* is generated recursively by the polynomial

$g2(x) = x^8+x^7+x^5+x^4+1$

as:

```
d(i) = PN_NUM[16+i] modulo 2, i = 0, 1,..., 7
d(i) = d(i-1) + d(i-3) + d(i-4) + d(i-8) modulo 2, i = 8, 9, ..., 254
```

The sequence $Z_n(i)$ is extended to length 256 chips by setting $Z_n(255) = Z_n(0)$.

Table 26-124 describes the mapping from $Z_n(i)$ to the real-valued binary sequences $C_{short,1,n}(i)$ and $C_{short,2,n}(i)$, i = 0, 1,..., 255

Table 26-124. Mapping from $Z_n(i)$ to $C_{short,1,n}(i)$ and $C_{short,2,n}(i)$

$Z_n(i)$	$C_{short,1,n}(i)$	$C_{short,2,n}(i)$
0	+1	+1
1	-1	+1
2	-1	-1
3	+1	-1

Finally, the complex-valued short scrambling sequence $C_{short,n}$, is defined as:

$$C_{short,n}(i) = C_{short.1,n}(i \bmod 256)\ (1 + j(-1)^i\ C_{short,2,n}(2\lfloor \frac{i \bmod 256}{2} \rfloor))\ ,\quad i = 0,1,2,...$$

Figure 26-167 illustrates the implementation of the short scrambling sequence generator for the 255 chip sequence to be extended by one chip.

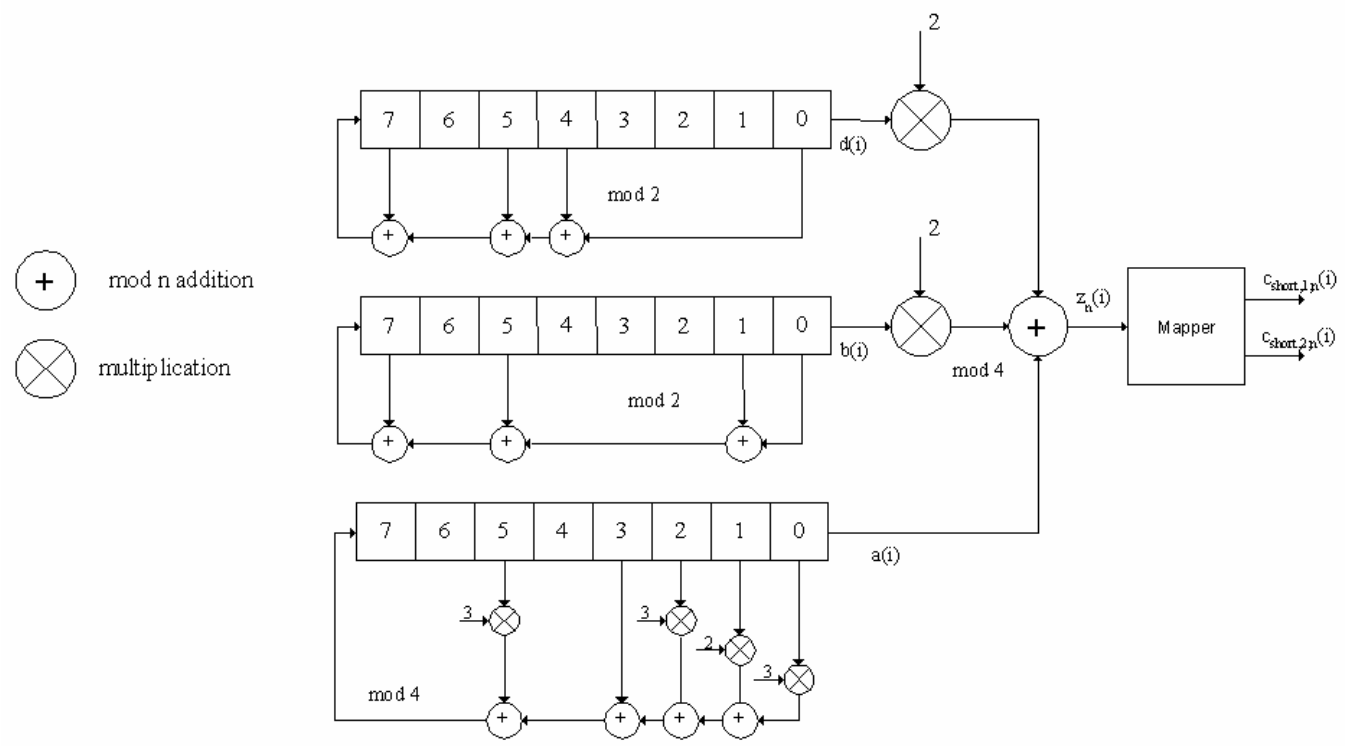

Figure 26-167. Uplink Short Scrambling Sequence Generator for 255 Chips

26.4.3.8.2.3 Downlink Scrambling Codes Generation

Configure the CGPE to generate downlink code by resetting the *UL_CODE* field of the CGPE BD (*UL_CODE* = 0).

The sequence of complex valued chips are scrambled (complex chip-wise multiplication) by a complex-valued scrambling code $S_{dl,n}$.

The scrambling code sequences are constructed by combining two real sequences into a complex sequence.

Each of the two real sequences are constructed as the position wise modulo 2 sum of 38400 chip segments of two binary m sequences generated by means of two generator polynomials of degree 18.

Let x and y be the two sequences respectively.

The x sequence is constructed using the primitive (over GF(2)) polynomial:

$1+X^7+X^{18}$.

The y sequence is constructed using the polynomial:

$1+X^5+X^7+ X^{10}+X^{18}$.

The sequence depending on the chosen scrambling code number n is denoted Z_n, in the sequel. Furthermore, let *x(i)*, *y(i)* and $Z_n(i)$ denote the i_{th} symbol of the sequence x, y, and Z_n, respectively.

The m-sequences x and y are constructed as:

Initial conditions:

$x(0)=1,\ x(1)=x(2)=\ldots=x(16)=x(17)=0.$

$y(0)=y(1)=\ldots=y(16)=y(17)=1.$

Recursive definition of subsequent symbols:

$x(i+18) = x(i+7) + x(i) \text{ modulo } 2,\ i=0,\ \ldots,\ 2^{18}-20.$

$y(i+18) = y(i+10)+y(i+7)+y(i+5)+y(i) \text{ modulo } 2,\ i=0,\ldots,\ 2^{18}-20.$

The n_{th} Gold code sequence Z_n, n=0,1,2,...,2^{18}-2, is then defined as:

$Z_n(i) = x((i+n) \text{ modulo } (2^{18}-1)) + y(i) \text{ modulo } 2,\ i=0,\ldots,\ 2^{18}-2.$

These binary sequences are converted to real valued sequences Z_n by the following transformation:

$$Z_n(i) = \begin{cases} +1 & \text{if } Z_n(i) = 0 \\ -1 & \text{if } Z_n(i) = 1 \end{cases} \quad \text{for } i = 0,1,\ldots,2^{18}-2$$

Finally, the n_{th} complex scrambling code sequence $S_{dl,n}$ is defined as:

$S_{dl,n}(i) = Z_n(i) + j\ Z_n((i+131072) \text{ modulo } (2^{18}-1)),\ i=0,1,\ldots,38399.$

Note that the pattern from phase 0 up to the phase of 38399 is repeated.

Figure 26-168 describe the Downlink Scrambling Code Generation.

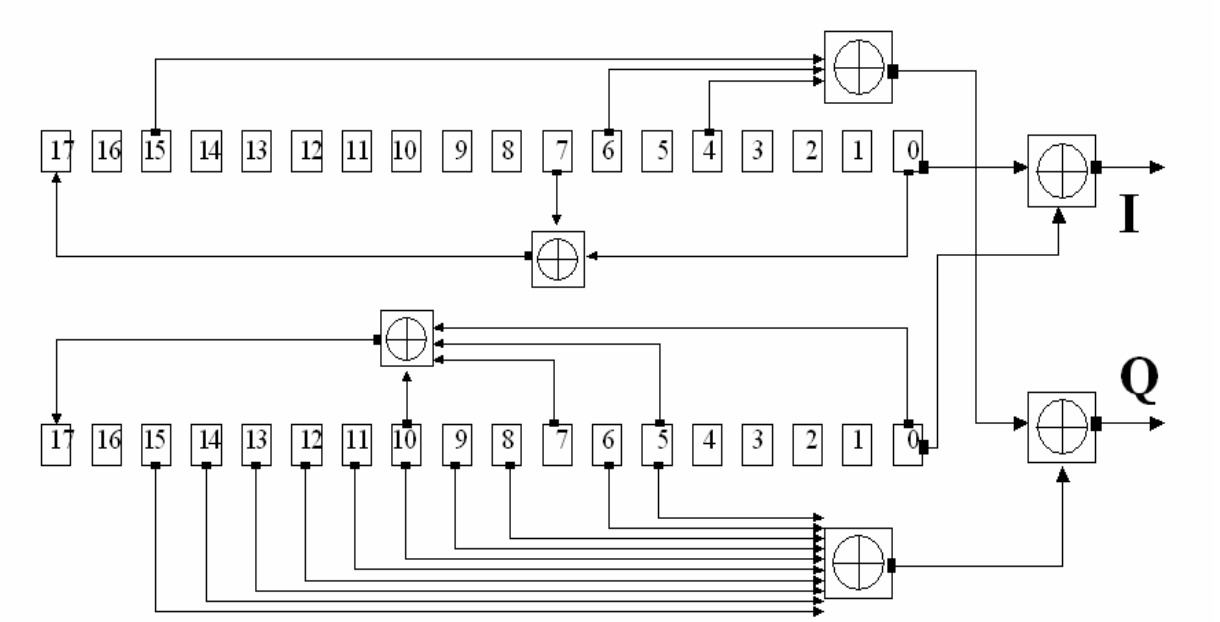

Figure 26-168. Configuration of Downlink Scrambling Code Generation

26.4.3.8.2.4 Code Generation Offset

The CGPE support generating code starting at any offset in the frame. This allows generating the scrambling code in portions where for each portion all which is required is to set the chip offset of the frame. The CG in return calculates internally the initial state for the given chip offset and generates the code starting the calculated initial state.

Controlling the chip offset for each CGPE job is done by setting the *START_OFFSET* field of the CGPE BD. The *START_OFFSET* field represent Sub-Slot alignment (256 chips alignment).

26.4.3.8.3 Output Data Structure

The CGPE support two types of generated output codes:

1. Each I and Q pair are represented by a pair of bits. A 128 bits of generated code include 64 such pairs.
2. Each I and Q pair are represented by 16 bits (8 bits I, and 8 bits Q). A 128 bits of generated code include 8 such pairs.

In case 16 bits representation for I,Q pair is chosen, it is up to the host to set the values of the 8 bits ‘0’ representation and 8 bits ‘1’ representation.

Controlling the generated code output type is done by setting the *OUT_MODE* field of the CGPE BD. If 16 bits representation for I,Q pair is chosen, the *CFG_VAL_0* and *CFG_VAL_1* fields of the CGPE BD determines the values to represent ‘0’ and ‘1’ respectively.

The CGPE also supports conjugating the output results. By setting the *CONJ_EN* bit of the CGPE BD, the output results is conjugated.

The size of the generated code is determined by the *CODE_SIZE* field of the CGPE BD. Its value (plus 1) represent the amount of 128 bits chunks to be generated by the CGPE. For example a value 5 indicates that the generated code size is: (5+1)*128 = 768 bits.

The generated code is placed (by MAPLE-B2) in the system memory in the address pointed by the *CODE_RSLT_PTR* field of the CRPE BD.

Figure 26-169 describe two examples of the output results of the CGPE per given BD configuration:

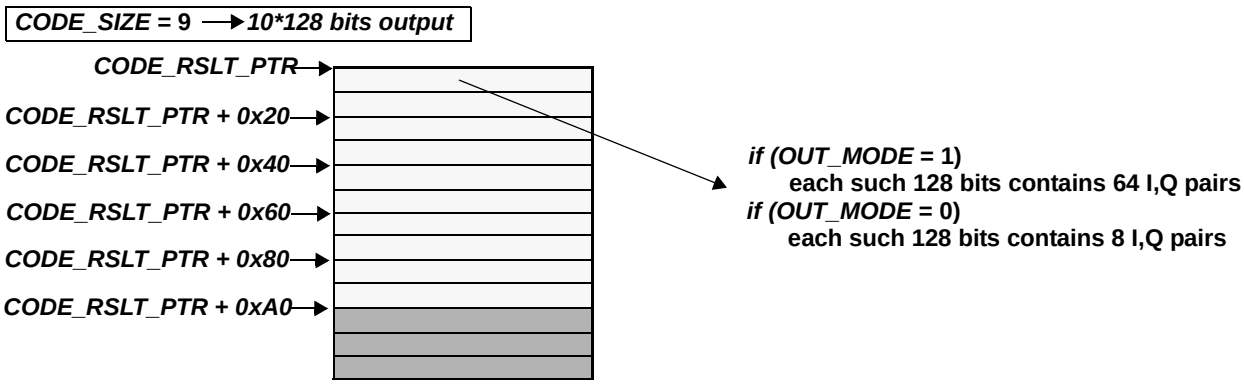

Figure 26-169. CGPE Output Data Structure Examples

26.4.3.9 CONVPE Convolution and Correlation Processing Operation

The MAPLE-B2 supports convolution and correlation tasks with implementation in frequency domain. This is done using the virtual processing element CONVPE. The CONVPE is an abstracted element which combines Fourier Transforms, Multiply/Accumulate, and associated control utilizing the following:

- 3 eFTPE engines.
- FDU logic (dedicated logic located in the EQPE block and utilizing its memory. See **Section 26.4.3.5.7**, *CONVPE Support—FDU Processing*, on page 26-186).
- Internal DMA
- RISC engines.
- MBus DMAs

A data flow diagram of CONVPE processing shown in **Figure 26-170**:

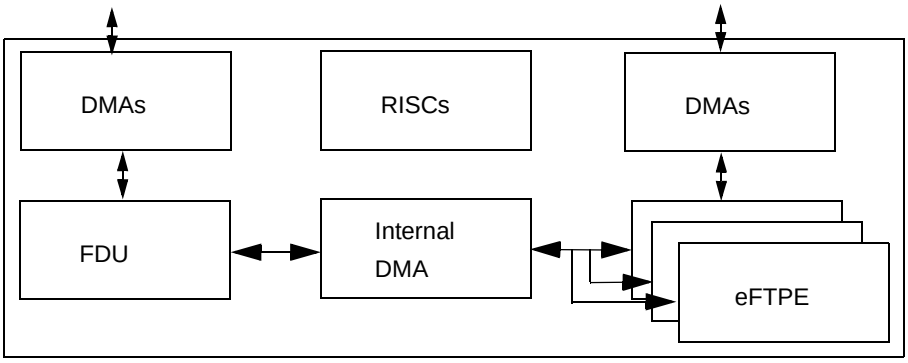

Figure 26-170. CONVPE Data Flow

Main processing flow of CONVPE based on FFT followed by Multiply-Accumulate functionality executed in FDU unit and followed by IFFT. First portion of the data flow is optional, and data streams which are available in frequency domain from system memory can be

fetched by the MAPLE-B2 system DMAs directly into FDU memories omitting this way portions of FFT processing.

26.4.3.9.1 CONVPE Programming

The CONVPE programming is based on Buffer Descriptors (BDs) that are populated with high level task parameters. These parameters include a pointer to a detailed Task Descriptor (TD) which is located in system memory. The high level tasks parameters embedded in the CONVPE BDs are minimized to the information required for task scheduling aspects and description of the TD type, location and size. **Figure 26-171** depicts this concept.

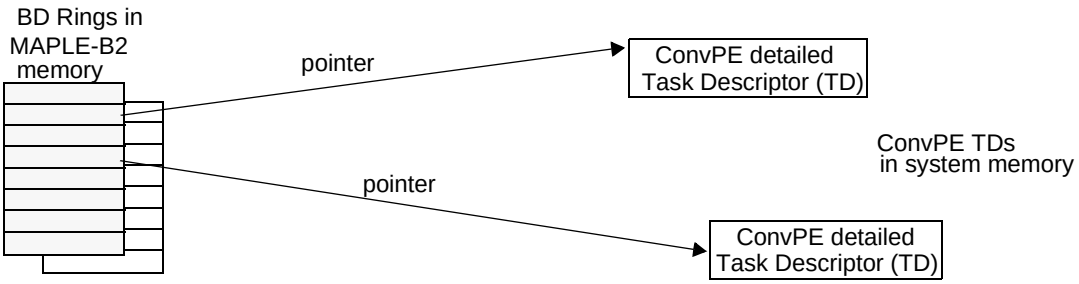

Figure 26-171. CONVPE Task Descriptors Concept

26.4.3.9.1.1 CONVPE Buffer Descriptor Structure

Section 26.5.4.9, *CONVPE Buffer Descriptor Structure*, on page 26-490 contains a detailed description of the CONVPE Buffer Descriptors structure as it should be written to the CONVPE BD rings by the host.

26.4.3.9.1.2 CONVPE Detailed Tasks Descriptors

The following sections describe in details each of the possible tasks as described in the *TASK_TYPE* field of the CONVPE BD.

26.4.3.9.1.3 RACH Preamble Correlations Task Description

The UMTS RACH task performs correlations between RACH preamble signatures and antenna data diversity branches. Number of RACH signatures and number of antenna data diversity branches are parameters of the task which can be configured by the host. In addition, coherent correlation window size and data overlaps for frequency domain correlation implementation are parameters that provide the user-required flexibility for this task. **Section 26.5.4.10**, *CONVPE RACH Preamble Correlations Task Descriptor*, on page 26-491 provides a detailed description of the Task Descriptor (TD) layout used for RACH Preamble Correlation.

The RACH correlation task is performed on a data stream with overlaps due to nature of frequency domain implementation. The overlap size is typically defined based on Base Station deployment cell radius. **Figure 26-172** demonstrates and example of correlation task with the relevant parameters

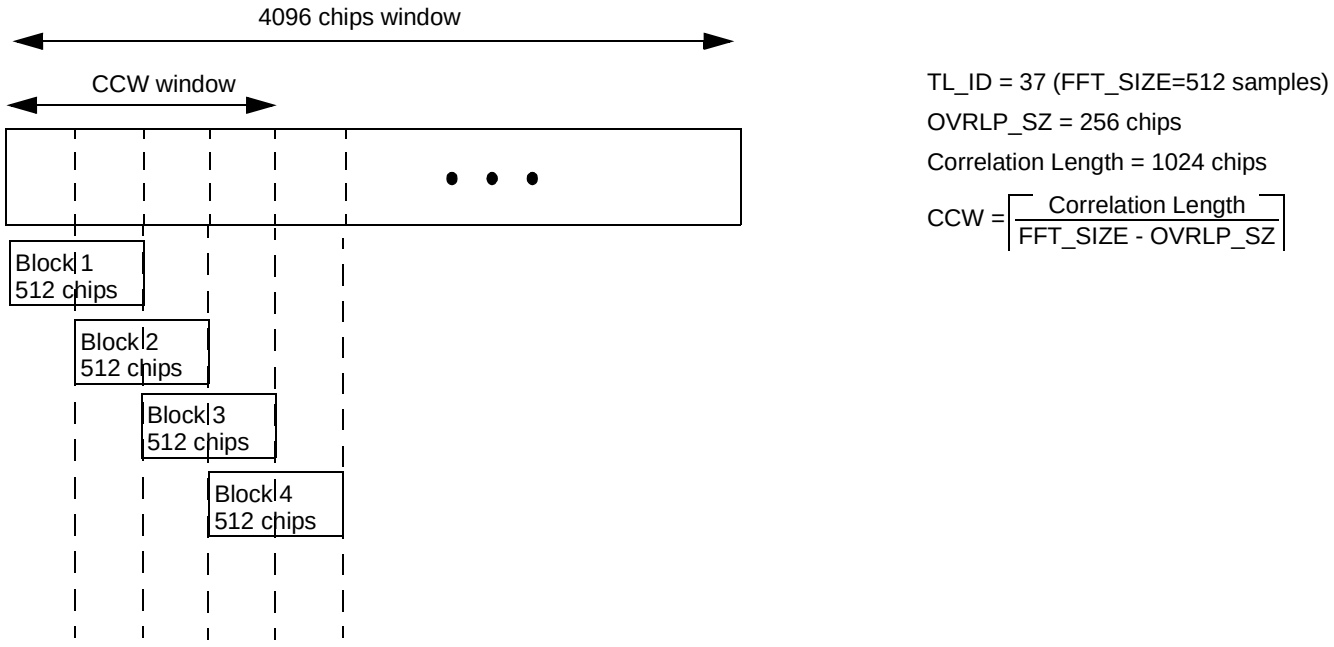

Figure 26-172. RACH Correlation Task Input Data Parameters

26.4.3.9.1.3.1 RACH Preamble Task Limitations

The following configuration limitation applies to the RACH preamble correlation task:

```
BLOCKS_NUM = Sum(SIGN_INDX[i]) x ANT_DIV_BCH ; i = 0,...,15
BLOCK_SIZE = 4 x FFT_SIZE[TL_ID] ; //FFT_SIZE is the number of samples in the FFT transform
1) CCW x BLOCK_SIZE x ANT_DIV_BCH /2 ≤ 16384
2) if (BLOCKS_NUM > 4)
     if ((BLOCKS_NUM-1)%8 ≥ 4)
          (Ceiling(BLOCKS_NUM/8)+1) x BLOCK_SIZE ≤ 12288
     else
          Ceiling(BLOCKS_NUM/8) x BLOCK_SIZE ≤ 12288
```

Following is an example of a valid task:

- Task's parameters:
  - *TL_ID* = 37 (FFT_SIZE=512)
  - *ANT_DIV_BCH* = 2
  - *SING_INDX* = 0x0351
  - *CCW* = 8
- Calculations:
  - BLOCKS_NUM = 5 x 2 = 10
  - BLOCK_SIZE = 4 x 512 = 2048

- Limitations check:
  - 1) 8 x 2048 x 2 / 2 = 16384 ≤ 16384
  - 2) (10 > 4) ==> ((10 - 1) % 8 < 4) ==> Ceiling(10/8) x 2048 = 4096 ≤ 12288

26.4.3.9.1.3.2 RACH Preamble Input Data Structure - Antenna data

The input antenna data can be in frequency or in time domain. The data structure is based on a continuos buffer with start address and constant offset between data vectors. Based on the *ANT_FD* field, the data vector consists of chips in time domain with 8 bit I, 8 bit Q representation (*ANT_FD* = 0) or in frequency domain with 16 bit I, 16 bit Q representation (*ANT_FD* = 1). For a given RACH CONVPE task the data structure can not be mixed between frequency and time domain representation. **Figure 26-173** shows an example of this data structure.

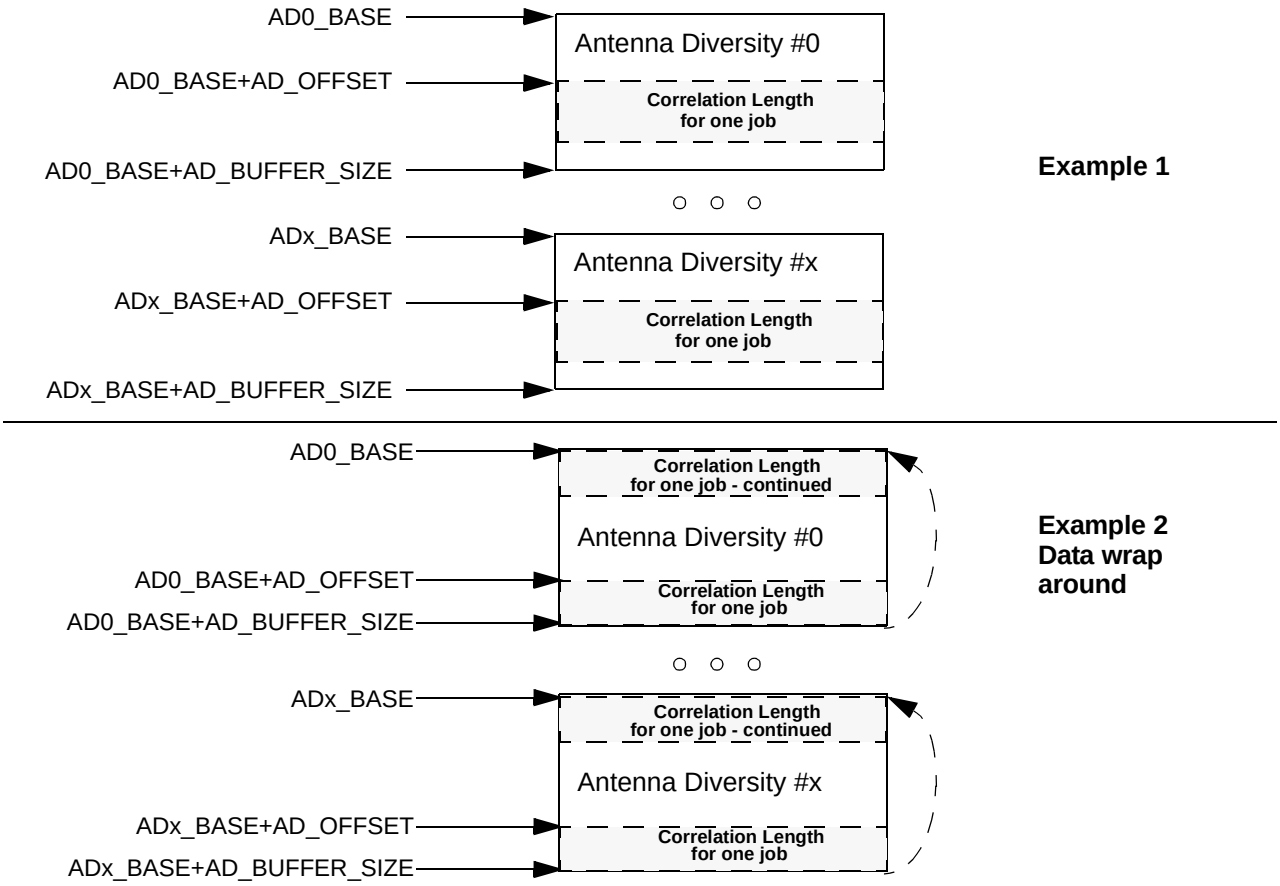

Figure 26-173. Input Antenna Data Structures

The base address *ADx_BASE* is 8 bytes aligned pointer in system memory. The offset is represented by a 32 bit word providing flexibility to allocation of the different antenna data in system memory. The order of antenna stream diversity branches is arbitrary selected by the host, and represents the order of the results located based on *CORR_RSLT_ADDR* base address.

If the input antenna data is available in the frequency domain, its representation should be in block floating point. The block floating point exponent per each diversity branch data vector is 8 bit wide representing a range of -127 to 128. The exponents are concatenated one after another and located at the address pointed by *AD_FD_SCALE_ADDR*.

26.4.3.9.1.3.3 RACH Preamble Input Data Structure - Signatures

The MAPLE-B2 expects the input signatures in frequency domain. These signatures should be generated in frequency domain prior to calling the RACH task with zero padding equals the overlap size (*OVRLP_SZ*) of the RACH task per frequency domain block. **Figure 26-174** shows the signatures expected data structure in system memory. The signatures are located based on *SIGN_ADDR* field. Signatures relevant to the specific RACH job are indicated by *SIGN_INDX* field. Every bit which in *SIGN_INDX* field represents one of 16 different signatures in use if bit is set.

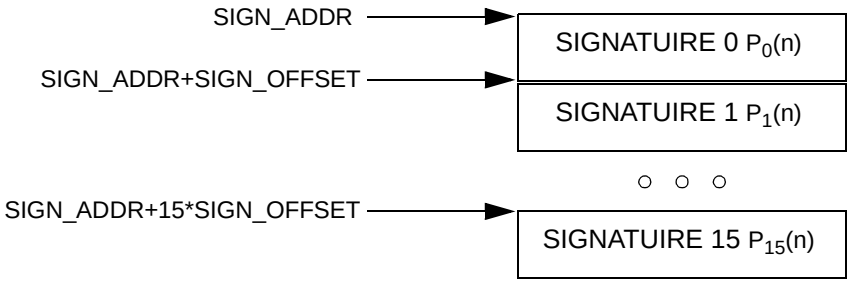

Figure 26-174. Signatures Data Structure in system memory

26.4.3.9.1.3.4 RACH Preamble Output Data Structure

Figure 26-175 shows the structure of the results as placed in system memory. RACH preamble correlation results are located in system memory based on *CORR_RSLT_ADDR*.

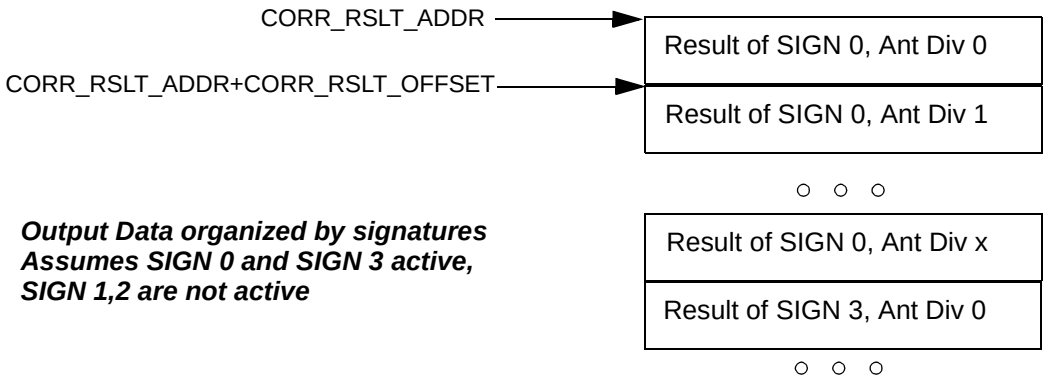

Figure 26-175. RACH Preamble Correlation Results Data Structure in system memory

The correlation results per antenna diversities for each signature are in the same order as the antenna diversities inputs. The size of each result vector is based on the Overlap Size (*OVRLP_SZ)* field. Results are represented in 16I, 16Q format, thus results are offset from each other by 4*[IFFT Transform Length] bytes.

If the antenna data is input to the CONVPE RACH preamble correlations task in the time domain (*ANT_FD* = 0), and the frequency domain antenna data is required in system memory for future tasks, *ANT_FFT_WBE* field should be set. In that case the MAPLE-B2 outputs the frequency domain antenna data into system memory. These frequency domain antenna data results are written to address as described in the *ANT_DATA_FD_ADDR* pointer and are organized in the same order as the input data. The output results data structure is based on 16I,16Q values with block floating point exponent located based on *AD_FD_SCALE_ADDR* pointer with 8 bit exponent for each FFT segment. The following figure describe the frequency domain antenna diversities outputs:

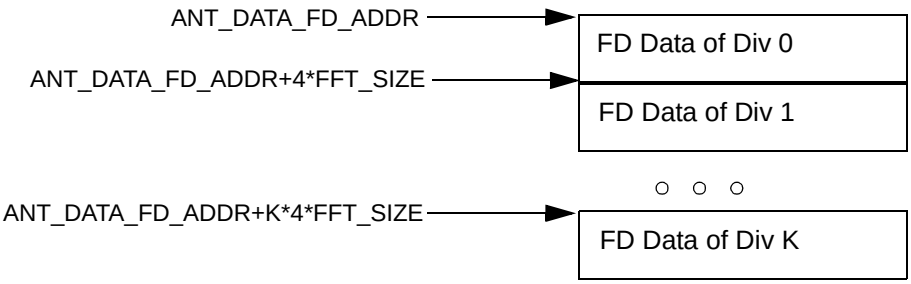

Figure 26-176. Antenna Data optional outputs in Freq. domain example for RACH task

Note: If the input data for CONVPE RACH preamble correlation task is already in frequency domain, *ANT_DATA_FD_ADDR* pointer and respective data structure are not used. The input data in frequency domain should be based on *AD_BASE* pointer and relative data structure as shown in **Figure 26-173**.

26.4.3.9.1.4 Path Searcher Correlations Descriptor

The MAPLE -B2 executes Path Searcher correlations in frequency domain utilizing CONVPE functionality. The correlations are performed between antenna diversity branches and pilot sequences per user. The correlation is performed on maximum coherent window equivalent to one radio slot.

The pilot sequences are generated, by the CONVPE, in time domain and transformed to frequency domain as part of the correlation task. Per user parameters of scrambling sequence, type of code, frequency correction parameters, slot format and offsets are supplied as part of the CONVPE Path Searcher task.

The task is executed with multiple antenna diversities over number of users in a single descriptor. Thus, the descriptor contains two portions, first portion is task generic, with shared information for all users. This portion describes the antenna data and correlation parameters. The second portion is user specific, which defines the per-user parameters of the task, focusing on scrambling sequence, slot format, offsets and frequency correction parameters. Path search of up to 16 users can be executed in a single task.

Section 26.5.4.11, *CONVPE Path Searcher Task Descriptor*, on page 26-495 has a detailed description of the CONVPE UMTS Path searcher task fields as they should be written by the host in system memory pointed by the CONVPE Buffer Descriptor *TASK_ADDR* field.

26.4.3.9.1.4.1 CONVPE Path Search Task limitations

The following configuration limitation applies to the Path Search correlation task:

```
BLOCKS_NUM = (NUSERS+1) x ANT_DIV_BCH ;
BLOCK_SIZE = 4 x FFT_SIZE[TL_ID] ; //FFT_SIZE is the number of samples in the FFT transform
1) CCW x BLOCK_SIZE x ANT_DIV_BCH / 2 ≤ 16384
2) if (BLOCKS_NUM > 4)
     if ((BLOCKS_NUM-1)%8 ≥ 4)
          (Ceiling(BLOCKS_NUM/8)+1) x BLOCK_SIZE ≤ 12288
     else
          Ceiling(BLOCKS_NUM/8) x BLOCK_SIZE ≤ 12288
```

Following is an example of a valid task:

- Task’s parameters:
  - *TL_ID* = 37; // (FFT_SIZE=512)
  - *ANT_DIV_BCH* = 2;
  - *CCW* = 8;
  - *NUSERS* = 7
- Calculations:
  - BLOCKS_NUM = 8 x 2 = 16
  - BLOCK_SIZE = 4 x 512 = 2048
- Limitations check:
  - 1) 8 x 2048 x 2 / 2 = 16384 ≤ 16384
  - 2) (16 > 4) ==> (15%8 ≥ 4) ==> 3 x 2048 = 6144 ≤ 12288

Similar to RACH preamble correlations, input antenna data can be in frequency or in time domain. For details of the data structure see **Figure 26-173**.

CONVPE generates internally the pilot sequences in frequency domain, using the scrambling code of long or short type based on *LS* filed of task descriptor.

Path searcher correlation results are located in system memory based on the *U_CORR_RSLT_ADDR* field of the Task Descriptor. The results are located in consecutive form

in the same order as input data. Details of this data structure are shown in **Figure 26-175**, but instead of per-signature data structure, it is organized on per-user basis.

The size of each result vector is based on the overlap size (*OVRLP_SZ* field). Results are represented in 16I, 16Q format, thus results are offset from each other by 4**OVRLP_SZ* bytes. The results include a scaling exponent per vector, which is located based on the *AD_FD_SCALE_ADDR* field.

26.4.3.9.2 FDU Processing

As part of CONVPE processing (see **Section 26.4.3.9**, *CONVPE Convolution and Correlation Processing Operation*), the EQPE includes a dedicated logic (FDU logic) which assists with vector multiplication processing. The FDU logic, which is not functional during Equalization processing (LNEQ, MLEQ, TS and MIV modes), is targeted for CONVPE processing assist only. As both Equalization logic and FDU logic share the same EQPE internal resources (memories), they cannot work in parallel, that is, the EQPE is either in FDU processing mode or Equalization processing mode.

The FDU logic cannot be directly controlled by the host therefore has no programming model interface of its own. It can only be controlled by MAPLE-B2 firmware as part of the CONVPE processing. The following sections describe the FDU logic processing and functionality.

26.4.3.9.2.1 FDU Operation

The FDU operation in the job is defined on vectors of samples where each sample in the vector is 4 bytes of size (16I,16Q) in 1Q15 representation. In addition, each vector has one scaling factor, the scaling factor is 8-bit signed.

The FDU includes the following main buffers for samples:

1. A buffer. Size: 8KByte.
2. B buffer. Size: 32KByte.
3. C buffer. Size: 96KByte.
4. Output Buffer. Size: 32KByte.

and the following buffers which holds Scale values:

1. A Scale buffer
2. B Scale buffer
3. C Scale buffer
4. Output Scale buffer

In general, the FDU executes vectors Multiply/Accumulate operations. The following figure describe the high level functionality of the FDU:

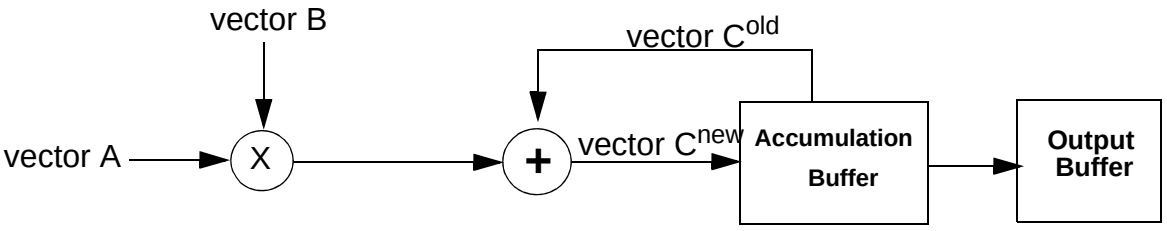

Figure 26-177. FDU High Level Functionality

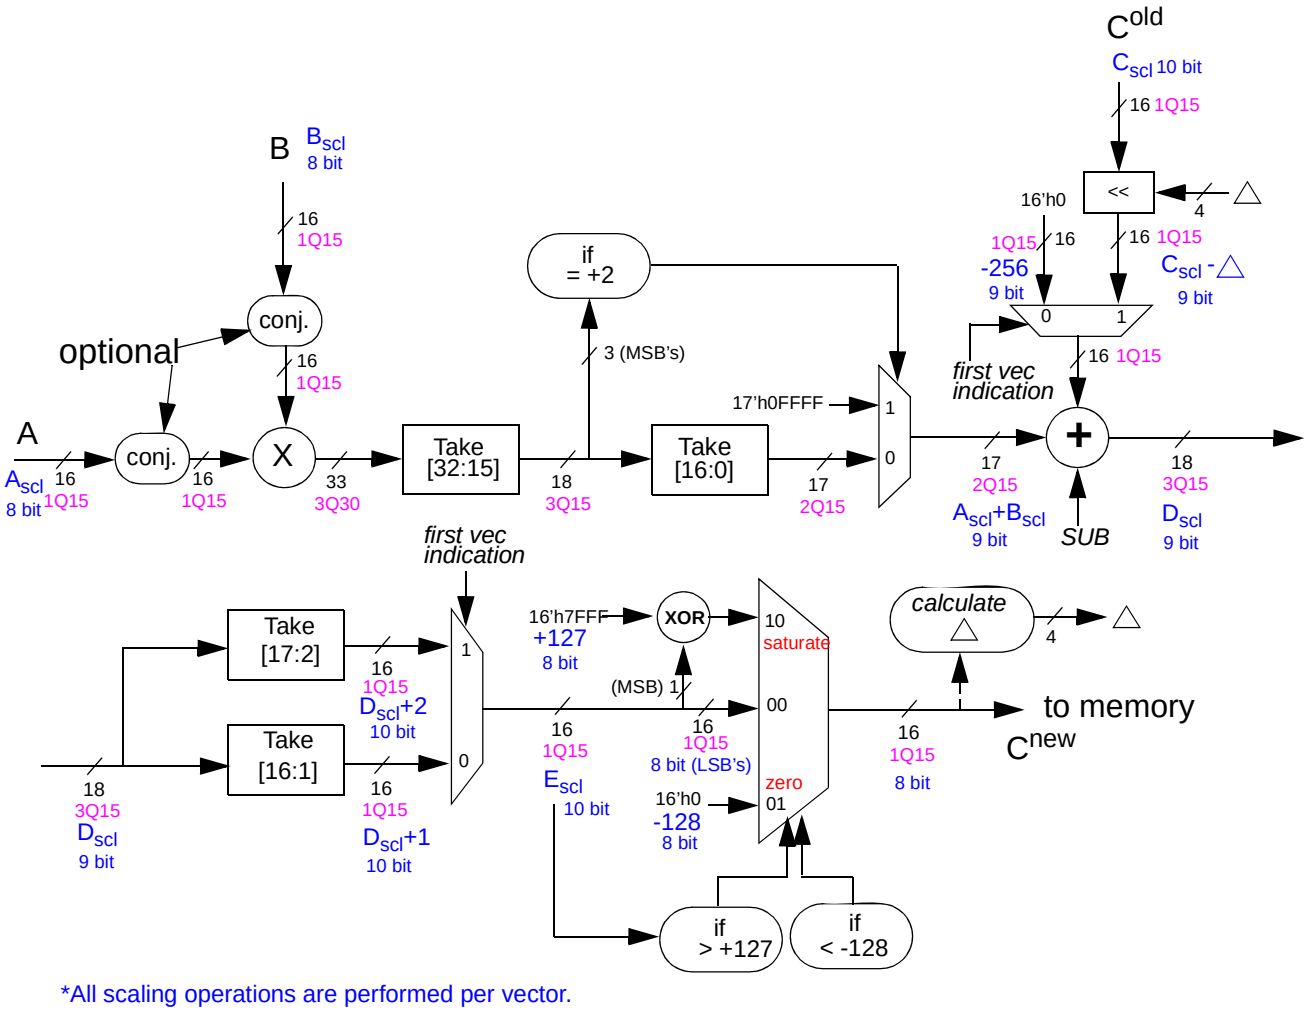
In addition to the basic functionality described in **Figure 26-177**, the FDU supports the following:

— Optional conjugation operation on A input vector or/and B input vector
— Optional subtraction operation instead of accumulate, that is, $C^{new} = A \times B - C^{old}$
— Saturation of overflown samples.

26.4.3.9.2.2 FDU Arithmetic Scheme

The FDU operates in block floating point arithmetic, which includes one scaling factor for each vector. The FDU detailed calculation implementation is described in **Figure 26-178**.



*All scaling operations are performed per vector.

Figure 26-178. FDU Calculation Implementation[1]

During the writing of the C^{new} samples to the memory, the FDU gathers statistics on the mantissa to locate the position of the leading '1' of the samples - this is called 'delta' sample (△) and it represents the number of shift-left operations that can be performed on the data without overflow. When the block is finished, the FDU writes the delta sample, to the delta buffer. This delta value is then used to adaptively scale up the mantissa to gain maximum precision.

Each delta samples is 8-bits with values 0-15.

1. The illustration describes the calculation when MODE=0, when MODE=1 the calculation is identical with B/C vectors are in opposite places.

26.4.3.9.2.3 FDU Scaling

The FDU performs block-floating-point arithmetic and therefore requires and produces one scaling factor for each vector. The FDU should get 2 types of scaling factors: A scaling factor and B scaling factor. On FDU processing completion the C scaling factor is available for further processing. As the FDU is capable of working on multiple vectors each of the scale values is kept in a dedicated buffer which can hold multiple values as per FDU requirements.

26.4.4 External Masters Support Using Serial RapidIO Doorbell

The MAPLE-B2 is capable of working with masters external to its DSP device, using the Serial RapidIO interface.

26.4.4.1 Serial RapidIO Doorbell Parameters Configuration

If an external master, which is connected via the Serial RapidIO port, wishes to master the MAPLE-B2, the following parameters must be initialized:

- **M<pe>[1]BR(H/L)PBxP[HOST_ID]**—16-bit parameter Host ID used by MAPLE-B2 for WORD3[EDID:DID] fields in the Type10 Outbound Doorbell Descriptor in the eMSG unit. For details, see **Section 16.3.9.1,** *Type10 Outbound Doorbell Descriptor Format*.
- **M<pe>BR(H/L)PBxP[P_TR_IF]**—4-bit parameter for the Port Target Interface for RapidIO Ports 1 and 2. This field is used by the MAPLE-B2 for the WORD4[TINT] field in the Type10 Outbound Doorbell Descriptor in the eMSG unit. For details, see **Section 16.3.9.1,** *Type10 Outbound Doorbell Descriptor Format*.
- **M<pe>BR(H/L)PBxP[EXT_MST]**—2 bit parameter which describes whether the MAPLE-B2's current ring's master is connected directly to one of the MAPLE-B2's regular interrupt lines or the ring's master is external and connected to the DSP device via the Serial RapidIO port.
- **HSPxBAP[BA]**—32 bit address which describes the address of the Hardware Semaphore used when trying to accesses the Serial RapidIO Doorbell controller. It is valid only if HSPxBAP[HS_EN] is set.
- **HSPxBAP[HS_EN]**—1 bit parameter which describes for the MAPLE-B2 whether it should use the Hardware Semaphore register when accessing the Doorbell controller. The bit should be set only if there are other possible masters on the Doorbell controller beside the MAPLE-B2. This feature is added to avoid any coherency problems due to multiple masters accessing simultaneously to a Doorbell controller.
- **MDHSIDCP[TV_HS_ID]**—8 bit parameter of eTVPE External Hardware Semaphore ID, used by the MAPLE-B2 when accessing the Hardware Semaphore register for eTVPE doorbell generation.

1. <pe> stands for TV, FF or DF.

- **MDHSIDCP[DF_HS_ID]**—8 bit parameter of DFTPE External Hardware Semaphore ID, used by the MAPLE-B2 when accessing the Hardware Semaphore register for DFTPE doorbell generation.
- **MDHSIDCP[FF_HS_ID]**—8 bit parameter of FFTPE External Hardware Semaphore ID, used by the MAPLE-B2 when accessing the Hardware Semaphore register for FFTPE doorbell generation.
- **MDGCP[BD_PR]**—2 bit parameter field used by the MAPLE-B2 to set the doorbell transaction priority in WORD4[FLOWLVL] field in the Type10 Outbound Doorbell Descriptor in the eMSG unit. For details, see **Section 16.3.9.1,** *Type10 Outbound Doorbell Descriptor Format*.
- **MDGCP[RET]**—8 bit parameter which is used by the MAPLE-B2 for the WORD0[RETRY] field in the Type10 Outbound Doorbell Descriptor in the eMSG unit. For details, see **Section 16.3.9.1,** *Type10 Outbound Doorbell Descriptor Format*. The *RET* field determines the number of times the doorbell controller attempts to transmit the doorbell.

Figure 26-179 describes a possible multiple DSP device system with Serial RapidIO connectivity:

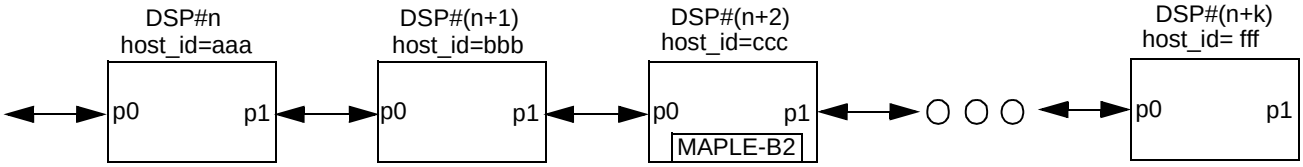


Figure 26-179. Possible Multiple DSP device Platform Connectivity

The example in **Figure 26-179** describes a possible platform with one DSP device containing an active MAPLE-B2 which is mastered by an external master located in any of the other DSP devices. If a master in DSP#n needs to master a BD ring in the MAPLE-B2 of DSP#(n+2), the values of the relevant parameters should be:

- *MBDR(H/L)PBxP[HOST_ID] = 0xaaa*. The host_id value of DSP#n
- *MBDR(H/L)PBxP[P_TR_IF] = 0x0*. The port target interface is RapidIO Port 1.
- *MBDR(H/L)PBxP[EXT_MST] = 0x1*. This parameter directs MAPLE-B2 to the door-bell controller of RapidIO Port 1 of the DSP.

If the MAPLE-B2 in Soc#(n+2) is not the only master for Doorbells, then:

- *HSP0BAP[HS_EN] = '1'*. This assures that whenever the MAPLE-B2 (or any other master in the DSP device) wishes to access the Doorbell controller, it first must lock the Semaphore, thus avoiding any coherency problem.
- *HSP0BSP[BA]* must be initialized with the address of the HS register to be used when trying to use the Doorbell.

- *MDHSIDCP[TV_HS_ID] = 0xA0*. User definition. Describes the MAPLE-B2's ID when accessing the Semaphore register for eTVPE rings.
- *MDHSIDCP[DF_HS_ID] = 0xA1*. User definition. Describes the MAPLE-B2's ID when accessing the Semaphore register for DFTPE rings.
- *MDHSIDCP[FF_HS_ID] = 0xA2*. User definition. Describes the MAPLE-B2's ID when accessing the Semaphore register for FFTPE rings.
- *MDGCP[BD_PR] =0x1*. Describes the transaction priority level. Written by MAPLE-B2 into WORD4[FLOWLVL] field in the Type10 Outbound Doorbell Descriptor.
- *MDGCP[RET] = 0x5*. User definition. Describes the number of times the message processor tries to re-send the Doorbell before asserting its interrupt. Written by MAPLE-B2 into the WORD0[RETRY] field in the Type10 Outbound Doorbell Descriptor.

Note: If the *HSP0BAP[HS_EN] = '0'*, that is, the MAPLE-B2 is the only doorbell master and therefore there is no need for external Semaphore, the MAPLE-B2 implements an internal semaphore to avoid contention between its internal RISC engines. This internal semaphore implementation requires no user configuration.

26.4.4.2 Operation Flow

Once the relevant parameters are configured to support an external host (BDR parameters, and Serial RapidIO parameters), the following flow should be maintained by the external host:

1. Place all input data related to the new jobs for the MAPLE-B2 in a system memory that is memory mapped with respect to the MAPLE-B2. The MAPLE-B2 can fetch its data only from its mapped system memory.
2. Place the new BDs in the external master's BD ring in MAPLE-B2 internal memory.

Upon job completion, the MAPLE-B2 outputs the relevant data to the system memory; and if the [INT_EN] bit in the BD is set, the MAPLE-B2 initiates a Doorbell interrupt. The following flow describes the MAPLE-B2's actual accesses on the MBus interface to issue a Doorbell interrupt and assumes the above parameters are configured:

- If *HSPxBAP[HS_EN]* is set:
  - Write access to the External HS register in address *HSPxBSP[BA]* and the data is *MDHSIDCP['pe'_HS_ID]* according to the PE.
  - Read access from the External HS reg in address *HSPxBSP[BA]*. If the read data equals *MDHSIDCP['pe'_HS_ID]*, then the Semaphore is locked for the PE, else MAPLE-B2 return to previous stage.
- Read access to Message Unit Status Register (MUSR). If the OMUB field is cleared, then the outbound message unit is not busy and the MAPLE-B2 can continue. If OMUB is set, MAPLE-B2 continues polling the field until it is cleared.

- Create the 32-byte outbound doorbell descriptor:
  - Set the descriptor type select field FTYPE=0b1010 to indicate doorbell type.
  - Set the retry field to indicate number or times the message unit should attempt to retry the doorbell before stopping.
  - Allocate buffer for the doorbell descriptor from one of the buffer pools available, preferable with the smallest buffer size (that is, 64-bytes).
  - For all other fields, see **Section 16.3.9.1,** *Type10 Outbound Doorbell Descriptor Format*
- Add the doorbell descriptor to a command descriptor and set FTYPE=0b1010 to indicate doorbell type.
- Enqueue the command descriptor onto the message queue.
- The message unit releases buffers used by the producer to hold the doorbell descriptor and data payload when the operation completes; if the buffer release bit (BR) is set in the message descriptor.

On doorbell operation completion, the doorbell controller interrupts the MAPLE-B2, which in turn, accesses the *MUSR* for completion status. The possible doorbell completion reasons are:

- Done response received: operation completed with no errors.
- Error response received: operation completed with error.
- Packet response time-out occurred: operation completed with error.
- The retry limit was exceeded: operation completed with error.

On doorbell completion interrupt assertion, the MAPLE-B2 performs the following:

1. Read access from the *MUSR*.
2. If *MUSR* status shows that the outbound message unit is idle (MUSR[OMUB]=0) and External HS is enabled (*HSPxBAP[HS_EN]* is set) then the MAPLE-B2 generates write access to External HS register with the *MDHSIDCP[‘pe’_HS_ID]* data to release the External HS.
3. If the MUIER[OTE] bit is set, the MAPLE-B2 asserts its general error interrupt and if the External HS is enabled (*HSPxBAP[HS_EN]* is set) then the MAPLE-B2 generates write access to External HS register with the *MDHSIDCP[‘pe’_HS_ID]* data to release the External HS.

Note: Generating Doorbell interrupts for every BD may cause a degradation in the MAPLE-B2 performance since it requires the MAPLE-B2 to configure a doorbell message Type10. If the controller is busy, the MAPLE-B2 waits until it is free to receive its Doorbell transmission configuration. Therefore, it is recommended to enable such doorbell interrupts only once in several BDs.

Note: The Doorbell interrupt does not cover all possible physical serial RapidIO errors. There are some additional errors indicated by a general serial RapidIO interrupt line. This interrupt line is not connected to the MAPLE-B2, thus cannot be detected by it.

26.4.5 MAPLE-B2 Internal Task Control

The MAPLE-B2 internal software programming is periodically rotatory, that is, after a BD completion it searches for the next BD; and if it fails to find a new BD, it hibernates for a time period as described in the MAPLE Timer Period Parameter (MP_TPP) and then starts a new search. There is no need for external intervention for the MAPLE-B2 to continuously process new BDs.

It is possible, though, to force the MAPLE-B2 to execute a certain routine. This is done using PSIF Command Register (PCR). By asserting the PCR[FLG] bit with the relevant PCR[opcode] field, the internal PSIF2 scheduler initiates a request to a RISC engine to execute one of the following routines:

- `MAPLE parse bd`. The MAPLE-B2 initiates the BD parse routines of all the PEs (eTVPE, FTPE_0, FTPE_1, FTPE_2, DEPE, EQPE, CONVPE and CRCPE), where each such routine scans the valid BD Rings of the relevant PE for a new valid BD to be execute.
- `Maple_parse_tvpe_bd`. The MAPLE-B2 initiates the eTVPE BD parse routine, which scans the valid eTVPE BD Rings for a new valid BD to execute.
- `Maple_parse_eftpe_0_bd`. The MAPLE-B2 initiates the eFTPE_0 BD parse routine, which scans the valid eFTPE_0 BD Rings for a new valid BD to execute.
- `Maple_parse_eftpe_1_bd`. The MAPLE-B2 initiates the eFTPE_1 BD parse routine, which scans the valid eFTPE_1 BD Rings for a new valid BD to execute.
- `Maple_parse_eftpe_2_bd`. The MAPLE-B2 initiates the eFTPE_2 BD parse routine, which scans the valid eFTPE_2 BD Rings for a new valid BD to execute.
- `Maple_parse_depe_bd`. The MAPLE-B2 initiates the DEPE BD parse routine, which scans the valid DEPE BD Rings for a new valid BD to execute.
- `Maple_parse_crcpe_bd`. The MAPLE-B2 initiates the CRCPE BD parse routine, which scans the valid CRCPE BD Rings for a new valid BD to execute.
- `Maple_parse_eqpe_bd`. The MAPLE-B2 initiates the EQPE BD parse routine, which scans the valid EQPE BD Rings for a new valid BD to execute.
- `Maple_parse_convpe_bd`. The MAPLE-B2 initiates the CONVPE BD parse routine, which scans the valid CONVPE BD Rings for a new valid BD to execute.
- `Maple_parse_cgpe_bd`. The MAPLE-B2 initiates the CGPE BD parse routine, which scans the valid CGPE BD Rings for a new valid BD to execute.
- `Maple_reset_crpe`. The MAPLE-B2 initiates a reset sequence for all the CRPE related processing elements (CRPE-ULF, CRPE-DL and CRPE-ULB). For details see **Section 26.4.3.6.4**, *CRPE Reset*.

- `Maple_crpe_ulb_init`. The MAPLE-B2 initiates the CRPE-ULB to start with data processing after all related CRPE-ULB configuration is completed. For details see **Section 26.4.3.6.1.1.5**, *Maple_crpe_ulb_init Routine Activation*.
- `Maple_crpe_ulf_init`. The MAPLE-B2 initiates the first data fetch of the CRPE-ULF in case of CRPE-ULF Interpolation Bypass mode is enabled. For details see **Section 26.4.3.6.2.6.3**, *`Input Data interface—Interpolation Bypass Mode`*.
- `Maple_crpe_3x_eftpe_clock_gate_control`. The MAPLE-B2 disable/enable the main input clock of the CRPE or the 3 x eFTPE modules. For details see **Section 26.4.6.2**, *Per Processing Element Static Clock Gating Scheme*.
- `Maple_update_eftpe_pre_post_buffer`. The MAPLE-B2 update the eFTPEs pre/post multiplication buffers as per described in the relevant parameters of the eFTPEs. For details see **Section 26.4.3.3.5.3**, *'One-Shot' Initialization of the Pre/Post Multiplication buffers*.

26.4.6 MAPLE-B2 Power Gating Scheme

The MAPLE-B2 is designed for minimum power consumption while not in use. Each of the PEs in the MAPLE-B2 is designed to halt its internal clock toggling while in idle state, and to automatically re-toggle it when in use. The internal RISC engines in the PSIF2 are also programed to halt their activity whenever the PEs are busy, or when no new valid BDs are found. This is implemented using internal timers which are responsible for the periodic wake-up of the RISC engines once they are halted.

On top of the above automatic mechanisms, the following power control schemes exists:

26.4.6.1 Dynamic Power gating Scheme

Both the EQPE and the eTVPE include additional power saving scheme which allow the MAPLE-B2 to dynamically power off and power on the EQPE/eTVPE according to BD validation, that is, if no EQPE/eTVPE BD is available to execute, the MAPLE-B2 power off the EQPE/eTVPE thus saving much of its static power consumption. It is possible to control the EQPE/eTVPE power scheme using the [EQPE_PWR]/[ETVPE_PWR] fields of the MAPLE Mode Configuration 0 Parameter (MMC0P).

26.4.6.2 Per Processing Element Static Clock Gating Scheme

Both the CRPE and the 3 x eFTPE include additional static power saving scheme which allow gating the input clocks to these Processing elements. As opposed to the Dynamic power gating scheme, the clock gating scheme is not automatic and requires host activation to enable/disable the clock. Disabling the clock of the CRPE/3 x eFTPE should be done when the relevant PE is not required for long periods of time (for example, over night power-down) and is not targeted to be dynamically switched on/off between Buffer Descriptors processing.

Disabling/enabling of the clocks for the CRPE/3 x eFTPE is done using the following flow:

1. Stop activating the relevant PEs and assure it is idle before continuing to next steps.
2. Set the MCGCP field with the required operation (disable or enable the CRPE or 3 x eFTPE clock). See **Section 26.5.3.1.3**, *MAPLE Clock Gating Control Parameter (MCGCP)* for parameter description.
3. Initiate the `Maple_crpe_3x_eftpe_clock_gate_control` routine (see **Section 26.4.5**, *MAPLE-B2 Internal Task Control*), which performs the actual clock gating according to the configuration of the MCGCP.
4. On completion of the `Maple_crpe_3x_eftpe_clock_gate_control` routine, the MAPLE-B2 zeros the MCGCP parameter indicating the completion of the task.

Some notes regarding activating this flow:

- The 3 eFTPE units share the same clock source. Disabling this clock disables all 3 units.
- Activating the routine should be executed after the relevant PE has completed all operation. For 3 x eFTPEs it means all related BDs are completed. For CRPE it means disabling the CPRI and confirm no data transfer between CPRI and CRPE occur.
- Both, enabling and disabling a clock in the same host command results in clock disabled.

26.4.7 Reset

The MAPLE-B2 has two types of reset:

- *External Hard/Soft Reset*.On assertion of external reset, the MAPLE-B2 resets all its activities and state machines. If soft reset is asserted, some of its internal configuration registers keep their values for debugging purposes. After every external reset, the API (*MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)) must be initiated to initialize the MAPLE-B2.
- *Internal Soft Reset*. It is possible to initiate an internal soft reset to the MAPLE-B2 using only the soft reset routine in the API. When called, it generates an internal soft reset to the whole MAPLE-B2 and initiate the MAPLE-B2 initialization sequence, which includes memories initialization and program upload to the MAPLE-B2 internal memory according to the chosen operation mode. For details on the API, see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG).

26.5 Programming Model

The MAPLE-B2 includes the following functional memories/configurations areas:

- *PSIF2 DRAM*. Internal PSIF2 memory that includes the parameter RAM, the CRPE control parameters and the buffer descriptor rings RAM.
- *eTVPE memory space*. Includes internal eTVPE memory used by MAPLE-B2 to input data into the eTVPE to output data from the eTVPE, and registers configuration area used by the host and MAPLE-B2 for eTVPE configuration.
- *eFTPE memories space*. Include internal eFTPE memories used by MAPLE-B2 to input data into the 3 eFTPE modules and to output data from the eFTPE modules and registers configuration area used by the host and MAPLE-B2 for eFTPE modules configuration.
- *DEPE memory space*. Includes internal DEPE memory used by MAPLE-B2 to input data into the DEPE and to output data from the DEPE, and registers configuration area used by MAPLE-B2 for DEPE configuration.
- *EQPE memory space*. Includes internal EQPE memory used by MAPLE-B2 to input data into the EQPE and to output data from the EQPE, and registers configuration area for EQPE configuration.
- *CRPE memory space*. Includes internal CRPE memory used by MAPLE-B2 (or external host) to input data into the CRPE and to output data from the CRPE, and registers configuration area used by MAPLE-B2 and external host for CRPE control and configuration.

The MAPLE-B2 contains both registers and a parameter RAM. The registers and parameters are treated similarly. The only difference is that the default values for the registers are the “Reset” values whereas the default values for parameters are the “Initialization” values. The default values for parameters apply only after the MAPLE-B2 initialization sequence is completed using its API (see *MAPLE-B2 Application Programmer Interface (API) User’s Guide* (MAPLEAPIUG)).

All registers/parameters are described as REG/PARAM_NAME<letter> and offset value. The “letter” describes the number of times this register is implemented, and the offset field describes the offset value needed to be added to get the address of the next register. For example, MTVBRHPAxP (x = 0...7, offset x∗0x8) means that the following registers are implemented:

- MTVBRHPA0P at offset 0x00000100
- MTVBRHPA1P at offset 0x00000108
- ...
- MBDRHPA7P at offset 0x00000138

Each of these memories/registers are accessed by the MBus Slave0 interface. MBus Slave1 interface is used for data transfer from Antenna I/F and into MAPLE-B2 memories only.

Figure 26-180 describes the internal MAPLE-B2 MBus slaves memory map partitioning.

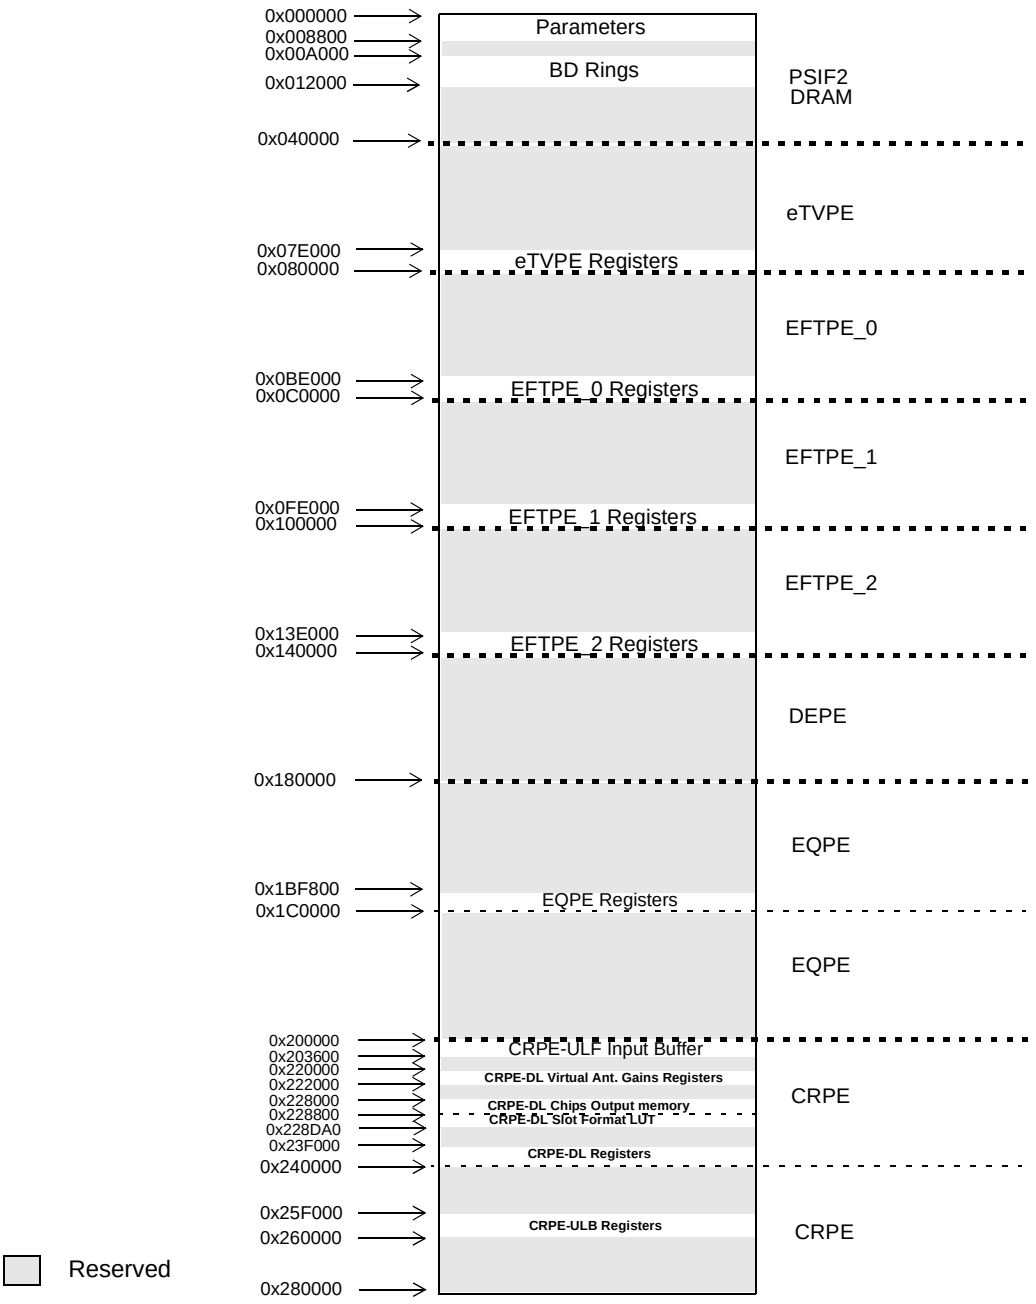

Figure 26-180. MBus Memory Map Partitioning

Note: Accessing Reserved areas may result in MAPLE-B2 entering an unknown state that may require a hard reset of the whole device!

Table 26-125 describes the MBus memory map in detail. Each of the memories/registers are accessed by the MBus Slave0 interface. MBus Slave1 interface is used for data transfer from Antenna interface and into MAPLE-B2 memories only.

Table 26-125. MAPLE-B2 MBus Memory Map

Address Range[1]	Description	Size (KB)
PSIF2 DRAM

1. The specified addresses are relative to MAPLE-B2 base_address, that is, for absolute address calculate MAPLE-B2_base + Address Range.

The SBus interface of the MAPLE-B2 is used to access the PSIF2 internal registers only. These registers use the MAPLE-B2 CCSR base address 0xFFF1C000.

Table 26-126 describes the SBus Memory Map.

26.5.1 MAPLE-B2 Programming

The MAPLE-B2 requires several levels of programming, including the following:

- Parameter initialization, which is done using the MAPLE-B2 application programmer interface (API). See **Section 26.5.2, *Initialization Parameters*** for details.
- Operational configuration of functional memory areas including the following:
  - Parameter RAM (includes control parameters for CRPE only)
  - RAM-based buffer descriptor rings, buffer descriptors, and task descriptors.
- PSIF2 and PE register configuration.

26.5.1.1 General Programming Guidelines

Following are few general guidelines which should be maintain while programming MAPLE-B2:

a. Reserved bits in parameters/registers must be written with the value of ‘0’ for future compatibility.

b. When a functional field is valid in a certain configuration/mode only, for all other configurations it should be written with the value of ‘0’ to prevent any miss-programming.

26.5.2 Initialization Parameters

There are five sets of configuration parameters (two system level and three PE-specific) that must be initialized by the MAPLE-B2 API prior to use. These parameters are the following:

- MAPLE Mode Configuration 0 and 1 Parameters (MMC[0–1]P)—General MAPLE-B2 initialization parameters. See **Section 26.5.2.1** and **Section 26.5.2.2**.
- eTVPE Mode Configuration Parameter (TVMCP)—General eTVPE related initialization parameters. See **Section 26.5.2.3**
- CRPE Uplink Batch Mode Configuration Parameter (CRUBMCP)—CRPE-ULB General configuration parameters. See **Section 26.5.2.5**.
- CRPE Down Link Output Mode Configuration Parameter (CDOMCP)—CRPE-DL Output mode related initialization parameters. See **Section 26.5.2.4**.

The following subsections include detailed descriptions of these parameters.

26.5.2.1 MAPLE Mode Configuration 0 Parameter (MMC0P)

The MMC0P parameter includes general parameters, to be initialized during the MAPLE-B2 API initialization. Following is the MMC0P fields description:

Offset	0x00000020 (MMC0P)											Access:		Read only		
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
				MB_ALC			MB_PR_SCH		MB3_DF_PR		MB2_DF_PR		MB1_DF_PR		MB0_DF_PR	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
			EQPE_PWR				ETVPE_PWR					ECC_EN				STD

Figure 26-181. MMC0P parameter structure

Table 26-127. MMC0P Fields Description

Bits	Description
31 – 29	Reserved.
28	MB_ALC — MBus Allocation. Indicates whether the system MBus initiators interfaces allocation to each of the Processing Elements (PEs) is done internally by MAPLE-B2 or determined by the MMC1P parameter. For details, refer to **Section 26.5.2.2**, *MAPLE Mode Configuration 1 Parameter (MMC1P)*. 0 — PEs allocation to each of the MBus interfaces is done internally by MAPLE-B2 1 — PEs allocation to each of the MBus interfaces is done according to MMC1P configuration.
27 – 26	Reserved.
25 – 24	**MB_PR_SCH — MBus Priority Scheme**. Indicates the MAPLE-B2 which MBus initiators priority scheme is applied. For details see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— All MAPLE-B2 MBus master accesses are initiated with fixed priority level as described in the [MB0_DF_PR], [MB1_DF_PR], [MB2_DF_PR] and [MB1_DF_PR] fields for MBus0, MBus1, MBus2 and MBus3 respectively. 01—All MAPLE-B2 MBus master accesses related to a certain BD are initiated with priority as described in the [MB_PR] field of the BD. Previous DMA commands already launched into the relevant DMA queue are not upgraded with their priority accordingly. 10—All MAPLE-B2 MBus master accesses related to a certain BD are initiated with priority as described in the [MB_PR] field of the BD. All DMA commands already launched into the relevant DMA queue are upgraded with their priority accordingly. 11—Reserved.
23 – 22	**MB3_DF_PR — MBus3 Default Priority**. Valid only if the [MB_PR_SCH] is set to ‘00’. Describe the default priority of the MBus3 master. For details see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The default MBus3 priority is ‘00’ (lowest priority) ... 11— The default MBus3 priority is ‘11’ (highest priority)
21 – 20	**MB2_DF_PR — MBus2 Default Priority**. Valid only if the [MB_PR_SCH] is set to ‘00’. Describe the default priority of the MBus2 master. For details see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The default MBus2 priority is ‘00’ (lowest priority) ... 11— The default MBus2 priority is ‘11’ (highest priority)
19 – 18	**MB1_DF_PR — MBus1 Default Priority**. Valid only if the [MB_PR_SCH] is set to ‘00’. Describe the default priority of the MBus1 master. For details see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The default MBus1 priority is ‘00’ (lowest priority) ... 11— The default MBus1 priority is ‘11’ (highest priority)
17 – 16	**MB0_DF_PR — MBus0 Default Priority**. Valid only if the [MB_PR_SCH] is set to ‘00’. Describe the default priority of the MBus0 master. For details see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The default MBus0 priority is ‘00’ (lowest priority) ... 11— The default MBus0 priority is ‘11’ (highest priority)
15 – 14	Reserved.

Table 26-127. MMC0P Fields Description

Bits	Description
13 – 12	**EQPE_PWR — EQPE Power control Mode**. Determined the power scheme used for the EQPE module. For details, refer to **Section 26.4.6**, *MAPLE-B2 Power Gating Scheme*. 00—EQPE Automatic power switching mode. The MAPLE-B2 power off the EQPE when there is no available EQPE BD. 01— EQPE power on. The EQPE always powered on. No power switching 10— EQPE power off. The EQPE is powered off. 11— Reserved.
11 – 10	Reserved.
9 – 8	**ETVPE_PWR — eTVPE Power control Mode**. Determined the power scheme used for the eTVPE module. For details, refer to **Section 26.4.6**, *MAPLE-B2 Power Gating Scheme*. 00—eTVPE Automatic power switching mode. The MAPLE-B2 power off the eTVPE when there is no available eTVPE BD. 01— eTVPE power on. The eTVPE always powered on. No power switching 10— eTVPE power off. The eTVPE is powered off. 11— Reserved.
7 – 5	Reserved.
4	**ECC_EN**. ECC memory protection Enable indication. If set the MAPLE-B2 enables ECC protection to all its internal memories which support ECC protection. 0 — ECC is disabled. 1 — ECC is enabled.
3 – 1	Reserved.
0	**STD**. MAPLE Standard operation mode. Determines which technology is currently supported in MAPLE-B2 0 — 3G Operation mode. Supporting both UMTS and 3GLTE technologies 1 — WiMAX Operation mode. Supporting both WiMAX and 3GLTE technologies.

26.5.2.2 MAPLE Mode Configuration 1 Parameter (MMC1P)

The MMC1P parameter includes general MBus related parameters, to be initialized during the MAPLE-B2 API initialization. All fields in this parameter are valid only if the [MB_ALC] field of the MMC0P parameter is set.

Note: When assigning a certain MBus engine to a Read/Write operation per PE, it may happen that some minor Write/Read operations occurs on that MBus engine as well.

Following is the MMC1P fields description:

Offset	0x00000024 (MMC1P)											Access:		Read only		
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	TV_W_B		TV_R_B		FT0_W_B		FT0_R_B		FT1_W_B		FT1_R_B		FT2_W_B		FT2_R_B	
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
	DE_W_B		DE_R_B		EQ_W_B		EQ_R_B		CR_W_B		CR_R_B		CRCG_W_B		CRC_R_B	

Figure 26-182. MMC1P parameter structure

Table 26-128. MMC1P parameter Fields Description

Bits	Description
31 – 30	**TV_W_B — eTVPE Write Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the eTVPE write its results to system memory 00 — eTVPE results are written using MBus 0 01 — eTVPE results are written using MBus 1 10 — eTVPE results are written using MBus 2 11 — eTVPE results are written using MBus 3
29 – 28	**TV_R_B — eTVPE Read Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the eTVPE read its input data from system memory 00 — eTVPE input data is read using MBus 0 01 — eTVPE input data is read using MBus 1 10 — eTVPE input data is read using MBus 2 11 — eTVPE input data is read using MBus 3
27 – 26	**FT0_W_B — EFTPE_0 Write Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the EFTPE_0 write its results to system memory 00 — EFTPE_0 results are written using MBus 0 01 — EFTPE_0 results are written using MBus 1 10 — EFTPE_0 results are written using MBus 2 11 — EFTPE_0 results are written using MBus 3
25 – 24	**FT0_R_B — EFTPE_0 Read Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the EFTPE_0 read its input data from system memory 00 — EFTPE_0 input data is read using MBus 0 01 — EFTPE_0 input data is read using MBus 1 10 — EFTPE_0 input data is read using MBus 2 11 — EFTPE_0 input data is read using MBus 3
23 – 22	**FT1_W_B — EFTPE_1 Write Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the EFTPE_1 write its results to system memory 00 — EFTPE_1 results are written using MBus 0 01 — EFTPE_1 results are written using MBus 1 10 — EFTPE_1 results are written using MBus 2 11 — EFTPE_1 results are written using MBus 3
21 – 20	**FT1_R_B — EFTPE_1 Read Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the EFTPE_1 read its input data from system memory 00 — EFTPE_1 input data is read using MBus 0 01 — EFTPE_1 input data is read using MBus 1 10 — EFTPE_1 input data is read using MBus 2 11 — EFTPE_1 input data is read using MBus 3
19 – 18	**FT2_W_B — EFTPE_2 Write Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the EFTPE_2 write its results to system memory 00 — EFTPE_2 results are written using MBus 0 01 — EFTPE_2 results are written using MBus 1 10 — EFTPE_2 results are written using MBus 2 11 — EFTPE_2 results are written using MBus 3
17 – 16	**FT2_R_B — EFTPE_2 Read Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the EFTPE_2 read its input data from system memory 00 — EFTPE_2 input data is read using MBus 0 01 — EFTPE_2 input data is read using MBus 1 10 — EFTPE_2 input data is read using MBus 2 11 — EFTPE_2 input data is read using MBus 3

Table 26-128. MMC1P parameter Fields Description

Bits	Description
15 – 14	**DE_W_B — DEPE Write Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the DEPE write its results to system memory 00 — DEPE results are written using MBus 0 01 — DEPE results are written using MBus 1 10 — DEPE results are written using MBus 2 11 — DEPE results are written using MBus 3
13 – 12	**DE_R_B — DEPE Read Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the DEPE read its input data from system memory 00 — DEPE input data is read using MBus 0 01 — DEPE input data is read using MBus 1 10 — DEPE input data is read using MBus 2 11 — DEPE input data is read using MBus 3
11 – 10	**EQ_W_B — EQPE Write Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the EQPE write its results to system memory 00 — EQPE results are written using MBus 0 01 — EQPE results are written using MBus 1 10 — EQPE results are written using MBus 2 11 — EQPE results are written using MBus 3
9 – 8	**EQ_R_B — EQPE Read Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the EQPE read its input data from system memory 00 — EQPE input data is read using MBus 0 01 — EQPE input data is read using MBus 1 10 — EQPE input data is read using MBus 2 11 — EQPE input data is read using MBus 3
7 – 6	**CR_W_B — CRPE Write Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the CRPE write its results to system memory 00 — CRPE results are written using MBus 0 01 — CRPE results are written using MBus 1 10 — CRPE results are written using MBus 2 11 — CRPE results are written using MBus 3
5 – 4	**CR_R_B — CRPE Read Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the CRPE read its input data from system memory 00 — CRPE input data is read using MBus 0 01 — CRPE input data is read using MBus 1 10 — CRPE input data is read using MBus 2 11 — CRPE input data is read using MBus 3
3 – 2	**CRCG_W_B — CRCPE/CGPE[1] Write Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the CRCPE and the CGPE write their results to system memory 00 — CRCPE and CGPE results are written using MBus 0 01 — CRCPE and CGPE results are written using MBus 1 10 — CRCPE and CGPE results are written using MBus 2 11 — CRCPE and CGPE results are written using MBus 3
1 – 0	**CRC_R_B — CRCPE Read Bus.** If MMC0P[MB_ALC] bit is set, indicates on which of the 4 MBus initiators the CRCPE read its input data from system memory 00 — CRCPE input data is read using MBus 0 01 — CRCPE input data is read using MBus 1 10 — CRCPE input data is read using MBus 2 11 — CRCPE input data is read using MBus 3

1. The CGPE only output data and does not require input data. That is the reason it is sharing only the write bus with the CRCPE.

26.5.2.3 MAPLE eTVPE Configuration Parameter (MTVCP)

If the eTVPE is used by the application, then during the MAPLE-B2 initialization (see *MAPLE-B Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)), the eTVPE configuration parameter in the API must be initialized:

Offset	0x00000028 (MTVCP)											Access:		Read only		
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
								SCRC	RANE		SEP_V	HE				
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
			ANDRE						CRC_AUTOSTOP	AQC_AUTOSTOP		POL				

Figure 26-183. MAPLE eTVPE Configuration Parameter

Table 26-129. MAPLE eTVPE Configuration Fields Description

Bits	Description
24	**SCRC - Steady CRC**. Steady CRC stop criteria indication. The eTVPE stop the decoding automatically once CRC result is equal to CRC results from previous iteration. Must not be set if [CRC_AUTOSTOP] is set. For details, see **Section 26.4.3.2.6.4.4**, *Turbo Stopping Criteria Configurations*, on page 26-55 0—Steady CRC stop criteria is disabled. 1—Steady CRC stop criteria is enabled.
23	**RANE - De-Randomizer Enable**. Valid only for MAPLE-B2 WiMAX operation mode. If enabled the eTVPE performs de-randomization on the hard outputs. 0—De-randomizer is disabled. 1—De-randomizer is enabled.
21	**SEP_V**. Separate Vectors indication. Valid only for MAPLE-B2 3G operation mode. Indicated which rate de-matching scheme is used for UMTS jobs 0—Single Mixed Vector rate de-matching scheme is applied. 1—Separate Vectors rate de-matching scheme is applied.
20	**HE - HARQ Enable**. Indicated whether HARQ operation in eTVPE is enabled, hence which input data structures for the eTVPE are allowed. For details, refer to **Section 26.4.3.2.5**, *eTVPE Input Data Structures*, on page 26-30. 0—HARQ processing is disabled. 1—HARQ processing is enabled.
13	**ANDRE - Automatic NDRE**. If enabled the eTVPE internally sets the number of Turbo engines (DRE) to achieve maximum performance. 0—Number of Turbo engines is defined by host using NDRE field of eTVPE BD 1—Number of Turbo engines is set internally by eTVPE.
7	**CRC_AUTOSTOP**. CRC check stop criteria indication. The eTVPE stop the decoding automatically once the Hard Output bits pass CRC check. Must not be set if [SCRC] is set. For details, refer to **Section 26.4.3.2.6.4.4**, *Turbo Stopping Criteria Configurations*, on page 26-55. 0—CRC check stop criteria is disabled. 1—CRC check stop criteria is enabled.

Table 26-129. MAPLE eTVPE Configuration Fields Description

Bits	Description
6	**AQC_AUTOSTOP**. Aposteriori Quality stop criteria indication. the eTVPE stop the decoding automatically once the all the soft-decoded bits pass the [AQTH] threshold field. For details, refer to **Section 26.4.3.2.6.4.4**, *Turbo Stopping Criteria Configurations*, on page 26-55. 0—AQC stop criteria is disabled. 1—AQC stop criteria is enabled.
4	**POL - Polarity**. Describe the eTVPE input data polarity: 0—Logic 0 is mapped as (- 1); Logic 1 is mapped as (+1); 1—Logic 0 is mapped as (+1); Logic 1 is mapped as (- 1);

26.5.2.4 CRPE-DL Output Mode Configuration Parameter (CDOMCP)

If the application uses chip rate download processing, then during the MAPLE-B2 initialization (see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)), the following CRPE-DL related parameter in the API must be initialized:

Offset	0x0000002C (CDOMCP)											Access:		Read only		
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	A15EN	A14EN	A13EN	A12EN	A11EN	A10EN	A9EN	A8EN	A7EN	A6EN	A5EN	A4EN	A3EN	A2EN	A1EN	A0EN
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
														RCS	RSEL	MOM

Figure 26-184. CRPE-DL Output Mode Configuration Parameter

Table 26-130. CRPE-DL Output Mode Configuration Fields Description

Bits	Description
31	**A15EN - Output Antenna 15 Enable** 0 - Output antenna 15 is disabled. 1 - Output antenna 15 is enabled.
30	**A14EN - Output Antenna 14 Enable** 0 - Output antenna 14 is disabled. 1 - Output antenna 14 is enabled.
29	**A13EN - Output Antenna 13 Enable** 0 - Output antenna 13 is disabled. 1 - Output antenna 13 is enabled.
28	**A12EN - Output Antenna 12 Enable** 0 - Output antenna 12 is disabled. 1 - Output antenna 12 is enabled.
27	**A11EN - Output Antenna 11 Enable** 0 - Output antenna 11 is disabled. 1 - Output antenna 11 is enabled.
26	**A10EN - Output Antenna 10 Enable** 0 - Output antenna 10 is disabled. 1 - Output antenna 10 is enabled.

Table 26-130. CRPE-DL Output Mode Configuration Fields Description

Bits	Description
25	**A9EN - Output Antenna 9 Enable** 0 - Output antenna 9 is disabled. 1 - Output antenna 9 is enabled.
24	**A8EN - Output Antenna 8 Enable** 0 - Output antenna 8 is disabled. 1 - Output antenna 8 is enabled.
23	**A7EN - Output Antenna 7 Enable** 0 - Output antenna 7 is disabled. 1 - Output antenna 7 is enabled.
22	**A6EN - Output Antenna 6 Enable** 0 - Output antenna 6 is disabled. 1 - Output antenna 6 is enabled.
21	**A5EN - Output Antenna 5 Enable** 0 - Output antenna 5 is disabled. 1 - Output antenna 5 is enabled.
20	**A4EN - Output Antenna 4 Enable** 0 - Output antenna 4 is disabled. 1 - Output antenna 4 is enabled.
19	**A3EN - Output Antenna 3 Enable** 0 - Output antenna 3 is disabled. 1 - Output antenna 3 is enabled.
18	**A2EN - Output Antenna 2 Enable** 0 - Output antenna 2 is disabled. 1 - Output antenna 2 is enabled.
17	**A1EN - Output Antenna 1 Enable** 0 - Output antenna 1 is disabled. 1 - Output antenna 1 is enabled.
16	**A0EN - Output Antenna 0 Enable** 0 - Output antenna 0 is disabled. 1 - Output antenna 0 is enabled.
2	**RCS - Rate Control Source** This field selects the source of CRPE-DL rate control event to be either interrupt or write access to CRPE Downlink Rate Control Register. 0 - The source of CRPE-DL rate control event is an interrupt. 1 - The source of CRPE-DL rate control event is a write accesses to CRPE Downlink Rate Control Register.
1	**RSEL - Rate Selector** This field selects CRPE-DL rate control event to be either new 16 chips chunk event or new 256 chips sub-slot event. 0 - CRPE-DL rate control event is new 16 chips chunk event. 1 - CRPE-DL rate control event is new sub-slot event.
0	**MOM - MAPLE Output Mode** 0 - CRPE-DL is operating at CPRI output mode. 1 - CRPE-DL is operating at MAPLE output mode.

26.5.2.5 CRPE-ULB Mode Configuration Parameter (CRUBMCP)

If the application uses the CRPE Uplink Batch operation, then during the MAPLE-B2 initialization (see *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)), the following CRPE-ULB related parameter in the API must be initialized:

Offset	0x00000030 (CRUBMCP)											Access:		Read only		
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
								DBL_ANT_EN					ISHA			
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
					DDS				DLY_SPRD	OOB		FC_MODE				INT_MODE

Figure 26-185. CRPE-ULB Mode Configuration Parameter

Table 26-131. CRPE-ULB Mode Configuration Fields Description

Bits	Description
31–25	Reserved
24	DBL_ANT_EN - Double Antenna Enable 0—Up to 48 Antennas are allowed; Maximum Interpolation of x16 1—Up to 96 Antennas are allowed; Maximum Interpolation of x8
23–20	Reserved
19–16	ISHA - Interpolation shift amount Contains the amount by which the sum of the interpolated (weight x chips) is shifted right before the result is truncated from 19bit to 8bit. For details see **Section 26.4.3.6.1.8.6**, *Interpolation Saturation During Internal Interpolation*. Valid values: 0 to15
15–12	Reserved
11	DDS - DD Saturation Valid if *FC_MODE* = 0 only; Selects whether to shift the result left by '1' or not 0—Shift left is disabled (output lower 16bits). Optional saturation. 1—Shift left is enabled (output higher 16bits). No saturation occurs.
10–8	Reserved
7	DLY_SPRD - Delay spread mode 0—Delay spread of up to 256 (*FOFFSET_H* of the Finger command allowed values of 0 to 511) 1—Delay spread of up to 512 (*FOFFSET_H* of the Finger command allowed values of 0 to 767)
6	OOB - One Output buffer Indicates if the CRPE-ULB functions with single Output Buffer or double Output buffer. for details see **Section 26.4.3.6.1.13**, *Output Buffer Capacity*. 0—Disabled; Output buffers 1 and 2 are double buffer. 1—Enabled; Output buffers 1 and 2 are concatenated into a single buffer.
5	Reserved
4–3	FC_MODE - Fingers Combine mode 0—FC bypass; fingers are output directly to output memory 1—FC with 16bit fixed point output per symbol, fixed scale, per the PCH command *EXP* field. 2—Reserved. 3—FC with 16bit floating point + 16bit exponent.

Table 26-131. CRPE-ULB Mode Configuration Fields Description

Bits	Description
2–1	Reserved
0	INT_MODE - Interpolation mode 0—Interpolation bypass 1—Internal interpolation enabled

26.5.3 Parameter RAM

The following sections describe the sets of parameter RAM.

26.5.3.1 General Parameter RAM Description

Table 26-132 describes the MAPLE-B2 general Parameter RAM in detail.

Table 26-132. Parameter RAM Detailed Description

Address	Parameters	Access	Initialization Value[1]	Section

Figure 26-186. MAPLE UCode Version Parameter

Table 26-133. MAPLE UCode Version Parameter Fields Description

Bits	Description
31–12	Reserved.
11–8	TDUC — Target Device firmware (uCode). Indicated to which device this uCode applies. 0000 The uCode is targeted for the MSBA8100 device 0001 The uCode is targeted for the MSC8156Rev1 device. 0010 The uCode is targeted for the MSC8156Rev2 device. 0011 The uCode is targeted for the MSC8157 device.
7–0	UCV — Ucode Version. This field describes the ucode and API version used to initiate the MAPLE-B2.

26.5.3.1.2 MAPLE Timer Period Parameter (MP_TPP)

This parameter sets the time periods between each time the internal RISC engines are being called to search for new Buffer Descriptor. For details, refer to **Section 26.4.5**, *MAPLE-B2 Internal Task Control*

Offset 0x00000018 (MP_TPP) Access: User read/write

Figure 26-187. MAPLE Timer Period Parameter

Table 26-134. MAPLE Timer Period Parameter Fields Description

Bits	Description
31–6	Reserved
5–0	TMR_PRD — Timer Period. Determines the periodical time (MAPLE clock cycles) which cause the internal RISC engine to search for the next Buffer Descriptor. The number of MAPLE clock cycles is determined according to the following: <MAPLE clock cycles> = (1 + TMR_PRD) * 1024. For details, refer to **Section 26.4.5, *MAPLE-B2 Internal Task Control***

26.5.3.1.3 MAPLE Clock Gating Control Parameter (MCGCP)

This parameter allows controlling (disabling/enabling) the input clocks for the CRPE and the 3 x eFTPE (shared clock gating for the 3 eFTPE modules), thus saving power when not in use for long periods of time (such as over-night shutdown). By setting this parameter and initiating the `Maple_crpe_3x_eftpe_clock_gate_control` routine (see **Section 26.4.5**, *MAPLE-B2 Internal Task Control*), the MAPLE-B2 disable/enable the clocks of the CRPE and 3 x eFTPE. For details see **Section 26.4.6.2**, *Per Processing Element Static Clock Gating Scheme*.

Figure 26-191. MAPLE Turbo Viterbi Puncturing Period Configuration y Parameter

Table 26-139. MAPLE Turbo Viterbi Puncturing Period Configuration y Parameter Fields Description

Bits	Description
31–30	Reserved
29–24	PPER<4y>—Puncturing Period. This field indicates the period of the puncturing if periodic puncturing is enabled. See **Section 26.4.3.2.5, *eTVPE Input Data Structures***. 1–63 possible values which stand for the possible periods
23–22	Reserved
21–16	PPER<4y+1>—Puncturing Period. This field indicates the period of the puncturing if periodic puncturing is enabled. See **Section 26.4.3.2.5, *eTVPE Input Data Structures***. 1–63 possible values which stand for the possible periods
15–14	Reserved
13–8	PPER<4y+2>—Puncturing Period. This field indicates the period of the puncturing if periodic puncturing is enabled. See **Section 26.4.3.2.5, *eTVPE Input Data Structures***. 1–63 possible values which stand for the possible periods
7–6	Reserved
5–0	PPER<4y+3>—Puncturing Period. This field indicates the period of the puncturing if periodic puncturing is enabled. See **Section 26.4.3.2.5, *eTVPE Input Data Structures***. 1–63 possible values which stand for the possible periods

Note: The order in which the PVEC[62:0] vector is read is from bit [0] to bit [62] (MTVPVxLCP[0] is the first bit and MTVPVx(H/L)CP[PPER] is the last bit in the punctured pattern), where PPER is defined in MTVPPCyP.

26.5.3.2.4 MAPLE Turbo Viterbi Polynomial Vector Set x Configuration 0 Parameter (MTVPVSxC0P)

These parameters, along with the MTVPVSxC1P parameters, define three sets of Viterbi polynomial configurations. The MAPLE-B2 determines with which set to configure the eTVPE according to the [VIT_SET] field of the eTVPE BD. For details, refer to **Section 26.5.4.2**, *eTVPE Buffer-Descriptor Structure*.

Table 26-140. MAPLE Turbo Viterbi Polynomial Vector Set x Configuration 0 Parameter Fields Description

Bits	Description
31–25	Reserved
24–16	M_POLYGEN1 - This field enables bits for the generation of the second parity bit. 0–(2^k - 1) possible values. K is the Viterbi Constraint Length.
15–9	Reserved
8–0	M_POLYGEN0 - This field enables bits for the generation of the first parity bit. 0–(2^k - 1) possible values. K is the Viterbi Constraint Length.

26.5.3.2.5 MAPLE Turbo Viterbi Polynomial Vector Set x Configuration 1 Parameter (MTVPVSxC1P)

These parameters, along with the MTVPVSxC0P parameters, define three sets of Viterbi polynomial configurations. The MAPLE-B2 determines with which set to configure the eTVPE according to the [VIT_SET] field of the eTVPE BD. For details, refer to **Section 26.5.4.2**, *eTVPE Buffer-Descriptor Structure*.

Figure 26-197. eFTPE x Update Pre-Multiplication Buffer Pointer Parameter

Table 26-146. eFTPE x Update Pre-Multiplication Buffer Pointer Field Descriptions

Bits	Description
31–0	PRE_BUF_PTR—Pre Multiplication Buffer Pointer. Valid during ‘Maple_update_eftpe_pre_post_buffers’ activation. If set to a value different than zero, the MAPLE-B2 uses this field as a pointer to the system memory where the new pre-multiplication buffer of eFTPE x is expected. The size of the buffer is described in *FTPExUBSP[PRE_BUF_SIZE]*.

26.5.3.3.5 eFTPE x Update Post-Multiplication Buffer Pointer Parameter (FTPExUPSMBPP)

This parameter indicates the MAPLE-B2 during the ‘Maple_update_eftpe_pre_post_buffers’ routine assertion (see **Section 26.4.5**) if to update the post-multiplication buffer of eFTPE x. for details see **Section 26.4.3.3.5.3**, *‘One-Shot’ Initialization of the Pre/Post Multiplication buffers*.

Figure 26-198. eFTPE x Update Post-Multiplication Buffer Pointer Parameter

Table 26-147. eFTPE x Update Post-Multiplication Buffer Pointer Field Descriptions

Bits	Description
31–0	POST_BUF_PTR—Post Multiplication Buffer Pointer. Valid during ‘Maple_update_eftpe_pre_post_buffers’ activation. If set to a value different than zero, the MAPLE-B2 uses this field as a pointer to the system memory where the new post-multiplication buffer of eFTPE x is expected. The size of the buffer is described in *FTPExUBSP[PST_BUF_SIZE]*.

26.5.3.3.6 eFTPE x Update Buffers Size Parameter (FTPExUBSP)

This parameter indicates the MAPLE-B2 during the ‘Maple_update_eftpe_pre_post_buffers’ routine assertion (see **Section 26.4.5**) the size of the pre and/or post multiplication buffers to be fetched. For details see **Section 26.4.3.3.5.3**, *‘One-Shot’ Initialization of the Pre/Post Multiplication buffers*.

Figure 26-199. eFTPE x Update Buffers Size Parameter

Table 26-148. eFTPE x Update Buffers Size Field Descriptions

Bits	Description
31–16	PRE_BUF_SIZE—Pre Multiplication Buffer Size. Valid during ‘Maple_update_eftpe_pre_post_buffers’ activation. If the relevant PRE_BUF_PTR is enabled (> 0), this field indicates the size (in bytes) of the new pre-multiplication buffer to be fetched by MAPLE-B2. Valid values: up to 8KB, which is the maximal size of the pre-multiplication buffer.
15–0	PST_BUF_SIZE—Post Multiplication Buffer Size. Valid during ‘Maple_update_eftpe_pre_post_buffers’ activation. If the relevant POST_BUF_PTR is enabled (> 0), this field indicates the size (in bytes) of the new post-multiplication buffer to be fetched by MAPLE-B2. Valid values: up to 8KB, which is the maximal size of the post-multiplication buffer.

26.5.3.3.7 eFTPE Complete Update Buffers Routine Parameter (FTPECUBRP)

This parameter must be cleared by the host before initiating the ‘Maple_update_eftpe_pre_post_buffers’ routine (see **Section 26.4.5**). Once the routine is completed the MAPLE-B set this parameter to ‘1’ indicating the host that the routine is completed and new Buffer Descriptors can be written into MAPLE-B2 internal memory. For details see **Section 26.4.3.3.5.3**, *‘One-Shot’ Initialization of the Pre/Post Multiplication buffers*

Table 26-151. MAPLE EQPE Y Buffer Mode Field Descriptions

Name	Description
31–1	Reserved
0	Y_MODE—Y buffer mode. Valid for LNEQ and MLEQ modes only. Indicates the order of the antenna buffers (after FFT processing) in the system memory. For details see **Section 26.4.3.5.4.1.1**, *Y Samples Input Data Structure*. 0 - The Y buffer in the system memory is ordered by successive columns from the same Rx antenna. 1 - The Y buffer in the system memory is ordered by same column from different Rx antenna.

26.5.3.5 CRPE Parameter RAM Descriptions

The CRPE uses different sets of parameter RAM and control parameters for each function, as follows:

- CRPE General parameters
- CRPE Uplink Batch Mode (CRPE-ULB)
- CRPE Uplink Fast Processing (CRPE-ULF)
- CRPE Downlink (CRPE-DL)

The following subsections define these parameter sets.

26.5.3.5.1 CRPE General Parameter Description

26.5.3.5.1.1 MAPLE CRPE Reset Completion Indication Parameter (MCRRCIP)

This parameter indicates the status of the CRPE reset routine. Once the routine is initiated, the status bit is set by the MAPLE-B2 indicating the reset routine is active. When reset assertion and all internal configuration is completed, the bit is reset.

Offset 0x00000040 (MCRRCIP) Access: User read

Figure 26-206. MAPLE CRPE-ULB Physical Channel x Output Buffer Interrupt Configuration

Table 26-157. MAPLE CRPE-ULB Physical Channel x Output Buffer Interrupt Configuration Fields Description

Bits	Description
31–29	Reserved
28	MASK— Enable/Disable indication for the check if channel should be added to finished channels buffer. Should be initialized to 1 on channel activation. Maintained by MAPLE-B2 and used to prevent false channel finish indications may caused due to counters wrap events. For details see **Section 26.4.3.6.1.15**, *Output Interrupt and Finished Channels Buffer Maintenance.* 0—Checks are disabled. 1—Checks are enabled.
27	Reserved
26–16	MARK— Indicated the SBS number after which the related channel needs to be added to the finished channels buffer. Self increment by MAPLE-B2 by *STEP* value during group check points when the *MARK* value is smaller than the current internal output SBS counter. This field should be initialized with the required number of offset SBS by the HOST during the channel activation. 0 to 1200 valid values
15–11	Reserved
10–0	STEP— Indicates the number of SBS between two MAPLE ULB interrupt assertions related to this channel. After each MAPLE-B2 CRPE-ULB interrupt assertion the value in *STEP* is being added by MAPLE-B2 to the MARK value which becomes the new threshold for the next interrupt assertion. For details see **Section 26.4.3.6.1.15**, *Output Interrupt and Finished Channels Buffer Maintenance.* Value of zero for the *STEP* field indicated the MAPLE-B2 that no interrupt should be asserted for this channel. 0 to 1200 valid values.

26.5.3.5.2.5 MAPLE CRPE-ULB Group <x> Configuration 1 Parameter (MCUBGxC1P)

The MCUBGxC1P to MCUBGxC4P parameters holds the uplink processing group configurations.

Figure 26-207. MAPLE CRPE-ULB Group x Configuration 1 Parameter

Table 26-158. MAPLE CRPE-ULB Group x Configuration 1 Fields Description

Bits	Description
31	Reserved
30–28	G_xNOC— Group Number of Cores. Indicates the number of cores assigned to this group. 0 - Single core is assigned to this group. 1 - two cores are assigned to this group. ... 7- eight cores are assigned to this group.
27–25	Reserved
24–16	G_xNOS— Group Number of Sub Slots. Holds the number of SBS commands list descriptors for each core in the command list dada-base. Valid values are 1 to 300.
15–2	G_xCDLBA — Group Cores Descriptors List Base Address. Pointer to list of cores descriptors related to this group. The base address is an offset in the Core Descriptors Memory and it must be 4 byte aligned.
1–0	Reserved.

26.5.3.5.2.6 MAPLE CRPE-ULB Group <x> Configuration 2 Parameter (MCUBGxC2P)

The MCUBGxC1P to MCUBGxC4P parameters holds the uplink processing group configurations.

Figure 26-208. MAPLE CRPE-ULB Group x Configuration 2 Parameter

Table 26-159. MAPLE CRPE-ULB Group x Configuration 2 Fields Description

Bits	Description
31–25	Reserved
24–16	G_xSCRP — Group x Sub slot Commands Read Pointer. This field counts cyclically (modulo *GNOS*) the Sub-Slot indicates the index in the (command) Sub-Slot descriptors list that the VCOP is going to process. It is used for accessing the Sub-Slot descriptor lists of all the cores in the group. Initialized by the user and then increment by MAPLE-B2. For details see **Section 26.4.3.6.1.5**, *CRPE-ULB Command Processing Flow* Values: 0...*GNOS*-1
15–9	Reserved
8–0	G_xSRP— Group x Sub-Slot read Pointer. This field indicates the sub slot index that the VCOP is going to read next from all antennas associated with the current group. Initialized by the user and then increment by MAPLE-B2. Values: 0...299

26.5.3.5.2.7 MAPLE CRPE-ULB Group <x> Configuration 3 Parameter (MCUBGxC3P)

The MCUBGxC1P to MCUBGxC4P parameters holds the uplink processing group configurations.

Table 26-160. MAPLE CRPE-ULB Group x Configuration 3 Fields Description

Bits	Description
31–28	Reserved
27–1]	G_xANTSZ — Antenna OVS Input Buffer size in 512 bytes multiplications (256 chips)
15–12	Reserved
11–0	G_xARP— Read pointer indication to all antennas in the group. Should be initialized by the host, and maintained by MAPLE-B2 during data read operations. This pointer indicates the offset in SBS (512 bytes / 256 chips) from the beginning of each antenna OVS buffer of the group. Calculating the group/antenna/Sub-Slot/OVS buffer address is done as follows: (*MCUBANTxDP[ABA] + OVS*ANTSZ + GxARP)*512*, where OVS = 0 to #(num of oversamples-1).

26.5.3.5.2.8 MAPLE CRPE-ULB Group <x> Configuration 4 Parameter (MCUBGxC4P)

The MCUBGxC1P to MCUBGxC4P parameters holds the uplink processing group configurations.

Offset 0x0000280C (MCUBGxC4P)
offset 0x10
x = 0...23

Table 26-163. MAPLE CRPE-ULB Configuration Fields Description

Bits	Description
31–18	Reserved
17–16	MB_PR — Valid only if the [MB_PR_SCH] of the MMC0P parameter (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*) is set to ‘01’ or ‘10’. Indicated the MBus accesses priority related to the CRPE-ULB. For details, see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The MBus accesses related to the CRPE-ULB are initiated with priority ‘00’ ... 11—The MBus accesses related to the CRPE-ULB are initiated with priority ‘11’
15–-7	Reserved.
6–5	IIL — Input Interpolation Level. Indicates the input interpolation level in case of external interpolation mode (*INT_MODE* = 0). 00 - Input interpolation is 2. 01 - Input interpolation is 4. 10 - Input interpolation is 8. 11 - Input interpolation is 16.
4–0	NOG — Number of Groups. Indicates the total number of groups. Valid values: 1 to 24

26.5.3.5.2.11 MAPLE CRPE-ULB Output Buffer Interrupt Configuration Parameter (MCUBOBICP)

This parameter describes the general output buffer interrupt configuration parameters.

Offset 0x00002B04 (MCUBOBICP) Access: User read/write

Figure 26-213. MAPLE CRPE-ULB Output Buffer Interrupt Configuration Parameter

Table 26-164. MAPLE CRPE-ULB Output Buffer Interrupt Configuration Fields Description

Bits	Description
31–26	Reserved
25–16	OB_INT_CHK_STEP — Output Buffer Interrupt Check Step. Indicates the time distance in number of SBS, where MAPLE-B2 is to check the finished physical channels buffer. If set to zero no checks are performed and no output buffer interrupt is issued. For details see **Section 26.4.3.6.1.15**, *Output Interrupt and Finished Channels Buffer Maintenance.*
15–10	Reserved
9–1	FCWP — Finished Channels Write Pointer. Write pointer to the finished channels buffer in 2 bytes unit. It is the offset from the beginning of the buffer. Increment modulo 512 when adding a channel to the buffer. Host should maintain a read pointer to the buffer to be able to read newly added finished channels up to the FCWP see **Section 26.4.3.6.1.15**, *Output Interrupt and Finished Channels Buffer Maintenance.*
0	Reserved

26.5.3.5.2.12 MAPLE CRPE-ULB Finished Channels Buffer <x> Parameter (MCUBFCBxP)

This set of parameters is a cyclic list maintained by MAPLE-B2 and includes the finished physical channels.

Offset 0x00002C00 (MCUBFCBxP)
offset 2
x = 0... 511

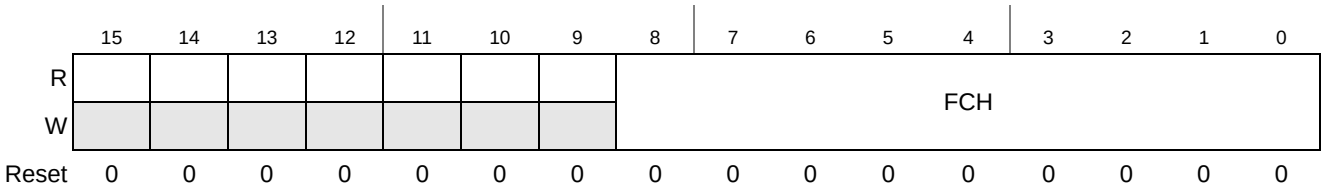

Figure 26-214. MAPLE CRPE-ULB Finished Channel Buffer Parameter

Table 26-165. MAPLE CRPE-ULB Finished Channel Buffer Fields Description

Bits	Description
15–9	Reserved
8–0	FCH — Finished Channel ID. A physical channel id of a finished channel. This array constitutes the finished channels buffer. MAPLE-B2 adds any new finished buffer to this buffer at the *MCUBOBICP[FCWP]* location and advances *MCUBOBICP[FCWP]*. For details see **Section 26.4.3.6.1.15**, *Output Interrupt and Finished Channels Buffer Maintenance.*

26.5.3.5.3 CRPE-ULF Parameters Description

The following subsections describe the CRPE-ULF description and control parameters. **Table 26-166** lists the MAPLE-B2 CRPE-ULF Parameter RAM sections.

Table 26-166. CRPE-ULF Parameter RAM Detailed Description

Address	Parameters	Access	Initialization Value[1]	Section
CRPE-ULF Parameter RAM

Figure 26-218. MAPLE CRPE-ULF Interpolation Bypass General Configuration

Table 26-170. MAPLE CRPE-ULF Interpolation Bypass General Configuration Fields Description

Bits	Description
31–27	TMR — Time (in clock cycles) to wait between last buffer check and next buffer check in 32 chips processing time window. The number of wait cycles are calculates as follows: (TMR + 4) x 130. 0—wait period is 520 cycles. 1—wait period is 650 cycles. ...
26–24	NOG — Number Of Groups. 0 - Single group 1 - Two groups. ... 7 - Eight groups.
23–16	SIZE — Size of OVS buffer in 512 byte resolution. Each antenna's buffer size is calculated as follows: SIZE x 512 x OVS. Size is common to all antenna buffers. 0—Reserved. 1—Size of OVS buffer is 512 Bytes 2—Size of OVS buffer is 1024 Bytes ...
15–6	RP — Joined Read pointer common to all groups antennas. The Read Pointer is 64 bytes aligned. The read pointer is increment by MAPLE-B2 when fetching new input data from all groups.
5–0	Reserved.

26.5.3.5.3.5 MAPLE CRPE-ULF General Configuration Parameter (MCUFGCP)

This parameter holds the general configuration parameters of the CRPE-ULF.

26.5.3.5.4 CRPE-DL Parameters Description

The following subsections describe the MAPLE-B2 CRPE-DL channels parameters and status fields. Most of the fields are updated by the host, some status fields are updated by MAPLE-B2. The parameters are implemented in MAPLE-B2's DRAM and used for channels' activation, termination and compression status update. The parameters contain all required information for performing symbols fetch from system buffer and chips transfers to system output buffers. **Table 26-174** lists the MAPLE-B2 CRPE-DL Parameter RAM sections.

Table 26-174. CRPE-DL Parameter RAM Detailed Description

Figure 26-222. MAPLE CRPE-DL Slot Channel <x> Parameter 0

Table 26-175. MAPLE CRPE-DL Slot Channel <x> Parameter 0 Fields Description

Bits	Description
31–14	MSBSZ — MAPLE-B2 System Buffer Size. Size of the channel's system buffer at 2 bytes unit. Range: 8 to (256K-1).
13	Reserved
12	MVALID — Valid indication for channel's parameters. Cleared by MAPLE-B2 at initialization after reset negation. Set by host upon parameters' update. Cleared by MAPLE-B2 when channel is terminated. 0 - Channel parameters are not valid. 1 - Channel parameters are valid.
11–9	Reserved
8	MSTARTED — Indication that channel has already been started. Cleared by MAPLE-B2 at initialization after reset negation. Cleared by host upon channel activation. Set by MAPLE-B2 at first channel's slot. Cleared by MAPLE-B2 when channel is terminated. 0 - Channel has not been started. 1 - Channel has been started.
7–4	MESL — MAPLE-B2 End Slot. Slot to stop the channel. Valid only when *MCONT*=0. Range: 0 to14.
3–0	MSSL — MAPLE-B2 Start Slot. When *STARTED*=0 and *MVALID*=1, *MSSL* defines the slot in which the channel starts. *MSSL* also defines channel's transition slot from non-compressed mode to compressed mode or vice-versa. Valid only when *MSTARTED*=0. Range: 0-14.

26.5.3.5.4.2 MAPLE CRPE-DL Slot Channel <x> Parameter 1 (MCDLSCxP1)

These parameters and status fields, along with *MCDLSCxP0*, *MCDLSCxP2* and *MCDLSCxRPP* parameters, control the channel #x activation, termination, compressed status update and symbols' fetch from system buffer. MAPLE-B2 checks these parameters and status fields once every slot.

Table 26-176. MAPLE CRPE-DL Slot Channel <x> Parameter 1 Fields Description

Bits	Description
31	Reserved
30	MCMPN — MAPLE-B2 Compressed Mode Next. This field indicates compressed mode status of channel starting from *MSSL* and *MSSBS* (including). 0 - Non Compressed Mode. 1 - Compressed Mode.
29	MCMPC — MAPLE-B2 Compressed Mode Current. This field indicates compressed mode status of channel up until *MSSL* and *MSSBS* (not including). MAPLE-B2 overrides *MCMPC* by *MCMPN* when input stream associated with *MSSL* and *MSSBS* is handled. 0 - Non Compressed Mode. 1 - Compressed Mode.
28	MSYNC — MAPLE-B2 Synchronization Channel. Synchronization channel indication. For synchronization channel, 512 bytes are fetched at each slot, starting with *MSSL*=*MSSBS*=0. 0 - Non Synchronization Channel. 1 - Synchronization Channel.
27–13	Reserved
12	MCONT — MAPLE-B2 Continuing Channel. Indication that following *MSSL* and *MSSBS*, channel processing should continue, ignoring *MESL* and *MESBS*. 0 - non continuing channel, *MESL* and *MESBS* represent valid termination point of the channel. 1 - continuing channel, *MESL* and *MESBS* are non-valid and ignored.
11–8	MESBS — MAPLE-B2 End Sub Slot. Channel's processing ends at this sub-slot position at *ESL* slot. Valid only when *MCONT*=0. Range: 0-9.

Table 26-176. MAPLE CRPE-DL Slot Channel <x> Parameter 1 Fields Description

Bits	Description
7–4	MSSBS — MAPLE-B2 Start Sub Slot. Channel's processing starts from this sub-slot position at *MSSL* slot. Valid only when *MSTARTED*=0 and *MVALID*=1. Range: 0-9.
3	MSFR — MAPLE-B2 Spreading Factor Reduction. This field indicates whether the channel is reducing spreading factor by 2 when operating at compressed mode. 0 - Spreading factor is not reduced when operating at compressed mode. 1 - Spreading factor is reduced by 2 when operating at compressed mode.
2–0	MSF — MAPLE-B2 Spreading Factor This field indicates the spreading factor at non-compressed mode. 0 - spreading factor = 4 1 - spreading factor = 8 2 - spreading factor = 16 3 - spreading factor = 32 4 - spreading factor = 64 5 - spreading factor = 128 6 - spreading factor = 256 7 - spreading factor = 1 (for synchronization channels)

26.5.3.5.4.3 MAPLE CRPE-DL Slot Channel <x> Parameter 2 (MCDLSCxP2)

These parameters and status fields, along with *MCDLSCxP0*, *MCDLSCxP1* and *MCDLSCxRPP* parameters, control the channel #x activation, termination, compressed status update and symbols' fetch from system buffer. MAPLE-B2 checks these parameters and status fields once every slot.

Figure 26-233. MAPLE CRPE-DL Number Of Channels Limit Parameter

Table 26-186. MAPLE CRPE-DL Number Of Channels Limit Parameter Fields Description

Bits	Description
31–24	Reserved
23–16	MNOFCL — MAPLE Number Of Fast Channels Limit. This field defines a limit to the number of supported fast channels. This limit includes the external-sttd channels. For a limit of k channels, first k sets fast channels parameters are operational. Range: 0-200. **Note**: Though the number of supported sets of parameters for fast channels may exceed 100, actual transmission of only up to 100 fast channels should be active at the same time.
15–10	Reserved
9–0	MNORCL — MAPLE Number Of Regular Channels Limit. This field defines a limit to the number of supported channels. This limit does not include the external-sttd channels. For a limit of k channels, channels #0-#(k-1) are supported in addition to their optional coupled channels #512–#(k+511). Range: 0-512.

26.5.3.5.4.13 MAPLE CRPE-DL General Configuration Parameter (MCDLGCP)

This parameter defines the general configuration parameters of the CRPE-DL.

Offset 0x00008984 (MCDLGCP) Access: User read/write

Figure 26-234. MAPLE CRPE-DL General Configuration Parameter

Table 26-187. MAPLE CRPE-DL General Configuration Parameter Fields Description

Bits	Description
31–2	Reserved
1–0	MB_PR — Valid only if the *MB_PR_SCH* of the *MMC0P* parameter (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*) is set to ‘01’ or ‘10’. Indicated the MBus accesses priority related to CRPE-DL. For details, see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The MBus accesses related to the CRPE-DL are initiated with priority ‘00’ ... 11—The MBus accesses related to the CRPE-DL are initiated with priority ‘11’

26.5.3.6 Serial RapidIO Doorbell Support Attributes Parameters

For the functional description of the Serial RapidIO parameters, see **Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell*."**

26.5.3.6.1 Serial RapidIO Outbound RapidIO Doorbell Port 1 Base Address Parameter (SORDP0BAP)

This parameter defines the base address of the Serial RapidIO Outbound Doorbell controller of port 1 for MAPLE-B2.

Offset 0x00000480 (SORDP0BAP) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 26-235. Serial RapidIO Outbound RapidIO Doorbell Port 1 Base Address Parameter

Table 26-188. Serial RapidIO Outbound RapidIO Doorbell Port 1 Base Address Parameter Fields Description

Bits	Description
31–0	BA—Base Address of the Outbound Doorbell controller for port 1. Using this field MAPLE-B2 assumes the following addresses for the Outbound Doorbell controller of port 1: OD0MR BA + 0x0 OD0SR BA + 0x4 OD0DPR BA + 0x18 OD0DATR BA + 0x1C OD0RETCR BA + 0x2C This parameter is valid only if MBDR(H/L)PBxP[EXT_MST] equals '01'.

26.5.3.6.2 Serial RapidIO Outbound RapidIO Doorbell Port 2 Base Address Parameter (SORDP1BAP)

This parameter defines the base address of the Serial RapidIO Outbound Doorbell controller of port 2 for MAPLE-B2.

Offset 0x00000484 (SORDP1BAP) Access: User read/write

Figure 26-236. Serial RapidIO Outbound RapidIO Doorbell Port 2 Base Address Parameter

Table 26-189. Serial RapidIO Outbound RapidIO Doorbell Port 2 Base Address Parameter Field Description

Bits	Description
31–0	BA—Base Address of the Outbound Doorbell controller for port 2. Using this field MAPLE-B2 assumes the following addresses for the Outbound Doorbell controller of port 2: OD0MR[1] BA + 0x0 OD0SR BA + 0x4 OD0DPR BA + 0x18 OD0DATR BA + 0x1C OD0RETCR BA + 0x2C This parameter is valid only if MBDR(H/L)PBxP[EXT_MST] equals ’10’.

1. For details on the Doorbell controller registers see RMU_block_guide_Rev0.pdf section 4.4.1.1

26.5.3.6.3 Hardware Semaphore Port 1 Base Address Parameter (HSP0BAP)

This parameter defines the base address and the enable bit of the external Hardware Semaphore register to be used when accessing the Serial RapidIO Doorbell controller of port 0 for the MAPLE-B2. If the enable bit is set, the Serial RapidIO Doorbell can only be accessed if the semaphore is locked by the MAPLE-B2.

Offset 0x00000488 (HSP0BAP) Access: User read/write

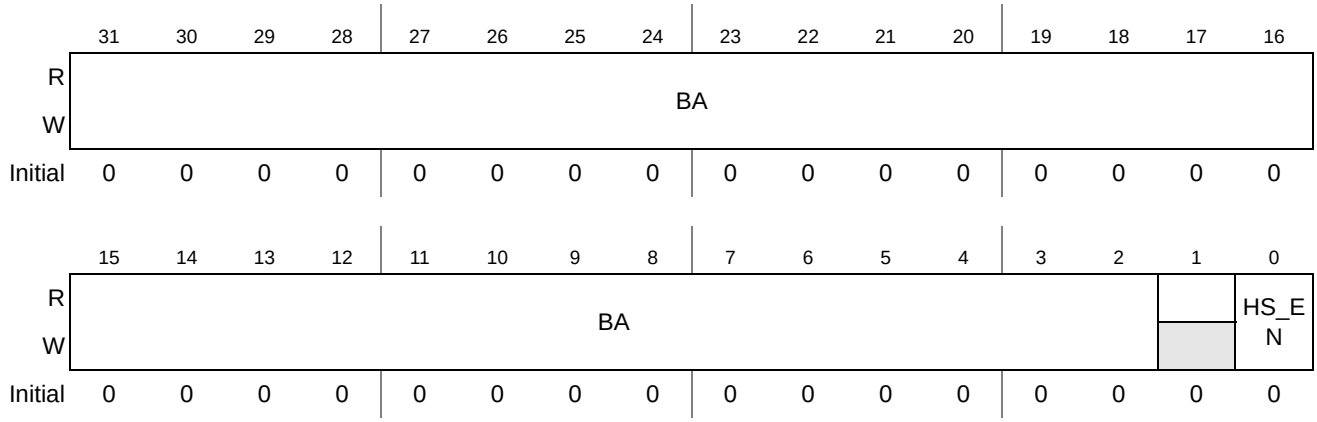

Figure 26-237. Hardware Semaphore Port 1 Base Address Parameter

Table 26-190. Hardware Semaphore Port 1 Base Address Parameter Field Description

Bits	Description
31–2	BA—Base Address of the hardware Semaphore register. If the HSP0BAP[HS_EN] is enabled and the MBDR(H/L)PBxP[EXT_MST] equals'01', then the MAPLE-B2 conditions its access to the Serial RapidIO Doorbell controller by locking the semaphore pointed to by this field. The address in this field must be 4 bytes aligned.
1	Reserved.
0	HS_EN—Hardware Semaphore Enable. If set, the MAPLE-B2 must lock the external semaphore located in address HSP0BAP[BA] with the PE ID (MDHSIDCP['pe'_HS_ID]) before it can access the doorbell controller of port 1. 0 - The MAPLE-B2 uses internal semaphore implementation to arbitrate between the PEs trying to access the doorbell controller port 1 1 - The MAPLE-B2 uses the external semaphore located at address HSP0BAP[BA] to arbitrate between the PEs and other external potential doorbell controller masters of port 1.

26.5.3.6.4 Hardware Semaphore Port 2 Base Address Parameter (HSP1BAP)

This parameter defines the base address and the enable bit of the external Hardware Semaphore register to be used when accessing the Serial RapidIO Doorbell controller of port 1 for the MAPLE-B2. If the enable bit is set, the Serial RapidIO Doorbell can only be accessed if the semaphore is locked by the MAPLE-B2.

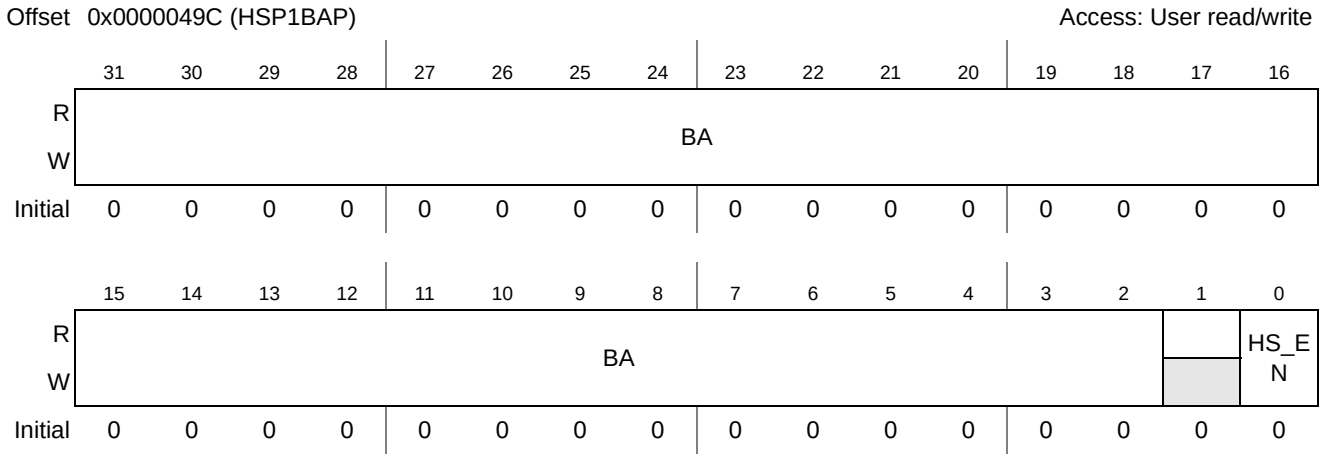

Figure 26-238. Hardware Semaphore Port 2 Base Address Parameter

Table 26-191. Hardware Semaphore Port 2 Base Address Parameter Field Description

Bits	Description
31–2	BA—Base Address of the hardware Semaphore register. If the HSP1BAP[HS_EN] is enabled and the MBDR(H/L)PBxP[EXT_MST] equals'10', then the MAPLE-B2 conditions its access to the Serial RapidIO Doorbell controller by locking the semaphore pointed to by this field. The address in this field must be 4 bytes aligned.
1	Reserved.
0	HS_EN—Hardware Semaphore Enable. If set, the MAPLE-B2 must lock the external semaphore located in address HSP1BAP[BA] with the PE ID (MDHSIDCP['pe'_HS_ID]) before it can access the doorbell controller of port 2. 0 - The MAPLE-B2 uses internal semaphore implementation to arbitrate between the PEs trying to access the doorbell controller port 2 1 - The MAPLE-B2 uses the external semaphore located at address HSP1BAP[BA] to arbitrate between the PEs and other external potential doorbell controller masters of port 2.

26.5.3.6.5 MAPLE-B Doorbell Hardware Semaphore ID Configuration Parameter (MDHSIDCP)

This parameter defines the ID number by which it locks the Hardware Semaphore register for MAPLE-B2.

Offset 0x00000490 (MDHSIDCP) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 26-239. MAPLE-B Hardware Semaphore ID

Table 26-192. MAPLE-B Hardware Semaphore ID Field Description

Bits	Description
31 – 24	CRC_HS_ID—CRCPE Hardware Semaphore ID. If the HSP(0/1)BAP[HS_EN] is enabled and the MCRCBR(H/L)PBxP[EXT_MST] equals'01'/'10', then the MAPLE-B2 must lock the External Hardware Semaphore (HS) before accessing the sRIO Doorbell controller. Accessing the HS for the CRCPE rings is done using the ID described in this field
23 –16	TV_HS_ID—eTVPE Hardware Semaphore ID. If the HSP(0/1)BAP[HS_EN] is enabled and the MTVBR(H/L)PBxP[EXT_MST] equals'01'/'10', then the MAPLE-B2 must lock the External Hardware Semaphore (HS) before accessing the sRIO Doorbell controller. Accessing the HS for the eTVPE rings is done using the ID described in this field.
15–8	DF_HS_ID—DFTPE Hardware Semaphore ID. If the HSP(0/1)BAP[HS_EN] is enabled and the MDFBR(H/L)PBxP[EXT_MST] equals'01'/'10', then the MAPLE-B2 must lock the External Hardware Semaphore (HS) before accessing the sRIO Doorbell controller. Accessing the HS for the DFTPE rings is done using the ID described in this field.
7–0	FF_HS_ID—FFTPE Hardware Semaphore ID. If the HSP(0/1)BAP[HS_EN] is enabled and the MFFBR(H/L)PBxP[EXT_MST] equals'01'/'10', then the MAPLE-B2 must lock the External Hardware Semaphore (HS) before accessing the sRIO Doorbell controller. Accessing the HS for the FFTPE rings is done using the ID described in this field.

26.5.3.6.6 MAPLE-B Doorbell General Configuration Parameter (MDGCP)

This parameter defines general parameters to be used while accessing the sRIO doorbell controller.

Offset 0x00000494 (MDGCP) Access: User read/write

Figure 26-240. MAPLE-B Hardware Semaphore ID

Table 26-193. MAPLE-B Hardware Semaphore ID Field Description

Bits	Description
31–10	Reserved.
9–8	BD_PR—sRIO Doorbell ‘Transaction flow level’. Defines the Priority of the doorbell transaction. This field is written by the MAPLE-B2 to the *OM0DATR[DTFLOWLVL]* register of the Doorbell controller.
7–0	RET—sRIO Doorbell ‘Retry error threshold’. Defines the number of times the Doorbell unit attempts to transmit the Doorbell. This field is written by the MAPLE-B2 to the *OD0RETCR[RET]* register of the Doorbell controller.

26.5.4 Descriptors

Descriptors include buffer descriptor (BD) rings, BDs, and task descriptors. The BD rings and BDs include general MAPLE-B2 BD rings and BDs and sets specific for individual PEs.

26.5.4.1 General BD Ring and BD Parameters

Table 26-194 lists the MAPLE-B2 general BD Ring and BD parameters.

Table 26-194. General BD Ring and BD Parameters

1. All the parameters in the parameter RAM are initialized during the MAPLE-B2 API initialization sequence, and are not hardware reset values. See the *MAPLE-B2 Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)

The following subsections configure the BD rings and BDs.

Note: The MAPLE-B2 general configuration parameters should be initialized by the host after the MAPLE-B2 initialization.

26.5.4.1.1 MAPLE BD Rings Configuration Parameter 0 (MBDRCP0)

This parameter, along with the MBDRCP1 and MBDRCP2 parameters, determines the number of high/low BD rings used and the arbitration scheme between the high/low BD rings for each of the PEs.

Offset 0x00000004 (MBDRCP0) Access: User read/write

26.5.4.1.4 MAPLE <yy>PE BD Ring High Priority A <x> Parameter (M<yy>BRHPAxP)

These parameters, along with **M<yy>BRHBxP,** describe the attributes of a High-Priority yyPE BD ring. The <yy> stands for: TV (eTVPE), F0 (eFTPE_0), F1 (eFTPE_1), F2 (eFTPE_2), DE (DEPE), CRC (CRCPE), EQ (EQPE), CONV (CONVPE). There are 8 such parameters for each PE, one for each possible High-Priority BD ring related to the PE. The following table describes all the instantiations of this parameter:

Table 26-198. M<yy>BRHPAxP Instantiation

Figure 26-244 describe the M<yy>BRHPAxP structure:

Offset see **Table 26-198** Access: User read/write

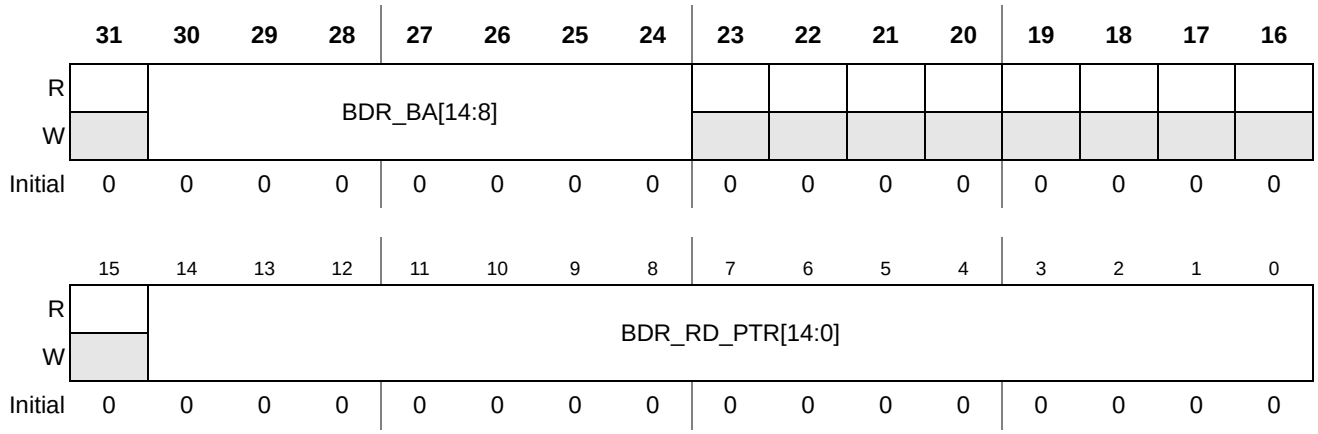

Figure 26-244. MAPLE <yy>PE BD Ring High Priority A <x> Parameter

Table 26-199. MAPLE <yy>PE BD Ring High Priority A <x> Parameter Fields Description

Bits	Description
31	Reserved
30–24	BDR_BA[14:8]—BD Ring Base Address. Points to the base address of the BD ring in the PSIF2 DRAM. The address must be aligned to 256 bytes. Therefore the field range is 14:8. The B.A. should be within the 32KBytes of BD memory in the DRAM. The given address is relative to the start address of the BD memory in the DRAM. 0x00 to 0x7F BD Ring Base Address for <yy>PE High Priority Ring x. (stands for base address 0x0000 to 0x7F00)
23–15	Reserved
14–0	BDR_RD_PTR[14:0]—BD Ring Read Pointer. This pointer points to the current BD in the ring the MAPLE-B2 is currently processing. It is increment by the MAPLE-B2 after BD has started processing. The host can use this pointer to track the MAPLE-B2's progress in the BD ring. This read pointer must be initialized once by the host when initializing the BDR_BA field with the same value as BDR_BA (BDR_RD_PTR[14:0] = {BDR_BA[14:8],0...0}), and must not be overwritten once the operation starts. Altering the contents of this pointer by the host results in unexpected results. The pointer should be relative to the start address of the BD memory in the DRAM. Therefore, the range of addresses should be: 0x0000 to 0x7FFF Read Pointer for <yy>PE High Priority Ring x

26.5.4.1.5 MAPLE <yy>PE BD Ring High Priority B <x> Parameter (M<yy>BRHPBxP)

These parameters, along with **M<yy>BRHAxP,** describe the attributes of a High-Priority yyPE BD ring. The <yy> stands for: TV (eTVPE), F0 (eFTPE_0), F1 (eFTPE_1), F2 (eFTPE_2), DE (DEPE), CRC (CRCPE), EQ (EQPE), CONV (CONVPE). There are 8 such parameters for each PE, one for each possible High-Priority BD ring related to the PE. The following table describes all the instantiations of this parameter:

Figure 26-245. MAPLE <yy>PE BD Ring High Priority B <x> Parameter

Table 26-201. MAPLE <yy>PE BD Ring High Priority B <x> Parameter Fields Description

Bits	Description
31–16	HOST_ID—16 bits of Host ID for Serial RapidIO door-bell support for an External (to DSP device) master connected to the DSP device by Serial RapidIO port and is the owner of this ring. This field is valid only if MTVBRHPBxP[EXT_MST] equals ‘01’ or’10’.
15–12	P_TR_IF—Port Target Interface. Determines which RapidIO port to use for this doorbell. This field is used by the MAPLE-B2 for the Word4[TINT] field in the Type10 Outbell Doorbell descriptor.
11–10	EXT_MST—External Master. Describes if the Ring owner can receive any of the MAPLE-B2 regular interrupt lines, and an interrupt (one out of 16) is generated if the [INT_EN] bit in the BD is set; or if the ring owner is connected to the DSP device via Serial RapidIO port and the Serial RapidIO door-bell interrupt is generated if the [INT_EN] bit in the BD is set. For details see **Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell*.”** ‘00’ The master of this ring can receive any of the MAPLE-Bs regular interrupts, therefore a regular interrupt is generated according to MTVBRHPBxP[INT_TRGT]. ’01’ The master of this ring is External (connected via Serial RapidIO port), therefore a Serial RapidIO door-bell interrupt is generated. The door-bell should be initiated via Serial RapidIO port 1 (**Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell***”). ‘10’ The master of this ring is External (connected via Serial RapidIO port), therefore a Serial RapidIO door-bell interrupt is generated. The door-bell should be initiated via Serial RapidIO port 2 (**Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell***”). ‘11’ Reserved
9	Reserved.
8–4	INT_TRGT—Defines which regular interrupt is to be asserted due to task completion in this BD ring.This field is valid only if MTVBRHPBxP[EXT_MST] equals ’00’. 00000 irq0 00001 irq1 ... 11111 irq31
3–1	Reserved
0	VLD—Valid Bit. Describes if the current BD ring is valid. The MAPLE-B2 uses this bit to determine the BD Ring’s validation, therefore any change in any of the BD Ring’s parameters must be done while the VLD bit is cleared. 0 BD ring is not valid. 1 BD ring is valid.

26.5.4.1.6 MAPLE <yy>PE BD Ring Low Priority A <x> Parameter (M<yy>BRLPAxP)

These parameters, along with **M<yy>BRLBxP,** describe the attributes of a Low-Priority <yy>PE BD ring. The <yy> stands for: TV (eTVPE), F0 (eFTPE_0), F1 (eFTPE_1), F2 (eFTPE_2), DE (DEPE), CRC (CRCPE), EQ (EQPE), CONV (CONVPE). There are 8 such parameters for each PE, one for each possible Low-Priority BD ring related to the PE. The following table details all the instantiations of this parameter:

Figure 26-246. MAPLE <yy>PE BD Ring Low Priority A <x> Parameter

Table 26-203. MAPLE <YY>PE BD Ring Low Priority A <x> Parameter Fields Description

Bits	Description
31	Reserved
30–24	BDR_BA[14:8]—BD Ring Base Address. Points to the base address of the BD ring in the PSIF2 DRAM. The address must be aligned to 256 bytes, and therefore, the field range is 14:8. The B.A should be within the 32Kbytes of BD memory in the DRAM. The given address is relative to the start address of the BD memory in the DRAM. 0x00 to 0x7F BD Ring Base Address for <yy>PE Low Priority Ring x. (stands for base address 0x0000 to 0x7FFF)
23–15	Reserved
14–3	BDR_RD_PTR[14:0]—BD Ring Read Pointer. This pointer points to the current BD in the ring the MAPLE-B2 is currently processing. It is post-increment by the MAPLE-B2, after BD has started processing. The host can use this pointer to track the MAPLE-B2's progress in the BD ring. This read pointer must be initialized once by the host when initializing the BDR_BA field, and with the same value as BDR_BA (BDR_RD_PTR[14:0] = {BDR_BA[14:8],0...0}), and must not be overwritten once the operation starts. Altering the contents of this pointer by the host results in unexpected results. The pointer should be relative to the start address of the BD memory in the DRAM, therefore the range of addresses should be: 0x0000 to 0x7F00 Read Pointer for <yy>PE Low Priority Ring x
2–0	Reserved

26.5.4.1.7 MAPLE <yy>PE BD Ring Low Priority B <x> Parameter (M<yy>BRLPBxP)

These parameters, along with **M<yy>BRLAxP,** describe the attributes of a Low-Priority <yy>PE BD ring. The <yy> stands for: TV (eTVPE), F0 (eFTPE_0), F1 (eFTPE_1), F2 (eFTPE_2), DE (DEPE), CRC (CRCPE), EQ (EQPE), CONV (CONVPE). There are 8 such parameters for each PE, one for each possible Low-Priority BD ring related to the PE. The following table details all the instantiations of this parameter:

Table 26-204. M<yy>BRLPBxP Instantiation

Figure 26-247 describe the M<yy>BRLPbxP structure:

Offset see **Table 26-204** Access: User read/write

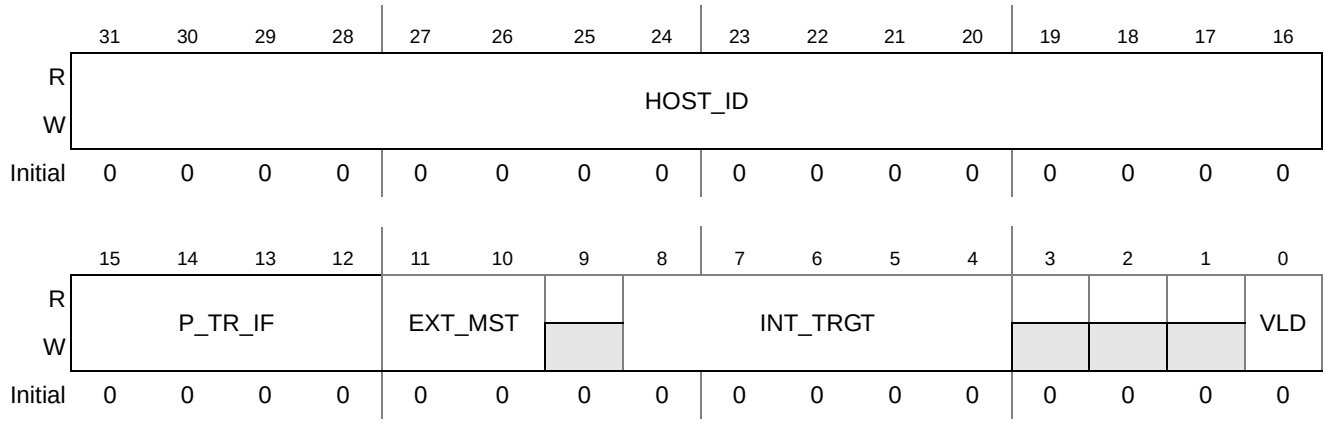

Figure 26-247. MAPLE <yy>PE BD Ring Low Priority B <x> Parameter

Table 26-205. MAPLE <yy>PE BD Ring Low Priority B <x> Parameter Fields Description

Bits	Description
31–16	HOST_ID–16 bits of Host ID for Serial RapidIO door-bell support for an external (to DSP device) master connected to the DSP device by Serial RapidIO port and is the owner of this ring. This field is valid only if M<yy>BRLPBxP[EXT_MST] equals ‘01’ or ‘10’.
15–12	P_TR_IF—Port Target Interface. Determines which RapidIO port to use for this doorbell. This field is used by the MAPLE-B2 for the Word4[TINT] field in the Type10 Outbound Doorbell descriptor.
11–10	EXT_MST—External Master. Describes if the Ring owner can receive any of the MAPLE-B2’s regular interrupt lines, and a regular interrupt (one out of 32) is generated if the [INT_EN] bit in the BD is set; or if the ring owner is connected to the DSP device via Serial RapidIO port and a Serial RapidIO door-bell interrupt is generated if the [INT_EN] bit in the BD is set. For details see **Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell*.”** ’00’ The master of this ring can receive any of the MAPLE-Bs regular interrupts, therefore a regular interrupt is generated according to MTVBRLPBxP[INT_TRGT]. ’01’ The master of this ring is external (connected via Serial RapidIO port), therefore a Serial RapidIO door-bell interrupt is generated. The door-bell should be initiated via Serial RapidIO port 1 (**Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell***”). ’10’ The master of this ring is external (connected via Serial RapidIO port), therefore a Serial RapidIO door-bell interrupt is generated. The door-bell should be initiated via Serial RapidIO port 2 (**Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell***”). ’11’ Reserved
9	Reserved.
8–4	INT_TRGT—Defines which regular interrupt is to be asserted due to task completion in this BD ring. This field is valid only if M<yy>BRLPBxP[EXT_MST] equals ’00’. 00000 irq0 00101 irq1 ... 11111 irq31
3—1	Reserved.
0	VLD—Valid Bit. Describes if the current BD ring is valid. The MAPLE-B2 uses this bit to determine the BD Ring’s validation, therefore, any change in any of the BD Ring’s parameters must be done while the VLD bit is cleared. 0 BD ring is not valid. 1 BD ring is valid.

26.5.4.2 eTVPE Buffer-Descriptor Structure

The following is a description of the eTVPE Buffer Descriptors structure as they should be written to the eTVPE BD rings by the host. Some of the fields may not be relevant for some configurations and are ignored by MAPLE-B2.

Figure 26-248. eTVPE Buffer Descriptor Structure (Continued)

Table 26-206. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
OWNER	**Owner bit**. When set by the host, MAPLE-B2 is the BD owner and the job is not complete. When cleared by MAPLE-B2, the job is done and the host is the BD owner. 0—The host is BD owner 1—MAPLE-B2 is BD owner
WRAP	**Wrap bit**. When set by the host, MAPLE-B2 updates the [BDR_RD_PTR[14:5]] field with [BDR_BA[14:8]], that is, it expects to find the next BD at the Base Address of the ring. When cleared by the host, MAPLE-B2 expects to find the next BD at: [BDR_RD_PTR[14:5]] + BD size. For details, see **Section 26.5.4.1.4** or **Section 26.5.4.1.6**

Table 26-206. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
INT_EN	**Interrupt Enable**. If set, MAPLE-B2 issues an interrupt/door-bell interrupt at the end of this job. If cleared, no interrupt is issued. 0—End of job interrupt is NOT issued. 1—End of job interrupt is issued.
L_MAP	**LogMAP Algorithm**. Valid only for Turbo decoding (ALG=0). Describes the LogMAP algorithm. 0—MaxLogMAP 1—Hybrid Linear LogMAP (Max*).
STD	**Standard**. Determines which standard technology this job relates to. 0—UMTS or WiMAX technology for 3G or WiMAX operation modes respectively. 1—3GLTE standard.
VIT_K[2:0]	**Viterbi Constraint Length (K)**. Valid only for Viterbi decoding (ALG=1). Describes the encoding constraint length.Valid only during Viterbi decoding: 000—Reserved 001—K=5. 010—K=6. 011—K=7. 100—K=8. 101—K=9. 110 to 111—Reserved.
TBZE	**Trace Back from Zero Enable**. Valid only for Viterbi decoding (ALG=1) and only if Zero Tail trellis termination is assumed (ZTTB=1). If set, the trace back calculation starts from Zero state, regardless of the maximum path calculations. If cleared the trace back calculation starts from the winning state of the maximum calculation regardless if the result was the Zero state. 0—The Trace back calculation always starts from the winner of the maximum path calculations. 1—The Trace Back calculation always starts from state zero.
ZTTB	**Zero Tail or Tail Biting trellis termination**. 0—Tail Biting trellis termination assumed. 1—Zero Tail trellis termination assumed. **Notes:** **1.** For Turbo decoding (ALG=0) it should be configured as Zero Tail for 3G technologies (3GLTE or UMTS) and as Tail Biting for WiMAX technology. **2.** For Viterbi operation Tail Biting configuration implies WAVA* algorithm as described in **Section 26.4.3.2.6.7**, *Tail Biting Viterbi Processing (WAVA*)*.
CRC_EN	**CRC check enable**. Valid only for Turbo decoding. If set the eTVPE perform CRC check on the Hard Output results generated in the last iteration. The polynomial type is to be determined by the [CRC_POLY] field of the eTVPE BD. The CRC results are described in the [ERROR_STATUS] field of the BD. If the MTVCP[SCRC] bit or MTVCP[CRC_AUTOSTOP] bit is set, that is, CRC stopping criteria is enabled, CRC check is executed regardless of this bit configuration. (see **Section 26.4.3.2.6.10**, *CRC Check*, on page 26-69). 0—CRC check on the Hard Output is disabled. 1—CRC check on the Hard Output is enabled.
ENC_RATE[1:0]	**Encoder Rate**. Describes the encoding rate used for this job. 00—1/2 (Viterbi decoding only) 01—1/3 10—1/4 (Viterbi decoding only) 11—Reserved.
HAOE	**HARQ Accumulator Output Enable**. Valid only if the HARQ Enable bit ([HE]) of the MTVCP parameter is set. Determines whether the MAPLE-B2 is to output the HARQ accumulator after the HARQ stage in the eTVPE. If enabled the MAPLE-B2 output the HARQ result to the address pointed by the HA_OUT_BASE_ADDR field. 0—No HARQ accumulator buffer is being output. 1—HARQ accumulator buffer is being output to address pointed by HA_OUT_BASE_ADDR field.
ALG	**Decoding Algorithm Type**. 0—Turbo algorithm 1—Viterbi algorithm

Table 26-206. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
PUNC_SCHM[3:0]	**Puncturing Scheme**. Valid only for Viterbi processing ([ALG]=1). Selects one of the 10 possible depuncturing schemes as described in MTVPVxHCP and MTVPVxLCP. See also **Section 26.4.3.2.6.5.1**, *Viterbi Periodic Depuncturing*. 0000—Reserved. 0001—execute Periodic depuncture scheme #0 0010—execute Periodic depuncture scheme #1 ... 1010—execute Periodic depuncture scheme #9 1011 to 1111—Reserved.
MAX_ITER[3:0]	**Maximum number of iterations**. Valid only during Turbo decoding. Describes the Maximum number of full iterations to be executed assuming stop criteria was not reached. If stop criteria is not enabled, the MAX_ITER field represent the total number of iterations to be executed by the eTVPE. The MAX_ITER value is increment internally by one to represent the values 2 to 16. This value should always be larger than or equals to MIN_ITER. 1 to 15—maximum number of iterations 2 to 16, respectively.
MIN_ITER[3:0]	**Minimum number of iterations**. Valid only during Turbo decoding and only if one of the stop criteria is enabled. Describes the Minimum number of iterations executed by the eTVPE when stop criteria is enabled. The eTVPE starts with its stop criteria checks only after it has reached the number of iterations described in MIN_ITER field. This value should always be smaller or equal to MAX_ITER. 1 to 15—minimum number of iterations 2 to 16, respectively.
IN_D_STRCT[2:0]	**Input Data Structure**. Describes the possible input data structures in system memory to be fetched by MAPLE-B2 into the eTVPE. 000—LTE HARQ. See **Section 26.4.3.2.5.2**, *LTE HARQ Input Data Structure*. 001—WiMAX HARQ. See **Section 26.4.3.2.5.3**, *WiMAX HARQ Input Data Structure*. 010—E-DCH HARQ with Mixed Vector. See **Section 26.4.3.2.5.4**, *E-DCH HARQ with Mixed Vector Input Data Structure*. 011—E-DCH HARQ with Separate Vectors. See **Section 26.4.3.2.5.5**, *E-DCH HARQ with Separate Vectors Input Data Structure* 100—Sub-Block Interleaved. See **Section 26.4.3.2.5.6**, *Sub-Block Interleaved Input Data Structure* 101—UMTS Mixed. See **Section 26.4.3.2.5.7**, *UMTS Mixed Input Data Structure*. 110—Separate Vectors. See **Section 26.4.3.2.5.8**, *Separate Vectors Input Data Structure*. 111—Reserved.

Table 26-207. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Field	Description
BS[14:0]	**Block Size**. Describes the current tasks decoded block size in bits. For Turbo decoding it does not include Tail bits (if exist). Following are the valid values for this files: For 3GLTE: 0x28 to 0x1800 (40 to 6144 bits) according to the allowed K values block sizes as described in Table 5.1.3-3 (3GPP TS 36.212 V9.3.0) For WiMAX: 0x30 to 0x12C0 (48 to 4800 bits) For UMTS: 0x28 to 0x13FA (40 to 5114 bits) For Viterbi: 0x14 to 0x1800 (20 to 6144 bits)
LLMAP_LCF[7:0]	**Linear LogMAP correction factor**. Valid only for Turbo decoding and only if Max* LogMAP algorithm is enabled (L_MAP=1). The value of this field must be even. For details, see **Section 26.4.3.2.6.4.2**, *Turbo Processing Implementation*." 128 possible even decimal values.
CRC_POLY[1:0]	**CRC Polynomial**. Describes which Polynomial to use if CRC check or CRC stop criteria is required. For details, refer to **Section 26.4.3.2.6.10, *CRC Check*** 00—CRC24 with the following Polynomial: $D^{24} + D^{23} + D^6 + D^5 + D + 1$ 01—CRC24 with the following Polynomial: $D^{24} + D^{23} + D^{18} + D^{17} + D^{14} + D^{11} + D^{10} + D^7 + D^6 + D^5 + D^4 + D^3 + D + 1$ 10—CRC16-CCITT with the following polynomial: $D^{16} + D^{12} + D^5 + 1$ 11—Reserved.
NDRE[1:0]	**Number of DRE engines**. Valid only during Turbo decoding and only if MTVCP[ANDRE] is cleared. Determines the number of internal Turbo engines which participate in the decoding process. For details, see **Section 26.4.3.2.6.4.3**, *Number of Turbo Processing Elements (DREs)*. 00—Single DRE. 01—Two DRE engines. 10—Four DRE engines 11—Reserved.
MB_PR[1:0]	**MBus Priority**. Valid only if the [MB_PR_SCH] of the MMC0P parameter (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*) is set to '01' or '10'. Indicated the MBus accesses priority related to this BD. For details, see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The MBus accesses related to that BD are initiated with priority '00' ... 11—The MBus accesses related to that BD are initiated with priority '11'

Table 26-208. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x8

Name	Description
HOE	**Hard Output Enable**. Controls the availability of hard-output results from the eTVPE decoder. If set the MAPLE-B2 outputs the Hard Output results to the address in system memory as specified in HRD_RSLT_ADDR. 1—Hard output enabled 0—Hard output disabled
SOE[1:0]	**Soft Output Enable**. Controls the availability, and type of the soft-output results from the decoder, applicable for Turbo decoding only. For details, see **Section 26.4.3.2.7**, *eTVPE Output Data Structure* 00—No Soft Output 01—Aposteriori Output Enabled (16 bit systematic data only) 10—Extrinsic Output Enabled (16 bits systematic data only). 11—Turbo Soft Outputs (8 bits systematic and parities).
DPNC	**Depuncturing**. Valid only during Turbo decoding (ALG=0), UMTS standard job and when input data structure is 'E-DCH HARQ with Mixed Vector' or 'E-DCH HARQ with Separate Vectors' ([IN_D_STRCT]=2 or 3). Indicates the eTVPE which Rate De-Matching process to execute. 0— The eTVPE performs De-repetition process. 1— The eTVPE performs Depuncturing process.
TASK_ID[7:0]	**Task ID**—Task ID tag, supplied by host, assists in identification of its task when directly accessing the eTVPE to inquire task status. When MAPLE-B2 assigns the job to the eTVPE, it copies the TASK_ID into the eTVPE, thus allowing the host to track the eTVPE jobs.
VIT_SET[1:0]	**Viterbi Set**. Valid only for Viterbi decoding ([ALG]=1). Describes which set of Viterbi polynomial is used for the current job: 00—Reserved. 01—MAPLE-B2 use MTVPVS1CxP parameters to configure the internal eTVPE polynomials. 10—MAPLE-B2 use MTVPVS2CxP parameters to configure the internal eTVPE polynomials. 11—MAPLE-B2 use MTVPVS3CxP parameters to configure the internal eTVPE polynomials. For details, see **Section 26.4.3.2.6.5.1**, *Viterbi Periodic Depuncturing*
BUF_SIZE[17:0]	**Buffer Size**. Describes the input data buffer size (in bytes) to be fetched by MAPLE-B2 during the input stage. For details, see **Section 26.4.3.2.5**, *eTVPE Input Data Structures* 40B to 100KB - possible input block sizes. **Warm-up Size**. When working with Viterbi large block sizes, the BUF_SIZE field indicates the warm-up size required by MAPLE-B2. For details see **Section 26.4.3.2.6.8, *Viterbi Large Blocks Partitioning Support*** Warm-up values must be a multiplication of 8

Table 26-209. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0xC

Name	Description
HRD_RSLT_ADDR[31:0]	**Hard Result Address**. Describes the base address in system memory in which the MAPLE-B2 provides Hard Output results, if enabled (HOE=1).

Table 26-210. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x10

Name	Description
BASE_ADDR[31:0]	**Base Address**. — Points to the start address of the input buffer in case single input stream is required. — Points to the start address in the system memory of the first out of several input vectors. The start address of the other vectors is distances form this pointer by [VEC_OFFSET] multiplications. For details, see **Section 26.4.3.2.5.8**, *Separate Vectors Input Data Structure*.

Table 26-211. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x14

Name	Description
VEC_OFFSET[15:0]	**Vectors Offset**. Valid only for Separate Vectors and E-DCH HARQ with Separate Vectors input data structures. Describes the relative offset between the vectors in the system memory. For details, see **Section 26.4.3.2.5.8**, *Separate Vectors Input Data Structure*.
W_16M	**WiMAX 802.16m indication**. Valid only for WiMAX technology jobs and for Separate Vectors input data structure. Indicates that the required technology is 802.16m. 0— WiMAX 802.16e is assumed. 1— WiMAX 802.16m is assumed.
SFT_RSLT_OFF[2:0]	**Soft Results Offset**. Valid only if 3 vectors of soft outputs are required ([SOE] = 3). Describe the offset of second/third output vector with respect t the first/second output vector in system memory. For details, see **Section 26.4.3.2.8**, *Output Data Types* 000—Second/third vector start address is 256 bytes after first/second vector start address. 001—Second/third vector start address is 512 bytes after first/second vector start address. 010—Second/third vector start address is 1K bytes after first/second vector start address. 011—Second/third vector start address is 2K bytes after first/second vector start address. 100—Second/third vector start address is 4K bytes after first/second vector start address. 101—Second/third vector start address is 8K bytes after first/second vector start address. 110 to 111—Reserved.
HOFF[2:0]	**Hard Output Offset**. Valid only for UMTS standard or Viterbi processing. Describe the bit offset of the first byte in which the first valid bit is to be written. If greater than zero, the MAPLE-B2 writes the first byte in the system memory with bit resolution. For details, see **Section 26.4.3.2.8**, *Output Data Types*. 000—The first output bit is to be written to first bit of first byte. 001—The first output bit is to be written to second bit of first byte. 010—The first output bit is to be written to third bit of first byte. ... 111—The first output bit is to be written to eighth bit of first byte.
LLR_OUT_SF[3:0]	**LLR Output Shift**. Determines which 8 bits of the internal 16 bit wide soft outputs are going to be output. For details, see **Section 26.4.3.2.8**, *Output Data Types*. 0—soft output bits 7:0 are selected. 1—soft output bits 8:1 are selected. 2—soft output bits 9:2 are selected. 3—soft output bits 10:3 are selected. 4—soft output bits 11:4 are selected. 5—soft output bits 12:5 are selected. 6—soft output bits 13:6 are selected. 7—soft output bits 14:7 are selected. 8—soft output bits 15:8 are selected.

Table 26-212. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x18

Name	Description
IHBSA[14:0]	**Input HARQ Buffer Start Address**. Describe the address location of the first bit of the input stream in the HARQ accumulator buffer. For details, see **Section 26.4.3.2.6.2**, *HARQ Combining*.
FTH	**First Time HARQ**. Indicates whether this HARQ buffer is the first one hence no HARQ accumulator exist nor should be supplied. 0—This job is not the first HARQ buffer, hence HARQ accumulator should be supplied. 1—This job is the first HARQ buffer, hence accumulator should be internally reset.
IHBSZ[14:0]	**Input HARQ Buffer Size**. Describe the size of the current HARQ input stream into the accumulator. For details, see **Section 26.4.3.2.6.2**, *HARQ Combining*.

Table 26-213. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x1C)

Name	Description
HUS[1:0]	**HARQ Up Scale**. Describe the required up scaling of the HARQ input stream before being added into the HARQ accumulator buffer. 0—The Input data is not pre scaled before being added to the accumulator 1—The Input data is up scaled by 2 before being added to the accumulator 2—The Input data is up scaled by 4 before being added to the accumulator 3—The Input data is up scaled by 8 before being added to the accumulator
W1E	**Weight 1 Enable**. Describe whether accumulator data that is covered by input data is multiplied by W1 before being added to input data and updated as new accumulator data. For details, see **Section 26.4.3.2.6.2**, *HARQ Combining*. 0—Accumulator data covered by input data is **not** multiplied by W1 and is being added as is to input data result. 1—Accumulator data covered by input data is multiplied by W1 before being added to input data result
W2E	**Weight 2 Enable**. Describe whether input data is multiplied by W2 before being added to accumulator data result and updated as new accumulator data. For details, see **Section 26.4.3.2.6.2**, *HARQ Combining*. 0—Input data is **not** multiplied by W2 and is being added as is to accumulator data result. 1—Input data is multiplied by W2 before being added to accumulator data result
W3E	**Weight 3 Enable**. Describe whether accumulator data which is not covered by input data is multiplied by W3 before being updated as new accumulator data. For details, see **Section 26.4.3.2.6.2**, *HARQ Combining*. 0—Accumulator data that is not covered by input data is **not** multiplied by W3 before being updated as new accumulator data. 1—Accumulator data that is not covered by input data is multiplied by W3 before being updated as new accumulator data.
W1[7:0]	**Weight 1**. Valid only if W1E is set. Un-singed number between 0 and 255. All Accumulator data that is covered by new data is multiplied by W1/256 before being added to the new accumulator. For details, see **Section 26.4.3.2.6.2**, *HARQ Combining*.
W2[7:0]	**Weight 2**. Valid only if W2E is set. Un-singed number between 0 and 255. All input data is multiplied by W2/256 before being added to the new accumulator.
W3[7:0]	**Weight 3**. Valid only if W3E is set. Un-singed number between 0 and 255. All Accumulator data that is not covered by new data is multiplied by W3/256 before being added to the new accumulator.

Table 26-214. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x20

Name	Description
SFT_RSLT_ADDR[31:3]	**Soft Result Address**. The address where the MAPLE-B2 provides the Soft Output results if enabled ([SOE]= 1, 2, 3). The [SFT_RSLT_ADDR] field must be aligned to 8 bytes.

Table 26-215. eTVPE Buffer Descriptor Names Description of 4 Bytes at Offset 0x24

Name	Description
E_PARAM_PTR[31:3]	**E parameters pointer**. Valid only during Turbo decoding ([ALG]=0), UMTS standard job and when input data structure is 'E-DCH HARQ with Mixed Vector' or 'E-DCH HARQ with Separate Vectors' ([IN_D_STRCT]=2 or 3). A pointer to the E parameters data structure in the system memory used by the eTVPE to perform the Rate De-Matching process. For more detail see **Section 26.4.3.2.6.1**, *E-DCH Rate De-Matching*.

Table 26-216. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x28

Name	Description
HA_IN_BASE_ADDR [31:0]	**HARQ Accumulator Input Base Address**. Points to base address of the HARQ Accumulator buffer to be fetched by MAPLE-B2 into the eTVPE before the new input stream.

Table 26-217. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x2C

Name	Description
PF_BUF_SIZE[15:0]	**Parity First Buffer Size**. Describe the actual buffer size of the PF vector during 'E-DCH HARQ with Separate Vectors' input data structure. For details, see **Section 26.4.3.2.5.5**, *E-DCH HARQ with Separate Vectors Input Data Structure*
PS_BUF_SIZE[15:0]	**Parity Second Buffer Size**. Describe the actual buffer size of the PS vector during 'E-DCH HARQ for Separate Vectors' input data structure.

Table 26-218. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x30

Name	Description
HA_OUT_BASE_ADDR [31:0]	**HARQ Accumulator Output Base Address**. Points to base address of the HARQ Accumulator buffer in the system memory where the MALE-B2 is to output the new HARQ buffer after eTVPE combining.

Table 26-219. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x34

Name	Description
[31:0]	Reserved.

Table 26-220. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x38

Name	Description
[31:0]	Reserved.

Table 26-221. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x3C

Name	Description
HSC[14:0]	**HARQ Saturation Counter**. Valid after [OWNER] bit is cleared by MAPLE-B2, and if the HARQ operation is enabled ([HE] bit of the MTVCP parameter). Indicates the number of accumulator bytes that were overflown during the HARQ operation, thus saturated.
CMP_RSN[2:0]	**Complete Reason**. Valid after [OWNER] bit is cleared by MAPLE-B2. Indicates the reason for eTVPE job completion. 000— Complete due to MAX_ITER value reached 001— Complete due to Aposteriori quality Stop Criteria 010— Complete due to CRC check Stop Criteria 011— Complete due to both Aposteriori quality check Stop Criteria and CRC check Stop Criteria 100— Complete due to CRC Steady Stop Criteria. 101— Complete due to both Aposteriori quality check Stop Criteria and CRC Steady Stop Criteria 110 to 111—Reserved.

Table 26-221. eTVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x3C

Name	Description
ERR_ST[3:0]	**Task Error Status Code**. Valid only after [OWNER] bit is cleared by MAPLE-B2. 0000—No Error 0001—CRC check on Hard Output results failed. 0010—eTVPE stopped due to CRC check or CRC steady stop criteria, but failed on CRC check or CRC steady on next iteration executed by the eTVPE. For details, see **Section 26.4.3.2.6.4.9**, *Stopping Criteria Status Reports*. 0011—Reserved. 0100—eTVPE stopped due to Aposteriori Quality stop criteria, but failed on Aposteriori Quality on next iteration executed by the eTVPE.For details, see **Section 26.4.3.2.6.4.9**, *Stopping Criteria Status Reports* 0101 to 1111—Reserved.
ZT_MAX	**Zero Tail Max**. Valid only during Viterbi Zero Tail decoding ([ALG]=1, [ZTTB]=1) while Trace Back from zero is enabled ([TBZE]=1) and after [OWNER] bit is cleared by MAPLE-B2. This bit is set by MAPLE-B2 only if the maximum calculation result, before the trace-back execution, did not point to state zero, as expected in the Viterbi Zero Tail algorithm.
ITER_CNT[3:0]	**Iteration Count**. Valid only during Turbo decoding and after [OWNER] bit is cleared by MAPLE-B2. Status field which describes the actual number of full iterations executed for this job. The actual iteration number is ITER_CNT +1.

The following restrictions apply:

- When the host is writing a new BD to its ring it must be done “bottom-up”, that is, the [OWNER] bit must be the last write access to the PSIF DRAM. If several BDs are written to the same ring, only the OWNER bit of the first written BD must be the last to be written.
- All reserved bits in the BD must be set to zero for future compatibility.
- Once the [OWNER] bit is set by the host, the BD content must not be changed. It is re-written only after the [OWNER] bit was clear by MAPLE-B2.
- The status fields in the BD are valid only after the [OWNER] bit is clear by the MAPLE-B2.

26.5.4.3 eFTPE Buffer Descriptor Structure

A description of the eFTPE Buffer Descriptors structure expected by the host for the eFTPE BD rings is outlined in **Figure 26-249**. Some of the fields are status fields which are written by the MAPLE-B2 upon job completion. Other fields may be relevant only for certain configurations and is ignored by the MAPLE-B2 if another configuration is used. The length of the basic BD is 48 bytes, and it includes a potential extension to 96 bytes (BD control bit dependent). It means that the next BD location should be located either 48 bytes or 96 bytes after the current BD address.

Figure 26-249. eFTPE Buffer Descriptor Structure (Continued)

Table 26-222. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
OWNER	**Owner bit**. When set by the host, MAPLE-B2 is the BD owner and the job is not complete. When cleared by MAPLE-B2, the job is done and the host is the BD owner. 0—The host is BD owner 1—MAPLE-B2 is BD owner
WRAP	**Wrap bit**. When set by the host, MAPLE-B2 updates the [BDR_RD_PTR[14:5]] field with [BDR_BA[14:8]], that is, it expects to find the next BD at the Base Address of the ring. When cleared by the host, MAPLE-B2 expects to find the next BD at: [BDR_RD_PTR[14:5]] + BD size. For details, see **Section 26.5.4.1.4**, *MAPLE <yy>PE BD Ring High Priority A <x> Parameter (M<yy>BRHPAxP)* or **Section 26.5.4.1.6**, *MAPLE <yy>PE BD Ring Low Priority A <x> Parameter (M<yy>BRLPAxP)*
INT_EN	**Interrupt Enable**. If set, MAPLE-B2 issues an interrupt at the end of this job. If cleared no interrupt is issued. 0—End of job interrupt is NOT issued. 1—End of job interrupt is issued.

Table 26-222. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
TASK_ID[7:0]	**Task ID**. Task ID tag, supplied by host, assists it in identification of its task when directly accessing the eFTPE to inquire task status.
FC_CG	**Frequency Correction or Code Generation extension**. Indicates if either Frequency Correction feature or Code Generation feature are enabled hence BD extension is applicable. For details see **Section 26.5.4.3.2**, *eFTPE Buffer Descriptor's Extension*. 0—BD extension is not applicable. BD size is 48 bytes. 1—BD extension is applicable. BD size is 96 bytes.
DSTZP[11:0]	**Data Size to Zero Padding**. Indicates the actual amount of samples required to be padded by zeros. The eFTPE pads the given value with zeros till the transform size indicated by the *TL_ID* is reached. *DSTZP* is limited by the transform length (*DSTZP* < transform length) and its value should be a product of 4 if short input is disabled (*SINS* = 0) or product of 8 is short input is enabled (*SINS* = 1). Valid Range: 0 to 2044.
TL_ID[5:0]	**Transform Length ID**. This field determines the executed transform length. See **Table 26-246** for DFT/FFT Transform Length encoding.

Table 26-223. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
AIUS	**Adaptive Input Scaling**. Valid only in Adaptive Scale mode (*SCL_TYPE*=0). Indicates if the eFTPE is to perform adaptive up scale of the input data to maximize calculation precision. For details see **Section 26.4.3.3.9.4.7**, *Adaptive Input Scaling*. 0—The input samples are processed as is. 1—The input samples are adaptively scaled up.
PRMUR	**Pre Multiplier Repeat**. Valid only if BD repeat (*BD_RPT* > 0) and vector pre multiplication are enabled (*PME*=1,3). Indicates the eFTPE if all the repeated iterations use the same Pre-Multiplier buffer, or if each iteration has a different buffer. For details see **Section 26.4.3.3.5.1**, *Pre-Multiplication Processing Support in the eFTPE*. 0—Use different buffer for each iteration. 1—Use the same repeated pre multiplier buffer for all iterations. **Note**: *PRMUR* should not be cleared if *PME*=1.
PSMUR	**Post Multiplier Repeat**. Valid only if BD repeat (*BD_RPT* > 0) and vector post multiplication are enabled (*PSTMV*=3). Indicates the eFTPE if all the repeated iterations use the same Post-Multiplier buffer, or if each iteration has a different buffer. For details see **Section 26.4.3.3.5.2**, *Post-Multiplication processing support in the eFTPE*. 0—Use different buffer for each iteration. 1—Use the same repeated pre multiplier buffer for all iterations. **Note**: *PSMUR* should not be cleared if *PSTMV*=1.
PSTMV	**Post multiplier Vector enable**. If enabled, the eFTPE multiplies each output sample with a complex value according the post-multiply memory content. For details see **Section 26.4.3.3.5.2**, *Post-Multiplication processing support in the eFTPE*. 00—Post-Multiplier is disabled. 01—Post-Multiplier is enabled. The eFTPE uses the post-multiplier memory without updating it 10—Reserved. 11—Post-Multiplier is enabled. The MAPLE-B2 update the post-multiplier memory with new data from system memory pointed by the *POM_PTR* field of the eFTPE BD.

Table 26-223. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
ZP	**Zero Padding**. Indicates the eFTPE to add zero padding to the input data according to the *DSTZP* and *TL_ID* fields. For details see **Section 26.4.3.3.4.1.2**, *Zero Padding Support*. 0—No zero padding is done to input samples. 1—Zero padding is added according to the *DSTZP* and *TL_ID* fields. **Note:** Zero Padding should not be enabled along with zero insertion process enabled by ZI bit.
SINS	**Short Input Structure**. Valid only for FFT/iFFT processing. Indicates the input sample structure of the eFTPE. For details see **Section 26.4.3.3.4.1**, *Input Data Structures*. 0—Input sample structure is 32 bits: 16I and 16Q. 1—Input sample structure is 16 bits: 8I and 8Q.
CPRE	**Cyclic Prefix Removal Enable**. Valid only if BD Repeat option is enabled. If set, the MAPLE-B2 skip the cyclic prefix addition when fetching the next job during BD repeat. For details see **Section 26.4.3.3.4.1.3**, *Cyclic Prefix Removal for FFT BD Repeat*. 0—Cyclic Prefix Removal is disabled. 1—Cyclic Prefix Removal is enabled.
PO_SCL[1:0]	**Post Multiplier Scaling**. Valid during User Defined Scale mode only (*SCL_TYPE*=1) and if the Vector post multiplication is enabled (*PSTMV*=1). Indicates the scaling amount that should be applied on the vector post multiplication results. Valid Range: 0 to 2.
GRDC	**Guard Removal of DC**. Valid only if the *GR* bit of the eFTPE BD is set. Indicates the MAPLE-B2 whether a ‘DC’ sample is expected after FFT processing. Foe details see **Section 26.4.3.3.4.2.1**, *Guard Band Removal for FFT*. 0— The MAPLE-B2 outputs the ‘DC’ sample as part of the data. 1— The MAPLE-B2 does not output the ‘DC’ sample as part of the data.
AFS	**Align to First Scale**. Valid only if repeat mode and Adaptive Scaling are enabled (*BD_RPT* > 0, *SCL_TYPE* = 0). Allows applying identical scale value to all jobs of the BD repeat according to the scale result of the first job. For details see **Section 26.4.3.3.3**, *Identical Output Scale Alignment for BD Repeat*. 0—No special alignment is performed to all tasks in the repeat job. 1—All tasks in the repeat BD shares the same output scale value (according to the first task). If Extra Scaling is enabled (*EXS* > 0), it is applied for the first task only.
EXS[1:0]	**Extra Scaling**. Valid only if Adaptive Scaling is enabled and no if Overall Scaling is applied. Indicates the eFTPE to perform down scaling (by the value of this field) of the final scale results. Fro details see **Section 26.4.3.3.9.4.8**, *Extra Scaling*. Valid Range: 0 to 2.
PSTME	**Post Multiplication Enable**. If set, the eFTPE multiplies all FFT/DFT output samples with the complex value as described in *PSTM_REAL* and *PSTM_IMG* of the eFTPE BD. For details, refer to **Section 26.4.3.3.5.2, *Post-Multiplication processing support in the eFTPE*** 0—Post Multiplication is disabled. 1—Post Multiplication is enabled.
CPIE	**Cyclic Prefix Insertion Enable**. If set, the MAPLE-B2 generates additional Cyclic Prefix to the FFT output. For details, refer to **Section 26.4.3.3.4.2.2**, *Cyclic Prefix Insertion for iFFT* 0—Cyclic Prefix Insertion is disabled. 1—Cyclic Prefix Insertion is enabled.
GR	**Guard Removal**. Guard Removal output data mode enable. Valid only during FFT operation (*ITE* = 0) and must be cleared for any other operation. For details, see **Section 26.4.3.3.4.2.1**, *Guard Band Removal for FFT* 0—Guard Removal output data mode is disabled 1—Guard Removal output data mode is enabled

Table 26-223. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
PME[1:0]	**Pre-Multiply Enable**. If enabled, the eFTPE multiplies each input sample with a complex value according the pre-multiply memory content. For details, see **Section 26.4.3.3.5.1**, *Pre-Multiplication Processing Support in the eFTPE* 00—Pre-Multiplier is disabled. 01—Pre-Multiplier is enabled. The eFTPE uses the pre-multiplier memory without updating it 10—Reserved. 11—Pre-Multiplier is enabled. The MAPLE-B2 update the pre-multiplier memory with new data from system memory pointed by the *PRM_PTR* filed of the eFTPE BD.
OVA_SCL	**Overall Scaling**. Valid only for adaptive scaling (*SCL_TYPE*=0). If set, the total scaling of the transform stages is aligned with the *ADP_OVA_SCL* field in the BD. 0—No overall scaling is specified. 1—The eFTPE aligns the total accumulated scaling with the scaling value specified in the *ADP_OVA_SCL* filed in the BD.
SCL_TYPE	**Scaling Type**. Selects the scaling method to be used between the transform stages as described in **Section 26.4.3.3.9.4, *eFTPE Internal Scaling Calculations***." 0—Adaptive scaling is performed. 1—User defined scaling is performed.
ITE	**Inverse Transform Enable**. If set, an inverse transform is executed. 0—FFT/DFT is executed. 1—iFFT/iDFT is executed.
GI	**Guard Insertion**. Guard Insertion input data mode enable. Valid only during iFFT operation and must be cleared for any other operation. For details, see **Section 26.4.3.3.4.1.1**, *Guard Band Insertion for iFFT* 0—Guard Insertion input data mode is disabled 1—Guard Insertion input data mode is enabled **Notes: 1.** Do not enable Guard Insertion with Zero Padding (enabled by *ZP* bit). **2.** Do not enable Guard Insertion with internal code generation (enabled by *CG* bit)
DSS[2:0]	**Data Size Set**. Indicates the MAPLE-B2 which set of Data Size parameters (see **Section 26.5.3.3.1**, *eFTPE Data Size Set x Parameter 0 (FTPEDSSxP0)* to **Section 26.5.3.3.3**, *eFTPE Data Size Set x Parameter 2(FTPEDSSxP2)*) to use for the Guard Insertion or Guard Removal operations. For details, see **Section 26.4.3.3.4.1.1**, *Guard Band Insertion for iFFT* and **Section 26.4.3.3.4.2.1**, *Guard Band Removal for FFT* 000—Data Size register in eFTPE are assumed to be updated. Valid only if *GI* is set. 001—The Data size used for Guard Insertion or Guard Removal is taken from Set #1. 010—The Data size used for Guard Insertion or Guard Removal is taken from Set #2. ... 111—The Data size used for Guard Insertion or Guard Removal is taken from Set #7.

Table 26-224. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x8

Name	Description
IBA[31:3]	**Input Buffer Address**. This field points to the input buffer location in system memory, where MAPLE-B2 is to fetch the data. The address must be aligned to an 8 byte address.
MB_PR[1:0]	**MBus Priority**. Valid only if the *MB_PR_SCH* of the MMC0P parameter (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*) is set to '01' or '10'. Indicated the MBus accesses priority related to this BD. For details, see **Section 26.4.2.4, *MBus Priority Scheme Configuration*** 00— The MBus accesses related to that BD are initiated with priority '00' ... 11—The MBus accesses related to that BD are initiated with priority '11'

Table 26-225. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0xC

Name	Description
OBA[31:3]	**Output Buffer Address**. This field points to the output buffer location in system memory, where MAPLE-B2 is to write the result data. The address must be aligned to an 8 byte address.
OFF16	**Offset in 16 Bytes**. Valid only for DFT/iDFT operation and when the BD repeat option is enabled (BD_RPT > 0). Indicates the MAPLE-B2 that the input buffers during the repeat are expected with offset equal the CPS field value multiplied by 16 Bytes. For details see **Section 26.4.3.3.4.1.5**. 0— No offset between input buffers during repeat is expected. 1— The Offset between the input buffers during the repeat is the CPS field value multiplied by 16 Bytes.
OFFKB	**Offset in KBytes**. Valid only for FFT operation and when the BD repeat option is enabled (BD_RPT > 0). Indicates the MAPLE-B2 that the input buffers during the repeat are expected with offset equal the CPS field value in KBytes. For details see **Section 26.4.3.3.4.1.4**. 0— No offset between input buffers during repeat is expected. 1— The Offset between the input buffers during the repeat is described in the CPS field (in KBytes).

Table 26-226. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x10

Name	Description
PM_SCL	**User scaling after pre-multiplication**. Valid only if the *SCL_TYPE* field of the BD is set, that is, user defined scaling is chosen. Determines the scaling amount of the results of the pre-multiplication. 0—no scaling is performed after the pre-multiplication stage. 1—the results of the pre-multiplication stage are scaled down (shift right) by 1 bit.
USR_SCL0[2:0]	**User scaling after stage 0**. Valid only if the *SCL_TYPE* field of the BD is set, that is, user defined scaling is chosen. Determines the scaling amount of the results of stage 0. 000—no scaling is performed after stage 0 001—the results of stage 0 are scaled down (shift right) by 1 bit. 010—the results of stage 0 are scaled down (shift right) by 2 bits. 011—the results of stage 0 are scaled down (shift right) by 3 bits. 100—the results of stage 0 are scaled down (shift right) by 4 bits. 101 to 111— Reserved
USR_SCL1[2:0]	**User scaling after stage 1**. Valid only if the *SCL_TYPE* field of the BD is set, that is, user defined scaling is chosen. Determines the scaling amount of the results of stage 1. 000—no scaling is performed after stage 1 001—the results of stage 1 are scaled down (shift right) by 1 bit. 010—the results of stage 1 are scaled down (shift right) by 2 bits. 011— the results of stage 1 are scaled down (shift right) by 3 bits. 100—the results of stage 1 are scaled down (shift right) by 4 bits. 101 to 111— Reserved
USR_SCL2[2:0]	**User scaling after stage 2**. Valid only if the *SCL_TYPE* field of the BD is set, that is, user defined scaling is chosen. Determines the scaling amount of the results of stage 2. 000—no scaling is performed after stage 2 001—the results of stage 2 are scaled down (shift right) by 1 bit. 010—the results of stage 2 are scaled down (shift right) by 2 bits. 011—the results of stage 2 are scaled down (shift right) by 3 bits. 100—the results of stage 2 are scaled down (shift right) by 4 bits. 101 to 111— Reserved

Table 26-226. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x10

Name	Description
USR_SCL3[2:0]	**User scaling after stage 3**. Valid only if the *SCL_TYPE* field of the BD is set, that is, user defined scaling is chosen. Determines the scaling amount of the results of stage 3. 000—no scaling is performed after stage 3 001—the results of stage 3 are scaled down (shift right) by 1 bit. 010—the results of stage 3 are scaled down (shift right) by 2 bits. 011—the results of stage 3 are scaled down (shift right) by 3 bits. 100—the results of stage 3 are scaled down (shift right) by 4 bits. 101 to 111— Reserved
USR_SCL4[2:0]	**User scaling after stage 4**. Valid only if the *SCL_TYPE* field of the BD is set, that is, user defined scaling is chosen. Determines the scaling amount of the results of stage 4. 000—no scaling is performed after stage 4 001—the results of stage 4 are scaled down (shift right) by 1 bit. 010—the results of stage 4 are scaled down (shift right) by 2 bits. 011—the results of stage 4 are scaled down (shift right) by 3 bits. 100—the results of stage 4 are scaled down (shift right) by 4 bits. 101 to 111— Reserved
USR_SCL5[2:0]	**User scaling after stage 5**. Valid only if the *SCL_TYPE* field of the BD is set, that is, user defined scaling is chosen. Determines the scaling amount of the results of stage 5. 000—no scaling is performed after stage 5 001—the results of stage 5 are scaled down (shift right) by 1 bit. 010—the results of stage 5 are scaled down (shift right) by 2 bits. 011—the results of stage 5 are scaled down (shift right) by 3 bits. 100—the results of stage 5 are scaled down (shift right) by 4 bits. 101 to 111— Reserved
IN_SCL[3:0]	**Input Scaling**. Valid only if *AIUS* is disabled. Determines the up scaling of the input data before the processing of the first stage or before the pre-multiplication stage (if enabled). 0000—no scaling is performed on the input data before stage 0 0001—the input data is scaled up (shift left) by 1 before stage 0. 0010—the input data is scaled up (shift left) by 2 before stage 0. ... 1111—the input data is scaled up (shift left) by 15 before stage 0.
ADP_OVA_SCL[7:0]	**Adaptive Overall Scaling**. Valid only if Adaptive Scaling is chosen (*SCL_TYPE*==0), and the *OVA_SCL* field in the BD is set. Determines the Overall scale the eFTPE is to perform. The value of this field is compared with the total scaling accumulated by the adaptive scaling between the stages, and the output data is scaled up/down to fit the required overall scaling. Supported values: -128:127

Table 26-227. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x14

Name	Description
PRM_PTR[31:3]	**Pre-Multiplier Pointer**. Points to the address in the system memory where the new data for pre-multiplier memory is located. If the *PME* field equals ‘11’ the MAPLE-B2 updates the content of the eFTPE pre-multiplier memory with the data pointed by this field.

Table 26-228. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x18

Name	Description
BD_STAT_PTR[31:3]	**BD Status Pointer**. This field points to the location in system memory where the MAPLE-B2 outputs the *CMP_RSN*[2:0] and the *ADP_OVA_SCL_ST*[7:0] status fields of each of the jobs in the BD repeat option or of a single job in a non repeat mode. The pointer must be 8 byte aligned. Configuring this field to 0x00000000 disables this feature.

Table 26-229. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x1C

Name	Description
PSTM_REAL[15:0]	**Post Multiplication Real**. Valid only if the *PSTME* bit is enabled. Describe the Real part in 1q15 representation of the complex number to be multiplied with the FFT/DFT samples after the processing. Can receive any value with the only limitation that ([PSTM_REAL]^2 + [PSTM_IMG]^2) < 2
PSTM_IMG[15:0]	**Post Multiplication Imaginary**. Valid only if the *PSTME* bit is enabled. Describe the Imaginary part in 1q15 representation of the complex number to be multiplied with the FFT/DFT samples after the processing. Can receive any value with the only limitation that ([PSTM_REAL]^2 + [PSTM_IMG]^2) < 2

Table 26-230. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x20

Name	Description

CPS[8:0]	**Cyclic Prefix Size**. Valid only if either *CPIE*, *CPRE*, *OFF16 or OFFKB* bits are enabled. Indicates the following:
	If (*CPIE*==1 & *ITE*==1): the number of iFFT samples in the CP to be re-read from the eFTPE output buffer and concatenated to the system output buffer as described in **Section 26.4.3.3.4.2.2**, *Cyclic Prefix Insertion for iFFT*.
	If (*CPRE*==1 & *ITE*==0): the number of FFT samples in the CP to be skipped from the input buffer in the system memory during BD repeat operation as described in **Section 26.4.3.3.4.1.3**, *Cyclic Prefix Removal for FFT BD Repeat*.
	If (*OFF16*==1): the expected offset multiplied by 16 Bytes between the DFT/iDFT input buffers during DFT/iDFT BD repeat operation. For details see **Section 26.4.3.3.4.1.5**, *Input Buffers Offset (in 16 Bytes multiplication) for DFT/iDFT BD Repeat*.
	If (*OFFKB*==1 & *ITE*==0): the expected offset in KBytes between the FFT input buffers during FFT BD repeat operation. For details see **Section 26.4.3.3.4.1.4**, *Input Buffers Offset (in KBs) for FFT BD Repeat*.
	
	0 to 511 for 1 to 512 samples/KBytes or 16 bytes multiplications.

BD_RPT[6:0]	**BD Repeat**. This field allows the use of the same BD, for multiple jobs with identical input parameters. For details, see **Section 26.4.3.3.2, *BD Repeat Option*** 0—BD repeat disabled. The BD is used once as normal BD 1 to 127— BD repeat enabled. This BD is used for 2 -128 jobs, respectively.
CMP_RSN[2:0]	**Complete Reason**. This field describes the work completion status. 000—Task completed OK. 001— Reserved. 010—Task completed with saturation event.[1] 011 to 111—Reserved.
ADP_OVA_SCL_ST[7:0]	**Adaptive Overall Scaling Status**. Valid only if Adaptive Scaling is enabled (*SCL_TYPE* = 0). It describes the total Adaptive scaling applied during the processing stages[2]. Supported values: -128:127

1. If *BD_RPT* is enabled then the saturation indication for each Transform block in the repeat process is specified in the external memory pointer (if enabled), pointed by the *BD_STAT_PTR* field.
2. If *BD_RPT* is enabled the Adapting Overall Scaling indication for each Transform block in the repeat process is specified in the external memory pointer (if enabled), pointed by the *BD_STAT_PTR* field.

Table 26-231. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x24

Name	Description
INP_EXP_PTR[31:3]	In non-repeat mode (*BD_RPT*=0): **Input Exponent[7:0]**. Should be written to bits [31:24] of this field. Indicates the input exponent value (scale) of the current task. Used by the eFTPE when calculating the overall scaling and when Adaptive Overall Scaling is used. For details see **Section 26.4.3.3.9.4.5**, *Input Exponent* Supported values: -128:127 In Repeat mode (*BD_RPT* > 0): **Input Exponent Pointer**. Points to an address in the system memory where the Input Exponent values of all the tasks in the job are placed. Setting this pointer to zero indicates the MAPLE-B2 to use Input Exponent value of zero to all repeated tasks. For details see **Section 26.4.3.3.9.4.5**, *Input Exponent*. The pointer must be 8 bytes aligned.

Table 26-232. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x28

Name	Description
POM_PTR[31:3]	**Post-Multiplier Pointer**. Points to the address in the system memory where the new data for post-multiplier memory is located. If the *PSTMV* field equals '11' the MAPLE-B2 updates the content of the eFTPE post-multiplier memory with the data pointed by this field.

Table 26-233. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x2C

Name	Description
[31:0]	Reserved.

26.5.4.3.1 Buffer Descriptor Special Notes

- When the host is writing a new BD to its ring it must be done "bottom-up", that is, the *OWNER* bit must be the last write access to the PSIF2 DRAM. If several BDs are written to the same ring, only the *OWNER* bit of the first written BD must be the last to be written.
- All reserved bits in the BD must be set to zero for future compatibility.
- Once the *OWNER* bit is set by the host, the BD content must not be changed. It is re-written only after the *OWNER* bit was clear by MAPLE-B2.
- The status fields in the BD are valid only after the *OWNER* bit is clear by the MAPLE-B2.

26.5.4.3.2 eFTPE Buffer Descriptor's Extension

If either the Frequency Correction feature (see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*) or the internal Code Generation feature (see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*) are enabled, the eFTPE BD size is increased from 48 bytes to 96 bytes. **Figure 26-250** outlines the 48 bytes extension to the eFTPE BD as described in **Figure 26-249**. The validity of the BD extension is determined by the *FC_CG* bit of the eFTPE BD.

Figure 26-250. eFTPE extension Buffer Descriptor Structure

Table 26-234. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x30

Name	Description
FCG	**Frequency Correction Generation**. Indicates the eFTPE to perform frequency correction calculation as described in **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE* on the data either before processing (pre frequency correction) or after the processing (post frequency correction). 0—No frequency correction generation occur. 1—Frequency correction generation function is enabled either before or after the processing.
CG	**Code Generation**. If set, indicates the eFTPE to internally generate the scrambled pilot code as described in **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation* and to perform the relevant processing as described in the BD. When Code Generation is enabled no input data is expected by the eFTPE. 0—Code Generation is disabled. 1—Code Generation is enabled.
FCPRE	**Frequency Correction Pre Multiply**. Valid only if *FCG* is enabled. Indicates the eFTPE if to perform the Frequency Correction calculation on the data prior to the DFT/FFT processing or after the processing. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*. 0—Use frequency correction function as vector post multiplication argument. 1—Use frequency correction function as pre multiplication argument. **Note:** Frequency correction cannot be applied in the same phase with other vector multiplication process.
FCISC[15:0]	**Frequency Correction Input Step Counter**. Valid only if *FCG* is enabled. Indicates the step counter initial value for starting the frequency correction argument generation. Its value should be small or equal to the *FCSS* field. If Step Size (*FCSS*) equals 1, this field should be set to 0x0. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*. Supported values: 0 to 65532 which are products of 4.

Table 26-235. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x34

Name	Description
FCB_REAL[15:0]	**Frequency Correction Base Value Real Part**. Valid only if *FCG* is enabled. Describe the real part value of the Frequency Correction base value. Supported values: 1 to 65535
FCB_IMAG[15:0]	**Frequency Correction Base Value Imaginary Part**. Valid only if *FCG* is enabled. Describe the imaginary part value of the Frequency Correction base value. Supported values: 1 to 65535

Table 26-236. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x38

Name	Description
FCS[11:0]	**Frequency Correction Size**. Valid only if *FCG* is enabled. The number of frequency correction arguments that should be generated. When using zero padding or Guard insertion, the size of correction should be equal to the actual data size, i.e *DSTZP* if using zero padding, or 2*half_data_size if using guard insertion. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*. Supported values: 4 to 2048 which are products of 4.
FCSS[15:0]	**Frequency Correction Step Size**. Valid only if *FCG* is enabled. The number of samples that should be corrected with the same correction factor before the correction factor is increment by the shift value. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*. Supported values: 1 or values between 4–65532 which are products of 4.

Table 26-237. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x3C

Name	Description
FCS_REAL[15:0]	**Frequency Correction Shift Value Real Part**. Valid only if *FCG* is enabled. Describe the real part value of the Frequency Correction shift value. Supported values: 1 to 65535
FCS_IMAG[15:0]	**Frequency Correction Shift Value Imaginary Part**. Valid only if *FCG* is enabled. Describe the imaginary part value of the Frequency Correction shift value. Supported values: 1 to 65535

Table 26-238. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x40

Name	Description
FCF_REAL_ST[15:0]	**Frequency Correction Factor Real Part**. Valid only if *FCG* is enabled. Status field which indicates the real part of the next argument to be generated after current frequency correction job end. Can be used as the *FCB_RAEL* input of the next job.
FCF_IMAG_ST[15:0]	**Frequency Correction Factor Imaginary Part**. Valid only if *FCG* is enabled. Status field which indicates the imaginary part of the next argument to be generated after current frequency correction job end. Can be used as the *FCB_IMAG* input of the next job.

Table 26-239. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x44

Name	Description
SCOS[15:0]	**Step Counter State**. Valid only if *FCG* is enabled. Status field which indicates the internal step counter state after the last frequency correction argument was generated for the current job. Can be used as the *FCISC* field of the next successive job. Supported values: 0 to 65532.

Table 26-240. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x48

Name	Description
NNPI[2:0]	**Next Number of Pilots**. Valid only if *CG* is enabled. Indicates the number of pilot bits in the next frame. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported values: 0 to 5 representing 3 to 8.
CO[15:0]	**Chip Offset**. Valid only if *CG* is enabled. Describe the offset to be taken as starting point for scrambling code generation. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported values: 0 to 38399.

Table 26-241. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4C

Name	Description
CNPI[2:0]	**Current Number of Pilots**. Valid only if *CG* is enabled. Describe the number of pilot bits in the current frame. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported values: 0 to 5 representing 3 to 8.
SGO[3:0]	**Slot Generation Off**. Valid only if *CG* is enabled. Each bit represent one slot starting from the current slot (LSB bit) and to the next 3 slots. If set, the bit represents a slot in which the current generated user's pilot does not exist. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*.
LSS	**Long Scrambling Sequence**. Valid only if *CG* is enabled. Indicates the scrambling sequence generation mode. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. 0—The generation machine works in short scrambling sequence mode. 1—The generation machine works in long scrambling sequence mode.
SSN[23:0]	**Scrambling Sequence Number**. Valid only if *CG* is enabled. Indicates the number of the Scrambling sequence. Supported values: 0 to 2^{24} - 1.

Table 26-242. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x50

Name	Description
CL[12:0]	**Code Length**. Valid only if *CG* is enabled. Indicates the number of scrambled symbols to be generated. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported values: 0 to 2048 which are products of 4.
SN[3:0]	**Slot Number**. Valid only if *CG* is enabled. Indicates the index of slot in the frame. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported values: 0 to 14.

Table 26-243. eFTPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x54

Name	Description
NNPIS[2:0]	**Next Number of Pilots State**. Valid only if *CG* is enabled. A status field which indicates the number of pilots to be taken for the next job. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported reported values: 0 to 5 represents number of pilots 3 to 8.
NSGO[3:0]	**Next Slot Generation Off**. Valid only if *CG* is enabled. A status field which indicates that slot generation is off for next job. Bit [0] of this field represent the *SGO* bit for the next job position, and the following bits represent the next 3 slots. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported reported values: **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*.
NSN[3:0]	**Next Slot Number**. Valid only if *CG* is enabled. A status field which indicates the slot number of next chip to be generated for next job. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported reported values: 0 to 14.
NCO[15:0]	**Next Chip Offset**. Valid only if *CG* is enabled. A status field which indicates the chip offset to be taken as starting point for scrambling code generation for next job. The reported chip offset is the next chip following the last chip included in the current code generation processing. For details see **Section 26.4.3.3.8**, *WCDMA Scrambled Pilot Code Generation*. Supported reported values: 0 to 38399.

9	144	19	432	29	960	39	2048

26.5.4.4 DEPE BD and Header Structures

The DEPE uses BDs to configure the general DEPE operation. In addition, the DEPE uses header structures to specialize the operations for 3GLTE, WiMAX, and UMTS operations.

26.5.4.4.1 DEPE Buffer Descriptor Structure

A description of the DEPE Buffer Descriptor structure expected by the host for the DEPE BD rings is outlined in **Figure 26-251**. Some of the fields are status fields which are written by the MAPLE-B2 upon job completion. Other fields may be relevant only for certain configurations and is ignored by the MAPLE-B2 if another configuration is used. The total length of the BD is 64 bytes, and its size does not depend on the configuration, that is, the next BD location should be located 64 bytes after the current BD address regardless of the BD configuration.

Figure 26-251. DEPE Buffer Descriptor Structure (Continued)

Table 26-247. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
OWNER	**Owner bit**. When set by the host, MAPLE-B2 is the BD owner and the job is not complete. When cleared by MAPLE-B2, the job is done and the host is the BD owner. 0—The host is BD owner 1—MAPLE-B2 is BD owner
WRAP	**Wrap bit**. When set by the host, MAPLE-B2 updates [BDR_RD_PTR] with [BDR_BA] (see **Section 26.5.4.1.4**), that is, it expects to find the next BD at the Base Address of the ring. When cleared by the host, MAPLE-B2 expects to find the next BD at: [BDR_RD_PTR] + BD size.
INT_EN	**Interrupt Enable**. If set, MAPLE-B2 issues an interrupt/doorbell interrupt at the end of this job. If cleared no interrupt is issued. 0—End of job interrupt is NOT issued. 1—End of job interrupt is issued.
16M	**WiMAX 802.16m**. If set, indicates the MAPLE-B2 that this DEPE job is to be processed using the 802.16m parameters. 0—The job is to be processed assuming WiMAX 802.16e is required. 1—The job is to be processed assuming WiMAX 802.16m is required.
STD	**Standard**. Indicates to which of the two optional supported technologies this job relates in a given MAPLE-B2 operation mode. 0—The current job is UMTS or WiMAX job for 3G or WiMAX operation mode respectively. 1—The current job is 3GLTE job
IBS[7:0]	**Input Buffer Size**. Describes the number of 32 bits words which should be fetched by MAPLE-B2 to execute the current BD. If the current BD includes multiple Headers ([NOH]>0), the IBS should describe the input data size of all Headers. For details, see **Section 26.4.3.4.4.2**, *Input Data Structure for Multiple Tasks*. For UMTS with [TB] bit set, this field is ignored. For details, refer to **Section 26.4.3.4.5.4.6**, *UMTS Transport Block (TB) Support*. 0x2 - 0xC8 possible values representing 8 to 800 bytes.

Table 26-247. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0 (Continued)

Name	Description
NOH[4:0]	**Number of Headers**. Describes the number of Headers related to this BD. If set to Zero and [HBA] is also set to zero, the MAPLE-B2 expect to find the DEPE Header inside the BD, else the MAPLE-B2 fetches the Header from system memory address pointed by [HBA]. 00000—The Current job includes 1 Header. 00001—The current job includes 2 Headers. ... 11111—The current job includes 32 Headers.
OBS[10:0]	**Output Buffer Size**. Describes the total number of 32 bits words which should be written by MAPLE-B2 from DEPE output buffer and into the system memory on job completion.If the current BD includes multiple Headers ([NOH]>0), the [OBS] should describe the output data size of all Headers. For 3GLTE standard this field is ignored. For UMTS Separate Vectors this field indicates the size of the systematic vector only. For details, see **Section 26.4.3.4.6**, *DEPE Output Data Structure*. For UMTS Transport Block BD, this field indicates the total size of the TB (see **Section 26.4.3.4.5.4.6**, *UMTS Transport Block (TB) Support*). 0x2 to 0x580 possible values representing 8 bytes to 5.5 Kbytes.

Table 26-248. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
IBA[31:2]	**Input Buffer Address**. This field points to the input buffer location in system memory, where MAPLE-B2 is to fetch the data into the DEPE input buffer. The address pointer to system memory must be 4 bytes aligned.

Table 26-249. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x8

Name	Description
OBA[31:2]	**Output Buffer Address**. This field points to the output buffer location in system memory, where MAPLE-B2 is to write the data from the DEPE output buffer. The address pointer to the output buffer in system memory must be 4 bytes aligned.

Table 26-250. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0xC

Name	Description
HBA[31:3]	**Header Buffer Address**. This field points to the DEPE Headers buffer location in the system memory if multiple Headers are included in this job ([NOH]>0). If single Header is included in this job ([NOH]=0), this field is optional: by clearing it to zero the MAPLE-B2 takes the Header from the BD (offsets 0x20 to 0x3C). By assigning the [HBA] with any value different than zero, the MAPLE-B2 fetches the single Header from system memory as pointed by this field and ignores the Header fields in the BD. The address pointer must be 8 bytes aligned.

Table 26-251. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x10

Name	Description
BD_STS_PTR[31:2]	**BD Status Pointer**. Points to an address in system memory where MAPLE-B2 is to write the RMNA status fields in case [NOH] > 0 or in case [NOH] = 0 and this field is not zeroed. For details, see **Section 26.4.3.4.5.1**, *3GLTE Processing*.

Table 26-252. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x14

Name	Description
MB_PR[1:0]	**MBus Priority**. Valid only if the [MB_PR_SCH] of the MMC0P parameter (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*) is set to '01' or '10'. Indicated the MBus accesses priority related to this BD. For details, see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The MBus accesses related to that BD are initiated with priority '00' ... 11—The MBus accesses related to that BD are initiated with priority '11'
OBO[4:0]	**Output Buffer Offset**. Indicates the value of the Output Buffer Offset filed of the DEPE Header. Used by the MAPLE-B2 to calculate the amount of data to be output from the DEPE output buffer and into the system memory.
TASK_ID[7:0]	**Task ID**. Supplied by host and used by MAPLE-B2 if a serial RapidIO doorbell interrupt is required. For details, refer to **Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell***
COE	**Concatenate Output Enable**. Valid only for single Header job ([NOH]=0).If set, the MAPLE-B2 merges the first 32 bits word of the DEPE output buffer with the first 32 bits word of the output buffer in the system memory pointed by [OBA], thus allowing concatenating the current job to a previous job in the system memory. For details, refer to **Section 26.4.3.4.6.1**, *Output Buffer Offset and Concatenate Output Support (3GLTE and UMTS).* 0—Concatenate Output is disabled. MAPLE-B2 output the DEPE output buffer as is. 1—Concatenate Output is enabled. MAPLE-B2 merges the first word of the DEPE output buffer with the first word of the system output buffer.

Table 26-253. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x18

Name	Description
ESVO[3:0]	**Encoded Separate Vectors Offset**. Valid only for UMTS standard and when Separate vectors output data structure is enabled ([SVE] = 1). Indicates the MAPLE-B2 the offset between the 3 output vectors in the system memory. For details, refer to **Section 26.4.3.4.6.3**, *Separate Vectors Output Data Structure for UMTS*. 0000—The offset between the vectors in system memory is 128 bits 0001—The offset between the vectors in system memory is 256 bits 0010—The offset between the vectors in system memory is 512 bits 0011—The offset between the vectors in system memory is 1K bits 0100—The offset between the vectors in system memory is 2K bits 0101—The offset between the vectors in system memory is 4K bits 0110—The offset between the vectors in system memory is 8K bits 0111—The offset between the vectors in system memory is 16K bits 1000—The offset between the vectors in system memory is 32K bits 1001—The offset between the vectors in system memory is 64K bits 1010—The offset between the vectors in system memory is 128K bits 1011 to 1111—Reserved.
PFS[10:0]	**Parity First Size**. Valid only for UMTS standard and when Separate vectors output data structure is enabled ([SVE] = 1). Describes the total number of 32 bits words which should be written by MAPLE-B2 from DEPE output buffer and into the system memory to output the parity first vector from DEPE output buffer.For details, refer to **Section 26.4.3.4.6.3**, *Separate Vectors Output Data Structure for UMTS*. 0x1 to 0x7FF possible values representing 4 bytes to 2 Kbytes.

Table 26-253. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x18 (Continued)

Name	Description
SVE	**Separate Vectors Enable**. Valid only for UMTS standard and for single Header BD (NOH=0). Indicates the MAPLE-B2 that the Bit Collection is disabled hence the DEPE outputs 3 separate vectors and not single stream. For details, see **Section 26.4.3.4.6.3**, *Separate Vectors Output Data Structure for UMTS*. 0—Separate Vectors mode is disabled. 1—Separate Vectors mode is enabled.
TB	**Transport Block indication.** Valid only for UMTS standard and for certain configuration of the Bit Collection Scheme. Indicates the MAPLE-B2 that the current BD represent a full Transport Block job for the DEPE. The MAPLE-B2 uses the single Header attached to the BD (either in the BD or pointed by the [HBA] field of the DEPE BD) to internally generate the Headers for all CBs composing this TB. For more detail, refer to **Section 26.4.3.4.5.4.6**, *UMTS Transport Block (TB) Support*. 0— The current job is a Code Block job. 1— The current job is a Transport Block job.
PSS[10:0]	**Parity Second Size**. Valid only for UMTS standard and when Separate vectors output data structure is enabled ([SVE] = 1). Describes the total number of 32 bits words which should be written by MAPLE-B2 from DEPE output buffer and into the system memory to output the parity second vector from DEPE output buffer.For details, refer to **Section 26.4.3.4.6.3**, *Separate Vectors Output Data Structure for UMTS*. 0x1 to 0x7FF possible values representing 4 bytes to 2 Kbytes.

Table 26-254. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x1C

Name	Description
RMNA[14:0]	**Rate Matching Number of Actual output bits**. Relevant only for 3GLTE. Describes the actual number of output bits generated by the DEPE and output to system memory by MAPLE-B2.if [NOH] > 0 the RMNA status field of all the tasks is concatenated by MAPLE-B2 and written to the system memory to the location pointed by [BD_STS_PTR]. For details, see **Section 26.4.3.4.5.1**, *3GLTE Processing*

Table 26-255. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x20

Name	Description
DEPE_HEADER_1[31:0]	**First 4 bytes word of DEPE Header**. Relevant for all Standards. See **Section 26.5.4.4.3**, *DEPE Headers Structure*

Table 26-256. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x24

Name	Description
DEPE_HEADER_2[31:0]	**Second 4 bytes word of DEPE Header**.Relevant for all Standards. See **Section 26.5.4.4.3**, *DEPE Headers Structure*

Table 26-257. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x28

Name	Description
DEPE_HEADER_3[31:0]	**Third 4 bytes word of DEPE Header**.Relevant for 3GLTE and UMTS Standards only. See **Section 26.5.4.4.3**, *DEPE Headers Structure*

Table 26-258. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x2C

Name	Description
DEPE_HEADER_4[31:0]	**Fourth 4 bytes word of DEPE Header**. Relevant for 3GLTE and UMTS Standards only. See **Section 26.5.4.4.3**, *DEPE Headers Structure*

Table 26-259. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x30

Name	Description
DEPE_HEADER_5[31:0]	**Fifth 4 bytes word of DEPE Header**. Relevant for UMTS Standard only. See **Section 26.5.4.4.3**, *DEPE Headers Structure*

Table 26-260. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x34

Name	Description
DEPE_HEADER_6[31:0]	**Sixth 4 bytes word of DEPE Header**. Relevant for UMTS Standard only. See **Section 26.5.4.4.3**, *DEPE Headers Structure*

Table 26-261. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x38

Name	Description
DEPE_HEADER_7[31:0]	**Seventh 4 bytes word of DEPE Header**. Relevant for UMTS Standard only. See **Section 26.5.4.4.3**, *DEPE Headers Structure*

Table 26-262. DEPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x3C

Name	Description
DEPE_HEADER_8[31:0]	**Eighth 4 bytes word of DEPE Header**. Relevant for UMTS Standard only. See **Section 26.5.4.4.3**, *DEPE Headers Structure*

26.5.4.4.2 Buffer Descriptors Notes

- Once the [OWNER] bit is set by the host, the BD content must not be changed. It can be re-written only after the [OWNER] bit was cleared by MAPLE-B2.
- All reserved bits in the BD must be set to zero for future compatibility.
- All the status fields in the BD are updated by the MAPLE-B2 once the job is complete, that is, they are valid only after the owner bit is cleared by the MAPLE-B2.
- When a host is writing a new BD to its ring, it must be done “bottom-up”, that is, the [OWNER] bit must be the last write access to the PSIF2 DRAM. If several BDs are written to the same ring, only the OWNER bit of the first written BD must be the last to be written.

26.5.4.4.3 DEPE Headers Structure

The DEPE Headers are used to provide the DEPE with the Code Block (CB) encoding parameters. Each DEPE CB encoding task requires its Header. A single DEPE BD may include up to 32 CBs encoding tasks, thus requires up to 32 Headers. The size of the DEPE Header differs according to the standard. The WiMAX Header is of 8 bytes size, the 3GTLE is of 16 bytes size and the UMTS is of 32 bytes size. If a DEPE BD includes single CB encoding task, its Header can be included in the DEPE BD as described in **Section 26.5.4.4.1**, *DEPE Buffer Descriptor Structure*. A description of the DEPE Headers structure for the different supported standards is outlined in sections **Section 26.5.4.4.3.1**, *DEPE Header Structure for 3GLTE* to **Section 26.5.4.4.3.4**, *DEPE Header Structure for UMTS*.

26.5.4.4.3.1 DEPE Header Structure for 3GLTE

The DEPE Header Structure for 3GLTE is outlined in **Figure 26-252**:

Offset	DEPE_HEADER_1

W		RMNI														

Figure 26-252. DEPE Header Structure for 3GLTE

Table 26-263. DEPE Header Structure for 3GLTE - Field Description

Name	Description
NOF[5:0]	**Number of Filler bits**. Number of filler bits needed to be added to the current data block. For more detail see **Section 26.4.3.4.5.1**, *3GLTE Processing* 000000— No filler bits are needed 000001— 1 filler bit is needed ... 111111— 63 filler bits are needed
OBO[4:0]	Output Buffer Offset. Offset of the first bit of the encoded block in the DEPE output buffer. Used for concatenating the current CB with previous CB from the same transport block in system memory. For details, see **Section 26.4.3.4.6.1**, *Output Buffer Offset and Concatenate Output Support (3GLTE and UMTS)*. 00000— The first bit of the encoded block is at offset 0. ... 11111— The first bit of the encoded block is at offset 31.
IBO[4:0]	**Input Buffer Offset**. Offset of the first bit of the input CB in the MAPLE-B2 input buffer pointed by [IBA] field of the DEPE BD. Used for supporting CB segmentation.Required due to the lack of filler bits in expected input. For details, see **Section 26.4.3.4.4.1**, *Input Buffer Offset Support (3GLTE and UMTS only)*. 00000— The first bit of the input CB is at offset 0. ... 11111— The first bit of the input CB is at offset 31.
CBSI [7:0]	Code Block Size Index Select one of 188 CB sizes supported in 3GLTE 0—CB size is 40 1—CB size is 44 ... 186— CB size is 6080 187— CB size is 6144 188 to 255— Reserved.
CM	CRC Mode Select the CRC polynomial. Valid only if [CD] = 0. For details, see **Section 26.4.3.4.5.1**, *3GLTE Processing*. 0— CB CRC polynomial ($D^{24} + D^{23} + D^6 + D^5 + D + 1$) 1— Transport block CRC polynomial ($D^{24} + D^{23} + D^{18} + D^{17} + D^{14} + D^{11} + D^{10} + D^7 + D^6 + D^5 + D^4 + D^3 + D + 1$)
LH	**Last Header indication**. Indicated the MAPLE-B2 that this Header is the last Header in the BD. If [NOH] > 0, this bit should be set only for the last Header. If [NOH] == 0, this bit should be set for the single Header. 0—This Header is **not** the last Header in the BD. 1—This Header is the last Header in the BD.

Table 26-263. DEPE Header Structure for 3GLTE - Field Description

Name	Description
CD	CRC Disable Indicates the DEPE whether to perform CRC calculation. If enabled, the CRC polynomial is determined using [CM]. 0—CRC is enabled. 1—CRC is disabled.
NOH[4:0]	**Number of Headers**. Number of Headers included in this job. 00000— The Current job includes 1 Header. 00001— The current job includes 2 Headers. ... 11111— The current job includes 32 Headers.
RMNO[14:0]	Rate Matching Number of Output bits The required number of encoded bits after rate matching. Since the DEPE does not support repetition, the value of this field must **not** be greater than the value of [RMNI].
RMS[14:0]	Rate Matching Start bit The starting bit in the virtual circular buffer, that is, the virtual circular buffer index of the first bit in the output stream. For details, refer to **Section 26.4.3.4.5.1**, *3GLTE Processing*.
RMNI[14:0]	Rate Matching Number of Input bits Number of encoded bits in the virtual circular buffer. For details, see **Section 26.4.3.4.5.1**, *3GLTE Processing*.

26.5.4.4.3.2 DEPE Header Structure for WiMAX (802.16e)

The DEPE Header Structure for WiMAX (802.16e) is outlined in **Figure 26-253**:

Offset	DEPE_HEADER_1

Figure 26-253. DEPE Header Structure for WiMAX

Table 26-264. DEPE Header Structure for WiMAX - Field Description

Name	Description
RMNO[13:0]	Rate Matching Number of Output bits The required number of encoded bits after rate matching. Since the DEPE does not support repetition, the value of this field must **not** be greater than 3*(Code Block Size).
RMS[13:0]	Rate Matching Start bit The starting bit in the virtual circular buffer, that is, the virtual circular buffer index of the first bit in the output stream. For details, refer to **Section 26.4.3.4.5.2**, *WiMAX Processing (802.16e)*.
CBSI [4:0]	Code Block Size Index 0— CB size is 48 1— CB size is 72 2— CB size is 96 3— CB size is 144 4— CB size is 192 5— CB size is 216 6— CB size is 240 7— CB size is 288 8— CB size is 360 9— CB size is 384 10—CB size is 432 11— CB size is 480 12— CB size is 960 13— CB size is 1920 14— CB size is 2880 15— CB size is 3840 16— CB size is 4800 17-31— Reserved
RD	**Randomizer Disable** 0— Randomizer is enabled. 1— Randomizer is disabled.
LH	**Last Header indication**. Indicated the MAPLE-B2 that this Header is the last Header in the BD. If [NOH] > 0, this bit should be set only for the last Header. If [NOH] == 0, this bit should be set for the single Header. 0—This Header is **not** the last Header in the BD. 1—This Header is the last Header in the BD.
CD	CRC Disable Indicates the DEPE whether to perform CRC calculation. 0—CRC is enabled. 1—CRC is disabled.
NOH[4:0]	**Number of Headers**. Number of Headers included in this job. 00000— The Current job includes 1 Header. 00001— The current job includes 2 Headers. ... 11111— The current job includes 32 Headers.

26.5.4.4.3.3 DEPE Header Structure for WiMAX (802.16m)

The DEPE Header Structure for WiMAX (802.16m) is outlined in **Figure 26-254**:

Offset	DEPE_HEADER_1															
	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 26-254. DEPE Header Structure for WiMAX

Table 26-265. DEPE Header Structure for WiMAX - Field Description

Name	Description
CLSB	Circularly Left Shift B Sub-block. 0— B Sub-block is circularly left shift by 0 bits. 1— B Sub-block is circularly left shift by 1 bit.
RMNO[13:0]	Rate Matching Number of Output bits The required number of encoded bits after rate matching. As the DEPE supports internal bit collection only (no bit selection support), this field must be set with **CB_Size * 3**, where CB_Size is the actual Code Block Size encoded in the CBSI field. Valid Range: 3 * Code Block Size
CLSY	Circularly Left Shift Y Sub-block. 0— Y Sub-block is circularly left shift by 0 bits. 1— Y Sub-block is circularly left shift by 1 bit.
CLSW	Circularly Left Shift W Sub-block. 0— W Sub-block is circularly left shift by 0 bits. 1— W Sub-block is circularly left shift by 1 bit.
CBSI [5:0]	**Code Block Size Index**. See **Table 26-266**

Table 26-265. DEPE Header Structure for WiMAX - Field Description

Name	Description
RD	**Randomizer Disable**. Must be set to 1 as Randomization is not supported for 802.16m
LH	**Last Header indication**. Indicated the MAPLE-B2 that this Header is the last Header in the BD. If [NOH] > 0, this bit should be set only for the last Header. If [NOH] == 0, this bit should be set for the single Header. 0—This Header is **not** the last Header in the BD. 1—This Header is the last Header in the BD.
CD	CRC Disable. Must be set to 1 as CRC calculation is not supported for 802.16m
NOH[4:0]	**Number of Headers**. Number of Headers included in this job. 00000— The Current job includes 1 Header. 00001— The current job includes 2 Headers. ... 11111— The current job includes 32 Headers.

Figure 26-255. DEPE Header Structure for UMTS

Table 26-267. DEPE Header Structure for UMTS - Field Description

Name	Description
PFEM2[18:0]	Parity First E_{minus} #2 Error decrement variable (e_{minus}) for second rate matching stage of the parity first stream.
CBS[12:0]	Code Block Size The number of bits in the current CB. The size can vary from 40 to 5114. Other values are reserved.
BCT[1:0]	Bit Collection Type 00— Systematic, first parity and second parity are collected in separate vectors. 01— Systematic, first parity and second parity bits are interleaved by a rectangular interleaver with 2 rows 10— Systematic, first parity and second parity bits are interleaved by a rectangular interleaver with 4 rows 11— Systematic, first parity and second parity bits are interleaved by a rectangular interleaver with 6 rows
OBO[4:0]	Output Buffer Offset. Offset of the first bit of the encoded block in the DEPE output buffer. Used for concatenating the current CB with previous CB from the same transport block in system memory. For details, see **Section 26.4.3.4.6.1**, *Output Buffer Offset and Concatenate Output Support (3GLTE and UMTS)*. 00000— The first bit of the encoded block is at offset 0. ... 11111— The first bit of the encoded block is at offset 31.
IBO[4:0]	**Input Buffer Offset**. Offset of the first bit of the input CB in the MAPLE-B2 input buffer (in system memory) pointed by [IBA] field of the DEPE BD. Used for supporting CB segmentation. For details, see **Section 26.4.3.4.4.1**, *Input Buffer Offset Support (3GLTE and UMTS only)*. 00000— The first bit of the input CB is at offset 0. ... 11111— The first bit of the input CB is at offset 31.
CBC	**Continuous Bit Collection**. Indicates the DEPE that the current CB is a following CB in a current TB executed successively and in order in the DEPE to support full TB bit collection. For details, see **Section 26.4.3.4.5.4.6**, *UMTS Transport Block (TB) Support* 0— Continuous Bit Collection is disabled. 1— Continuous Bit Collection is enabled.
P[3:0]	Number of Physical channels This field indicates the number of physical channel allocated for the current job. This is ignored if bit collection is not done by a rectangular interleaver (that is, if BCM=0 or BCT=0). 0— reserved 1— one physical channel is allocated for the current job. 2— two physical channels are allocated for the current job. ... 15—fifteen physical channels are allocated for the current job.
BCM	Bit Collection Mode 0— Systematic, first parity and second parity are interlaced. 1— Bit collection is done according to BCT
REP	Repetition. For details, refer to **Section 26.4.3.4.5.4**, *UMTS Processing*. 0— RM2 implements puncturing. 1— RM2 implements repetition.
RRM	Reset Rate Matching machine Indicates the DEPE whether to reset the error parameters or to resume with the current internal error parameters values assuming the current CB is the successive CB in the transport block of the previous task. For details, see **Section 26.4.3.4.5.4**, *UMTS Processing*. 0— Rate matching machines are not reset and initial error parameters are not loaded to the RM machines 1— Rate matching machines are reset and are load with initial error parameters.

Table 26-267. DEPE Header Structure for UMTS - Field Description

Name	Description
SD	Scrambling Disable Indicated the DEPE whether to perform scrambling. Should be enabled for FDD processing only. 0— Scrambling is enabled. 1— Scrambling is disabled.
LH	**Last Header indication**. Indicated the MAPLE-B2 that this Header is the last Header in the BD. If [NOH] > 0, this bit should be set only for the last Header. If [NOH] == 0, this bit should be set for the single Header. 0—This Header is **not** the last Header in the BD. 1—This Header is the last Header in the BD.
CD	CRC Disable Indicates the DEPE whether to perform CRC calculation. 0—CRC is enabled. 1—CRC is disabled.
NOH[4:0]	**Number of Headers**. Number of Headers included in this job. 00000— The Current job includes 1 Header. 00001— The current job includes 2 Headers. ... 11111— The current job includes 32 Headers.
PSEM2[15:0]	Parity Second E_{minus} #2 Error decrement variable (e_{minus}) for the second RM stage of the second parity stream.
PEM1[15:0]	Parity E_{minus} #1 This parameter is used to calculate the error decrement variable (e_{minus}) for the first RM stage of the parity streams. For E-DCH processing must be disabled by clearing to zero.
SEI[15:0]	Systematic E_{ini} Initial error variable (e_{ini}) for systematic stream RM.
SEM[15:0]	Systematic E_{minus} Error decrement variable (e_{minus}) for systematic stream RM.
PSEI2[15:0]	Parity Second E_{ini} #2 Initial error variable (e_{ini}) for the second rate matching stage of the second parity stream.
PFEI2[15:0]	Parity First E_{ini} #2 Initial error variable (e_{ini}) for the second rate matching stage of the first parity stream.
PSEI1[15:0]	Parity Second E_{ini} #1 Initial error variable (e_{ini}) for the first rate matching stage of the second parity stream. For E-DCH processing must be disabled by assigning to any value bigger than zero.
PFEI1[15:0]	Parity First E_{ini} #1 Initial error variable (e_{ini}) for the first rate matching stage of the first parity stream. For E-DCH processing must be disabled by assigning to any value bigger than zero.
PSO[15:0]	Parity Second Offset This field is valid when [BCM] is set, and indicates the offset of the parity second bits in the output vector
PFO[15:0]	Parity First Offset This field is valid when [BCM] is set, and indicates the offset of the parity first bits in the output vector
NCB[5:0]	Number of Code Block Indicates the number of CBs in the current TB. Used for calculating the X parameter. For details, see **Section 26.4.3.4.5.4**, *UMTS Processing*
EPFEI2[2:0]	Extension for Parity First E_{ini} #2 3 bits extension for [PFEI2]

Table 26-267. DEPE Header Structure for UMTS - Field Description

Name	Description
EPSEI2[1:0]	Extension for Parity Second E_{ini} #2 2 bits extension for [PSEI2].
EPSEI1[1:0]	Extension for Parity Second E_{ini} #1 2 bits extension for [PSEI1]
EPFEI1[2:0]	Extension for Parity First E_{ini} #1 3 bits extension for [PFEI1]
EPSEM2[1:0]	Extension for Parity Second E_{minus} #2 2 bits extension for [PSEM2]
EPEM1[2:0]	Extension for Parity E_{minus} #1 3 bits extension for [PEM1]. For E-DCH processing must be disabled by clearing to zero.
ESEI[1:0]	Extension for systematic E_{ini} 2 bits extension for [SEI]
ESEM[1:0]	Extension for Systematic E_{minus} 2 bits extension for [SEM]

26.5.4.5 EQPE BD Structure

A description of the EQPE Buffer Descriptor structure expected by the host for the EQPE BD rings is outlined in **Figure 26-256**. Some of the fields are status fields which are written by the MAPLE-B2 upon job completion. Other fields may be relevant only for certain configurations and is ignored by the MAPLE-B2 if another configuration is used. The total length of the BD is 128 bytes, and its size does not depend on the configuration, that is, the next BD location should be located 128 bytes after the current BD address regardless of the BD configuration.

Figure 26-256. EQPE Buffer Descriptor Structure (Continued)

Table 26-268. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
OWNER	**Owner bit**. When set by the host, MAPLE-B2 is the BD owner and the job is not complete. When cleared by MAPLE-B2, the job is done and the host is the BD owner. 0—The host is BD owner 1—MAPLE-B2 is BD owner
WRAP	**Wrap bit**. When set by the host, MAPLE-B2 updates [BDR_RD_PTR] with [BDR_BA] (see **Section 26.5.4.1.4**), that is, it expects to find the next BD at the Base Address of the ring. When cleared by the host, MAPLE-B2 expects to find the next BD at: [BDR_RD_PTR] + BD size.

Table 26-268. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0 (Continued)

Name	Description
INT_EN	**Interrupt Enable**. If set, MAPLE-B2 issues an interrupt/doorbell interrupt at the end of this job. If cleared no interrupt is issued. 0—End of job interrupt is NOT issued. 1—End of job interrupt is issued.
POST_IDFT	**Post IDFT**. Valid only for LNEQ processing. If set, MAPLE-B2 performs additional iDFT processing on the EQPE output columns. This operation is performed internally using one of the eFTPE machines of the MAPLE-B2. For details see **Section 26.4.3.5.9**, *Pre/Post DFT/iDFT Processing*. 0—Post iDFT processing is disabled. No iDFT processing is performed on the EQPE outputs. 1—Post iDFT processing is enabled.
FH	**Full / Hermitian Matrix**. Valid only for Matrix Inversion processing (ALG=3). Indicates if the input and output matrices are Hermitian or Full. 0—The input and output matrices are Hermitian. 1—The input and output matrices are Full.
ALG[1:0]	**Algorithm**. Indicates the required processing type of the job. 0—Linear Equalization (LNEQ). 1—Maximum Likelihood Equalization (MLEQ). 2—Tree Search processing (TS). 3—Matrix Inversion processing (MIV).
INTRP[1:0]	**Interpolation mode**. Valid only for LNEQ and MLEQ processing (ALG=0,1). Indicates the interpolation mode for the current job. For details see **Section 26.4.3.5.5.7**, *CE Matrix Interpolation*. 0—II2 (Internal Interpolation with 2 references). 1—II4 (Internal Interpolation with 4 references). 2—External Interpolation 3—No Interpolation. **Note:** II4 is not supported for the case of Rx=7 with Lx=2,3 (8x4 and 8x3 antenna configurations).
Lx[1:0]	For LNEQ, MLEQ and TS processing (ALG=0,1,2): **Number of Layers**. Indicates the number of the transmit layers. 0—1 Layer. 1—2 Layers. 2—3 Layers. 3—4 Layers. For MIV processing (ALG=3): **Matrix Dimension**. Indicates the dimensions of the input matrix to invert. 0—1x1. 1—2x2. 2—3x3. 3—4x4.
Rx[2:0]	**Number of Receive antennas**. Valid only for LNEQ and MLEQ processing (ALG=0,1). Indicates the number of receive antennas. 0—1 Rx antenna. 1—2 Rx antennas. 2—Reserved. 3—4 Rx antennas. 4 to 6—Reserved. 7—8 Rx antennas.

Table 26-268. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0 (Continued)

Name	Description
COLS[3:0]	**Number of Columns**. Valid only for LNEQ, MLEQ and TS modes (ALG=0,1,2). Indicates the number of columns in the sub-carrier grid. For details see **Section 26.4.3.5.3**, *EQPE Sub-Carrier Grid*. 0—1 column 1—2 columns. ... 15—16 columns. **Note:** For LNEQ mode the allowed range of COLS is 0 to 11.

ROWS[11:0]	For LNEQ, MLEQ and TS processing modes (ALG=0,1,2):
	Number of Rows. Indicates the number of rows in the sub-carrier grid. For details see **Section 26.4.3.5.3**
	• Valid Range for LNEQ:
	if (*Lx* = 0,1) then supported values are: 11 to 2047 indicating 12 to 2048 rows respectively.
	if (*Lx* = 2,3) the supported values are: 11 to 1991 indicating 12 to 1992 rows respectively.
	Note: In LNEQ mode (ROWS+1) must be a multiplication of 12
	• Valid Range for MLEQ and TS[1]:
	if (*Lx* = 0,1) then supported values are: 0 to 2047 indicating 1 to 2048 rows respectively.
	if (*Lx* = 2,3) the supported values are: 0 to 1356 indicating 1 to 1357 rows respectively.
	For MIV processing: (ALG=3): **Number of matrices**. Indicates the number of matrix to invert in current job. Valid Range: 0 to 4095 indicating 1 to 4096 matrices respectively.

1. In TS mode only, if *R_SCL_TYPE*=1 then the size of the sub-carrier grid is limited to 4096, that is (*ROWS*+1)*(*COLS*+1) <= 4096

Table 26-269. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
MB_PR[1:0]	**MBus Priority**. Valid only if the *MB_PR_SCH* of the MMC0P parameter (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*) is set to '01' or '10'. Indicated the MBus accesses priority related to this BD. For details, see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The MBus accesses related to that BD are initiated with priority '00' ... 11—The MBus accesses related to that BD are initiated with priority '11'
PST_SCLR	**Post Scalar Multiplication**. Valid only if the *POST_IDFT* bit is set. If enabled, the iDFT results (*(COLS+1)*(Lx+1)* different results) are multiplied by different scalar values specified in the address pointed by the *PST_SCLR_PTR*. For details see **Section 26.4.3.5.9.2**, *Post iDFT Processing*. 0—Post scalar multiplication is disabled. 1—Post scalar multiplication is enabled.
F_DFT	**Feedback DFT**. Valid only for LNEQ processing and if the F_EN bit is set. If set, MAPLE-B2 performs DFT processing on the feedback cancellation inputs prior to the EQPE processing. For details see **Section 26.4.3.5.9**, *Pre/Post DFT/iDFT Processing*. 0—Pre DFT processing of the feedback inputs is disabled. 1—Pre DFT processing of the feedback inputs is enabled.
C_EN	**C Matrix Enable**. Valid only for LNEQ processing (ALG=0). Indicates whether external C matrix is to be used for the current job or assume internally that C=I (Identity matrix). For details see **Section 26.4.3.5.4.6**, *C Samples*. 0—EQPE assume C=I (no need to supply C matrix) 1—EQPE uses external C matrix.

Table 26-269. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
F_EN	**Feedback Cancellation Enable**. Valid only for LNEQ processing. Indicates that feedback cancellation is required for the current job. For details see **Section 26.4.3.5.4.8**, *F Samples*. 0—Cancellation is disabled for the current job. 1—Cancellation is enabled for the current job.
LTC[1:0]	**Layer To Cancel**. Valid only for LNEQ processing and when the F_EN bit is set. Indicates which layer is required to be cancelled for the current job. 0—Perform cancellation of layer 0 1—Perform cancellation of layer 1 2—Perform cancellation of layer 2 3—Perform cancellation of layer 3 **Note:** LTC configuration must maintain the following: LTC <= Lx.
ALIGN0[1:0]	**Output Alignment Type #0**. Indicates the output alignment type of layer #0 for LNEQ, MLEQ and TS modes, or the output alignment type for MIV mode. For details see **Section 26.4.3.5.6.2**, *Output Samples Alignment (Scaling)*. 0—Max scale output alignment (valid for LNEQ or MIV only). For LNEQ it means max scale per column. For MIV it indicates single scale per matrix. 1—User defined output alignment. 2—No alignment, that is, scale per output sample (floating point representation) 3—Global max alignment. Valid for MIV only. Indicates shared scale for all output matrices.
ALIGN1[1:0]	**Output Alignment Type #1**. Indicates the output alignment type of layer #1 for LNEQ, MLEQ and TS modes. For details see **Section 26.4.3.5.6.2**, *Output Samples Alignment (Scaling)*. 0—Max scale output alignment per column (valid for LNEQ only). 1—User defined output alignment. 2—No alignment, that is, scale per output sample (floating point representation) 3—Reserved.
ALIGN2[1:0]	**Output Alignment Type #2**. Indicates the output alignment type of layer #2 for LNEQ, MLEQ and TS modes. For details see **Section 26.4.3.5.6.2**, *Output Samples Alignment (Scaling)*. 0—Max scale output alignment per column (valid for LNEQ only). 1—User defined output alignment. 2—No alignment, that is, scale per output sample (floating point representation) 3—Reserved
ALIGN3[1:0]	**Output Alignment Type #3**. Indicates the output alignment type of layer #3 for LNEQ, MLEQ and TS modes. For details see **Section 26.4.3.5.6.2**, *Output Samples Alignment (Scaling)*. 0—Max scale output alignment per column (valid for LNEQ only). 1—User defined output alignment. 2—No alignment, that is, scale per output sample (floating point representation) 3—Reserved
LD0	**Layer Discard of Layer #0**. Valid for LNEQ processing only. Indicates that layer #0 can be discarded. for details see **Section 26.4.3.5.6.3.3**, *Layer Discarding*. 0—Output layer #0 1—Discard layer #0.
LD1	**Layer Discard of Layer #1**. Valid for LNEQ processing only and if Lx >= 1. Indicates that layer #1 can be discarded. for details see **Section 26.4.3.5.6.3.3**, *Layer Discarding*. 0—Output layer #1 1—Discard layer #1
LD2	**Layer Discard of Layer #2**. Valid for LNEQ processing only and if Lx >= 2. Indicates that layer #2 can be discarded. for details see **Section 26.4.3.5.6.3.3**, *Layer Discarding*. 0—Output layer #2 1—Discard layer #2

Table 26-269. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
LD3	**Layer Discard of Layer #3**. Valid for LNEQ processing only and if Lx >= 3. Indicates that layer #3 can be discarded. for details see **Section 26.4.3.5.6.3.3**, *Layer Discarding*. 0—Output layer #3 1—Discard layer #3
PST_VEC	**Post Vector Multiplication**. Valid only if the *POST_IDFT* bit is set. If enabled, the iDFT results are multiplied by the vectors pointed by the *PST_VEC_PTR* pointer of the EQPE BD. The MAPLE-B2 supports shared vector for all iDFT results of each layer (a total of *Lx* vectors).For details see **Section 26.4.3.5.9.2**, *Post iDFT Processing*. 0—Post vector multiplication is disabled. 1—Post vector multiplication is enabled.
M[2:0]	**M parameter**. Tree search width for QRD-M Equalization. Valid only for $Lx \geq 1$. For details see **Section 26.4.3.5.5.3**, *QRD-M Equalization (MLEQ)*. 0—M=4. 1—M=8 2—M=16 3—M=32 4—M=64. 5 to 7—Reserved **Note:** M=64 is not supported for $Lx > 1$.
MOD0[1:0]	**Modulation of layer #0**. Valid for MLEQ and TS processing only (ALG=1,2). Indicates the modulation type of layer #0. For details see **Section 26.4.3.5.8.2**, *EQPE Outputs for MLEQ and TS modes* 0—QPSK modulation. 1—16QAM modulation. 2—64QAM modulation. 3—Reserved.
MOD1[1:0]	**Modulation of layer #1**. Valid for MLEQ and TS processing only (ALG=1,2). Indicates the modulation type of layer #1. 0—QPSK modulation. 1—16QAM modulation. 2—64QAM modulation. 3—Reserved.
MOD2[1:0]	**Modulation of layer #2**. Valid for MLEQ and TS processing only (ALG=1,2). Indicates the modulation type of layer #2. 0—QPSK modulation. 1—16QAM modulation. 2—64QAM modulation. 3—Reserved.
MOD3[1:0]	**Modulation of layer #3**. Valid for MLEQ and TS processing only (ALG=1,2). Indicates the modulation type of layer #3. 0—QPSK modulation. 1—16QAM modulation. 2—64QAM modulation. 3—Reserved.

Table 26-270. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x8

Name	Description
ALIGN_VAL0[7:0]	**User defined output alignment value for layer 0**. Valid only when ALIGN0=1. Indicates the required scale of the output results of layer #0 (in case of LNEQ, MLEQ or TS) or of the matrix results (in case of MIV processing). All output samples are aligned to this value. Range: -128 to 127.
ALIGN_VAL1[7:0]	**User defined output alignment value for layer 1**. Valid only when ALIGN1=1. Indicates the required scale of the output results of layer #1 (in case of LNEQ, MLEQ or TS). All output samples are aligned to this value. Range: -128 to 127.
ALIGN_VAL2[7:0]	**User defined output alignment value for layer 2**. Valid only when ALIGN2=1. Indicates the required scale of the output results of layer #2 (in case of LNEQ, MLEQ or TS). All output samples are aligned to this value. Range: -128 to 127.
ALIGN_VAL3[7:0]	**User defined output alignment value for layer 3**. Valid only when ALIGN3=1. Indicates the required scale of the output results of layer #3 (in case of LNEQ, MLEQ or TS). All output samples are aligned to this value. Range: -128 to 127.

Table 26-271. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0xC

Name	Description
W_ROW[7:0]	**Weight shared Rows**. Valid only when internal interpolation modes are enabled (INTRP=0,1). Indicates the number of rows in the sub-carrier grid that share the same interpolation weights. For details see **Section 26.4.3.5.4.7**, *W Samples*. 0—All the rows in the sub-carrier of the current job share the same interpolation weights. 1 to 255—Number of rows after which the weights changes. (*ROWS* + 1) must be an integer multiplication of *W_ROW*
S_TYPE	**S Matrix Type**. Valid for LNEQ processing only. Indicates the type of the input S matrix. 0—Real, diagonal matrix 1—Hermitian matrix
S_COL[3:0]	**S Shared Columns**. Valid for LNEQ, MLEQ and TS processing only. Indicates the number of columns in the sub-carrier grid which share the same S matrix. For details see **Section 26.4.3.5.4.5**, *S Matrix*. 0—All the columns in the sub carrier grid share the same S matrix. 1—Switch the S matrix every column. 2—Switch the S matrix every 2 columns. ... 8—Switch the S matrix every 8 columns. 9 to 15—Reserved.
S_ROW[7:0]	**S Shared Rows**. Valid for LNEQ, MLEQ and TS processing only. Indicates the number of rows in the sub-carrier grid which share the same S matrix. For details see **Section 26.4.3.5.4.5**, *S Matrix*. 0—All the rows in the sub-carrier grid share the same S matrix. 1—Switch the S matrix every row. 2—Switch the S matrix every 2 rows. ... 255—Switch the S matrix every 255 rows.

Table 26-272. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x10

Name	Description
W_SIZE[15:0]	**Weight Size**. Used by the MAPLE-B2 to calculate the total size (in bytes) of the weights. For details see **Section 26.4.3.5.4.7**, *W Samples*.
S_SIZE[15:0]	**S matrix Size**. Used by the MAPLE-B2 to calculate the total size of the S matrices (in bytes) to be fetched into the EQPE. For details see **Section 26.4.3.5.4.5**, *S Matrix*. Valid range: 0x1 to 0x4000

Table 26-273. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x14

Name	Description
TASK_ID[15:0]	**Task ID**. Targeted for user tracing and identifying of jobs. Used by MAPLE-B2 if a serial RapidIO doorbell interrupt is required. For details, refer to **Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell***
RM_SCL_TYPE	**R/M Matrix Scale Type**. Valid for TS and MIV modes only. Indicates the scale type of the input R matrix (for TS mode) or input matrix (for MIV mode). For details see **Section 26.4.3.5.4.3**, *R Samples* and **Section 26.4.3.5.4.4**, *M Samples*. 0—Single shared scale value for all matrices in the job. 1—Different scale value for each input matrix.
S_SCL_TYPE	**S matrix Scale Type**. Valid for LNEQ, MLEQ and TS modes only (ALG=0,1,2). Indicates the scale type of the S matrix. for more detail see **Section 26.4.3.5.4.5**, *S Matrix*. 0—Single shared scale value for all input S matrices. 1—Different scale value for each input S matrix.
C_SCL	**C matrix Scale value**. Valid only for LNEQ processing (ALG=0) and only if C_EN=1. Describe the scale value of the input C matrices. Range: -128 to 127.

Table 26-274. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x18

Name	Description
RR0[15:0]	**Rank Reduction of Layer #0 columns**. Valid for LNEQ processing (ALG=0) only. Each bit indicates wether to perform rank reduction to the matching column of layer #0. For details see **Section 26.4.3.5.6.3.2**, *Rank Reduction*. RR0[x]=0: Do not reduce column x of layer #0. RR0[x]=1: Reduce column x of layer #0.
RR1[15:0]	**Rank Reduction of Layer #1 columns**. Valid for LNEQ processing only (ALG=0) and if Lx >= 1. Each bit indicates wether to perform rank reduction to the matching column of layer #1. For details see **Section 26.4.3.5.6.3.2**, *Rank Reduction*. RR0[x]=0: Do not reduce column x of layer #1. RR0[x]=1: Reduce column x of layer #1.

Table 26-275. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x1C

Name	Description
RR2[15:0]	**Rank Reduction of Layer #2 columns**. Valid for LNEQ processing only (ALG=0) and if Lx >= 2. Each bit indicates wether to perform rank reduction to the matching column of layer #2. For details see **Section 26.4.3.5.6.3.2**, *Rank Reduction*. RR0[x]=0: Do not reduce column x of layer #2. RR0[x]=1: Reduce column x of layer #2.
RR3[15:0]	**Rank Reduction of Layer #3 columns**. Valid for LNEQ processing only (ALG=0) and if Lx = 3. Each bit indicates wether to perform rank reduction to the matching column of layer #3. For details see **Section 26.4.3.5.6.3.2**, *Rank Reduction*. RR0[x]=0: Do not reduce column x of layer #3. RR0[x]=1: Reduce column x of layer #3.

Table 26-276. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x20

Name	Description
Y_POINTER[31:4]	**Y pointer**. Valid for LNEQ, MLEQ and TS modes only (ALG=0,1,2). A pointer to the base address in the system memory where the MAPLE-B2 expects to find the Y inputs of the EQPE. For details see **Section 26.4.3.5.4.1.1**, *Y Samples Input Data Structure*. The pointer must be 16 bytes aligned (bits [3:0] are reserved).

Table 26-277. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x24

Name	Description
Y_OFFSET[11:0]	**Y Offset**. Valid for LNEQ, MLEQ and TS modes only (ALG=0,1,2). Indicates the offset from the Y pointer base address where the Y inputs for the current job are to be fetched by MAPLE-B2. For details see **Section 26.4.3.5.4.1.1**, *Y Samples Input Data Structure*.
Y_GAP[11:0]	**Y Gap**. Valid for LNEQ, MLEQ and TS modes only (ALG=0,1,2). Indicates the gap between Y vectors. Used by MAPLE-B2 to calculate the Y inputs location. For details see **Section 26.4.3.5.4.1.1**, *Y Samples Input Data Structure*.

Table 26-278. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x28

Name	Description
H_POINTER0[31:4] or R_POINTER[31:4] or M_POINTER[31:4]	**For LNEQ or MLEQ modes**: **H Pointer #0**. A pointer to the base address in the system memory where the MAPLE-B2 expects to find the first reference input data. In case of external interpolation or non interpolation (INTRP=2,3) modes, this pointer points to the only reference input data buffer. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.2**, *H Samples*. **For TS mode:** **R Pointer**. A pointer to the base address in the system memory where the MAPLE-B2 expects to find the R matrices input data buffer. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.3**, *R Samples*. **For MIV mode:** **M Pointer**. A pointer to the base address in the system memory where the MAPLE-B2 expects to find the input matrices data buffer. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.4**, *M Samples*.

Table 26-279. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x2C

Name	Description
H_POINTER1[31:4]	**H Pointer #1**. Valid only for Internal interpolation mode (INTRP=0,1). A pointer to the base address in the system memory where the MAPLE-B2 expects to find the second reference input data. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.2**, *H Samples*.

Table 26-280. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x30

Name	Description
H_POINTER2[31:4]	**H Pointer #2**. Valid only for Internal interpolation mode with 4 reference (INTRP=1). A pointer to the base address in the system memory where the MAPLE-B2 expects to find the third reference input data. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.2**, *H Samples*.

Table 26-281. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x34

Name	Description
H_POINTER3[31:4]	**H Pointer #3**. Valid only for Internal interpolation mode with 4 references (INTRP=1). A pointer to the base address in the system memory where the MAPLE-B2 expects to find the forth reference input data. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.2**, *H Samples*.

Table 26-282. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x38

Name	Description
S_POINTER[31:1]	**S Pointer**. Valid only for LNEQ, MLEQ and TS modes (ALG=0,1,2). A pointer to the base address in the system memory where the MAPLE-B2 expects to find the S matrix input data. The pointer must be 2 bytes aligned (bit [0] is reserved). For details see **Section 26.4.3.5.4.5**, *S Matrix*.

Table 26-283. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x3C

Name	Description
W_POINTER[31:4]	**W Pointer**. Valid only for LNEQ and MLEQ modes (ALG=0,1) and only when internal interpolation is used (INTRP=0,1). A pointer to the base address in the system memory where the MAPLE-B2 expects to find the interpolation weights input data buffer. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.7**, *W Samples*.

Table 26-284. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x40

Name	Description
SCL_PTR_BA[31:4]	**Scale Pointers Base Address**. A pointer to a base address in the system memory which is used for calculating the actual scale input buffers for the current job. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4**, *EQPE Input Samples and Data Structures*.

Table 26-285. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x44

Name	Description
S_SCL_OFFSET[7:0]	**S matrix Scale Offset**. An offset address relative to the SCL_PTR_BA pointer where the S matrices scale values are expected. The MAPLE-B2 expect to find the S matrices scale values at address: SCL_PTR_BA + (16 x S_SCL_OFFSET). For details see **Section 26.4.3.5.4.5**, *S Matrix*.
H_SCL_OFFSET[7:0]	**H reference matrix Scale Offset**. An offset address relative to the SCL_PTR_BA pointer where the H reference matrices scale values are expected for NLEQ and MLEQ modes or the R matrices scale values are expected for the TS mode. The MAPLE-B2 expect to find the H reference matrices (or R matrices) scale values at address: SCL_PTR_BA + (16 x H_SCL_OFFSET). For details see **Section 26.4.3.5.4.2**, *H Samples*.
Y_SCL_OFFSET[7:0]	**Y samples Scale Offset**. An offset address relative to the SCL_PTR_BA pointer where the Y matrices scale values are expected. The MAPLE-B2 expect to find the Y matrices scale values at address: SCL_PTR_BA + (16 x Y_SCL_OFFSET). For details see **Section 26.4.3.5.4.1.1**, *Y Samples Input Data Structure*.
F_SCL_OFFSET[7:0]	**F samples Scale Offset**. An offset address relative to the SCL_PTR_BA pointer where the F matrices scale values are expected. The MAPLE-B2 expect to find the F matrices scale values at address: SCL_PTR_BA + (16 x F_SCL_OFFSET). For details see **Section 26.4.3.5.4.8**, *F Samples*.

Table 26-286. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x48

Name	Description
OUT_POINTER0[31:4]	**For LNEQ, MLEQ and TS modes:** **Output Pointer for output samples of layer #0**. A pointer to the base address in the system memory where the MAPLE-B2 is to write the output samples (mantissa) of layer #0. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.8.1**, *EQPE Outputs for LNEQ* and **Section 26.4.3.5.8.2**, *EQPE Outputs for MLEQ and TS modes*. **For MIV mode:** **Output pointer.** A pointer to the base address in the system memory where the MAPLE-B2 is to write the output samples (mantissa) of MIV processing. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.8.3**, *EQPE Outputs for MIV*.

Table 26-287. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4C

Name	Description
OUT_POINTER1[31:4]	**Output Pointer for output samples of layer #1**. Valid only for LNEQ, MLEQ and TS modes and only if $Lx > 0$. A pointer to the base address in the system memory where the MAPLE-B2 is to write the output samples (mantissa) of layer #1. The pointer must be 16 bytes aligned (bits [3:0] are reserved).

Table 26-288. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x50

Name	Description
OUT_POINTER2[31:4]	**Output Pointer for output samples of layer #2**. Valid only for LNEQ, MLEQ and TS modes and only if $Lx > 1$. A pointer to the base address in the system memory where the MAPLE-B2 is to write the output samples (mantissa) of layer #2. The pointer must be 16 bytes aligned (bits [3:0] are reserved).

Table 26-289. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x54

Name	Description
OUT_POINTER3[31:4]	**Output Pointer for output samples of layer #3**. Valid only for LNEQ, MLEQ and TS modes and only if *Lx* > 2. A pointer to the base address in the system memory where the MAPLE-B2 is to write the output samples (mantissa) of layer #3. The pointer must be 16 bytes aligned (bits [3:0] are reserved).

Table 26-290. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x58

Name	Description
F_POINTER[31:4]	**F Pointer**. Valid only for LNEQ mode (ALG=0) and only when F_EN is set. A pointer to the base address in the system memory where the MAPLE-B2 expects to find the feedback input data buffer to be cancelled by the EQPE. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.8**, *F Samples*.

Table 26-291. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x5C

Name	Description
C_POINTER[31:4]	**C Pointer**. Valid only for LNEQ mode (ALG=0) and only when C_EN is set. A pointer to the base address in the system memory where the MAPLE-B2 expects to find the C matrices input data buffer. The pointer must be 16 bytes aligned (bits [3:0] are reserved). For details see **Section 26.4.3.5.4.6**, *C Samples*.

Table 26-292. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x60

Name	Description
OUT_SCL_OFF0[7:0]	**For LNEQ, MLEQ and TS modes:** **Output Scaling Offset for output scales of layer #0**. An offset address in the system memory relative to the OUT_POINTER0 field where the MAPLE-B2 is t output the scales vector of layer #0. The address of the scales vector is calculates as follows: Address = (OUT_POINTER0 x 16Bytes) + (OUT_SCL_OFF0 x 256Bytes). If the value of this field is zeroed then the MAPLE-B2 places the scale vector on the next byte aligned address after the completion of the mantissa samples pointed by the OUT_POINTER0. For details see **Section 26.4.3.5.8.1**, *EQPE Outputs for LNEQ* and **Section 26.4.3.5.8.2**, *EQPE Outputs for MLEQ and TS modes*. **For MIV mode:** **Output pointer.** An offset address in the system memory relative to the OUT_POINTER0 field where the MAPLE-B2 is to write the output scales vector of the MIV processing. The address of the scales vector is calculates as follows: Address = (OUT_POINTER0 x 16Bytes) + (OUT_SCL_OFF0 x 256Bytes). If the value of this field is zeroed then the MAPLE-B2 places the scale vector on the next byte aligned address after the completion of the mantissa samples pointed by the OUT_POINTER0. For details see **Section 26.4.3.5.8.3**, *EQPE Outputs for MIV*.
OUT_SCL_OFF1[7:0]	**Output Scaling Offset for output scales of layer #1**.Valid only for LNEQ, MLEQ and TS modes and only if *Lx* > 0. An offset address in the system memory relative to the OUT_POINTER1 field where the MAPLE-B2 is t output the scales vector of layer #1. The address of the scales vector is calculates as follows: Address = (OUT_POINTER1 x 16Bytes) + (OUT_SCL_OFF1 x 256Bytes). If the value of this field is zeroed then the MAPLE-B2 places the scale vector on the next byte aligned address after the completion of the mantissa samples pointed by the OUT_POINTER1.
OUT_SCL_OFF2[7:0]	**Output Scaling Offset for output scales of layer #2**.Valid only for LNEQ, MLEQ and TS modes and only if *Lx* > 1. An offset address in the system memory relative to the OUT_POINTER2 field where the MAPLE-B2 is t output the scales vector of layer #2. The address of the scales vector is calculates as follows: Address = (OUT_POINTER2 x 16Bytes) + (OUT_SCL_OFF2 x 256Bytes). If the value of this field is zeroed then the MAPLE-B2 places the scale vector on the next byte aligned address after the completion of the mantissa samples pointed by the OUT_POINTER2.
OUT_SCL_OFF3[7:0]	**Output Scaling Offset for output scales of layer #3**.Valid only for LNEQ, MLEQ and TS modes and only if *Lx* > 2. An offset address in the system memory relative to the OUT_POINTER3 field where the MAPLE-B2 is t output the scales vector of layer #3. The address of the scales vector is calculates as follows: Address = (OUT_POINTER3 x 16Bytes) + (OUT_SCL_OFF3 x 256Bytes). If the value of this field is zeroed then the MAPLE-B2 places the scale vector on the next byte aligned address after the completion of the mantissa samples pointed by the OUT_POINTER3.

Table 26-293. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x64

Name	Description
SING[14:0]	**Singularity**. Status indication writing by MAPLE-B2 and valid only after OWNER bit negation. Valid only for LNEQ, MLEQ MIV modes (ALG=0,1,3). Indicates the number of R matrices (after QR de-composition) which have one or more diagonal elements (positive real values) with exponent which is smaller than the threshold value set in the EQ_THRESH[SING] register (**Section 26.5.5.4.1**). For details see **Section 26.4.3.5.10**, *EQPE Status Indications*.

Table 26-294. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x68

Name	Description
PST_SCLR_PTR[31:3]	**Post Scalar Pointer**. Valid only if the *PST_SCLR* bit is enabled. A pointer to the system memory where the scalar post multiplication values (L_X x *COLS* different values) in 1q15 representation for the real part and 1q15 representation for the imaginary part are expected. These values are used as scalar values to be multiplied by the iDFT results of each job. For details see **Section 26.4.3.5.9.2**, *Post iDFT Processing*. The only limitation on the scalar value is: ([*PST_SCLR_REAL*]^2 + [*PST_SCLR_IMAG*]^2) < 2

Table 26-295. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x6C

Name	Description
PST_VEC_PTR[31:3]	**Post Vector Multiplication Pointer**. Valid only if *PST_VEC* bit is set. Points to the address in the system memory where the vectors for the iDFT post-multiplier memory are located. The MAPLE-B2 expects *Lx* vectors to be used for all iDFT results related to that layer. The MAPLE-B2 fetches the vectors prior to the iDFT processing. For details see **Section 26.4.3.5.9.2**, *Post iDFT Processing*.

Table 26-296. EQPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x70

Name	Description
H_OFFSET[11:0]	**H Offset**. Valid for LNEQ and MLEQ modes only (ALG=0,1). Indicates the offset from the H pointer base address (of the relevant reference symbol) where the H inputs for the current job are to be fetched by MAPLE-B2. For details see **Section 26.4.3.5.4.2.2**, *H Samples Input Data Structure*.
H_GAP[11:0]	**H Gap**. Valid for LNEQ and MLEQ modes only (ALG=0,1). Indicates the gap between H vectors to be fetched by MAPLE-B2. Used by MAPLE-B2 to calculate the H inputs location. For details see **Section 26.4.3.5.4.2.2**, *H Samples Input Data Structure*.
CONS_H	**Consecutive H**. Valid for LNEQ and MLEQ modes only (ALG=0,1). If reset, the MAPLE-B2 assume that the H vectors are consecutive in the system memory (H_OFFSET=0, H_GAP=(ROWS+1)). For details see **Section 26.4.3.5.4.2.2**, *H Samples Input Data Structure*. 0—The H input vectors are assumed consecutive. H_OFFSET and H_GAP fields are written with the values of 0 and ROWS+1 respectively. 1—The H input vectors offsets are calculated according to H_OFFSET and H_GAP.

The following restrictions apply:

- Once the [OWNER] bit is set by the host, the BD content must not be changed. It can be re-written only after the [OWNER] bit was cleared by MAPLE-B2.
- All reserved bits in the BD must be set to zero for future compatibility.
- All the status fields in the BD are updated by the MAPLE-B2 once the job is complete, that is, they are valid only after the owner bit is cleared by the MAPLE-B2.

When a host is writing a new BD to its ring, it must be done “bottom-up”, that is, the [OWNER] bit must be the last write access to the PSIF2 DRAM. If several BDs are written to the same ring, only the OWNER bit of the first written BD must be the last to be written.

26.5.4.6 CRPE-ULB Core Descriptor, Finger and PCH Commands Structures

The following sections describe the CRPE-ULB data structures used for controlling the CRPE-ULB operation.

26.5.4.6.1 CRPE-ULB Core Descriptors

Cores belonging to group g are organized in a list inside the VCOP parameter memory starting at address *MCUBGxC1P[GCDLBA]*.This address must be within the Group Core Descriptors memory area as described in **Table 26-153**. Each such Core Descriptor structure is described in **Figure 26-257**.

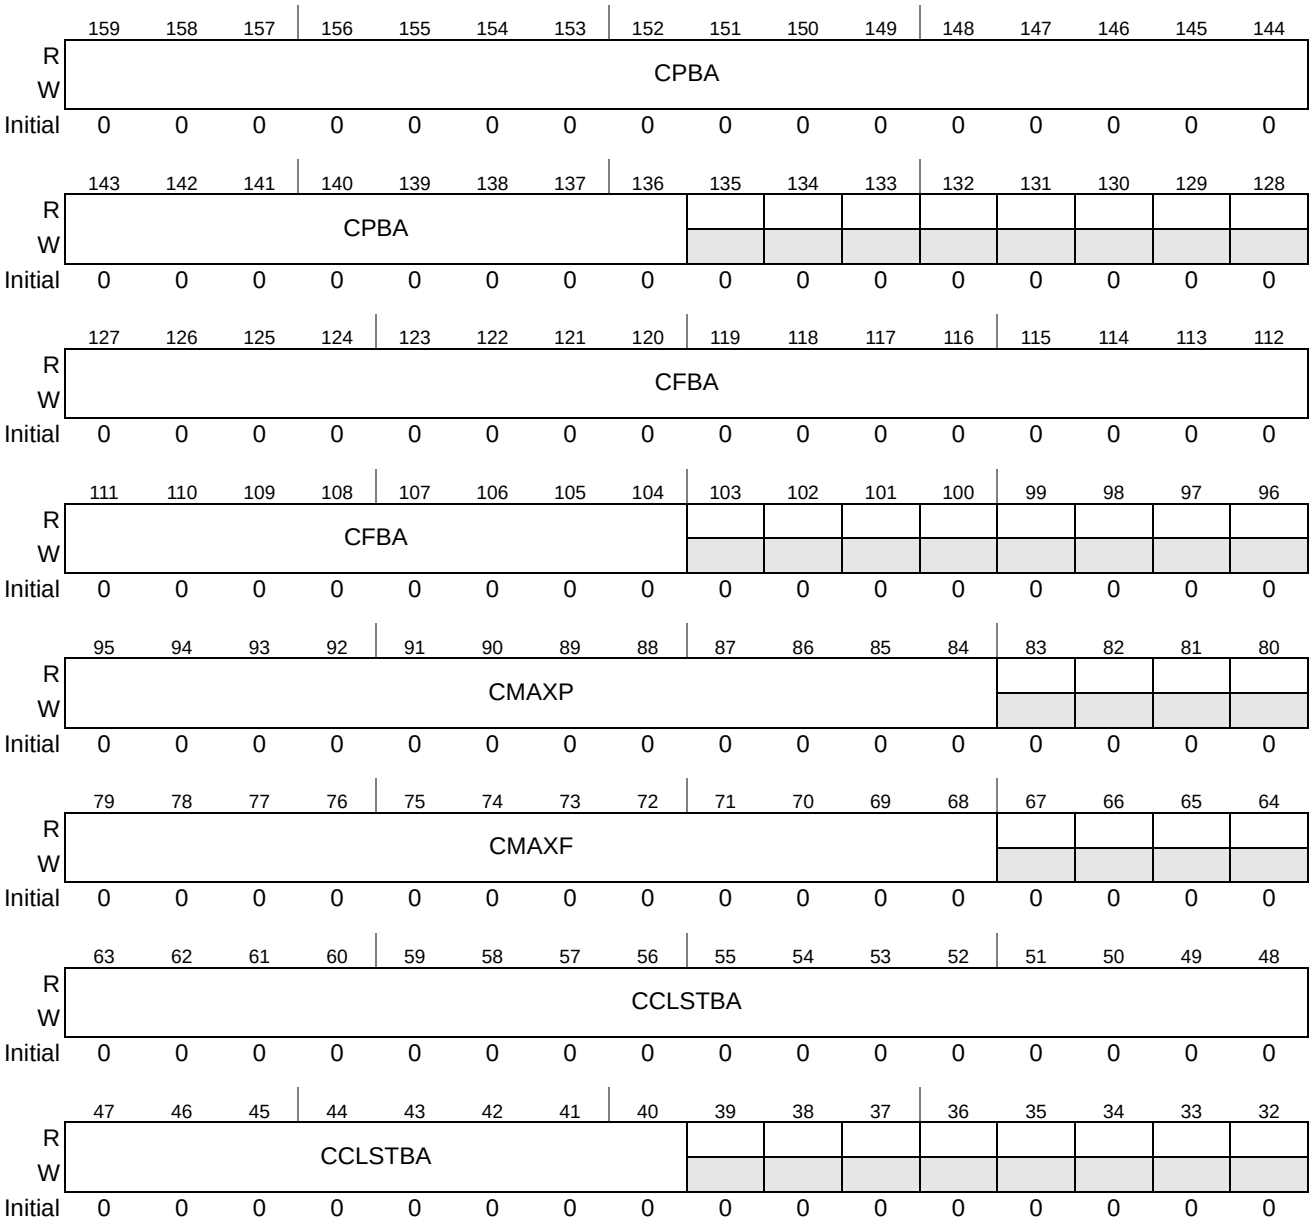

Figure 26-257. CRPE-ULB Core Descriptor Structure

Table 26-297. MAPLE CRPE-ULB Core Descriptor Fields Description

Name	Description
CPBA[159:136]	**Core PCH commands Base Address**. Indicates the base address of the first PCH commands list of the first Sub-Slot of the Core. Each list has a reserved allocation of *CMAXP**16 bytes. All the lists are concatenated.
CFBA[127:104]	**Core Fingers command Base Address**. Indicates base address of the first Finger command list of the first Sub-Slot of the Core. Each list has a reserved allocation of *CMAXF**16 bytes. All the lists are concatenated.
CMAXP[95:84]	**Command List Maximum Size of PCH**. Indicates the size in 16 bytes of memory allocated to PCH command list for each Sub-Slot of the Core.
CMAXF[79:68]	**Command List Maximum Size of Fingers**. Indicates the size in 16 bytes of memory allocated to Finger command list for each Sub-Slot of the Core.
CCLSTBA[63:40]	**Core Command List Sizes Table Base Address**. Indicates the Base Address (256 bytes granularity) of the Command List Size table for the Core. For details see **Section 26.4.3.6.1.5.1**, *Core Descriptors and Command List Size Table*.
CSWP[8:0]	**Core Sub Slot Write Pointer**. The Sub-Slot index indicating the index of the next Sub-Slot for which PCH and Finger commands belonging to the core are to be written. Should be maintained by Core (increment when PCH/Fingers command of Sub-slot are ready). Valid Range: 0-299.

26.5.4.6.2 CRPE-ULB Finger Command Structure

Each antenna finger related to a certain PCH of a certain Core should maintain a list of parameters describing its attributes. These attributes are held in a Finger command data structure as described in **Figure 26-258**. It is up to the Core to update the fingers attributes in the finger command which is then being fetched by the MAPLE-B2 into the CRPE-ULB for processing.

Figure 26-258. CRPE-ULB Finger Command Entry

Table 26-298. CRPE-ULB Finger Command Entry Fields Description

Field	Bits	Description
	127-93	Reserved
FMO	92-88	FMO - Finger Memory Offset Valid in Finger Combining bypass mode only (*CRUBMCP[FC_MODE]*=0); Indicates the finger offset relative to the PCH base address in the PCH output buffer. for details see **Section 26.4.3.6.1.14**, *Output Buffer Data Structure*. Valid values 0 to 31.
AID	87-80	Antenna ID Indicates the antenna index in which the finger exists. Valid values: • 0 to 47 if *CRUBMCP[DBL_ANT_EN]* = 0; • 0 to 95 if *CRUBMCP[DBL_ANT_EN]* = 1;

Field	Bits	Description
	79-73	Reserved
PCH_ID	72-64	PCH ID indicates the PCH the finger is associated with. Valid values: 0 to 511
GAIN_I	63-48	Complex Gain I portion Represent the I portion of the complex gain to be multiplied by the symbols extracted from the finger during Finger Combining stage. The number is fixed point number of 1Q15. for details see **Section 26.4.3.6.1.12**, *Finger Combining*. Valid values (-2^{15}) to ($+2^{15} - 1$).
GAIN_Q	47-32	Complex Gain Q portion Represent the Q portion of the complex gain to be multiplied by the symbols extracted from the finger during Finger Combining stage. The number is fixed point number of 1Q15. for details see **Section 26.4.3.6.1.12**, *Finger Combining*. Valid values (-2^{15}) to ($+2^{15} - 1$).
	31-30	Reserved
FOFFSET_H	29-20	Finger Offset High Portion Indicating the finger start offset from the first sample/chip in the input buffer. Valid values: • 0 to 767 if *CRUBMCP[DLY_SPRD]* = 1; • 0 to 511 if *CRUBMCP[DLY_SPRD]* = 0;
FOFFSET_L	19–16	Finger Offset Low Portion Indicating the finger start offset in (up to) 1/16 resolution. For details see **Section 26.4.3.6.1.8.5**, *Internal Interpolation Control* Valid values: • 0 to 15 if *CRUBMCP[DBL_ANT_EN]* = 0; • 0,2,4,6,8,10,12,14 if *CRUBMCP[DBL_ANT_EN]* = 1;
CMD	15–12	Finger Command type. 0 - NULL command 1 - modify finger gain 2 - add finger 3- remove finger 4- reserved 5 - modify finger 6 to 15 - reserved
FID	11–0	Finger ID Contains a unique Finger ID number. Valid values 0 to 3,327

26.5.4.6.3 CRPE-ULB PCH Command Structure

Each PCH of a certain Core should maintain a list of parameters describing its attributes. These attributes are held in a PCH command data structure as described in **Figure 26-259**. It is up to the Core to update the PCH attributes in the PCH command which is then being fetched by the MAPLE-B2 into the CRPE-ULB for processing.

Figure 26-259. CRPE-ULB PCH Command Entry

Table 26-299. CRPE-ULB PCH Command Entry Fields Description

Field	Bits	Description
—	127–125	Reserved
NOF	124–120	NOF - Number of Fingers Valid only if *CRUB_MCP[FC_MODE]* = 0. Indicate the number of maximum fingers for the PCH; Must be valid and unchanged throughput the entire duration of the PCH activity. Valid values: 0 to 31
—	119–118	Reserved

Table 26-299. CRPE-ULB PCH Command Entry Fields Description

Field	Bits	Description
ODT	117–116	Output Data Type. Selects which portion of processed PCH is to be output from the CRPE-ULB. for details see **Section 26.4.3.6.1.14**, *Output Buffer Data Structure* 0—Real portion 1—Imaginary portion 2—Complex (both portions) 3—Compressed.
—	115–113	Reserved
CS	112	Code Select. Selected between long and short scrambling code 0—Long Code 1—Short Code.
—	111–109	Reserved
GRP_ID	108–104	Group ID Selects to which group the PCH belongs. Valid values: 0 to 23.
—	103–102	Reserved
EXP	101–96	Output Exponent. Valid only if *CRUB_MCP[FC_MODE]* = 1. Indicates the value of the constant exponent (signed) to be used for the Finger Combining results. Values are -32 to +31
FCOR_I	95–80	Frequency Correction I portion Represent the I portion of the frequency correction factor to be multiplied by the finger complex gain in the finger Combining stage. The number is fixed point format of 2Q14. For details see **Section 26.4.3.6.1.12**, *Finger Combining*. Valid values (–128) to (+127)
FCOR_Q	79–64	Frequency Correction Q portion Represent the Q portion of the frequency correction factor to be multiplied by the finger complex gain in the finger Combining stage. The number is fixed point format of 2Q14. For details see **Section 26.4.3.6.1.12**, *Finger Combining*. Valid values (-128) to (+127)
OVSF	63–56	**OVSF Code ID** - Orthogonal Variable Spreading Factor Code ID as defined in the 3GPP technology. For details see **Section 26.4.3.6.1.10**, *Despreading*. Valid values: 0 to 255.
SCRI	55–32	Scrambling Init code value. The initial value of the scrambling code, as its defined in the 3GPP technology. Values are 0 to (2^{24} – 1).
—	31–25	Reserved
PCH_ID	24–16	PCH ID indicates the PCH ID the command is intended for. Valid values of 0 to 511.
CMD	15–12	CMD - PCH Command 0 to 5 - reserved. 6 - PCH command - add / modify PCH 7 - PCH command - remove PCH 8 - PCH command - reset *FCOR_I_VAL* and *FCOR_Q_VAL*. See **Section 26.4.3.6.1.12.2**, *Frequency Correction Factor* for details. 9 to 15 - reserved
	11	Reserved
SF	10–8	Spreading Factor valid values: 0 to 7 representing Spreading Factor of : $2^{(SF+1)}$
CSBO	7–0	Channel SubSlot Offset. Indicates the offset (in units of Sub-Slot), between the PCH scrambling code initial point and its first sub-slot. For details see **Section 26.4.3.6.1.9.1**, *Scrambling Data Offset*. Values are 0 to 149

26.5.4.7 CRCPE Buffer Descriptor Structure

A description of the CRC Buffer Descriptor structure expected by the host for the CRCPE BD rings is outlined in **Figure 26-260**. Some of the fields are status fields which are written by the MAPLE-B2 upon job completion. Other fields may be relevant only for certain configurations and is ignored by the MAPLE-B2 if another configuration is used. The total length of the BD is 32 bytes, and its size does not depend on the configuration, that is, the next BD location should be located 32 bytes after the current BD address regardless of the BD configuration.

Figure 26-260. CRCPE Buffer Descriptor Structure (Continued)

Table 26-300. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
OWNER	**Owner bit**. When set by the host, MAPLE-B2 is the BD owner and the job is not complete. When cleared by MAPLE-B2, the job is done and the host is the BD owner. 0—The host is BD owner 1—MAPLE-B2 is BD owner
WRAP	**Wrap bit**. When set by the host, MAPLE-B2 updates [BDR_RD_PTR] with [BDR_BA] (see **Section 26.5.4.1.4**), that is, it expects to find the next BD at the Base Address of the ring. When cleared by the host, MAPLE-B2 expects to find the next BD at: [BDR_RD_PTR] + BD size.
INT_EN	**Interrupt Enable**. If set, MAPLE-B2 issues an interrupt/doorbell interrupt at the end of this job. If cleared no interrupt is issued. 0—End of job interrupt is NOT issued. 1—End of job interrupt is issued.
MB_PR[1:0]	**MBus Priority**. Valid only if the [MB_PR_SCH] of the MMC0P parameter (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*) is set to ‘01’ or ‘10’. Indicated the MBus accesses priority related to this BD. For details, see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The MBus accesses related to that BD are initiated with priority ‘00’ ... 11—The MBus accesses related to that BD are initiated with priority ‘11’
CHECK	**CRC Check**. If set, MAPLE-B2 performs CRC check on the input buffer. A CRC pass/fail indication is described in the FAIL status bit. If reset, MAPLE-B2 performs CRC calculation on the input buffer. The CRC result is placed in the CRC_RSLT status field and (optional) at the end of the input buffer in the system memory. 0—MAPLE-B2 performs CRC calculation on the input buffer 1—MAPLE-B2 performs CRC check on the input buffer.
UPDATE	**Update result in system memory**. Valid only if CHECK bit is reset. If set, MAPLE-B2 copies the CRC calculation result described in CRC_RSLT status field into the system memory at the end of the input buffer. 0—MAPLE-B2 does not update the input buffer with the CRC result. 1—MAPLE-B2 copies the CRC result described in the CRC_RSLT field into the system memory at the and of the input buffer
RVRS_IN	**Reverse Input CRC**. If reset, MAPLE-B2 performs byte reverse CRC calculation/check. For details, refer to **Section 26.4.3.7.3**, *Byte Reverse CRC Processing*. 0—MAPLE-B2 performs byte reverse CRC calculation/check. 1—MAPLE-B2 performs straight forward CRC calculation/check.

Table 26-300. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
RVRS_OUT	**Reverse Output**. If set, MAPLE-B2 performs reveres operation on the CRC result. For details, refer to **Section 26.4.3.7.6.1**, *Reverse Output Operation* 0—MAPLE-B2 performs reverse on the CRC result. 1—MAPLE-B2 outputs the CRC result as is.
INV_OUT	**Inverse Output**. If set, MAPLE-B2 performs inverse operation on the CRC result. For details, refer to **Section 26.4.3.7.6.2**, *Inverse Output Operation* 0—MAPLE-B2 does not perform inverse operation on the CRC result. 1—MAPLE-B2 performs inverse operation on the CRC result.
CRC_POLY[2:0]	**CRC Polynomial**. Describes which Polynomial to use for the CRC calculation/check. 000— CRC24 with the following Polynomial: $D^{24} + D^{23} + D^6 + D^5 + D + 1$ 001— CRC24 with the following Polynomial: $D^{24} + D^{23} + D^{18} + D^{17} + D^{14} + D^{11} + D^{10} + D^7 + D^6 + D^5 + D^4 + D^3 + D + 1$ 010— CRC16-CCITT with the following polynomial: $D^{16} + D^{12} + D^5 + 1$ 011— CRC16 with the following polynomial: $D^{16} + D^{15} + D^2 + 1$ 100— CRC32 with the following polynomial: $D^{32} + D^{26} + D^{23} + D^{22} + D^{16} + D^{12} + D^{11} + D^{10} + D^8 + D^7 + D^5 + D^4 + D^2 + D + 1$ 101— CRC18 with the following polynomial: $D^{18} + D^{17} + D^{14} + D^{13} + D^{11} + D^{10} + D^8 + D^7 + D^6 + D^3 + D^2 + 1$ 110— CRC12 with the following polynomial: $D^{12} + D^{11} + D^{10} + D^8 + D^5 + D^4 + 1$ 111— CRC6 with the following polynomial: $D^6 + D^5 + D^3 + D^2 + D^1 + 1$
CRC_BS[15:0]	**CRC Block Size**. Describes the input buffer size (in bytes). 2^1 to 0xFFFF possible values (2 bytes to 64Kbytes)

1. For CRC word generation the minimum block size is 2 bytes. For CRC check the minimum block size is 5 bytes (40 bits)

Table 26-301. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
CRC_IB[31:0]	**CRC Input Buffer**. This field points to the CRC input buffer location in system memory, where MAPLE-B2 is to read to perform CRC check/calculation.

Table 26-302. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x8

Name	Description
CRC_INIT[31:0]	**CRC Initialization value**. MAPLE-B2 uses this field as the CRC initialization value for the CRC processing. In case the CRC polynomial is of size of 6 bits (CRC_POLY =(111)), then the valid bits for this filed are [5:0] only. In case the CRC polynomial is of size of 12 bits (CRC_POLY =(110)), then the valid bits for this filed are [11:0] only. In case the CRC polynomial is of size of 16 bits (CRC_POLY =(010) or (011)), then the valid bits for this filed are [15:0] only. In case the CRC polynomial is of size of 18 bits (CRC_POLY =(101)), then the valid bits for this filed are [17:0] only. In case the CRC polynomial is of size of 24 bits (CRC_POLY =(000) or (001)), then the valid bits for this filed are [23:0] only. In case the CRC polynomial is of size of 32 bits (CRC_POLY =(100), then the valid bits for this filed are [31:0]. For details, refer to section **Section 26.4.3.7.4**, *CRC Initial Value*

Table 26-303. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0xC

Name	Description
CRC_RSLT[31:0]	**CRC Result**. Valid only if [CHECK] bit is reset and after [OWNER] bit is cleared by MAPLE-B2. Describes the result of the CRC calculation performed on the input buffer.

Table 26-304. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x10

Name	Description
FAIL	**CRC Fail**. Valid only if [CHECK] bit is set and after [OWNER] bit is cleared by MAPLE-B2. Status bit which indicates whether the CRC check has passed or failed. 0—CRC check has passed. 1—CRC check has failed.
TASKID[7:0]	**Task ID tag**. Supplied by host to track BDs. Also used by MAPLE-B2 if a serial RapidIO doorbell interrupt is required. For details refer to **Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell***

Table 26-305. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x14

Name	Description
[31:0]	**Reserved**.

Table 26-306. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x18

Name	Description
[31:0]	**Reserved**.

Table 26-307. CRCPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x1C

Name	Description
[31:0]	**Reserved**.

The following restrictions apply to the CRCPE BDs:

- Once the [OWNER] bit is set by the host, the BD content must not be changed. It can be re-written only after the [OWNER] bit was cleared by MAPLE-B2.
- All reserved bits in the BD must be cleared to zero for future compatibility.
- All the status fields in the BD are updated by the MAPLE-B2 once the job is complete, that is, they are valid only after the owner bit is cleared by the MAPLE-B2.

When a host is writing a new BD to its ring, it must be done “bottom-up”, that is, the [OWNER] bit must be the last write access to the PSIF2 DRAM. If several BDs are written to the same ring, only the OWNER bit of the first written BD must be the last to be written.

26.5.4.8 CGPE Buffer Descriptor Structure

A description of the Code Generator Buffer Descriptor structure expected by the host for the CGPE BD rings is outlined in **Figure 26-261**. Some of the fields are status fields which are written by the MAPLE-B2 upon job completion. Other fields may be relevant only for certain configurations and is ignored by the MAPLE-B2 if another configuration is used. The total length of the BD is 32 bytes, and its size does not depend on the configuration, that is, the next BD location should be located 32 bytes after the current BD address regardless of the BD configuration.

Figure 26-261. CGPE Buffer Descriptor Structure (Continued)

Table 26-308. CGPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
OWNER	**Owner bit**. When set by the host, MAPLE-B2 is the BD owner and the job is not complete. When cleared by MAPLE-B2, the job is done and the host is the BD owner. 0—The host is BD owner 1—MAPLE-B2 is BD owner
WRAP	**Wrap bit**. When set by the host, MAPLE-B2 updates [BDR_RD_PTR] with [BDR_BA] (see **Section 26.5.4.1.4**), that is, it expects to find the next BD at the Base Address of the ring. When cleared by the host, MAPLE-B2 expects to find the next BD at: [BDR_RD_PTR] + BD size.
INT_EN	**Interrupt Enable**. If set, MAPLE-B2 issues an interrupt at the end of this job. If cleared no interrupt is issued. 0—End of job interrupt is NOT issued. 1—End of job interrupt is issued.
MB_PR[1:0]	**MBus Priority**. Valid only if the [MB_PR_SCH] of the MMC0P parameter (see **Section 26.5.2.1**, *MAPLE Mode Configuration 0 Parameter (MMC0P)*) is set to ‘01’ or ‘10’. Indicated the MBus accesses priority related to this BD. For details, see **Section 26.4.2.4**, *MBus Priority Scheme Configuration* 00— The MBus accesses related to that BD are initiated with priority ‘00’ ... 11—The MBus accesses related to that BD are initiated with priority ‘11’
CODE_SIZE[7:0]	**Code Size**. Indicated the size of the required generated code. The size value is of 128 bits multiplication: 0—Generated Code size is 128 bits. 1—Generated Code size is 256 bits. 2—Generated Code size is 384 bits. ... 255—Generated Code size is 32768 bits.

Table 26-309. CGPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
TASKID[7:0]	**Task ID tag**. Supplied by host to track BDs. Also used by MAPLE-B2 if a serial RapidIO doorbell interrupt is required. For details, refer to **Section 26.4.4, *External Masters Support Using Serial RapidIO Doorbell***
PN_NUM[23:0]	**Pseudo random Number**. Uplink Scrambling (UL_CODE=1): The initial state of X sequence (bits [0:13]) used for uplink long Code generation. Downlink Scrambling (UL_CODE=0): Scrambling Code number (bits [0:14]) used for Downlink scrambling code generation. Valid range: 0x0000 to 0x5FFF

Table 26-310. CGPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x8

Name	Description
SF[3:0]	**Spreading Factor**. Required for hadamard code generation. The actual spreading factor is 2^{SF}: 0—Spreading Factor is 1. 1—Spreading Factor is 2. 2—Spreading Factor is 4. ... 8—Spreading Factor is 256. 9 to 15—Reserved.
OVSF_NUM[7:0]	**OVSF Number**. Orthogonal Variable Spreading Factor code number corresponding to the selected Spreading Factor (SF). Valid Range: $0 \leq OVSF\_NUM \leq (2^{SF} - 1)$.
START_OFFSET[15:8]	**CG Start Offset**. Indicates the start point for codes generation corresponding to specific chip number in the frame. Required for the scrambling code generation. The START_OFFSET value represent Sub-Slot alignment, that is, the value of 0x1 represent chip offset of 256. Valid range: 0 to 149.

Table 26-311. CGPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0xC

Name	Description
CONJ_EN	**Conjugate Enable**. Indicates whether the resulting code is conjugated. 0—The Code results (I,Q) are not conjugated. 1—The Code results (I,Q) are conjugated.
LONG_MODE	**Long Mode**. Valid only during Uplink mode (UL_CODE = 1). Indicates whether long or short code is generated. 0—Generate Uplink Scrambling Short code. 1—Generate Uplink Scrambling Long code.
UL_CODE	**Uplink Code**. Indicates if Uplink or Downlink codes are generated. 0—Generate Downlink codes 1—generate Uplink codes.
OUT_MODE	**Output Mode**. Indicates the code output format. 0—The generated code format is pairs of 8 bits I and 8 bits Q, that is, 8 I,Q pairs for each 128 bits of generated code. 1— The generated code format is pairs of single bit I and single bit Q, that is, 64 I,Q pairs for each 128 bits of generated code.
CFG_VAL_1[7:0]	**Configuration Value of 1**. Valid only if output mode is 8 bits representation (OUT_MODE = 1). Indicates that the value represent is a generated code bit with the value of 1.
CFG_VAL_0[7:0]	**Configuration Value of 0**. Valid only if output mode is 8 bits representation (OUT_MODE = 1). Indicates that the value represented is a generated code bit with the value of 0.

Table 26-312. CGPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x10

Name	Description
CODE_RSLT_PTR[31:0]	**Code Result Pointer**. Pointer to the system memory where the MAPLE-B2 is to write the generated code.

Table 26-313. CGPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x14

Name	Description
[31:0]	**Reserved**.

Table 26-314. CGPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x18

Name	Description
[31:0]	**Reserved**.

Table 26-315. CGPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x1C

Name	Description
[31:0]	**Reserved**.

The following restrictions apply to the CGPE BDs:

- Once the [OWNER] bit is set by the host, the BD content must not be changed. It can be re-written only after the [OWNER] bit was cleared by MAPLE-B2.
- All reserved bits in the BD must be cleared to zero for future compatibility.

When a host is writing a new BD to its ring, it must be done “bottom-up”, that is, the [OWNER] bit must be the last write access to the PSIF2 DRAM. If several BDs are written to the same ring, only the OWNER bit of the first written BD must be the last to be written.

26.5.4.9 CONVPE Buffer Descriptor Structure

The following is a description of the CONVPE Buffer Descriptors structure as they should be written to the CONVPE BD rings by the host.

Table 26-316. CONVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x0

Name	Description
OWNER	**Owner bit**. When set by the host, MAPLE-B2 is the BD owner and the job is not complete. When cleared by MAPLE-B2, the job is done and the host is the BD owner. 0—The host is BD owner 1—MAPLE-B2 is BD owner
WRAP	**Wrap bit**. When set by the host, MAPLE-B2 updates [BDR_RD_PTR] with [BDR_BA] (see **Section 26.5.4.1.4**, *MAPLE <yy>PE BD Ring High Priority A <x> Parameter (M<yy>BRHPAxP)*), that is, it expects to find the next BD at the Base Address of the ring. When cleared by the host, MAPLE-B2 expects to find the next BD at: [BDR_RD_PTR] + BD size.
INT_EN	**Interrupt Enable**. If set, MAPLE-B2 issues an interrupt/doorbell interrupt at the end of this job. If cleared no interrupt is issued. 0—End of job interrupt is NOT issued. 1—End of job interrupt is issued.
TASK_ID	Task ID. Describes the task number, set by host and used by the host.
TASK_TYPE [2:0]	Task Type. Describes the type of the task to be executed. 000 - Reserved 001 - UMTS RACH correlation 010 - UMTS Path Searcher correlation 011 - Reserved 100 - Reserved 101 - Reserved 110 - Reserved 111 - Reserved
TASK_DESCR_SIZE[11:0]	**Task Descriptor Size.** Describes the detailed task descriptor size in bytes.

Table 26-317. CONVPE Buffer Descriptor Fields Description of 4 Bytes at Offset 0x4

Name	Description
TASK_ADDR [31:3]	Task Descriptor Address. Address for detailed task descriptor in system memory. The *TASK_ADDR* field must be aligned to 8 bytes.

26.5.4.10 CONVPE RACH Preamble Correlations Task Descriptor

The following is a description of the CONVPE UMTS RACH correlations task fields as they should be written by the host in system memory pointed by the CONVPE buffer descriptor *TASK_ADDR* field.

Figure 26-263. CONVPE RACH Task Descriptor Structure (Continued)

Table 26-318. UMTS RACH Task Descriptor Fields Description

Name	Description
ANT_DIV_BCH[3:0]	Antenna Diversity Branches. Describes number of data streams for correlation. 0,1—Reserved. 2— Two data streams. 3— Reserved. 4— Four data streams. 5— Reserved. 6— Six data streams. 7— Reserved. 8— Eight data streams. 9 to 15— Reserved.
RSLT_OVA_SCL	**Results Overall Scaling**. If set, the total scaling of the correlation results is aligned with the *ADP_OVA_SCL* field in the Task Descriptor (TD). 0—No overall scaling is specified. 1—The CONVPE aligns the total accumulated scaling with the scaling value specified in the *ADP_OVA_SCL* filed in the TD.
ANT_FFT_WBE	**Antenna Data FFT Write Back Enable.** Relevant only if *ANT_FD* =0. Indicates if frequency domain chips need to be written to system memory. 0—Frequency domain results are **not** written to system memory. 1—Frequency domain results are written to system memory as pointed in the *ANT_DATA_FD_ADDR* field.
ANT_FD	**Antenna Data in Frequency Domain.** Indicates if antenna data is stored in system memory in frequency domain (already passed FFT processing) or in time domain 0—Time domain antenna data, represented as 8I, 8Q per chip, fixed point time domain chips vector 1—Frequency domain antenna data, represented as 16I, 16Q, block floating frequency domain chips vector
CCW[4:0]	**Coherent Correlation Window**. Describes the Coherent Correlation Window (CCW) size in multiples of FFT transforms needed to perform the task, including the overlap. FFT size is defined in by *TL_ID* field. For details see **Figure 26-172**. 0x0—Reserved 0x1—CCW of single FFT transform length ..... 0x18—CCW of 24 FFT transform lengths 0x19—0x1F - Reserved
SIGN_INDX [15:0]	**Signatures Index.** Describes number and index of RACH signatures to correlate with the data streams Every bit enables the relevant preamble signature as described in *Table 3 of 3GPP specification 25.213 - Preamble Signatures*. The signatures are zero padded according to the *OVRLP_SIZE*, conjugated, flipped and stored in frequency domain as part of pre-processing done before the CONVPE RACH correlation task. bit 0—represents $P_0(n)$ .... bit 15—represents $P_{15}(n)$

Table 26-318. UMTS RACH Task Descriptor Fields Description

Name	Description
RSLT_ADP_OVA_SCL [7:0]	**Results Adaptive Overall Scaling**. Valid only if the *RSLT_OVA_SCL* field in the TD is set. Determines the Overall scale the CONVPE is to perform on the correlation results. The value of this field is compared with the total scaling accumulated by the adaptive scaling between the stages, and the output data is scaled up/down to fit the required overall scaling. The field apply to all the results of current correlation task. Supported values: –128 to 127.
AD_UPDATE_EN	Update the Antenna Data buffer. 0—Write CCW amount of antenna data, starting at offset 0 of the antenna buffer. 1—Write AD_UPDATE_NUM amount of antenna data, starting at the last offset used of the antenna buffer.
TL_ID[5:0]	**Transform Length ID**. This field determines the executed transform length. See **Table 26-246** for DFT/FFT Transform Length encoding. Valid values for RACH correlation operation are: 35, 36, 37, 38, 39 representing 128, 256, 512, 1024 and 2048 points transforms respectively.
AD_UPDATE_NUM[4:0]	**Number of FFT transforms to write to the antenna buffer.** Valid only if AD_UPDATE_EN is set. 0x0— Write to the antenna buffer is disabled. 0x1— Write a single FFT transform length. ..... 0x18—Write 24 FFT transform lengths. 0x19—0x1F - Reserved
OVRLP_SZ [10:0]	**Overlap Size.** Describes number of chips to overlap for data streams processing. Represents the delay spread in chips for correlation in frequency domain. 0x000 - No overlap 0x7FF - 2047 chips overlap
ANT_DATA_FD_ADDR [31:0]	**Antenna Data in Frequency Domain Address.** Applicable only if *ANT_FFT_WBE* bit is set. This is the pointer to a data structure that contains the antenna datApost FFT for further use by other tasks. The data structure is organized as shown in **Figure 26-176**
AD_FD_SCALE_ADDR[31:0]	**Antenna Data Scale Values Pointer.** Points to scale values (exponents) for block floating point representation of the antenna data. Each exponent represented by 8 bit value. The scale values are concatenated one after another in same order as antenna data vectors. Number of values is equivalent to *ANT_DIV_BCH * CCW* • If *ANT_FD* =1, the MAPLE-B2 fetches the concatenated scale values according to this pointer. • If *ANT_FD* = 0 & *ANT_FFT_WBE* = 1, the MAPLE-B2 uses this pointer to write the concatenated scale values of the FFT processing results.
AD_OFFSET [31:0]	**Antenna Data Offset**. Describes the offset of the antenna data belonging to antenna diversity to be processed in this correlation task. *ADx_BASE* + *AD_OFFSET* defines the start address from which to read the relevant antenna data for the diversity X in this correlation task. For details, see **Figure 26-173**.
AD_BUFFER_SIZE[31:0]	**Antenna Data Buffer Size.** Defines the size (in bytes) of the antenna diversity circular buffer. For details, see **Figure 26-173**.
SIGN_ADDR [31:3]	**Signatures Base Address**. Points to the start address in the system memory of the first out of several signature vectors stored in frequency domain. The start address of the next vectors is distances form this pointer by *SIGN_OFFSET* multiplications. For details, see **Figure 26-174**. Total number of vectors is based on *SIGN_INDX* field. The size of each signature vector depends on FFT size and overlap size. The *SIGN_ADDR* field must be aligned to 8 bytes.
SIGN_OFFSET [15:0]	**Signature Offset**. Describes the relative offset between the signature vectors in the system memory. For details, see **Figure 26-174**.
CORR_RSLT_OFFSET [15:0]	**Correlation Results Offset**. Describes the relative offset between the correlation results vectors in the system memory. For details, see **Figure 26-174**.
CORR_RSLT_ADDR[31:0]	**Correlation Results Address.** Points to the start address of all the correlation results requested in this job. Organized as shown in **Figure 26-174**

Table 26-318. UMTS RACH Task Descriptor Fields Description

Name	Description
CORR_RSLT_SCALE_ADDR [31:0]	**Correlation Results Scale Values Pointer.** Points to scale values (exponents) for block floating point representation of the correlation results. Each exponent represented by 8 bit value. The scale values are concatenated one after another in same order as antenna data vectors.
ADx_BASE [31:3]	Antenna Data X Base Pointer. Points to the start address of circular buffer in the system memory with the antenna diversity X, representing one of the diversity branches. For details, see **Figure 26-173**. Total number of pointers is defined by *ANT_DIV_BCH* The *ADx_BASE* field must be aligned to 8 bytes.

26.5.4.11 CONVPE Path Searcher Task Descriptor

The following is a description of the CONVPE UMTS Path searcher correlations task fields as they should be written by the host in system memory pointed by the CONVPE buffer descriptor *TASK_ADDR* field.

Figure 26-264. CONVPE Path Searcher Task Descriptor Structure (Continued)

Table 26-319. UMTS Path Searcher Task Descriptor Fields Description

Name	Description
ANT_DIV_BCH[3:0]	Antenna Diversity Branches. Describes number of data streams for correlation. 0,1—Reserved. 2— Two data streams. 3— Reserved. 4— Four data streams. 5— Reserved. 6— Six data streams. 7— Reserved. 8— Eight data streams. 9 to 15— Reserved.
RSLT_OVA_SCL	**Results Overall Scaling**. If set, the total scaling of the correlation results is aligned with the *ADP_OVA_SCL* field in the TD. 0—No overall scaling is specified. 1—The CONVPE aligns the total accumulated scaling with the scaling value specified in the *ADP_OVA_SCL* filed in the BD.
ANT_FFT_WBE	**Antenna Data FFT Write Back Enable.** Relevant only if *ANT_FD* =0. Indicates if frequency domain chips need to be written to system memory. 0—Frequency domain results are **not** written to system memory. 1—Frequency domain results are written to system memory as pointed in the *ANT_DATA_FD_ADDR* field.
ANT_FD	**Antenna Data in Frequency Domain.** Indicates if antenna data is stored in system memory in frequency domain (already passed FFT processing) or in time domain 0—Time domain antenna data, represented as 8I, 8Q per chip, fixed point time domain chips vector 1—Frequency domain antenna data, represented as 16I, 16Q, block floating frequency domain chips vector
CCW[4:0]	**Coherent Correlation Window**. Describes the Coherent Correlation Window (CCW) size in multiples of FFT transforms needed to perform the task, including the overlap. FFT size is defined in by *TL_ID* field. For details see **Figure 26-172**. 0x0—Reserved 0x1—CCW of single FFT transform length ..... 0x18—CCW of 24 FFT transform lengths 0x19—0x1F - Reserved
NUSERS[7:0]	**Number of Users.** Describes number of users for Path Searcher task in this descriptor. 0x00—1 user 0x01—2 users ..... 0xFF—256 users
AD_UPDATE_EN	Update the Antenna Data buffer. 0—Write CCW amount of antenna data, starting at offset 0 of the antenna buffer. 1—Write AD_UPDATE_NUM amount of antenna data, starting at the last offset used of the antenna buffer.
TL_ID[5:0]	**Transform Length ID**. This field determines the executed transform length. See **Table 26-246** for DFT/FFT Transform Length encoding. Valid values for RACH correlation operation are: 35, 36, 37, 38, 39 representing 128, 256, 512, 1024 and 2048 points transforms respectively.
AD_UPDATE_NUM[4:0]	**Number of FFT transforms to write to the antenna buffer.** Valid only if AD_UPDATE_EN is set. 0x0— Write to the antenna buffer is disabled. 0x1— Write a single FFT transform length. ..... 0x18—Write 24 FFT transform lengths. 0x19—0x1F - Reserved

Table 26-319. UMTS Path Searcher Task Descriptor Fields Description

Name	Description
OVRLP_SZ [10:0]	**Overlap Size.** Describes number of chips to overlap for data streams processing. Represents the delay spread in chips for correlation in frequency domain. 0x000—No overlap 0x7FF—2047 chips overlap
ANT_DATA_ FD_ADDR [31:0]	**Antenna Data in Frequency Domain Address.** Applicable only if *ANT_FFT_WBE* bit is set. This is the pointer to a data structure that contains the antenna datApost FFT for further use by other tasks. The data structure is organized as shown in **Figure 26-176**.
AD_FD_ SCALE_ ADDR[31:0]	**Antenna Data Scale Values Pointer.** Points to scale values (exponents) for block floating point representation of the antenna data. Each exponent represented by 8 bit value. The scale values are concatenated one after another in same order as antenna data vectors. Number of values is equivalent to *ANT_DIV_BCH * CCW* • If *ANT_FD* =1, the MAPLE-B2 fetches the concatenated scale values according to this pointer. • If *ANT_FD* = 0 & *ANT_FFT_WBE* = 1, the MAPLE-B2 uses this pointer to write the concatenated scale values of the FFT processing results.
AD_OFFSET [15:0]	**Antenna Data Offset**. Describes the offset of the antenna data belonging to antenna diversity X to be processed in this correlation task. *ADx_BASE* + *AD_OFFSET* defines the start address from which to read the relevant antenna data for the diversity X in this correlation task. For details, see **Figure 26-173**.
AD_BUFFER_ SIZE[15:0]	**Antenna Data Buffer Size.** Defines the size (in bytes) of the antenna diversity circular buffer. For details, see **Figure 26-173**.
U_CORR_ RSLT_ OFFSET[15:0]	**User Correlation Results Offset.** Describes the relative offset between the correlation results vectors in the system memory. For details, see **Figure 26-175**
ADx_BASE [31:3]	Antenna Data X Base Pointer. Points to the start address of circular buffer in the system memory with the antenna diversity X, representing one of the diversity branches. For details, see **Figure 26-173**. Total number of pointers is defined by *ANT_DIV_BCH* The *AD_BASE* field must be aligned to 8 bytes.
The fields below are per user, and appear in task descriptor according to *NUSERS* field.	
SCRM_SEQ [23:0]	**Scrambling Sequence.** A 24-bit word that specifies user scrambling sequence, as defined in 3GPP specification.
CNPI[2:0]	**Number of Pilots.** Number of pilots per slot in current radio frame. Valid Range: 0 to 5 representing 3 to 8.
FC_EN	**Frequency Correction Enable.** If set indicates that frequency correction should be performed on the pilot sequences generated for this user. 1—Frequency correction enabled 0—Frequency correction disabled, all the fields related to frequency correction are not relevant.
LS	**Long or short.** Scrambling sequence selection 1—Long sequence 0—Short sequence
SOIF[3:0]	**Slot Offset in Frame.** Slot number in frame to start the correlation
RSLT_ADP_ OVA_SCL [7:0]	**Results Adaptive Overall Scaling**. Valid only if the *RSLT_OVA_SCL* field in the BD is set. Determines the Overall scale the CONVPE is to perform on the correlation results. The value of this field is compared with the total scaling accumulated by the adaptive scaling between the stages, and the output data is scaled up/down to fit the required overall scaling. The field apply to all the results of current correlation task. Valid values: -128 to +127.
COIF[15:0]	**Chip Offset in Frame.** Specifies the user chip's offset to start the correlation in current window. Should meet the following condition: *SOIF**2560 ≤ *COIF* < (*SOIF*+1)*2560 The delay is specified in chips with possible values range 0 to 38399 chips

Table 26-319. UMTS Path Searcher Task Descriptor Fields Description

Name	Description
FCB_REAL [15:0]	**Frequency Correction Base Value Real Part**. Valid only if *FC_EN* is enabled. Describes the real part value of the Frequency Correction initialization. Valid values: 1 to 65535
FCB_IMAG [15:0]	**Frequency Correction Base Value Imaginary Part**. Valid only if *FC_EN* is enabled. Describe the imaginary part value of the Frequency Correction initialization. Valid values: 1 to 65535
FCISC[15:0]	**Frequency Correction Input Step Counter**. Valid only if *FC_EN* is enabled. Indicates the step counter initial value for starting the frequency correction argument generation. Its value should be small or equal to the *FCSS* field. If Step Size *FCSS* equals 1, this field should be set to 0x0. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE*. Valid values: 0 to 65532 which are products of 4.
FCSS[15:0]	**Frequency Correction Step Size**. Valid only if *FC_EN* is enabled. The number of samples that should be corrected with the same correction factor before the correction factor is increment by the shift value. For details see **Section 26.4.3.3.7**, *Frequency Correction Support in eFTPE* Supported values: 1 or values between 4–65532 which are products of 4.
FCS_REAL [15:0]	**Frequency Correction Shift Value Real Part**. Valid only if *FC_EN* is enabled. Describe the real part value of the Frequency Correction shift value. Supported values: 1 to 65535
FCS_IMAG [15:0]	**Frequency Correction Shift Value Imaginary Part**. Valid only if *FC_EN* is enabled. Describe the imaginary part value of the Frequency Correction shift value. Supported values: 1 to 65535
U_CORR_RSLT_ADDR [31:0]	**User Correlation Results Address.** Points to the start address of all the correlation results requested in this job per user. Organized as shown in **Figure 26-175**
U_CORR_RSLT_SCALE_ADDR[31:0]	User Correlation Results Scale Values Pointer. Points to scale values (exponents) for block floating point representation of the correlation results. Each exponent represented by 8 bit value. The scale values are concatenated one after another in same order as antenna data vectors.

26.5.5 Registers

The MAPLE-B2 includes several sets of programmable registers that configure and monitor the operation of MAPLE-B2 and the individual PEs. The following subsections provide detailed listings of the registers along with detailed descriptions of the register layouts and bit field descriptions

26.5.5.1 PSIF2 Registers (SBus)

The PSIF2 registers can be accessed via the MAPLE-B2s SBus port only. The SBus interface of the MAPLE-B2 is used to access the PSIF2 internal registers only. **Table 26-126** describes the SBus Memory Map. The base address is 0xFFF1D000.

26.5.5.1.1 PSIF Command Register (PCR)

This register is the MAPLE-B2 command register. It is used for initializing a specific MAPLE-B2 routines.

Offset 0x00001000(PCR) Access: User read/write

Figure 26-265. PSIF2 Command Register

Table 26-320. PSIF2 Command Register Fields Description

Field	Description
31–17	Reserved.
16	FLG - Command semaphore flag. Set by the host and cleared by the MAPLE-B2 once execution is done. Once set, the MAPLE-B2 executes the requested routine as described in PCR[OPCODE], and cleared the FLG bit.

Table 26-320. PSIF2 Command Register Fields Description

Field	Description
15–6	Reserved.
5–0	OPCODE - On assertion of the PCR[FLG], the MAPLE-B2 executes the task encoded in this field according to the following encoding: ‘000000’ - Reserved. ‘000001’ - Maple_parse_bd. For details, see **page 26-312**. ‘000010’ - Maple_parse_tvpe_bd. For details, see **page 26-312**. ‘000011’ - Maple_parse_ftpe_0_bd. For details, see **page 26-312**. ‘000100’ - Maple_parse_ftpe_1_bd. For details, see **page 26-312**. ‘000101’ - Maple_parse_ftpe_2_bd. For details, see **page 26-312**. ‘000110’ - Maple_parse_depe_bd. For details, see **page 26-312**. ‘000111’ - Maple_parse_crcpe_bd. For details, see **page 26-312**. ‘001000’ - Maple_parse_eqpe_bd. For details, see **page 26-312**. ‘001001’ - Maple_parse_convpe_bd. For details, see **page 26-312**. ‘001010’ - Maple_parse_cgpe_bd. For details, see **page 26-312**. ‘001011’ - Maple_reset_crpe. For details, see **page 26-312**. ‘001100’ - Maple_crpe_ulb_init. For details see **page 26-313** ‘001101’ - Maple_crpe_ulf_init. For details see **page 26-313** ‘001110’ - Maple_crpe_3x_eftpe_clock_gate_control. For details see **page 26-313** ‘001111’ - Reserved. ‘010000’ - Maple_update_eftpe_pre_post_buffers. For details see **page 26-313** ‘010001’ to ‘111111’ - Reserved.

26.5.5.1.2 PSIF PIC Event Register 0 (PSPICER0)

This register describes which Buffer Descriptors Rings events are set. These events can be cleared only by the host writing this register with the value of 1 in the relevant bit. The bits in this event register are set only if the interrupt configuration is level (see **Section 26.5.5.1.5**, *PSIF PIC Edge/Level Register 0 (PSPICELR0)*

Offset 0x00001600 (PSPICER0) Access: User read/write

Figure 26-266. PSIF PIC Event Register 0

Table 26-321. PSIF PIC Event Register 0 Fields Description

Bits	Description
31–0	BDR_DONE[31:0]—Buffer Descriptor Done. 32 interrupt lines which can be asserted due to Buffer Descriptors completion. Each of these interrupts can be assigned to any of the BD rings (see **Section 26.5.4.1.5** or **Section 26.5.4.1.7**), and can be configured as edge or level. Read ‘0’ Buffer Descriptor Ring Done event did not occur Read ‘1’ Buffer Descriptor Ring Done event occur Write ‘1’ Clear bit if set.

26.5.5.1.3 PSIF PIC Event Register 1 (PSPICER1)

This register describes which event caused the assertion of the MAPLEs general error interrupt, which is a level interrupt only. Any assertion of any of these events causes the assertion of the MAPLEs general error interrupt. These events can be cleared only by the host writing this register with the value of 1 in the relevant bit.

Offset 0x00001604 (PSPICER1) Access: User read/write

31–5	Reserved
[4]	CRPE_ULF_ERR. CRPE-ULF Error Indication. For error type see **Section 26.5.5.6.6**, *ULF Event Status Register (ULFESR)*. Assertion of CRPE-ULF error indication requires CRPE reset as described in **Section 26.4.3.6.4**, *CRPE Reset*. 0 — No CRPE-ULF error indication occurred. 1 — CRPE-ULF error occurred. See **Section 26.5.5.6.6**, *ULF Event Status Register (ULFESR)* for error type.
[3–1]	Reserved.
0	eMSG_ERR

26.5.5.1.4 PSIF PIC Event Register 2 (PSPICER2)

This register describes ECC error events from all MAPLE-B2 memory groups which are ECC protected. Assertion of any of these bits causes the assertion of the MAPLE-B2s general ECC error event, which is a level interrupt only. These events can be cleared only by the host writing this register with the value of 1 in the relevant bit. Enabling the ECC memory protection in MAPLE-B2 is done by setting the [ECC_EN] bit of the MMC0P parameter in the API (see *MAPLE-B Application Programmer Interface (API) User's Guide* (MAPLEAPIUG)).

Figure 26-268. PSIF PIC Event Register 2

Table 26-323. PSIF PIC Event Register 2 Fields Description

Bits	Description
31–13	reserved.
12	CRUF_ECC — CRPE-ULF memory ECC Error. This bit indicates that an ECC has occur in one of the CRPE-ULF internal memories. For details see **Section 26.4.3.1.1, *Memory Error Correction/Detection Support***. (need to replace with section's ECC) Read '0' ECC Error event in one of the CRPE-ULF internal memories did not occur Read '1' ECC Error event in one of the CRPE-ULF internal memories occur Write '1' Clear bit if set.
11	CRUB_ECC — CRPE-ULB memory ECC Error. This bit indicates that an ECC has occur in one of the CRPE-ULB internal memories. For details see **Section 26.4.3.1.1, *Memory Error Correction/Detection Support***. (need to replace with section's ECC) Read '0' ECC Error event in one of the CRPE-ULB internal memories did not occur Read '1' ECC Error event in one of the CRPE-ULB internal memories occur Write '1' Clear bit if set.
10	CRDL_ECC — CRPE-DL memory ECC Error. This bit indicates that an ECC has occur in one of the CRPE-DL internal memories. For details see **Section 26.4.3.1.1, *Memory Error Correction/Detection Support***. (need to replace with section's ECC) Read '0' ECC Error event in one of the CRPE-DL internal memories did not occur Read '1' ECC Error event in one of the CRPE-DL internal memories occur Write '1' Clear bit if set.

Table 26-323. PSIF PIC Event Register 2 Fields Description (Continued)

Bits	Description
9	EQ_ECC — EQPE memory ECC Error. This bit indicates that an ECC has occur in one of the EQPE internal memories. For details see **Section 26.4.3.5.11**, *EQPE ECC Support*. Read ‘0’ ECC Error event in one of the EQPE internal memories did not occur Read ‘1’ ECC Error event in one of the EQPE internal memories occur Write ‘1’ Clear bit if set.
8	EF2_ECC —EFTPE_2 memory ECC Error. This bit indicates that an ECC has occur in one of the EFTPE_2 internal memories. For details see **Section 26.4.3.3.12, *eFTPE ECC Support***. Read ‘0’ ECC Error event in one of the EFTPE_2 internal memories did not occur Read ‘1’ ECC Error event in one of the EFTPE_2 internal memories occur Write ‘1’ Clear bit if set.
7	EF1_ECC —EFTPE_1 memory ECC Error. This bit indicates that an ECC has occur in one of the EFTPE_1 internal memories. For details see **Section 26.4.3.3.12, *eFTPE ECC Support***. Read ‘0’ ECC Error event in one of the EFTPE_1 internal memories did not occur Read ‘1’ ECC Error event in one of the EFTPE_1 internal memories occur Write ‘1’ Clear bit if set.
6	EF0_ECC —EFTPE_0 memory ECC Error. This bit indicates that an ECC has occur in one of the EFTPE_0 internal memories. For details see **Section 26.4.3.3.12, *eFTPE ECC Support***. Read ‘0’ ECC Error event in one of the EFTPE_0 internal memories did not occur Read ‘1’ ECC Error event in one of the EFTPE_0 internal memories occur Write ‘1’ Clear bit if set.
5	TV_CD_PERR—eTVPE CDL memory Parity Error. This bit indicates that Parity Error has occurred in the eTVPE Channel Data Memory. Read ‘0’ Parity Error in the eTVPE Channel Data memory event did not occur Read ‘1’ Parity Error in the eTVPE Channel Data memory event occur Write ‘1’ Clear bit if set.
4	TV_D_ECC—eTVPE DRE memory ECC Error. This bit indicates that ECC Error has occurred in the eTVPE DRE Memories. Read ‘0’ ECC Error in the eTVPE DRE memories event did not occur Read ‘1’ ECC Error in the eTVPE DRE memories event occur Write ‘1’ Clear bit if set.
3	TV_E_ECC—eTVPE EXT memory ECC Error. This bit indicates that ECC Error has occurred in the eTVPE Extrinsic Memories. Read ‘0’ ECC Error in the eTVPE Extrinsic memories event did not occur Read ‘1’ ECC Error in the eTVPE Extrinsic memories event occur Write ‘1’ Clear bit if set.
2	TV_H_ECC—eTVPE HARQ memory ECC Error. This bit indicates that ECC Error has occurred in the eTVPE HARQ Memories. Read ‘0’ ECC Error in the eTVPE HARQ memories event did not occur Read ‘1’ ECC Error in the eTVPE HARQ memories event occur Write ‘1’ Clear bit if set.
1	DRAM_ECC—DRAM memory ECC Error. This bit indicates that ECC Error has occurred in the DRAM Memories in PSIF2. Read ‘0’ ECC Error in DRAM memories event did not occur Read ‘1’ ECC Error in the event DRAM memories occur Write ‘1’ Clear bit if set.
0	IRAM_ECC—IRAM memory ECC Error. This bit indicates that ECC Error has occurred in the IRAM Memories in PSIF2. Read ‘0’ ECC Error in IRAM memories event did not occur Read ‘1’ ECC Error in the event IRAM memories occur Write ‘1’ Clear bit if set.

26.5.5.1.5 PSIF PIC Edge/Level Register 0 (PSPICELR0)

For each Buffer Descriptors Ring interrupt, this register describes whether it is output as an edge or level interrupt.

Offset 0x0000160C (PSPICELR0) Access: User read/write

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 26-269. PSIF PIC Edge/Level Register 0

Table 26-324. PSIF PIC Edge/Level Register 0 Field Description

Bits	Description
31–0	BDR_DONE_EL[31:0]—BDR_DONE interrupt Edge/Level indication.Each bit in this register fits its event in the PSPICER0[31:0] register. For each of these bits: ‘0’ The interrupt assertion is of ‘level’ type. ’1’ The interrupt assertion is of ‘edge’ type.

26.5.5.1.6 PSIF PIC Mask Register 0 (PSPICMR0)

This register describes the mask bit for each possible BDR_DONE interrupt line. For each of the bits in this register, if disabled (0), the relevant BDR_DONE interrupt line is not asserted in case of event. The relevant bit in the PSIF PIC Event Register 0 (PSPICER0) is still asserted (if the PSIF PIC Edge/Level Register 0 (PSPICELR0) configuration of that bit is 0, that is, level configuration).

Offset 0x00001610 (PSPICMR0) Access: User read/write

Figure 26-270. PSIF PIC Mask Register 0

Table 26-325. PSIF PIC Mask Register 0 Fields Description

Bits	Description
31–0	BDR_DONE_M[31:0]—Buffer Descriptor Done event Mask indication. For each of the bits: 0 The ipi_bdr_done[x] interrupt line is masked and are not asserted due to BDR_DONE[x] event assertion. 1 The ipi_bdr_done[x] interrupt line is enabled and an interrupt are asserted upon BDR_DONE[x] event assertion

26.5.5.1.7 PSIF PIC Mask Register 1 (PSPICMR1)

This register describes the mask bit for each possible event which trigger the MAPLE-B2s general error interrupt line. For each of the bits in this register, if disabled (0), the relevant event as described in PSIF PIC Event Register 1 (PSPICER1) does not cause the assertion of the MAPLE-B2s general error interrupt. The relevant bit in the PSIF PIC Event Register 1 (PSPICER1) is still asserted regardless of its mask bit.

26.5.5.1.8 PSIF PIC Mask Register 2 (PSPICMR2)

This register describes the mask bit for each possible event which trigger the MAPLE-B2s ECC general error interrupt line. For each of the bits in this register, if disabled (0), the relevant event as described in PSIF PIC Event Register 2 (PSPICER2) does not cause the assertion of the MAPLEs ECC general error interrupt. The relevant bit in the PSIF PIC Event Register 2 (PSPICER2) is still asserted regardless of its mask bit.

Offset 0x00001618 (PSPICMR2) Access: User read/write

Table 26-327. PSIF PIC Mask Register 2 Fields Description

Bits	Description
31–13	reserved.
12	CRUF_ECC_M — CRPE-ULF memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to CRPE-ULF memory ECC error event assertion. 1 Assertion of the CRPE-ULF memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
11	CRUB_ECC_M — CRPE-ULB memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to CRPE-ULB memory ECC error event assertion. 1 Assertion of the CRPE-ULB memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
10	CRDL_ECC_M — CRPE-DL memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to CRPE-DL memory ECC error event assertion. 1 Assertion of the CRPE-DL memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
9	EQ_ECC_M — EQPE memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to EQPE memory ECC error event assertion. 1 Assertion of the EQPE memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.

Table 26-327. PSIF PIC Mask Register 2 Fields Description (Continued)

Bits	Description
8	EF2_ECC_M — EFTPE_2 memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to EFTPE_2 memory ECC error event assertion. 1 Assertion of the EFTPE_2 memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
7	EF1_ECC_M — EFTPE_1 memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to EFTPE_1 memory ECC error event assertion. 1 Assertion of the EFTPE_1 memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
6	EF0_ECC_M — EFTPE_0 memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to EFTPE_0 memory ECC error event assertion. 1 Assertion of the EFTPE_0 memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
5	TV_CD_PERR_M—eTVPE CDL memory Parity Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to eTVPE CDL memory Parity error event assertion. 1 Assertion of the eTVPE CDL memory Parity error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
4	TV_D_ECC_M—eTVPE DRE memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to eTVPE DRE memory ECC error event assertion. 1 Assertion of the eTVPE DRE memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
3	TV_E_ECC_M—eTVPE Extrinsic memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to eTVPE Extrinsic memory ECC error event assertion. 1 Assertion of the eTVPE Extrinsic memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
2	TV_H_ECC_M—eTVPE HARQ memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to eTVPE HARQ memory ECC error event assertion. 1 Assertion of the eTVPE HARQ memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
1	DRAM_ECC_M—DRAM memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to DRAM memory ECC error event assertion. 1 Assertion of the DRAM memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.
0	IRAM_ECC_M—IRAM memory ECC Error event Mask indication. 0 The MAPLE-B2's ECC general error interrupt line does not assert due to IRAM memory ECC error event assertion. 1 Assertion of the IRAM memory ECC error event causes the assertion of the MAPLE-B2's ECC general error interrupt line.

26.5.5.1.9 PSIF PIC Interrupts Assertion Clocks Register (PSPICIACR)

For all the BDR_DONE interrupts, this register describes the number of PSIF2 clock cycles the interrupt is asserted in case it is configured as an edge interrupt.

Offset 0x0000161C (PSPICIACR) Access: User read/write

Table 26-339. EQPE Threshold Fields Description

Bits	Description
31–8	Reserved
7–0	SING_THRESH—Threshold for the singularity check.This field is in signed 1Q7 format and represents the exponent of the threshold. Any matrix which has one or more exponent of the diagonal values of the R matrix (after QR decomposition) which are smaller than the threshold value is reported as singular (close to singular). The total number of singular matrices is reported in EQPE BD *SING*] field which can be read after the EQPE job is finished.

26.5.5.4.2 EQPE ECC Event Register (EQ_ECCEVENT)

This register records ECC events of the EQPE memories. For details see **Section 26.4.3.5.11**, *EQPE ECC Support*.

Offset 0x001BFB08 Access: User read/write

Figure 26-282. EQPE ECC Event Register

Table 26-340. EQPE ECC Event Fields Description

Bits	Description
31	ECC_ERR — ECC Error - when set this bit indicates that a multiple-bit error has occurred in one of the EQPE memories. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - No ECC event has occur in any of EQPE memories. 1 - ECC event has occur in one of EQPE memories.
30–22	Reserved
21	OUT3_ECC — Output Buffer 3 multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
20	OUT2_ECC — Output Buffer 2 multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
19	OUT1_ECC — Output Buffer 1 multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
18	OUT0_ECC — Output Buffer 0 multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
17	OSCL_ECC — Output Scale buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
16	SCL_ECC — Input Scale buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
15	W1_ECC — Interpolation Weights 1 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
14	W0_ECC — Interpolation Weights 0 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
13	Y1_ECC — Y 1 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
12	Y0_ECC — Y 0 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
11	F1_ECC — Feedback 1 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.

Table 26-340. EQPE ECC Event Fields Description

Bits	Description
10	F0_ECC — Feedback 0 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
9	S1_ECC — S1 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
8	S0_ECC — S0 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
7	H7_ECC — H7 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
6	H6_ECC — H6 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
5	H5_ECC — H5 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
4	H4_ECC — H4 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
3	H3_ECC — H3 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
2	H2_ECC — H2 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
1	H1_ECC — H1 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.
0	H0_ECC — H0 buffer multiple bits ECC error. This bit can be cleared by the host, by writing 1 to this bit, writing 0 to this bit, has no effect. 0 - ECC event hasn't occurred. 1 - ECC multiple bits error has occurred.

26.5.5.5 CRPE-ULB Registers Description

Table 26-341 describes the CRPE-ULB registers in detail.

Table 26-341. CRPE-ULB Registers Detailed Description

Figure 26-290. ULF General Configuration Register

Table 26-350. ULF General Configuration Fields Description

Bits	Description
31–24	MNOF — Maximum Number Of Fingers. This field should be set to 200 (0xC8), which is the maximum number of fingers (in resolution of 16 fingers) representing 3200 supported fingers.
23–22	OBUR — Output Buffer Update Rate. This field set the rate the status of the output buffer is updated by ULF 0 - The status of the output buffer is updated up-to one time in 32 chips processing period. 1 - The status of the output buffer is updated up-to two times in 32 chips processing period. 2 - The status of the output buffer is updated up-to four times in 32 chips processing period. 3 - The status of the output buffer is updated up-to eight times in 32 chips processing period.
21	DDS — DD Shift. The intermediate DD result is shift DDS bits right. 0 - No shift to intermediate DD results. 1 - Intermediate DD results are right shifted by 1.
20	INB — Interpolation Bypass. 0 - Interpolation logic is enabled 1 - Interpolation logic is bypassed
19	MDS — Maximum Delay Spread. This field set the Maximum Delay Spread of the fingers 0 - The maximum delay spread is 256 chips 1 - The maximum delay spread is 512 chips
18	PCE — Pilot Correlation Enable. 0 - ULF doesn’t correlate the PILOT Soft Symbol with the corresponding PILOT bit 1 - ULF correlates the PILOT Soft Symbol with the corresponding PILOT bit
17–16	MP — MBus Priority. This field set the priority of the MBus Initiator requests. Range: 0 to 3. (0 is the highest priority).
15–14	OVS — Over Sampling. This field selects the Over Sampling rate (OVS) of the input data: 0 - Input data is with OVS_2 1 - Input data is with OVS_4 2 - Input data is with OVS_8 3 - Input data is with OVS_{16}
13	IBM — Input Buffer Mode. Should be set to 1 when working with CPRI (streaming mode) or if interpolation bypass is enabled. 0 - The input buffer is accessed directly. 1 - The input buffer is accesses through 32 chips windows.
12–8	NOA — Number of Antennas. This field indicates the number of active antennas. Range: 1 to 24.
7	ELD3— Early Late Disable #3. 0 - Early Late Processing is enabled for DPCCH TPC Soft Symbol. 1 - Early Late Processing is disabled for DPCCH TPC Soft Symbol.
6	ELD2 — Early Late Disable #2. 0 - Early Late Processing is enabled for DPCCH FBI Soft Symbol. 1 - Early Late Processing is disabled for DPCCH FBI Soft Symbol.
5	ELD1 — Early Late Disable #1. 0 - Early Late Processing is enabled for DPCCH/PRACH TFCI Soft Symbol. 1 - Early Late Processing is disabled for DPCCH/PRACH TFCI Soft Symbol.
4	ELD0 — Early Late Disable #0. 0 - Early Late Processing is enabled for DPCCH/PRACH PILOT Soft Symbol. 1 - Early Late Processing is disabled for DPCCH/PRACH PILOT Soft Symbol.
3–0	IS — Interpolation Shift. The intermediate interpolated data is shift IS bits right. 0 - Intermediate results are not shifted. ... 15 - Intermediate results are right shifted by 15.

26.5.5.6.2 ULF Secondary Configuration Register (ULFSCR)

This register (along with *ULFGCR*) defines the general configuration parameters of the CRPE-ULF.

Offset 0x0023E00C Access: User read/write

Table 26-354. ULF Output Buffer <x> Attributes Configuration Fields Description

Bits	Description
31–27	Reserved
26–24	GID — Group ID. This field sets the output buffer group ID. A packet is directed to an output buffer only if the packet's GID is identical to the output buffer GID.
23	TE7 — Type Enable #7 0 - General Purpose #1 Packets is discarded by this buffer 1 - General Purpose #1 Packets is accepted by this buffer
22	TE7 — Type Enable #6 0 - General Purpose #0 Packets is discarded by this buffer 1 - General Purpose #0 Packets is accepted by this buffer
21	TE5 — Type Enable #5 0 - HS-DPCCH Packets is discarded by this buffer 1 - HS-DPCCH Packets is accepted by this buffer
20	TE4 — Type Enable #4 0 - E-DPCCH Packets is discarded by this buffer 1 - E-DPCCH Packets is accepted by this buffer
19	TE3 — Type Enable #3 0 - DPCCH TPC Packets is discarded by this buffer 1 - DPCCH TPC Packets is accepted by this buffer

Table 26-354. ULF Output Buffer <x> Attributes Configuration Fields Description

Bits	Description
18	TE2 — Type Enable #2 0 - DPCCH FBI Packets is discarded by this buffer 1 - DPCCH FBI Packets is accepted by this buffer
17	TE1 — Type Enable #1 0 - DPCCH/RACH TFCI Packets is discarded by this buffer. 1 - DPCCH/RACH TFCI Packets is accepted by this buffer.
16	TE0 — Type Enable #0 0 - DPCCH/RACH PILOT Packets is discarded by this buffer. 1 - DPCCH/RACH PILOT Packets is accepted by this buffer.
15–0	SIZEx — This field set the size of the output buffer with 16 bytes granularity. The output buffer is enabled if this field is great than 0.

26.5.5.6.6 ULF Event Status Register (ULFESR)

This register includes bits which are set due to internal CRPE-ULF events. Clearing the bits is done by writing ‘1’ to relevant bit.

Offset 0x0023E280 Access: User read/write

26.5.5.7.1 CRPE-DL Chips Output Data Table (CDCODT)

The CRPE-DL Chips Output Data Table memory contains 4 bytes for each chip for each output antenna. There are 2 entries for each antenna at the output buffer. Each entry contains 16 chips of a single antenna. The memory consists of 16 bytes words, each word contains 4 complex output chips.

Following is the addressing order of the chips in the output buffer, starting from base address of 0x00228000:

- Base: chips 3-0, antenna 0, entry 0
- Base+16: chips 7-4, antenna 0, entry 0
- Base+2*16: chips 11-8, antenna 0, entry 0
- Base+3*16: chips 15-12, antenna 0, entry 0
- Base+4*16: chips 3-0, antenna 0, entry 1
- ...
- Base+63*16: chips 15-12, antenna 7, entry 1
- Base+64*16: chips 3-0, antenna 8, entry 0
- ...
- Base+127*16: chips 15-12, antenna 15, entry 1

Figure 26-300 describe each Output buffer entry data structure:

31-16	$CDATAI_{x+3,y}$ - Chip Data Real part of complex chip x+3 of output antenna y.
15-0	$CDATAQ_{x+3,y}$ - Chip Data Imaginary part of complex chip x+3 of output antenna y.

26.5.5.7.2 CRPE-DL Slot Format Look-Up Table (SFLUT)

This memory table contains 90 entries, each specifying a unique slot format. The information in this table defines the distribution of input symbols to up to 5 different fields in the slot. In addition, one of the fields is identified as TPC field. Each field is associated with one of 4

programable gain factors. Gain operation and TPC override require the knowledge of slot configuration.

Supported slot formats that are associated with Spreading Factor 4 include number of symbols that is divisible by 4 at each field of the slot. **Figure 26-301** describe each SFLUT entry data structure:

Figure 26-301. CRPE-DL Slot Format Look-up Table

The following table describe the SFLUT field description:

Table 26-362. CRPE-DL Slot Format Look-up Table Fields Description

Bits	Description
127–58	Reserved.
57–55	GUF_x - Gain Update Field. This field defines at which field in the slot gain factors should be updated. Gain update field must contain at least one symbol. 0 - The updated gain factors take affect at the beginning of the first field in the slot. 1 - The updated gain factors take affect at the beginning of the second field in the slot. 2 - The updated gain factors take affect at the beginning of the third field in the slot. 3 - The updated gain factors take affect at the beginning of fourth field in the slot. 4 - The updated gain factors take affect at the beginning of fifth field in the slot. 5-7 - reserved.
54–53	$FFTGF_x$ - Fifth Field Gain Factor. This field defines which gain factor is associated with fifth field. The gain factors values are programmed at Virtual Antenna Gains Control Registers (*CDVAGLR0*). 0 - fifth field is associated with *CDVAGLR0[FSTRG]* 1 - fifth field is associated with *CDVAGLR0[SNDRG]* 2 - fifth field is associated with *CDVAGLR0[TRDRG]* 3 - fifth field is associated with *CDVAGLR0[FRTRG]*
52–51	$FRTGF_x$ - Fourth Field Gain Factor. This field defines which gain factor is associated with fourth field. The gain factors values are programmed at Virtual Antenna Gains Control Registers (*CDVAGLR0*). 0 - fourth field is associated with *CDVAGLR0[FSTRG]* 1 - fourth field is associated with *CDVAGLR0[SNDRG]* 2 - fourth field is associated with *CDVAGLR0[TRDRG]* 3 - fourth field is associated with *CDVAGLR0[FRTRG]*
50–49	$TRDGF_x$ - Third Field Gain Factor. This field defines which gain factor is associated with third field. The gain factors values are programmed at Virtual Antenna Gains Control Registers (*CDVAGLR0*). 0 - third field is associated with *CDVAGLR0[FSTRG]* 1 - third field is associated with *CDVAGLR0[SNDRG]* 2 - third field is associated with *CDVAGLR0[TRDRG]* 3 - third field is associated with *CDVAGLR0[FRTRG]*
48–47	$SNDGF_x$ - Second Field Gain Factor. This field defines which gain factor is associated with second field. The gain factors values are programmed at Virtual Antenna Gains Control Registers (*CDVAGLR0*). 0 - second field is associated with *CDVAGLR0[FSTRG]* 1 - second field is associated with *CDVAGLR0[SNDRG]* 2 - second field is associated with *CDVAGLR0[TRDRG]* 3 - second field is associated with *CDVAGLR0[FRTRG]*
46–45	$FSTGF_x$ - First Field Gain Factor. This field defines which gain factor is associated with first field. The gain factors values are programmed at Virtual Antenna Gains Control Registers (*CDVAGLR0*). 0 - first field is associated with *CDVAGLR0[FSTRG]* 1 - first field is associated with *CDVAGLR0[SNDRG]* 2 - first field is associated with *CDVAGLR0[TRDRG]* 3 - first field is associated with *CDVAGLR0[FRTRG]*

Table 26-362. CRPE-DL Slot Format Look-up Table Fields Description

Bits	Description
44–42	$TPCFN_x$ - TPC Field Number. 0 - TPC is the first field. 1 - TPC is the second field. 2 - TPC is the third field. 3 - TPC is the fourth field. 4 - TPC is the fifth field. 5 - TPC field is not present. Range: 0-5.
41–32	$FRTFS_x$ - Fourth Field Separator This bit indicates the offset of the first symbol of fifth field in the slot. Input symbols with offset higher or equal to this offset belong to the fifth field. Input symbols with offset lower than this offset belong to one of the following fields: first, second, third or fourth field. Range: 0-640. 640 is out of the slot range, used for non existent field separator.
31–30	Reserved
29–20	$TRDFS_x$ - Third Field Separator This bit indicates the offset of the first symbol of fourth field in the slot. Input symbols with offset higher or equal to this offset belong to one of the following fields: fourth or fifth field. Input symbols with offset lower than this offset belong to one of the following fields: first, second or third field. Range: 0-640. 640 is out of the slot range, used for non existent field separator.
19–10	$SNDFS_x$ - Second Field Separator This bit indicates the offset of the first symbol of third field in the slot. Input symbols with offset higher or equal to this offset belong to one of the following fields: third, fourth or fifth field Input symbols with offset lower than this offset belong to one of the following fields: first or second field. Range: 0-640. 640 is out of the slot range, used for non existent field separator.
9–0	$FSTFS_x$ - First Field Separator This bit indicates the offset of the first symbol of second field in the slot. Input symbols with offset higher or equal to this offset belong to one of the following fields: second, third, fourth or fifth field. Input symbols with offset lower than this offset belong to the first field. Range: 0-640. 640 is out of the slot range, used for non existent field separator.

26.5.5.7.3 CRPE-DL Scrambling Initialization Look-Up Table (SCRILUT)

This memory table contains 32 entries, each specifying a unique scrambling code (ranging from 0 to 8191). **Figure 26-302** describe each *SCRILUT* entry data structure:

Table 26-363. CRPE-DL Scrambling Initialization Look-up Table Fields Description

Bits	Description
127–13	Reserved.
12–0	SN_x - Scrambling Number Selection n selection for scrambling code $S_{dl,n}$, correlating with channel's non-compressed mode. Range: 0-8191.

26.5.5.7.4 CRPE-DL Normalization Value Configuration Register (CDNVCR)

This is the register defines the value of additional real gain multiplication factor. This additional gain operation is performed only if *CDNVCR[NVEN]*=1 and only if both: real part of the complex gain and imaginary part of the complex gain (see *CDVAGCLR1*) are non-zero values.

Offset 0x0023F148 Access: User read/write

Figure 26-304. CRPE-DL Virtual Antenna Gains Control Register 0

Table 26-365. CRPE-DL Virtual Antenna Gains 0 Fields Description

Bits	Description
63–48	FRTRG — Fourth Real Gain for virtual antennas. 16 bit field specifying the value of the **fourth** real gain used for virtual antennas. This field is a shadow field. It is becoming active at the beginning of a selected field as pointed by GUF at slot format LUT, and at a processing slot as according to GUS and GUN fields in CDVAGCLR. In addition, this field is becoming active at the beginning of the first slot of the channel.
47–32	TRDRG — Third Real Gain for virtual antennas. 16 bit field specifying the value of the **third** real gain used for virtual antennas. This field is a shadow field. It is becoming active at the beginning of a selected field as pointed by GUF at slot format LUT, and at a processing slot as according to GUS and GUN fields in CDVAGCLR. In addition, this field is becoming active at the beginning of the first slot of the channel.
31–16	SNDRG — Second Real Gain for virtual antennas. 16 bit field specifying the value of the **second** real gain used for virtual antennas. This field is a shadow field. It is becoming active at the beginning of a selected field as pointed by GUF at slot format LUT, and at a processing slot as according to GUS and GUN fields in CDVAGCLR. In addition, this field is becoming active at the beginning of the first slot of the channel.
15–0	FSTRG — First Real Gain for virtual antennas. 16 bit field specifying the value of the **first** real gain used for virtual antennas. This field is a shadow field. It is becoming active at the beginning of a selected field as pointed by GUF at slot format LUT, and at a processing slot as according to GUS and GUN fields in CDVAGCLR. In addition, this field is becoming active at the beginning of the first slot of the channel.

26.5.5.7.6 CRPE-DL Virtual Antenna Gains Control Register 1 (CDVAGLR1)

This 8 bytes register is used for updating virtual antennas complex gain values for the channel and the timing specified in the *CDVAGCLR* register.

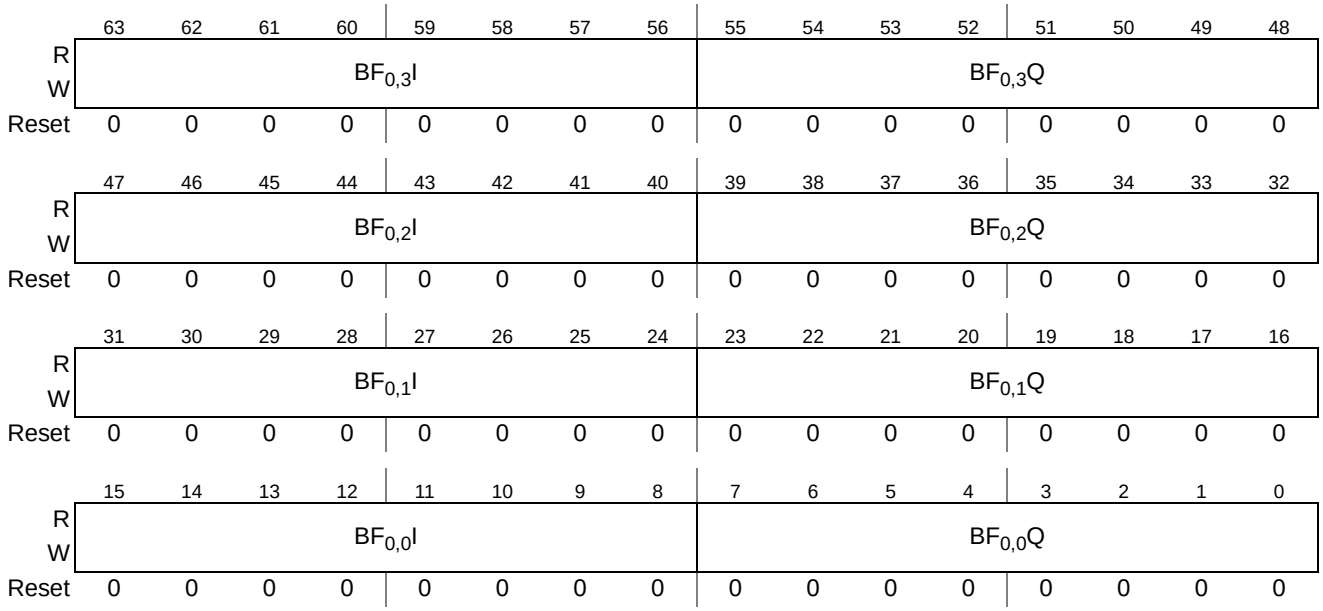

Figure 26-306. CRPE-DL Beam Forming 0 Control Register (Continued)

Table 26-367. CRPE-DL Beam Forming 0 Fields Description

Bits	Description
127–120	$BF_{1,3}I$ — Beam Forming 1,3 matrix I. This field is the real multiplication factor of 1,3 element of the Beam Forming Matrix, correlating with virtual antenna 1 and beam antenna 3.
119–112	$BF_{1,3}Q$ — Beam Forming 1,3 matrix Q. This field is the imaginary multiplication factor of 1,3 element of the Beam Forming Matrix, correlating with virtual antenna 1 and beam antenna 3.
111–104	$BF_{1,2}I$ — Beam Forming 1,2 matrix I. This field is the real multiplication factor of 1,2 element of the Beam Forming Matrix, correlating with virtual antenna 1 and beam antenna 2.
103–96	$BF_{1,2}Q$ — Beam Forming 1,2 matrix Q. This field is the imaginary multiplication factor of 1,2 element of the Beam Forming Matrix, correlating with virtual antenna 1 and beam antenna 2.
95–88	$BF_{1,1}I$ — Beam Forming 1,1 matrix I. This field is the real multiplication factor of 1,1 element of the Beam Forming Matrix, correlating with virtual antenna 1 and beam antenna 1.
87–80	$BF_{1,1}Q$ — Beam Forming 1,1 matrix Q. This field is the imaginary multiplication factor of 1,1 element of the Beam Forming Matrix, correlating with virtual antenna 1 and beam antenna 1.
79–72	$BF_{1,0}I$ — Beam Forming 1,0 matrix I. This field is the real multiplication factor of 1,0 element of the Beam Forming Matrix, correlating with virtual antenna 1 and beam antenna 0.
71–64	$BF_{1,0}Q$ — Beam Forming 1,0 matrix Q. This field is the imaginary multiplication factor of 1,0 element of the Beam Forming Matrix, correlating with virtual antenna 1 and beam antenna 0.
63–56	$BF_{0,3}I$ — Beam Forming 0,3 matrix I. This field is the real multiplication factor of 0,3 element of the Beam Forming Matrix, correlating with virtual antenna 0 and beam antenna 3.
55–48	$BF_{0,3}Q$ — Beam Forming 0,3 matrix Q. This field is the imaginary multiplication factor of 0,3 element of the Beam Forming Matrix, correlating with virtual antenna 0 and beam antenna 3.
47–40	$BF_{0,2}I$ — Beam Forming 0,2 matrix I. This field is the real multiplication factor of 0,2 element of the Beam Forming Matrix, correlating with virtual antenna 0 and beam antenna 2.
39–32	$BF_{0,2}Q$ — Beam Forming 0,2 matrix Q. This field is the imaginary multiplication factor of 0,2 element of the Beam Forming Matrix, correlating with virtual antenna 0 and beam antenna 2.

Table 26-367. CRPE-DL Beam Forming 0 Fields Description

Bits	Description
31–24	$BF_{0,1}I$ — Beam Forming 0,1 matrix I. This field is the real multiplication factor of 0,1 element of the Beam Forming Matrix, correlating with virtual antenna 0 and beam antenna 1.
23–16	$BF_{0,1}Q$ — Beam Forming 0,1 matrix Q. This field is the imaginary multiplication factor of 0,1 element of the Beam Forming Matrix, correlating with virtual antenna 0 and beam antenna 1.
15–8	$BF_{0,0}I$ — Beam Forming 0,0 matrix I. This field is the real multiplication factor of 0,0 element of the Beam Forming Matrix, correlating with virtual antenna 0 and beam antenna 0.
7–0	$BF_{0,0}Q$ — Beam Forming 0,0 matrix Q. This field is the imaginary multiplication factor of 0,0 element of the Beam Forming Matrix, correlating with virtual antenna 0 and beam antenna 0.

26.5.5.7.8 CRPE-DL Beam Forming Coefficients Values Control Register 1 (CDBFCVLR1)

This register is used for configuring the beam forming matrix elements of following virtual antennas and beam antennas:

Table 26-368. CRPE-DL Beam Forming 1 Fields Description

Bits	Description
127–120	$BF_{3,3}I$ — Beam Forming 3,3 matrix I. This field is the real multiplication factor of 3,3 element of the Beam Forming Matrix, correlating with virtual antenna 3 and beam antenna 3.
119–112	$BF_{3,3}Q$ — Beam Forming 3,3 matrix Q. This field is the imaginary multiplication factor of 3,3 element of the Beam Forming Matrix, correlating with virtual antenna 3 and beam antenna 3.
111–104	$BF_{3,2}I$ — Beam Forming 3,2 matrix I. This field is the real multiplication factor of 3,2 element of the Beam Forming Matrix, correlating with virtual antenna 3 and beam antenna 2.
103–96	$BF_{3,2}Q$ — Beam Forming 3,2 matrix Q. This field is the imaginary multiplication factor of 3,2 element of the Beam Forming Matrix, correlating with virtual antenna 3 and beam antenna 2.
95–88	$BF_{3,1}I$ — Beam Forming 3,1 matrix I. This field is the real multiplication factor of 3,1 element of the Beam Forming Matrix, correlating with virtual antenna 3 and beam antenna 1.
87–80	$BF_{3,1}Q$ — Beam Forming 3,1 matrix Q. This field is the imaginary multiplication factor of 3,1 element of the Beam Forming Matrix, correlating with virtual antenna 3 and beam antenna 1.
79–72	$BF_{3,0}I$ — Beam Forming 3,0 matrix I. This field is the real multiplication factor of 3,0 element of the Beam Forming Matrix, correlating with virtual antenna 3 and beam antenna 0.
71–64	$BF_{3,0}Q$ — Beam Forming 3,0 matrix Q. This field is the imaginary multiplication factor of 3,0 element of the Beam Forming Matrix, correlating with virtual antenna 3 and beam antenna 0.
63–56	$BF_{2,3}I$ — Beam Forming 2,3 matrix I. This field is the real multiplication factor of 2,3 element of the Beam Forming Matrix, correlating with virtual antenna 2 and beam antenna 3.
55–48	$BF_{2,3}Q$ — Beam Forming 2,3 matrix Q. This field is the imaginary multiplication factor of 2,3 element of the Beam Forming Matrix, correlating with virtual antenna 2 and beam antenna 3.
47–40	$BF_{2,2}I$ — Beam Forming 2,2 matrix I. This field is the real multiplication factor of 2,2 element of the Beam Forming Matrix, correlating with virtual antenna 2 and beam antenna 2.
39–32	$BF_{2,2}Q$ — Beam Forming 2,2 matrix Q. This field is the imaginary multiplication factor of 2,2 element of the Beam Forming Matrix, correlating with virtual antenna 2 and beam antenna 2.

Table 26-368. CRPE-DL Beam Forming 1 Fields Description (Continued)

Bits	Description
31–24	$BF_{2,1}I$ — Beam Forming 2,1 matrix I. This field is the real multiplication factor of 2,1 element of the Beam Forming Matrix, correlating with virtual antenna 2 and beam antenna 1.
23–16	$BF_{2,1}Q$ — Beam Forming 2,1 matrix Q. This field is the imaginary multiplication factor of 2,1 element of the Beam Forming Matrix, correlating with virtual antenna 2 and beam antenna 1.
15–8	$BF_{2,0}I$ — Beam Forming 2,0 matrix I. This field is the real multiplication factor of 2,0 element of the Beam Forming Matrix, correlating with virtual antenna 2 and beam antenna 0.
7–0	$BF_{2,0}Q$ — Beam Forming 2,0 matrix Q. This field is the imaginary multiplication factor of 2,0 element of the Beam Forming Matrix, correlating with virtual antenna 2 and beam antenna 0.

26.5.5.7.9 CRPE-DL Beam Forming Coefficients Values Control Register 2 (CDBFCVLR2)

This register is used for configuring the beam forming matrix elements of following virtual antennas and beam antennas:

virtual antenna 5, beam antennas 4–7; virtual antenna 4, beam antennas 4–7.

Table 26-369. CRPE-DL Beam Forming 2 Fields Description

Bits	Description
127–120	$BF_{5,7}I$ — Beam Forming 5,7 matrix I. This field is the real multiplication factor of 5,7 element of the Beam Forming Matrix, correlating with virtual antenna 5 and beam antenna 7.
119–112	$BF_{5,7}Q$ — Beam Forming 5,7 matrix Q. This field is the imaginary multiplication factor of 5,7 element of the Beam Forming Matrix, correlating with virtual antenna 5 and beam antenna 7.
111–104	$BF_{5,6}I$ — Beam Forming 5,6 matrix I. This field is the real multiplication factor of 5,6 element of the Beam Forming Matrix, correlating with virtual antenna 5 and beam antenna 6.
103–96	$BF_{5,6}Q$ — Beam Forming 5,6 matrix Q. This field is the imaginary multiplication factor of 5,6 element of the Beam Forming Matrix, correlating with virtual antenna 5 and beam antenna 6.
95–88	$BF_{5,5}I$ — Beam Forming 5,5 matrix I. This field is the real multiplication factor of 5,5 element of the Beam Forming Matrix, correlating with virtual antenna 5 and beam antenna 5.
87–80	$BF_{5,5}Q$ — Beam Forming 5,5 matrix Q. This field is the imaginary multiplication factor of 5,5 element of the Beam Forming Matrix, correlating with virtual antenna 5 and beam antenna 5.
79–72	$BF_{5,4}I$ — Beam Forming 5,4 matrix I. This field is the real multiplication factor of 5,4 element of the Beam Forming Matrix, correlating with virtual antenna 5 and beam antenna 4.
71–64	$BF_{5,4}Q$ — Beam Forming 5,4 matrix Q. This field is the imaginary multiplication factor of 5,4 element of the Beam Forming Matrix, correlating with virtual antenna 5 and beam antenna 4.
63–56	$BF_{4,7}I$ — Beam Forming 4,7 matrix I. This field is the real multiplication factor of 4,7 element of the Beam Forming Matrix, correlating with virtual antenna 4 and beam antenna 7.
55–48	$BF_{4,7}Q$ — Beam Forming 4,7 matrix Q. This field is the imaginary multiplication factor of 4,7 element of the Beam Forming Matrix, correlating with virtual antenna 4 and beam antenna 7.
47–40	$BF_{4,6}I$ — Beam Forming 4,6 matrix I. This field is the real multiplication factor of 4,6 element of the Beam Forming Matrix, correlating with virtual antenna 4 and beam antenna 6.
39–32	$BF_{4,6}Q$ — Beam Forming 4,6 matrix Q. This field is the imaginary multiplication factor of 4,6 element of the Beam Forming Matrix, correlating with virtual antenna 4 and beam antenna 6.

Table 26-369. CRPE-DL Beam Forming 2 Fields Description (Continued)

Bits	Description
31–24	$BF_{4,5}I$ — Beam Forming 4,5 matrix I. This field is the real multiplication factor of 4,5 element of the Beam Forming Matrix, correlating with virtual antenna 4 and beam antenna 5.
23–16	$BF_{4,5}Q$ — Beam Forming 4,5 matrix Q. This field is the imaginary multiplication factor of 4,5 element of the Beam Forming Matrix, correlating with virtual antenna 4 and beam antenna 5.
15–8	$BF_{4,4}I$ — Beam Forming 4,4 matrix I. This field is the real multiplication factor of 4,4 element of the Beam Forming Matrix, correlating with virtual antenna 4 and beam antenna 4.
7–0	$BF_{4,4}Q$ — Beam Forming 4,4 matrix Q. This field is the imaginary multiplication factor of 4,4 element of the Beam Forming Matrix, correlating with virtual antenna 4 and beam antenna 4.

Table 26-370. CRPE-DL Beam Forming 3 Fields Description

Bits	Description
127–120	$BF_{7,7}I$ — Beam Forming 7,7 matrix I. This field is the real multiplication factor of 7,7 element of the Beam Forming Matrix, correlating with virtual antenna 7 and beam antenna 7.
119–112	$BF_{7,7}Q$ — Beam Forming 7,7 matrix Q. This field is the imaginary multiplication factor of 7,7 element of the Beam Forming Matrix, correlating with virtual antenna 7 and beam antenna 7.
111–104	$BF_{7,6}I$ — Beam Forming 7,6 matrix I. This field is the real multiplication factor of 7,6 element of the Beam Forming Matrix, correlating with virtual antenna 7 and beam antenna 6.
103–96	$BF_{7,6}Q$ — Beam Forming 7,6 matrix Q. This field is the imaginary multiplication factor of 7,6 element of the Beam Forming Matrix, correlating with virtual antenna 7 and beam antenna 6.
95–88	$BF_{7,5}I$ — Beam Forming 7,5 matrix I. This field is the real multiplication factor of 7,5 element of the Beam Forming Matrix, correlating with virtual antenna 7 and beam antenna 5.
87–80	$BF_{7,5}Q$ — Beam Forming 7,5 matrix Q. This field is the imaginary multiplication factor of 7,5 element of the Beam Forming Matrix, correlating with virtual antenna 7 and beam antenna 5.
79–72	$BF_{7,4}I$ — Beam Forming 7,4 matrix I. This field is the real multiplication factor of 7,4 element of the Beam Forming Matrix, correlating with virtual antenna 7 and beam antenna 4.
71–64	$BF_{7,4}Q$ — Beam Forming 7,4 matrix Q. This field is the imaginary multiplication factor of 7,4 element of the Beam Forming Matrix, correlating with virtual antenna 7 and beam antenna 4.
63–56	$BF_{6,7}I$ — Beam Forming 6,7 matrix I. This field is the real multiplication factor of 6,7 element of the Beam Forming Matrix, correlating with virtual antenna 6 and beam antenna 7.
55–48	$BF_{6,7}Q$ — Beam Forming 6,7 matrix Q. This field is the imaginary multiplication factor of 6,7 element of the Beam Forming Matrix, correlating with virtual antenna 6 and beam antenna 7.
47–40	$BF_{6,6}I$ — Beam Forming 6,6 matrix I. This field is the real multiplication factor of 6,6 element of the Beam Forming Matrix, correlating with virtual antenna 6 and beam antenna 6.
39–32	$BF_{6,6}Q$ — Beam Forming 6,6 matrix Q. This field is the imaginary multiplication factor of 6,6 element of the Beam Forming Matrix, correlating with virtual antenna 6 and beam antenna 6.

Table 26-370. CRPE-DL Beam Forming 3 Fields Description (Continued)

Bits	Description
31–24	$BF_{6,5}I$ — Beam Forming 6,5 matrix I. This field is the real multiplication factor of 6,5 element of the Beam Forming Matrix, correlating with virtual antenna 6 and beam antenna 5.
23–16	$BF_{6,5}Q$ — Beam Forming 6,5 matrix Q. This field is the imaginary multiplication factor of 6,5 element of the Beam Forming Matrix, correlating with virtual antenna 6 and beam antenna 5.
15–8	$BF_{6,4}I$ — Beam Forming 6,4 matrix I. This field is the real multiplication factor of 6,4 element of the Beam Forming Matrix, correlating with virtual antenna 6 and beam antenna 4.
7–0	$BF_{6,4}Q$ — Beam Forming 6,4 matrix Q. This field is the imaginary multiplication factor of 6,4 element of the Beam Forming Matrix, correlating with virtual antenna 6 and beam antenna 4.

26.5.5.7.11 CRPE-DL Beam Forming Coefficients Values Control Register 4 (CDBFCVLR4)

This register is used for configuring the beam forming matrix elements of following virtual antennas and beam antennas:

virtual antenna 9, beam antennas 8-11; virtual antenna 8, beam antennas 8-11.

Table 26-371. CRPE-DL Beam Forming 4 Fields Description

Bits	Description
127–120	$BF_{9,11}I$ — Beam Forming 9,11 matrix I. This field is the real multiplication factor of 9,11 element of the Beam Forming Matrix, correlating with virtual antenna 9 and beam antenna 11.
119–112	$BF_{9,11}Q$ — Beam Forming 9,11 matrix Q. This field is the imaginary multiplication factor of 9,11 element of the Beam Forming Matrix, correlating with virtual antenna 9 and beam antenna 11.
111–104	$BF_{9,10}I$ — Beam Forming 9,10 matrix I. This field is the real multiplication factor of 9,10 element of the Beam Forming Matrix, correlating with virtual antenna 9 and beam antenna 10.
103–96	$BF_{9,10}Q$ — Beam Forming 9,10 matrix Q. This field is the imaginary multiplication factor of 9,10 element of the Beam Forming Matrix, correlating with virtual antenna 9 and beam antenna 10.
95–88	$BF_{9,9}I$ — Beam Forming 9,9 matrix I. This field is the real multiplication factor of 9,9 element of the Beam Forming Matrix, correlating with virtual antenna 9 and beam antenna 9.
87–80	$BF_{9,9}Q$ — Beam Forming 9,9 matrix Q. This field is the imaginary multiplication factor of 9,9 element of the Beam Forming Matrix, correlating with virtual antenna 9 and beam antenna 9.
79–72	$BF_{9,8}I$ — Beam Forming 9,8 matrix I. This field is the real multiplication factor of 9,8 element of the Beam Forming Matrix, correlating with virtual antenna 9 and beam antenna 8.
71–64	$BF_{9,8}Q$ — Beam Forming 9,8 matrix Q. This field is the imaginary multiplication factor of 9,8 element of the Beam Forming Matrix, correlating with virtual antenna 9 and beam antenna 8.
63–56	$BF_{8,11}I$ — Beam Forming 8,11 matrix I. This field is the real multiplication factor of 8,11 element of the Beam Forming Matrix, correlating with virtual antenna 8 and beam antenna 11.
55–48	$BF_{8,11}Q$ — Beam Forming 8,11 matrix Q. This field is the imaginary multiplication factor of 8,11 element of the Beam Forming Matrix, correlating with virtual antenna 8 and beam antenna 11.
47–40	$BF_{8,10}I$ — Beam Forming 8,10 matrix I. This field is the real multiplication factor of 8,10 element of the Beam Forming Matrix, correlating with virtual antenna 8 and beam antenna 10.
39–32	$BF_{8,10}Q$ — Beam Forming 8,10 matrix Q. This field is the imaginary multiplication factor of 8,10 element of the Beam Forming Matrix, correlating with virtual antenna 8 and beam antenna 10.

Table 26-371. CRPE-DL Beam Forming 4 Fields Description (Continued)

Bits	Description
31–24	$BF_{8,9}I$ — Beam Forming 8,9 matrix I. This field is the real multiplication factor of 8,9 element of the Beam Forming Matrix, correlating with virtual antenna 8 and beam antenna 9.
23–16	$BF_{8,9}Q$ — Beam Forming 8,9 matrix Q. This field is the imaginary multiplication factor of 8,9 element of the Beam Forming Matrix, correlating with virtual antenna 8 and beam antenna 9.
15–8	$BF_{8,8}I$ — Beam Forming 8,8 matrix I. This field is the real multiplication factor of 8,8 element of the Beam Forming Matrix, correlating with virtual antenna 8 and beam antenna 8.
7–0	$BF_{8,8}Q$ — Beam Forming 8,8 matrix Q. This field is the imaginary multiplication factor of 8,8 element of the Beam Forming Matrix, correlating with virtual antenna 8 and beam antenna 8.

Table 26-372. CRPE-DL Beam Forming 5 Fields Description

Bits	Description
127–120	$BF_{11,11}I$ — Beam Forming 11,11 matrix I. This field is the real multiplication factor of 11,11 element of the Beam Forming Matrix, correlating with virtual antenna 11 and beam antenna 11.
119–112	$BF_{11,11}Q$ — Beam Forming 11,11 matrix Q. This field is the imaginary multiplication factor of 11,11 element of the Beam Forming Matrix, correlating with virtual antenna 11 and beam antenna 11.
111–104	$BF_{11,10}I$ — Beam Forming 11,10 matrix I. This field is the real multiplication factor of 11,10 element of the Beam Forming Matrix, correlating with virtual antenna 11 and beam antenna 10.
103–96	$BF_{11,10}Q$ — Beam Forming 11,10 matrix Q. This field is the imaginary multiplication factor of 11,10 element of the Beam Forming Matrix, correlating with virtual antenna 11 and beam antenna 10.
95–88	$BF_{11,9}I$ — Beam Forming 11,9 matrix I. This field is the real multiplication factor of 11,9 element of the Beam Forming Matrix, correlating with virtual antenna 11 and beam antenna 9.
87–80	$BF_{11,9}Q$ — Beam Forming 11,9 matrix Q. This field is the imaginary multiplication factor of 11,9 element of the Beam Forming Matrix, correlating with virtual antenna 11 and beam antenna 9.
79–72	$BF_{11,8}I$ — Beam Forming 11,8 matrix I. This field is the real multiplication factor of 11,8 element of the Beam Forming Matrix, correlating with virtual antenna 11 and beam antenna 8.
71–64	$BF_{11,8}Q$ — Beam Forming 11,8 matrix Q. This field is the imaginary multiplication factor of 11,8 element of the Beam Forming Matrix, correlating with virtual antenna 11 and beam antenna 8.
63–56	$BF_{10,11}I$ — Beam Forming 10,11 matrix I. This field is the real multiplication factor of 10,11 element of the Beam Forming Matrix, correlating with virtual antenna 10 and beam antenna 11.
55–48	$BF_{10,11}Q$ — Beam Forming 10,11 matrix Q. This field is the imaginary multiplication factor of 10,11 element of the Beam Forming Matrix, correlating with virtual antenna 10 and beam antenna 11.
47–40	$BF_{10,10}I$ — Beam Forming 10,10 matrix I. This field is the real multiplication factor of 10,10 element of the Beam Forming Matrix, correlating with virtual antenna 10 and beam antenna 10.
39–32	$BF_{10,10}Q$ — Beam Forming 10,10 matrix Q. This field is the imaginary multiplication factor of 10,10 element of the Beam Forming Matrix, correlating with virtual antenna 10 and beam antenna 10.

Table 26-372. CRPE-DL Beam Forming 5 Fields Description

Bits	Description
31–24	$BF_{10,9}I$ — Beam Forming 10,9 matrix I. This field is the real multiplication factor of 10,9 element of the Beam Forming Matrix, correlating with virtual antenna 10 and beam antenna 9.
23–16	$BF_{10,9}Q$ — Beam Forming 10,9 matrix Q. This field is the imaginary multiplication factor of 10,9 element of the Beam Forming Matrix, correlating with virtual antenna 10 and beam antenna 9.
15–8	$BF_{10,8}I$ — Beam Forming 10,8 matrix I. This field is the real multiplication factor of 10,8 element of the Beam Forming Matrix, correlating with virtual antenna 10 and beam antenna 8.
7–0	$BF_{10,8}Q$ — Beam Forming 10,8 matrix Q. This field is the imaginary multiplication factor of 10,8 element of the Beam Forming Matrix, correlating with virtual antenna 10 and beam antenna 8.

26.5.5.7.13 CRPE-DL Beam Forming Coefficients Values Control Register 6 (CDBFCVLR6)

This register is used for configuring the beam forming matrix elements of following virtual antennas and beam antennas:

virtual antenna 13, beam antennas 12–15; virtual antenna 12, beam antennas 12–15.

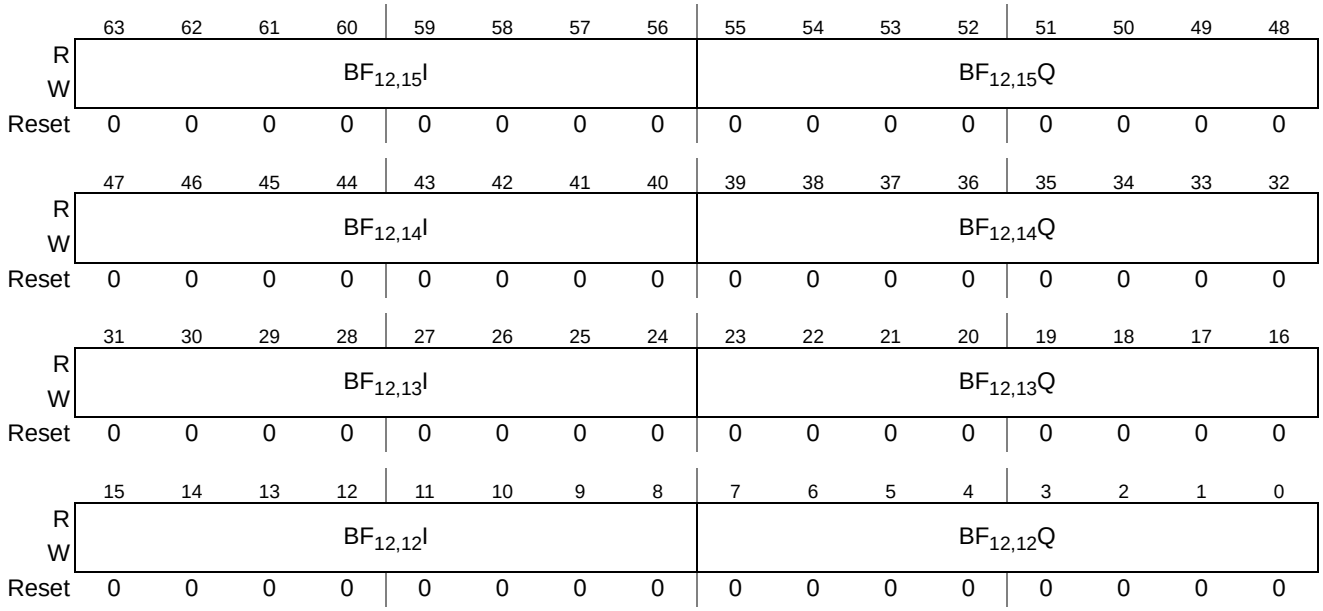

Figure 26-312. CRPE-DL Beam Forming 6 Control Register (Continued)

Table 26-373. CRPE-DL Beam Forming 6 Fields Description

Bits	Description
127–120	$BF_{13,15}I$ — Beam Forming 13,15 matrix I. This field is the real multiplication factor of 13,15 element of the Beam Forming Matrix, correlating with virtual antenna 13 and beam antenna 15.
119–112	$BF_{13,15}Q$ — Beam Forming 13,15 matrix Q. This field is the imaginary multiplication factor of 13,15 element of the Beam Forming Matrix, correlating with virtual antenna 13 and beam antenna 15.
111–104	$BF_{13,14}I$ — Beam Forming 13,14 matrix I. This field is the real multiplication factor of 13,14 element of the Beam Forming Matrix, correlating with virtual antenna 13 and beam antenna 14.
103–96	$BF_{13,14}Q$ — Beam Forming 13,14 matrix Q. This field is the imaginary multiplication factor of 13,14 element of the Beam Forming Matrix, correlating with virtual antenna 13 and beam antenna 14.
95–88	$BF_{13,13}I$ — Beam Forming 13,13 matrix I. This field is the real multiplication factor of 13,13 element of the Beam Forming Matrix, correlating with virtual antenna 13 and beam antenna 13.
87–80	$BF_{13,13}Q$ — Beam Forming 13,13 matrix Q. This field is the imaginary multiplication factor of 13,13 element of the Beam Forming Matrix, correlating with virtual antenna 13 and beam antenna 13.
79–72	$BF_{13,12}I$ — Beam Forming 13,12 matrix I. This field is the real multiplication factor of 13,12 element of the Beam Forming Matrix, correlating with virtual antenna 13 and beam antenna 12.
71–64	$BF_{13,12}Q$ — Beam Forming 13,12 matrix Q. This field is the imaginary multiplication factor of 13,12 element of the Beam Forming Matrix, correlating with virtual antenna 13 and beam antenna 12.
63–56	$BF_{12,15}I$ — Beam Forming 12,15 matrix I. This field is the real multiplication factor of 12,15 element of the Beam Forming Matrix, correlating with virtual antenna 12 and beam antenna 15.
55–48	$BF_{12,15}Q$ — Beam Forming 12,15 matrix Q. This field is the imaginary multiplication factor of 12,15 element of the Beam Forming Matrix, correlating with virtual antenna 12 and beam antenna 15.
47–40	$BF_{12,14}I$ — Beam Forming 12,14 matrix I. This field is the real multiplication factor of 12,14 element of the Beam Forming Matrix, correlating with virtual antenna 12 and beam antenna 14.
39–32	$BF_{12,14}Q$ — Beam Forming 12,14 matrix Q. This field is the imaginary multiplication factor of 12,14 element of the Beam Forming Matrix, correlating with virtual antenna 12 and beam antenna 14.

Table 26-373. CRPE-DL Beam Forming 6 Fields Description (Continued)

Bits	Description
31–24	$BF_{12,13}I$ — Beam Forming 12,13 matrix I. This field is the real multiplication factor of 12,13 element of the Beam Forming Matrix, correlating with virtual antenna 12 and beam antenna 13.
23–16	$BF_{12,13}Q$ — Beam Forming 12,13 matrix Q. This field is the imaginary multiplication factor of 12,13 element of the Beam Forming Matrix, correlating with virtual antenna 12 and beam antenna 13.
15–8	$BF_{12,12}I$ — Beam Forming 12,12 matrix I. This field is the real multiplication factor of 12,12 element of the Beam Forming Matrix, correlating with virtual antenna 12 and beam antenna 12.
7–0	$BF_{12,12}Q$ — Beam Forming 12,12 matrix Q. This field is the imaginary multiplication factor of 12,12 element of the Beam Forming Matrix, correlating with virtual antenna 12 and beam antenna 12.

26.5.5.7.14 CRPE-DL Beam Forming Coefficients Values Control Register 7 (CDBFCVLR7)

This register is used for configuring the beam forming matrix elements of following virtual antennas and beam antennas:

virtual antenna 15, beam antennas 12–15; virtual antenna 14, beam antennas 12–15.

Table 26-374. CRPE-DL Beam Forming 7 Fields Description

Bits	Description
127–120	$BF_{15,15}I$ — Beam Forming 15,15 matrix I. This field is the real multiplication factor of 15,15 element of the Beam Forming Matrix, correlating with virtual antenna 15 and beam antenna 15.
119–112	$BF_{15,15}Q$ — Beam Forming 15,15 matrix Q. This field is the imaginary multiplication factor of 15,15 element of the Beam Forming Matrix, correlating with virtual antenna 15 and beam antenna 15.
111–104	$BF_{15,14}I$ — Beam Forming 15,14 matrix I. This field is the real multiplication factor of 15,14 element of the Beam Forming Matrix, correlating with virtual antenna 15 and beam antenna 14.
103–96	$BF_{15,14}Q$ — Beam Forming 15,14 matrix Q. This field is the imaginary multiplication factor of 15,14 element of the Beam Forming Matrix, correlating with virtual antenna 15 and beam antenna 14.
95–88	$BF_{15,13}I$ — Beam Forming 15,13 matrix I. This field is the real multiplication factor of 15,13 element of the Beam Forming Matrix, correlating with virtual antenna 15 and beam antenna 13.
87–80	$BF_{15,13}Q$ — Beam Forming 15,13 matrix Q. This field is the imaginary multiplication factor of 15,13 element of the Beam Forming Matrix, correlating with virtual antenna 15 and beam antenna 13.
79–72	$BF_{15,12}I$ — Beam Forming 15,12 matrix I. This field is the real multiplication factor of 15,12 element of the Beam Forming Matrix, correlating with virtual antenna 15 and beam antenna 12.
71–64	$BF_{15,12}Q$ — Beam Forming 15,12 matrix Q. This field is the imaginary multiplication factor of 15,12 element of the Beam Forming Matrix, correlating with virtual antenna 15 and beam antenna 12.
63–56	$BF_{14,15}I$ — Beam Forming 14,15 matrix I. This field is the real multiplication factor of 14,15 element of the Beam Forming Matrix, correlating with virtual antenna 14 and beam antenna 15.
55–48	$BF_{14,15}Q$ — Beam Forming 14,15 matrix Q. This field is the imaginary multiplication factor of 14,15 element of the Beam Forming Matrix, correlating with virtual antenna 14 and beam antenna 15.
47–40	$BF_{14,14}I$ — Beam Forming 14,14 matrix I. This field is the real multiplication factor of 14,14 element of the Beam Forming Matrix, correlating with virtual antenna 14 and beam antenna 14.
39–32	$BF_{14,14}Q$ — Beam Forming 14,14 matrix Q. This field is the imaginary multiplication factor of 14,14 element of the Beam Forming Matrix, correlating with virtual antenna 14 and beam antenna 14.

Table 26-374. CRPE-DL Beam Forming 7 Fields Description (Continued)

Bits	Description
31–24	$BF_{14,13}I$ — Beam Forming 14,13 matrix I. This field is the real multiplication factor of 14,13 element of the Beam Forming Matrix, correlating with virtual antenna 14 and beam antenna 13.
23–16	$BF_{14,13}Q$ — Beam Forming 14,13 matrix Q. This field is the imaginary multiplication factor of 14,13 element of the Beam Forming Matrix, correlating with virtual antenna 14 and beam antenna 13.
15–8	$BF_{14,12}I$ — Beam Forming 14,12 matrix I. This field is the real multiplication factor of 14,12 element of the Beam Forming Matrix, correlating with virtual antenna 14 and beam antenna 12.
7–0	$BF_{14,12}Q$ — Beam Forming 14,12 matrix Q. This field is the imaginary multiplication factor of 14,12 element of the Beam Forming Matrix, correlating with virtual antenna 14 and beam antenna 12.

26.5.5.7.15 CRPE-DL Start Control Register (CDSLR)

Writing to this register resets the frame, slot, sub slot and chunk count of the CRPE-DL (in *CDPSSR* register) and starts writing the output buffers. The data is ignored.

Table 26-376. CRPE-DL TPC Command Control Fields Description

Bits	Description
31–29	Reserved.
28	TPCOV — TPC Override. This bit indicates that TPC overriding symbol should be used instead of associated input stream. 0 - TPC override is turned off. 1 - TPC override is turned on.
27–26	Reserved.
25–16	TPCID — TPC Channel ID. This field indicates the channel whose TPC is being updated. The fields correlate with channels numbered #TPCID and #TPCID+512.
15–8	TPCSI — TPC Symbol Real Part. 8 bit field specifying the real part of the complex TPC overriding symbol. Value relates to symbol without STTD operation.
7–0	TPCSQ — TPC Symbol Imaginary Part. 8 bit field specifying the imaginary part of the complex TPC overriding symbol. Value relates to symbol without STTD operation.

26.5.5.7.17 CRPE-DL Virtual Antennas Gain Command Control Register (CDVAGCLR)

This register defines the slot at which virtual antenna gains programmed in *CDVAGCLR0* and *CDVAGCLR1* start to affect. Until this slot, previously programmed gains are used. The use of the updated gains is synchronized to the beginning of the field pointed by associated *GUF* field from slot format LUT, and to the beginning of the first slot of the channel.

Bits	Description
31–26	Reserved.
25–16	VCID — Virtual Antenna Channel ID. This field specifies which physical channel gain parameters should be updated with the data written in the *CDVAGCLR0* and *CDVAGCLR1* registers. The fields correlate with channels numbered #VCID and #VCID+512.
15–5	Reserved.
4	GUN — Gain Update Next. This field is indicates whether gain update should take effect at slot pointed by GUS or at the next earliest update time. 0 - The gain should be updated at slot pointed by *GUS*. 1 - The gain should be updated at the next earliest update time.
3–0	GUS — Gain Update Slot. This field is specifying the slot number in frame to start using the new virtual antenna parameters. This field takes affect only while *GUN* field is cleared. In addition, new virtual antenna parameters are used at the beginning of the first slot of the channel. Range: 0-14.

26.5.5.7.18 CRPE-DL General Command Control Register (CDGCLR)

This register is used for updating the channel general parameters. An active channel should not override parameters as long as CRPE-DL is still processing the channel.

Figure 26-317. CRPE-DL General Command Control Register

Table 26-378. CRPE-DL General Command Control Fields Description

Bits	Description
63–57	CMSFIX — Compressed Mode Slot Format Index. A pointer to entry of Slot Format LUT, indicating slot format of compressed frames. Range: 0 to 89.
56–55	CMSCR — Compressed Mode Scrambling Code Index. This field indicates which scrambling code is used at compressed mode. 0 - Same as the one used in non-compressed mode. 1 - Left alternative scrambling code. 2 - Right alternative scrambling code. 3 - Reserved
54–53	Reserved
52–48	SCRIX — Scrambling Code Index. A pointer to entry of Scrambling Initialization LUT Memory, indicating SN of channel's scrambling code. Range: 0 to 31.
47–41	SFIX — Slot Format Index. A pointer to entry of Slot Format LUT, indicating slot format of non-compressed frames. Range: 0 to 89.
40	Reserved
39–36	VANTB — Virtual Antenna B. Destination Virtual Antenna B. Range: 0 to 15. **Note**: $VANTB_X$ must not equal $VANTA_X$.
35–32	VANTA — Virtual Antenna A. Destination Virtual Antenna A. Range: 0 to 15. **Note**: $VANTA_X$ must not equal $VANTB_X$.

Table 26-378. CRPE-DL General Command Control Fields Description

Bits	Description
31	TSTDEN — TSTD Enable. This field indicates whether CRPE-DL should perform TSTD operation. When TSTD operation is enabled, in even numbered slot channel output stream is targeted to Virtual Antenna A; while in odd numbered slot channel output stream is targeted to Virtual Antenna B. When TSTD operation is disabled, channel output streams are generated for both antennas. *TSTDEN* may be enabled only for synchronization channels. 0 - TSTD operation is disabled. 1 - TSTD operation is enabled.
30–29	STTD — STTD Operation Field. This field indicates how STTD operation relates to the channel. 00 - STTD operation should not be performed on the channel's input stream and there is no coupled channel on which the STTD operation is performed externally. This option can be associated with channels 0-511. This option must be selected when TSTDEN is enabled. 01 - STTD operation should not be performed on the channel's input stream and there is a coupled channel on which the STTD operation is performed externally. This option can be associated with channels 0-511. 10 - STTD operation should be performed on the channel's input stream in addition to the non-STTD operation. CRPE-DL should process the channel twice: one time without performing STTD operation and second time with STTD operation. The processed output stream without STTD operation is targeted to Virtual Antenna A, while the processed output stream with STTD operation is targeted to Virtual Antenna B. This option can be associated with channels 0-511. This option is not supported for channels with Spreading Factor 256. 11 - STTD operation was performed externally on the channel's input stream and there is a coupled channel on which the STTD operation is not performed externally. This option can be associated with channels 512–1023.
28	VANTABEN — Virtual Antenna B Enable. This field indicates whether channel's processing should be targeted to Virtual Antenna B in addition to Virtual Antenna A. VANTABEN must be set when STTD equals 2 and when TSTDEN is set. VANTABEN must be cleared when STTD equals 1 or 3. 0 - Channel is not targeted to Virtual Antenna B. 1 - Channel is targeted to Virtual Antenna B in addition to Virtual Antenna A.
27	SCH — Synchronization Channel. This field indicates whether the channel is a synchronization channel. When synchronization channel is processed, each slot produces only 256 chips, starting from offset 0. This option can be associated with channels 0-511. 0 - channel is not a synchronization channel. 1 - channel is a synchronization channel.
26	Reserved
25–16	GCCID — General Command Channel ID. This field indicates the channel whose general parameters are being updated. Range: 0 to 1023.
15–8	CMOVSF — Compressed Mode OVSF. This field indicates the Cch, SF, OVSF code used at compressed mode, used as specified in the standard. Range: 0 to 255.
7–0	OVSF — Orthogonal Variable Spreading Factor. This field indicates the Cch, SF, OVSF code, used as specified in the standard. Range: 0 to 255.

26.5.5.7.19 CRPE-DL Idle Period Control Register <x> (CDIPLRx)

These registers define the idle period of each virtual antenna. There are 16 such registers ($0 \leq x \leq 15$), where each register index refer to antenna index.

Offset 0x0023F0A0 Access: User read/write
offset 4

Table 26-379. CRPE-DL Idle Period Fields Description

Bits	Description
31	IPV_i — Idle Period Valid VA_i. This field is specifying if idle period should be performed for virtual antenna i. This bit is set by the user and cleared by CRPE-DL once idle period is performed from start to end. 0 - idle period should not be performed. 1 - idle period should be performed from start to end.
30–28	Reserved.
27–24	$IPESL_i$ — Idle Period End Slot VA_i. This field is specifying the end slot in frame of idle period for virtual antenna i. Range: 0 to 14
23–20	Reserved.
19–16	$IPESBS_i$ — Idle Period End Sub-Slot VA_i. This field is specifying the end sub-slot in slot of idle period for virtual antenna i. Range: 0 to 9
15–12	Reserved.
11–8	$IPSSL_i$ — Idle Period Start Slot VA_i This field is specifying the start slot in frame of idle period for virtual antenna i. Range: 0 to 14
7–4	Reserved.
3–0	$IPSSBS_i$ — Idle Period Start Sub-Slot VA_i. This field is specifying the start sub-slot in slot of idle period for virtual antenna i. Range: 0 to 9

26.5.5.7.20 CRPE-DL Beam Forming Coefficients Timing Command Control Register <x> (CDBFCTCLRx)

These registers define the time at which beam forming coefficients programmed in *CDBFCVLR* registers start to affect. Until this time previously programmed coefficients are used.

In addition, these registers also define the shift right operation that is performed after multiplication by beam-forming coefficients.

CDBFCTCLR0 correlates with *CDBFCVLR(0-1)* and virtual antennas 0-3, *CDBFCTCLR1* correlates with *CDBFCVLR(2–3)* and virtual antennas 4–7, *CDBFCTCLR2* correlates with

CDBFCVLR(4–5) and virtual antennas 8–11, and *CDBFCTCLR3* correlates with *CDBFCVLR(6–7)* and virtual antennas 12–15.

Bits	Description
31	BFSUN — Beam Forming Shift Update Next. This field is indicates whether beam forming shift number update should take effect at slot and sub-slot as pointed by *BFSUSL* and *BFSUSS* or at the next earliest sub-slot time. 0 - The shift number should be updated at slot and sub-slot as pointed by *BFSUSL* and *BFSUSS*. 1 - The gain should be updated at the next earliest sub-slot time.
30–29	Reserved.
28–24	BFSNUM — Beam Forming Shift Number. This field is directly specifying the number of shift right operations to perform after multiplication by beam-forming coefficients. Range: 0 to 16
23–20	BFSUSL — Beam Forming Shift Update Slot. This field is specifying the slot number in frame to start using the new beam forming shift number. Range: 0 to 14
19–16	BFSUSS — Beam Forming Shift Update Sub-Slot. This field is specifying the sub-slot number in slot to start using the new beam forming shift number. Range: 0 to 9
15–9	Reserved.
8	BFUN — Beam Forming Update Next. This field is indicates whether beam forming coefficients update should take effect at slot and sub-slot as pointed by *BFUSL* and *BFUSS* or at the next earliest sub-slot time. 0 - The gain should be updated at slot and sub-slot as pointed by *BFUSL* and *BFUSS*. 1 - The gain should be updated at the next earliest update time.
7–4	BFUSL — Beam Forming Update Slot. This field is specifying the slot number in frame to start using the new beam forming coefficients. Range: 0 to 14
3–0	BFUSS — Beam Forming Update Sub-Slot. This field is specifying the sub-slot number in slot to start using the new beam forming coefficients. Range: 0 to 9

26.5.5.7.21 CRPE-DL Combined Chips Shift Command Control Register <x> (CDCCSCLRx)

These registers define the shift right operation that is performed after chips accumulation.

CDCCSCLR0 correlates with virtual antennas 0-3, *CDCCSCLR1* correlates with virtual antennas 4–7, *CDCCSCLR2* correlates with virtual antennas 8–11, and *CDCCSCLR3* correlates with virtual antennas 12–15.

26.5.5.7.22 CRPE-DL Rate Control Register (CDRLR)

This register takes affect when Rate Control Source *RCS* field in *CDOMCP* initialization parameter (see **Section 26.5.2.4**, *CRPE-DL Output Mode Configuration Parameter (CDOMCP)*) is set. The register provide fields to indicate rate control events of new 16 chips chunk and new sub-slot. Only one rate control event takes affect, according to Rate Selector *RSEL* field value in *CDOMCP* initialization parameter.

The fields at this register are set by the host and cleared by the CRPE-DL.

27 Security Engine (SEC)

The Security Coprocessor version 3.1.0 (SEC) performs computationally intensive security functions including the following:

- Key generation and exchange
- Authentication
- Bulk encryption.

It is optimized to process all the algorithms associated with internet protocol security (IPSec), internet key exchange (IKE), secure sockets layer/transport layer security (SSL/TLS), internet small computer system interface (iSCSI), secure real-time transport protocol (SRTP), the **IEEE** 802.11i security standard, worldwide interoperability for microwave access (WiMAX), third generation (G3) A3/5 for global system for mobile communication (GSM) and Enhanced Data Rates for GSM evolution (EDGE), and GEA3 for general packet radio service (GPRS). For applications requiring security protection for sensitive data, the SEC provides encryption/decryption capability without imposing process loading on the device core processors. The SEC includes a controller, four data channels, and eight execution units (EUs) with a shared random number generator (RNGU) that use a common interface to the controller. The EUs perform the specific mathematical manipulations required by protocols used in cryptographic processing.

27.1 Architecture Overview

Since the SEC can act as a master on the internal system bus, it does not impose the data movement bottleneck on the core processing that is normally associated with slave-only processors. In addition, the SEC resides on the peripheral memory map of the processor, and therefore, when an application requires cryptographic functions, it simply creates descriptors for the SEC that define the cryptographic function to perform and the location of the data. The SEC bus-mastering capability permits the core processor to set up a channel with a few short register writes, leaving the SEC to perform reads and writes on system memory to complete the required task.

The security engine includes 8 different execution units (EUs). For EUs for which data flows in and out, each EU has buffer FIFOs of at least 256 bytes. EU types and features include the following:

- Advanced Encryption Standard Unit (AESU)
  - Implements the Rijndael symmetric key cipher per U.S. National Institute of Standards and Technology FIPS 197.
  - Modes providing data confidentiality: ECB, CBC, CCM, Counter, GCM, XTS, CBC-RBP, OFB-128, and CFB-128.
  - Modes providing data authentication: CCM, GCM, CMAC (OMAC1), and XCBC-MAC.
  - 128, 192, 256 bit key lengths (only 128 bit keys in XCBC-MAC)
  - Integrity Check Vector (ICV) checking in CCM, GCM, CMAC (OMAC1), and XCBC-MAC mode
  - XOR operations on 2–6 sources for RAID applications
- ARC Four Execution Unit (AFEU)
  - Implements a stream cipher compatible with the RC4 algorithm
  - 8-bit to 128-bit programmable key
- Cyclic Redundancy Check Unit (CRCU)
  - Implements CRC32C as required for iSCSI header and payload checksums, CRC32 as required for **IEEE** Standard 802 packets, as well as for programmable 32 bit CRC polynomials
  - ICV checking
- Data Encryption Standard Execution Unit (DEU)
  - DES, 3DES
  - Two key (K1, K2, K1) or Three Key (K1, K2, K3)
  - ECB, CBC, CFB-64 and OFB-64 modes for both DES and 3DES
- Kasumi Execution Unit (KEU)
  - Implements cipher and authentication modes F8 and F9 used in 3G, A5/3 for GSM and EDGE, and GEA3 for GPRS

  - 128-bit confidentiality key and 128-bit integrity key
  - ICV checking for F9
- SNOW3G Execution Unit (STEU)
  - Implements cipher and authentication modes UEA2 (F8) and UIA2 (F9)
  - 128-bit confidentiality key and 128-bit integrity key
  - ICV checking for F9
- Message Digest Execution Unit (MDEU)
  - Implements SHA with 160-bit, 224-bit, 256-bit, 384-bit, and 512-bit message digest (as specified by the FIPS 180-2 standard)
  - Implements MD5 with 128-bit message digest (as specified by RFC 1321)
  - Implements HMAC computation with either message digest algorithm (as specified in RFC 2104 and FIPS-198)
  - Implements SSL MAC computation
  - ICV checking
- Public Key Execution Unit (PKEU)
  - RSA and Diffie-Hellman with programmable field size up to 4096 bits
  - Elliptic curve cryptography
    - F_2m and F_p modes
    - Programmable field size up to 1023 bits
  - Run time equalization to protect against timing and power attacks
- Random Number Generator (RNGU). Combines a True Random Number Generator (TRNG) and a deterministic Pseudo-Random Number Generator (PRNG), based on SHA, as described in FIPS 186-2, Appendix 3.1.

In addition to the execution units, the SEC also includes:

- A context switching polychannel, permitting operation of up to four virtual channels, where each channel:
  - Can be configured for any of the core processors
  - Supports a queue of commands (descriptor pointers) to be executed
  - Provides dynamic arbitration for needed crypto-execution units
  - Manages up to two execution units (one ciphering and one hashing), and configures for any required data transfers from one to another
  - Performs flow-control management of buffer FIFOs on the inputs and outputs of execution units
  - Supports scatter/gather of input and output data (where the term data is used loosely, and includes keys, context, ICV values, and so forth), enabling concatenation of multiple segments of memory when reading or writing data
  - Masters data bursts on 32-byte boundaries to optimize bus throughput.
- Master and slave interfaces, with DMA capability

— 32-/36-bit address and 64-bit data
— Up to 333 MHz operation
— Master interface allows pipelined requests
— DMA data blocks can start and end on any byte boundary

27.1.1 Functional Diagram

A functional diagram of the SEC internal architecture is shown in **Figure 27-1**. The controller block is designed to transfer 64-bit sets between the bus and any register inside the SEC.

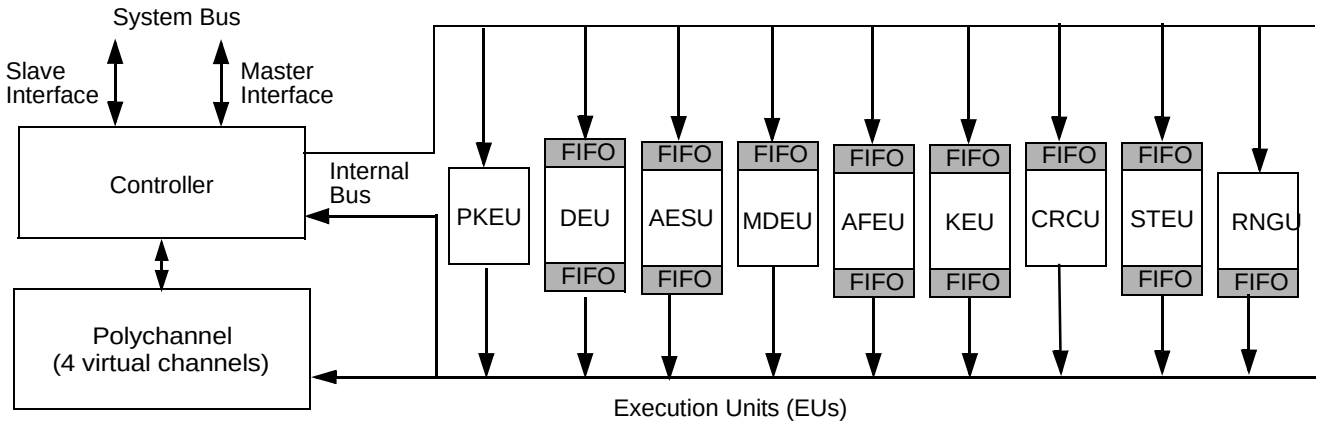

Figure 27-1. SEC Functional Diagram

The SEC interfaces with the system buses through the controller. The Slave Interface permits an external device to perform 32-bit or 64 bit writes on any register or FIFO inside the SEC Some locations permit byte writes. Reads may be of any length. Using the Master Interface, the controller can transfer blocks of 64-bit words between system memory and SEC FIFOs or registers.

A typical SEC operation begins when the core processor writes a descriptor pointer to the Fetch FIFO in one of the four SEC virtual channels. This write operation uses the slave interface (in which the core processor is master and SEC is the slave). Following the write, the channel directs the sequence of operations, using the master interface (for which the SEC is master). The channel uses the descriptor pointer to read the descriptor, then decodes the first 4 bytes of the descriptor to determine the operation to perform and the crypto-execution units needed to perform it. The channel requests the controller to assign the needed crypto-execution units. If necessary, the channel waits for the needed execution units to be free.

Next, the channel requests that the controller transfer the keys, context, and data from locations specified in the rest of the descriptor to the appropriate execution units. The controller satisfies the requests by making requests to the master interface per the programmable priority scheme. Data is fed into the execution units through their registers and input FIFOs. The execution units read from their input FIFOs and write processed data to their output FIFOs and registers. The

channel requests that the controller write data from the output FIFOs and registers back to system memory.

The channel indicates completion by sending a descriptor via an interrupt to the core processor or by a writeback of the descriptor header into core processor memory. For details about this signalling, see **Section 27.1.3**, *Polychannel*.

Upon completion of a descriptor, the channel checks the next entry in its Fetch FIFO, and, if non-zero, requests a burst read of the next descriptor. For most packets, the entire payload is too long to fit in an execution unit input or output FIFO. Therefore, the channel uses a flow control scheme for reading and writing data. The channel directs the controller to read bursts of input as necessary to keep refilling the input FIFO until the entire payload is fetched. Similarly, the channel directs the controller to write bursts of output whenever enough accumulates in the execution unit output FIFO.

The Polychannel processes up to four descriptors concurrently by implementing four virtual channels. Channels arbitrate for use of execution units, and wait if the needed execution unit is currently reserved by another channel. Each channel has its own FIFO of descriptor pointers to fetch and execute, and its own internal storage. The four channels, however, time-share a single control and datapath unit, and hence they are referred to as virtual channels. A programmable priority scheme uses round-robin or weighted priorities among these channels.

27.1.2 Controller

The controller manages the master and slave interfaces to the device system interface and the internal buses that connect all the various SEC modules. It receives service requests from the core processor (via the slave interface) and from the channels and schedules the required data transfers. The system bus interface and access to system memory are critical factors in performance, and the 64-bit master and slave interfaces of the SEC controller enable it to achieve performance unattainable on secondary buses.

27.1.2.1 Controller Operation

The controller can interface with the execution units in two ways:

- Channel-controlled access—A channel can request a particular service from any available execution unit. This is the normal operating mode.
- Core processor-controlled access—The core processor can move data into and out of any execution unit directly through memory-mapped EU registers. Typically, this is only used for debug. Intervention by a core during normal operation may drive an executing EU into an error condition.

27.1.2.1.1 Channel-Controlled Access

This type of access is the normal SEC operating mode. All direct interaction with the EUs is directed by the channel executing the descriptor. The core processor provides the initial descriptor pointer and handle the results when processing is complete, but is not involved in the EU processing. Processing begins when a descriptor pointer is written to the Fetch FIFO of one of the channels. The typical processing step are listed in **Section 27.1.4.1**.

27.1.2.1.2 Core Processor-Controlled Access

All execution units (EUs) are memory-mapped, and can be used entirely through register read/write access. The SEC operates as a slave, and the core processor must write the information normally provided through the descriptor into the appropriate registers and FIFOs of the SEC. This method is more processor intensive and requires a great deal of familiarity with the SEC registers. It is recommended that core processor-controlled access be used only for operations using a single EU and for debug purposes.

27.1.2.2 Descriptors and Link Tables

Since the SEC was designed for easy use and integration with existing systems and software, it uses descriptors to access all cryptographic functions. A descriptor specifies the cryptographic function to perform and contains pointers to all necessary input and output data locations. Some descriptor types perform multiple functions as required by specific protocols.

Each descriptor contains eight 64-bit/8-byte sets, consisting of the following:

- One 64-bit header. The header describes the required services and encodes information that indicates the EUs to use and the modes to set. It also indicates whether notification should be sent to the core processor when the descriptor operation is complete.
- Seven 64-bit pointers used to locate input or output data. Each pointer can point either directly to the data or to a link table that lists a set of data segments to concatenate. Link tables are used by the descriptors to allow concatenation of data parcels as required.

A sample descriptor is described in **Table 27-1**.

Table 27-1. Example Descriptor

Field Name	Value	Description
Header	0x20531E0800000000	Example header for IPsec ESP outbound using DES and MD-5
Length0 Extent0 Pointer0	16 0 (32 or 36-bit pointer)	Number of bytes in authenticate key Unused Pointer to authentication key
Length1 Extent1 Pointer1	16 0 (32 or 36-bit pointer)	Number of bytes in authentication-only data Unused Pointer to authentication-only data
Length2 Extent2 Pointer2	8 0 (32 or 36-bit pointer)	Length of input context (initialization vector—IV) Unused Pointer to input context

Table 27-1. Example Descriptor (Continued)

Field Name	Value	Description
Length3 Extent3 Pointer3	8 0 (32 or 36-bit pointer)	Number of bytes in cipher key Unused Pointer to cipher key
Length4 Extent4 Pointer4	1500 0 (32 or 36-bit pointer)	Number of bytes of data to be ciphered Unused Pointer to input data to perform ciphering upon
Length5 Extent5 Pointer5	1500 12 (32 or 36-bit pointer)	Number of bytes of data after ciphering Number of bytes in authentication result (ICV) Pointer to location where cipher output is to be written, followed by ICV
Length6 Extent6 Pointer6	8 0 (32 or 36-bit pointer)	Length of output Context (IV) Unused Pointer to location where altered Context is to be written

Note: For details, see **Section 27.7.1.1**, *Descriptor Structure*, on page 27-100.

27.1.3 Polychannel

The Polychannel implements four independent virtual channels for processing descriptors. The polychannel is a bridge between the channel operations and the controller and provides direct links to the controller and the EUs. It serves the following functions:

- Sends requests for block transfers received from the EUs to the controller to perform transfers among system memory, the EUs, and the channels.
- Configures the EUs before message processing begins.
- Maintains context when switching tasks.
- Notifies the controller when specified events occur.

The polychannel uses four counters to monitor processing events:

- Fetch FIFO Enqueue Count (FFEC).
- Descriptor Finished Count (DFC).
- Data Bytes In Count (DBIC).
- Data Bytes Out Count (DBOC).

During processing of a channel, the registers increment for each specified event type occurrence. When one of these counters rolls over (changes from maximum to 0), a corresponding bit is set in the Controller Interrupt Status Register if the event interrupt is enabled. This allows the user or system software to preset a value in the counter before processing starts, and then be notified when the preset threshold is reached.

27.1.4 Virtual Channels

Each channel contains the following addressable structures:

- *Fetch FIFO*. Holds a queue of pointers to descriptors waiting to be processed.
- *Configuration register*. Allows the user a number of options for SEC event signalling.
- *Status register*. Indicates the last unfulfilled bus request.
- *Descriptor buffer memory*. Stores the active descriptor and other temporary data.

27.1.4.1 Channel Processing

Whenever a channel is idle and its Fetch FIFO is non-empty, the channel reads the next descriptor pointer from the Fetch FIFO, unless the processing engine operation is stopped (which may require reinitialization or reset of the EU). Using this pointer, the channel fetches the descriptor and places it in its descriptor buffer. To process this descriptor, the channel directs execution of the following steps.

1. Analyze the descriptor header to determine the cryptographic services required, and request use of the appropriate EU(s) from the controller.
2. If required EUs are reserved by another channel, wait for the EU(s) to be available. If available, reserve the EU(s).
3. Configure the appropriate mode bits in the EU(s) for the required EU function.
4. Fetch parcels (up to 64K – 1 bytes long) from system memory using pointers from the descriptor buffer, and place them in either an EU input FIFO or EU registers (as appropriate). The term parcel refers here to any input or output of a cryptographic process, such as a key, hash result, input context, output context, or text-data. Context refers to either an initialization vector (IV) or other internal EU state that can be read out or loaded in. Text-data refers to the plaintext or ciphertext on which to operate. Each parcel transfer may involve using link tables to gather input data that has been split into multiple segments in system memory.
5. If the data size is greater than EU FIFO size, continue fetching input data and writing output data to memory, as required.
6. After writing the last input data to each EU input FIFO, write to the End of Message Register in the EU.
7. Wait for EU(s) to complete processing of text-data.
8. Upon completion, unload final results from the output FIFOs and Context Registers and write them to external memory using pointers in the descriptor buffer. This may involve using link tables to scatter output data into multiple segments in system memory.
9. Reset and release the EUs.

10. If done notification is enabled, perform this notification to the core processor to indicate descriptor completion.

27.1.4.2 Channel Completion

The channel indicates completion by sending a descriptor via an interrupt to the core processor or by a writeback to the descriptor header. In the case of a writeback, the value written back is identical to the header that was read, except for a DONE field, which is set to all 1s. The user performs this notification signalling at the end of every descriptor or at the end of selected descriptors.

27.1.4.3 Integrity Check Value (ICV) Generation and Checking

An EU operation can include generating an ICV and then comparing it against a received ICV. The result of the ICV checking can be sent to the core processor via interrupt or by a writeback of the descriptor header (but not by both methods). If both are enabled, the occurrence of an error interrupt prevents the writeback from occurring.

In the case of a writeback, the user can opt to do it at the end of every descriptor or only at the end of descriptors that call for ICV comparison. In the case of an error condition in a channel or its reserved EUs, the channel issues an interrupt to the core processor. The channel can be configured either to abort the current descriptor and proceed to the next one, or to halt and wait for core processor intervention.

Note: For details on configuring signalling, see **Section 27.7.6.1**, *Channel Configuration Registers for Channels 1–4 (CCR[1–4])*, on page 27-199. For detail on the writeback fields, see **Section 27.7.1.2**, *Descriptor Header*, on page 27-102.

27.1.4.4 Encryption and Hashing

Many security protocols involve both encryption and hashing of packet payloads. To accomplish this without requiring two passes through the data, channels can configure data flows through two EUs. In such cases, one EU is designated as the primary EU, and the other as the secondary EU. The primary EU receives its data from memory via the controller, and the secondary EU receives its data by snooping the SEC buses.

27.1.4.5 Snooping

There are two types of snooping.

- Input data can be fed to the primary EU and the same input data is snooped by the secondary EU. This is called in-snooping.
- Output data from the primary EU can be snooped by the secondary EU. This is called out-snooping.

Note: In the SEC, only the MDEU and the CRCU can be selected as the secondary EU. For details, see **Section 27.3**, *Polychannel*, on page 27-15.

27.1.5 Common EU Interface

The controller and the channels use a standardized common interface to the EUs. As shown in **Figure 27-2**, the main access to the EUs is through common input and output buses. EU FIFOs and registers are memory-mapped on these buses with 4 Kbytes allocated for each EU. Within each EU memory segment, standard addresses are used for common register types. In addition to this bus interface, each EU supplies three interrupt signals to the controller. Two of these (done interrupt and error interrupt) are routed by the controller to the channel currently using that EU.

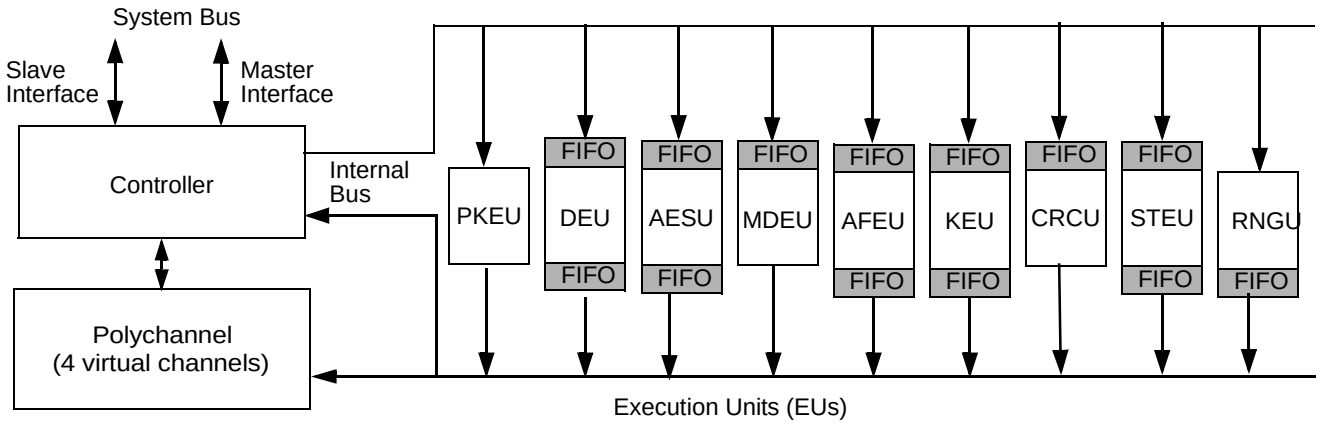

Figure 27-2. SEC Functional Diagram

The EUs are compatible with IPSec, IKE, SSL/TLS, iSCSI, SRTP, and **IEEE** Std. 802.11i, WiMAX, 3G, A5/3 for GSM and EDGE, and GEA for GPRS, processing and can work together to perform high-level cryptographic tasks. Each EU is described in detail in **Section 27.6**, *Execution Units*, on page 27-24.

27.2 SEC Controller

The controller within the SEC is responsible for mastering bus transfers on behalf of the channels. The controller interfaces to the core processors via the master and slave bus interfaces and to the channels and EUs via internal buses. All transfers between the core processors and the EUs are moderated by the controller. Some of the main functions of the controller are as follows:

- Accept and execute commands from the slave bus to read or write memory-mapped locations (up to 64 bits) anywhere in the SEC.
- Accept and execute requests from the polychannel to transfer blocks of bytes among system memory, EUs, and the channels.
- Realign read and write data using the proper byte alignment.
- Monitor interrupts from channels and pass them to a core processor.

27.2.1 Bus Transfers

The controller is involved in transfers on the system bus and the internal bus. The system bus actually refers to two buses:

- Slave bus for operating SEC as a slave
- Master bus for transactions with SEC as the master

The internal bus is a private 64-bit slave bus with the controller block as the sole master. All accesses to SEC from the system bus go through the controller. The controller also directs transfers over the internal bus.

For core-controlled access, the core uses the external slave bus to access the controller as a slave, and the controller relays the read or write accesses to the proper block over the internal bus. When a write command is received from the system bus, the controller takes the data and sends it to whichever internal location is indicated by the address. For a read, the controller goes to the internal location, fetches the requested data from the specified address (if allowed), and returns it over the system bus.

For channel-controlled access, the channels make requests to the controller to perform data transfers. The channel specifies data lengths and addresses for the internal and system buses. The controller can queue up to four requests. The controller dequeues requests and performs the required transfer. Most transfers involve not only the internal bus, but also the external master bus with the controller as bus master. Here are examples of the various types of bus-master transfers:

- Obtaining a descriptor:
  - channel makes request
  - controller arbitrates for use of the system bus and performs read from external memory
  - controller sends descriptor to channel over the internal bus
- Transferring data length parameter from a channel to the EU
  - channel makes request
  - controller transfers data from channel to EU over the internal bus
- Obtaining input data from external memory for input to an EU
  - channel makes request
  - controller arbitrates for use of the system bus and performs read from external memory
  - controller sends data to EU over the internal bus. If insnooping, data is sent to two EUs
- Writing output data from an EU back to external memory
  - channel makes request
  - controller begins reading data from the EU into a controller FIFO. If outsnooping, the same data is also read by another EU. Meanwhile, the controller arbitrates for use of the system bus.
  - controller performs write to external memory

- Status writeback
  - channel makes request
  - controller reads value from channel and arbitrates for use of the system bus
  - controller performs write to external memory, overwriting the writeback field of the descriptor's header

27.2.1.1 System Bus Master Read

The following list defines the sequence of events for a system bus read with the controller as master:

1. Channel asserts bus read request to the controller
2. Channel furnishes external read address, internal write address, and transfer length
3. Controller asserts request to the system bus through the Magenta master interface
4. Controller waits for system bus read to begin
5. When bus read begins, controller receives data from the master interface and performs a write to the appropriate internal address supplied by the channel. Data may be realigned byte-wise by the controller if either:
   - the external read address was not on an 8-byte boundary, or
   - the internal write address was not on an 8-byte boundary.
6. Transfer continues until the bus read is completed and the controller has written all data to the appropriate internal address. The master interface will continue making bus requests until the full data length has been read.

When the SEC performs a transaction as master, it is possible for the intended slave to terminate the transfer due to an error. The SEC transaction requests are posted to a target queue, after which the core must take responsibility for completing the transaction or signalling error. An error in an SEC initiated transaction is also reported by the SEC via the Channel Interrupt Status Register. The core processor can determine which channel generated the interrupt by checking the ISR for the channel ERROR bit.

27.2.1.2 System Bus Master Write

The following list is the sequence of events for a system bus write with the controller as master:

1. Channel asserts its bus write request to the controller.
2. Channel furnishes internal read address, external write address, and transfer length.
3. Controller performs a read from the appropriate internal address supplied by the channel, loads the write data into its FIFO, asserts a request to the system bus through the master bus interface, and waits for the system bus to become available.

4. When the system bus becomes available, the controller writes data from its FIFO to the master interface.

27.2.2 Controller Interrupts

The controller produces a single interrupt to each core, either a primary interrupt or a secondary interrupt. Only the Channel Error, Channel Done and Channel Done Overflow status bits can cause the secondary interrupt to assert. All other interrupt types assert the primary interrupt.

27.2.2.1 Controller Primary Interrupt

All interrupt outputs from other SEC blocks are fed to the controller as interrupt conditions. In addition, the controller itself detects some interrupt conditions. The controller maintains an Interrupt Status Register (ISR) with bits corresponding to all of these possible interrupt conditions. If an interrupt condition occurs and the corresponding bit of the Interrupt Enable Register (IER) is set, then the associated Interrupt Status Register bit is set, indicating the presence of a pending interrupt. When any bits are set in the Interrupt Status Register, the controller asserts its primary interrupt output line to the core processor. A primary interrupt generates an IRQ index vector of 201 in the EPIC modules in each core subsystem.

The SEC also allows configuration of specific channel interrupt conditions (specifically, Channel Error, Channel Done and Channel Done Overflow) as secondary interrupts by remapping the channel status register to its alternative (secondary) address using one of the RCA bits in the Master Control Register (MCR) (see **Section 27.7.4.1**, *Master Control Register (MCR)*, on page 27-179). If one of these channel errors occurs in this configuration, the controller generates a secondary interrupt to the cores (using a separate interrupt line). This generates an IRQ index vector of 202 in the EPIC modules in each core subsystem.

To handle an interrupt, the core processor must read the Interrupt Status Register to determine the source. It may then need to do further reads of interrupt status registers of other blocks to get more detailed information about the cause. In the case of a secondary interrupt, the core would only have to read the specific channel status register, but at the secondary address.

In some cases, the core processor may need to take action to clear the root cause of the interrupt. After that, the core processor can clear the desired bit of the Interrupt Status Register by writing a 1 to the corresponding bit of the Interrupt Clear Register (ICR). If the cause of the interrupt condition is not cleared, or if there is some other interrupt condition from the same source, then the Interrupt Status Register bit will clear for a cycle and go high again, and the interrupt output line to the core processor remains high. If the Interrupt Status Register bit is successfully cleared and no other interrupt conditions are present, the controller de-asserts its interrupt output. If any interrupts are still pending in the Interrupt Status Register, the interrupt output remains asserted. This process is valid for both the primary and secondary interrupt lines independently.

Note that EU interrupt conditions may be blocked at two different levels. There is an Interrupt Mask register in each EU that can block particular interrupt conditions before they reach the EU interrupt status register. In addition, interrupts from EUs can be individually blocked by bits of the controller Interrupt Enable Register before they reach the controller Interrupt Status Register. For normal operation, interrupts from EUs are typically disabled in the controller's Interrupt Enable Register, but they still reach the channel, and the channel produces Done or Error interrupts to the core processor as needed. Interrupt conditions from the channels and controller can only be blocked through the Controller Interrupt Enable Register.

A channel can generate frequent interrupts, especially if it is configured to interrupt at the completion of each descriptor. To make sure that the core processor receives the right number of interrupts, each channel Done interrupt has a special queuing feature. If multiple Channel Done interrupts are generated before the first is cleared, then the additional interrupts are counted by the controller. Each time the core processor clears a channel interrupt, the count is decremented. If the core processor clears the channel interrupt and the count reaches zero, the Channel Done interrupt is deasserted. If the count does not reach zero, the controller deasserts the interrupt for one cycle and then re-asserts it again.

Up to 15 interrupts can be queued for each channel. If the count of queued interrupts for any channel exceeds 15, the channel Done Overflow bit is set (see **Section 27.7.4.6**).

27.2.2.2 Controller Secondary Interrupt

Whenever the Channel Done, Channel Error or Channel Done Overflow bits are set in the Interrupt Status Register and the channel has been remapped to the alternative address by one of the RCA bits in the Master Control Register (MCR) (see **Section 27.7.4.1**, *Master Control Register (MCR)*, on page 27-179), the controller asserts the secondary interrupt output line to the secondary core processor. No other Interrupt Status Register status bits can cause the secondary interrupt to assert.

27.2.3 Controller Registers

The controller uses the following registers and structures:

- Master Control Register (MCR). This register allows the user to impose a real-time priority level on the internal arbiter for the controller bus access, to generate a software reset using a write to this register, and set the EU and bus priority counts for Channels 3 and 4. For details on this register and its programming model, see **Section 27.7.4.1**, *Master Control Register (MCR)*, on page 27-179.
- Controller Identification Register (CIR). This register provides an ID for the SEC used by software to verify the supported security revision levels. It is a duplicate of the information in the Controller IP Block Revision. For details on this register, see **Section 27.7.4.2**, *Controller Identification Register (CIDR)*, on page 27-182.

- Controller IP Block Revision Register (CIPBRR). This register contains a 64-bit value that identifies the version of the SEC 3.1 protocol supported by this device. For details on this register, see **Section 27.7.4.3**, *Controller IP Block Revision Register (CIPBRR)*, on page 27-182.
- Controller EU Assignment Status Register (CEUASR). This register records the assignment for each EU to a channel. If the EU is assigned a channel, it becomes inaccessible to any other channel. For details on this register, see **Section 27.7.4.4**, *EU Assignment Status (EUASR)*, on page 27-183.
- Controller Interrupt Enable Register (CIER). The CIER allows the user to enable or disable interrupt generation by specific sources. After reset, all sources are disabled. When a source is enabled by setting the corresponding bit in the CIER, it can set a bit in the Interrupt Status Register (ISR) which generates an interrupt to the core processor. For normal operation, enable all the channel interrupts and disable all the EU-specific interrupts. The channels generate the appropriate interrupts to the core processor. For details on this register, see **Section 27.7.4.5**, *Controller Interrupt Enable Register (CIER)*, on page 27-185.
- Controller Interrupt Status Register (CISR). The ISR contains fields representing all possible sources of interrupts. The Interrupt Status Register is cleared either by a reset, or by writing the appropriate bits active in the Interrupt Clear Register. For details on this register, see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189.
- Controller Interrupt Clear Register (CICR). The CICR provides a means clear the CISR. Writing a 1 to a bit in the CICR clears the corresponding bit in the ISR. If no other interrupt is pending, it also deasserts the interrupt output pin $\overline{\text{IRQ}}$. If the input source to the ISR remains active, the appropriate ISR bit sets the $\overline{\text{IRQ}}$ is reasserted shortly thereafter. The ICR bit clears automatically clear one cycle after it is written. For details on this register, see **Section 27.7.4.7**, *Controller Interrupt Clear Register (CICR)*, on page 27-192.

27.3 Polychannel

The polychannel is the main control unit in the SEC. It implements four independent channels for processing descriptors. The polychannel is a bridge between the channel operations and the controller and provides direct links to the controller and the EUs. It serves the following functions:

- Sends requests for block transfers received from the EUs to the controller to perform transfers among system memory, the EUs, and the channels.
- Configures the EUs before message processing begins.
- Maintains context when switching tasks.
- Notifies the controller when specified events occur.

The polychannel uses four counters to monitor processing events:

- Fetch FIFO Enqueue Count (FFEC).
- Descriptor Finished Count (DFC).
- Data Bytes In Count (DBIC).
- Data Bytes Out Count (DBOC).

During processing of a channel, the registers increment for each specified event type occurrence. When one of these counters rolls over (changes from maximum to 0), a corresponding bit is set in the Controller Interrupt Status Register if the event interrupt is enabled. This allows the user or system software to preset a value in the counter before processing starts, and then be notified when the preset threshold is reached.

27.4 Channels

The individual channels in the polychannel manage the execution of each cryptographic task, making use of one or more of the SEC execution units (EUs). Control information and data pointers for a given task are stored in the form of a descriptor (see Section 27.7.1, **Descriptors and Link Tables**) in system memory or in the channel itself. A descriptor determines which EUs are used, how they are configured, where to fetch needed data, and where to store the results.

27.4.1 Channel Operation

To invoke cryptographic tasks, the core processor constructs a descriptor, selects a channel, and writes a pointer to the descriptor into the selected channel Fetch FIFO. The Fetch FIFO can store up to 24 pointers. Operations performed by channels include the following (not necessarily in this order):

- If the channel is idle and its Fetch FIFO is non-empty, it reads the next descriptor pointer from the Fetch FIFO, and uses the pointer to read the descriptor into the channel descriptor buffer.
- Requests from the controller the assignment of one or more EUs for the exclusive use of the channel. When necessary, configures the secondary EU to snoop input or output data intended for the primary EU.
- Upon notification of completion of the EU reset sequence, initializes Mode Registers in the assigned EU.
- Initializes EUs and writes to EU registers (such as key size and text-data size).
- Transfers data parcels (up to 32 Kbytes) from system memory into the assigned EU input registers and FIFOs. This can involve using link tables to gather input data that is split into multiple segments stored in various locations in system memory. For the RAID-XOR descriptor type, the channel rotates among three data sources, fetching 32 bytes from each source.

- Transfers data parcels (up to 32 Kbytes) from assigned EU output registers and FIFOs to system memory space. This can involve using link tables to scatter output data into multiple segments which are stored in various locations of system memory.
- Initialize the End_of_Message Register (where applicable) in the assigned EU upon completion of last EU write indicated by the descriptor. The channel waits for a indication from the EU that processing of input text-data is complete before proceeding with further activity after writing end_of_message.
- Resets assigned EU(s).
- Releases assigned EU(s).
- When a descriptor is completely processed, provides feedback to the core processor, in the form of an interrupt and/or descriptor header write-back to system memory.
- When descriptor processing is halted due to an error, provides feedback to the core processor via an interrupt.
- The channel waits indefinitely for the controller to complete a requested activity before continuing to the next step of descriptor processing.
- The channel can generate two types of done notification signals when it completes operation on a descriptor—an interrupt and/or a writeback of the descriptor header.
- If selected, the done notification is performed at the end of processing either for every descriptor or selected descriptors.
- If enabled, the channel can also write back status information from the EU(s) involved in processing the descriptor.

Note: The done and status writebacks are not performed if the EU(s) generate any error during processing. The detected error can include, but is not limited to, a failing, unmasked ICV Check in an EU.

27.4.2 Arbitration Among Channels

All channels share a set of common resources, namely, use of EUs, use of the controller to perform data transfers, and use of the polychannel itself to implement channel activity. This section discusses the arbitration mechanisms for these shared facilities.

27.4.2.1 Arbitration for Use of the Polychannel

As previously mentioned, channels are implemented by time-sharing a common datapath and state machine in the polychannel. Each channel’s use of the polychannel is usually brief; a channel typically makes a single request to the controller for a data transfer, computes values for the next transfer, and then goes to sleep, waiting for data transfers to occur or for some EU to process more data.

When the executing channel goes to sleep, it leaves a wakeup condition indicating what event should wake up that channel again. When the wakeup condition is satisfied, the channel is ready

to resume executing. Next time the polychannel becomes free, that channel must arbitrate with any other channels that are also ready to execute.

With the current designs of the controller and magenta-to-copper gasket, there is a delay penalty whenever they change direction from write to read. To maximize data transfer efficiency, it is best to group memory read requests together and memory write requests together. When choosing which channel to execute next, the arbitrator first selects from channels waiting to do writes. When there are no more waiting to write, it begins selecting those waiting to read. It then switches back to handling writes, and so forth.

Within the read or write category, selection of the next channel to execute can be either round-robin or a weighted priority-based scheme, depending on the values of CHN3_BUS_PR_CNT and CHN4_BUS_PR_CNT in the Master Control Register (see **Section 27.7.4.1**). For more information, see **Section 27.4.2.4**.

27.4.2.2 Arbitration for Use of the Controller

No arbitration for use of the controller is necessary. Because channels execute one at a time, a channel experiences no contention when sending a request to the controller. In effect, when a channel wins arbitration for use of the polychannel, it wins use of the controller as well.

27.4.2.3 Arbitration for Use of Execution Units

While one channel has a particular EU reserved, it is possible for multiple other channels to request use of that same EU. Arbitration is necessary to determine which channel will get use of the EU next. To accomplish this, there is an arbiter for each type of execution unit.

EU arbitration can be either round-robin or a weighted priority-based scheme, depending on the values of CHN3_EU_PR_CNT and CHN4_EU_PR_CNT in the Master Control Register (see **Section 27.7.4.1**). For more information, see **Section 27.4.2.4**.

If a channel needs two EUs, a primary and a secondary, it requests them one at a time. Sometimes a channel will reserve one EU and then have to wait for some other channel(s) to finish before obtaining the second requested EU. Though such waiting may occur, the requests are always eventually satisfied. Deadlock is avoided through the following design rules:

1. The channel always requests the secondary EU first.
2. In cases where both a primary and secondary are used, the choices for primaries and secondaries are distinct sets. Primaries are AESU, AFEU, DES, and KFEU, and the secondaries are MDEU and CRCU.

Since primaries and secondaries are distinct sets, and primary and secondary requests are strictly ordered, no deadlock is possible.

27.4.2.4 Arbitration Algorithms

This section applies to both arbitration for use of the polychannel, and arbitration for use of execution units. Control fields for both are in the Master Control Register (see **Section 27.7.4.1**):

- CHN3_BUS_PR_CNT and CHN4_BUS_PR_CNT control polychannel arbitration
- CHN3_EU_PR_CNT and CHN4_EU_PR_CNT control EU arbitration

This section refers to generic control fields CHN3_xx_PR_CNT and CHN4_xx_PR_CNT, where the “xx” refers to either “BUS” or “EU”.

If both CHN3_xx_PR_CNT and CHN4_xx_PR_CNT are zero (the default), arbitration is round-robin, described in Section 27.4.2.4.1. If they are set to non-zero values, the arbiter implements a weighted priority scheme, described in Section 27.4.2.4.2.

The SEC does not dynamically adjust its own transaction priorities. System software, however, can adjust SEC transaction priority in realtime, with the change in priority taking effect immediately.

27.4.2.4.1 Round-Robin Arbitration

In round-robin arbitration, requesting channels are granted access in rotating numerical order: 1, 2, 3, 4, 1, 2, and so on.

27.4.2.4.2 Priority Arbitration

When arbitrating on the priority scheme, the priority is as follows:

- Channel 1—Highest priority
- Channel 2—Second highest priority, unless CHN3_xx_PR_CNT or CHN4_xx_PR_CNT has expired
- Channel 3—Third priority, unless CHN4_xx_PR_CNT expired
- Channel 4—Lowest priority, until CHN4_xx_PR_CNT expired

Initially, the priority is channel 1, channel 2, channel 3, and channel 4, in that order. In order to prevent channels 3 and 4 from being locked out, a weight-based scheme is used. When channel 3 has lost arbitration the number of times specified in CHN3_xx_PR_CNT, channel 3 replaces channel 2 as the second-highest priority in the next round of arbitration. Likewise, when channel 4 has lost arbitration the number of times specified in CHN4_xx_PR_CNT, channel 4 replaces channel 2 as the second-highest priority in the next round of arbitration. Channel 1 always has the highest priority, but it cannot make back to back requests, so the second highest priority channel will win arbitration either immediately, or after one win from channel 1.

27.4.3 Channel Registers and Structures

Each channel has its own set of registers and structures used for configuration, control, and data manipulation including the following:

- Channel Configuration Register (CCR). Configures the basic channel operation including burst size, extended addressing, and notification type. It also provides control functions such as continuing the operation, resetting the channel, writing back status and DONE, and using an Integrity Check Value (ICV). For details, see **Section 27.7.6.1**, *Channel Configuration Registers for Channels 1–4 (CCR[1–4])*, on page 27-199.
- Channel Pointer Register (CSR). Contains status fields and counters to report the current status of descriptor processing including the G_STATE (gather) and S_STATE (scatter) fields that report gather and scatter state machine status. For details, see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202.
- Current Descriptor Pointer Register (CDPR). Contains the address for the currently processing descriptor. For details, see **Section 27.7.6.3**, *Current Descriptor Pointer Register (CDPR)*, on page 27-207.
- Channel Fetch FIFO (FF). Each channel contains a Fetch FIFO to store a queue of pointers to descriptors to process. In a typical operation, the core processor creates a descriptor in memory containing all relevant mode and location information for the SEC and then launches the descriptor by writing its address to the SEC Fetch FIFO. The Fetch FIFO can hold up to 24 descriptor pointers at a time. When the channel reaches the end of the current descriptor, the next location in the Fetch FIFO is read to launch the next descriptor. The Fetch Address is written into the FIFO only if the write includes the least significant byte (bits 7–0). If the Extend Address Enable (EAE) bit is set, then the Extended Fetch Address must be written before or concurrently with the Fetch Address. Specifying a fetch address of 0 causes the channel to generate an error and stop. For details, see **Section 27.7.6.4**, *Channel Fetch FIFO (CFF)*, on page 27-209.
- Channel Descriptor Buffer (DB). As with any descriptor used by the SEC, the DB consists of an 8-byte header and seven 8-byte pointers with lengths. This structure is read-only because the descriptor is always fetched from system memory. For details, see **Section 27.7.6.5**, *Channel Descriptor Buffer (DB)*, on page 27-210.

27.4.4 Channel Interrupts

The channel can assert done and error interrupts to the controller. The status of the registered channel interrupts is available in the Controller Interrupt Status Register (CISR); see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189 for details. The channel does not have an internal interrupt mask, but the controller can be programmed to block channel interrupts via its Interrupt Enable Register (see **Section 27.7.4.5**, *Controller Interrupt Enable Register (CIER)*, on page 27-185 for details).

27.4.4.1 Channel Done Interrupt

Whether and when a channel done interrupt is generated depends on the setting of the Channel Configuration Register NT and CDIE bits (see **Section 27.7.6.1**, *Channel Configuration Registers for Channels 1–4 (CCR[1–4])*, on page 27-199). Assuming the CDIE (Channel Done Interrupt Enable) is set, the channel generates an interrupt event after every successfully completed descriptor (Notification Type set to Global), or after each successfully completed descriptor with the DN (Done Notification) bit set in the header of the descriptor. If the EU(s) signal any error during processing, the channel done interrupt is not generated. Even if multiple channel done interrupt events are generated by a channel before the first can be cleared by the core processor, the interrupt events are not lost. The controller queues channel done interrupts from each channel (see **Section 27.2.2**, *Controller Interrupts*, on page 27-13).

27.4.4.2 Channel Error Interrupt

The Channel Error Interrupt is generated when an error condition occurs during descriptor processing. The channel error interrupt is asserted as soon as the error condition is detected. The type of error condition is reflected in the ERROR field of the Channel Pointer Register (CSR). Refer to **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202 for a complete listing of error types.

27.4.4.3 Channel Reset

Channel reset is asserted when the core processor sets the RESET bit in the Channel Configuration Register (CCR). The effect of software reset on the channel varies according to what the channel is doing when the bit is set:

- If the RESET bit is set while the channel is requesting an EU assignment from the controller, the channel canceled its request by asserting the release output signals. The channel then resets all of its registers, clears the RESET bit, and returns the control state machine to the idle state.
- If the RESET bit is set after the channel is dynamically assigned an EU, the channel requests a write from the controller to set the software reset bit of the EU. A write to reset the secondary (MDEU) EU is also requested if one is reserved for snooping. The channel then asserts the appropriate release output signal to notify the controller that the channel has finished with the reserved EU(s). The channel then resets all the registers, clears the RESET bit, and returns the control state machine to the idle state.

27.5 Descriptors and Link Tables

SEC descriptors are designed to support the cryptographic computation of a single packet using a single descriptor. They are conceptually similar to descriptors used by most devices with DMA capability. The descriptors have a fixed length of 64 bytes. A descriptor consists of one header (8 bytes) and seven pointers with lengths (each 8 bytes). See **Section 27.7.1**, *Descriptors and Link Tables*, on page 27-100 for a detailed description of descriptor structure.

The descriptor header indicates which computations to perform and which EUs to use. The descriptor pointers identify input and output data locations. The pointer function capabilities include scatter/gather capability, which means that each pointer in a descriptor can be either a direct pointer to a contiguous parcel of data, or can be a pointer to a link table which is a list of pointers and lengths used to assemble the parcel. **Figure 27-3** shows the layout of a descriptor pointer.

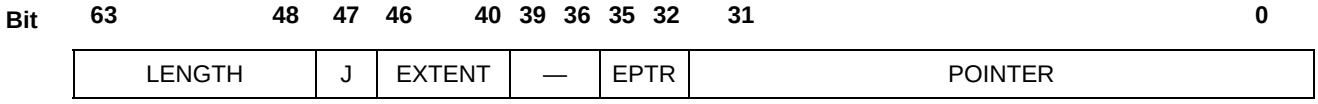

Figure 27-3. Descriptor Pointer Layout

When a link table is used to read input data, this is referred to as a gather operation; when used to write output data, it is referred to as a scatter operation. Although there are only seven pointers in descriptor, a link table identified by the pointer can have any number of 8-byte entries.

There are two kinds of entries, regular entries and next entries. Each regular entry specifies a memory segment by means of a 36-bit starting address (SEGPTR) and a 16-bit length (SEGLEN). A next entry is used at the end of a link table to specify that the list of memory segments is continued in another link table. In a next entry, the N bit is set, the SEGPTR field gives the address of the next link table, and the SEGLEN field must be 0. A chain of link tables may contain any number of link tables. See **Section 27.7.3**, *Link Tables*, on page 27-177 for details on the Link Table programming model. **Figure 27-4** shows the layout of a link table entry.

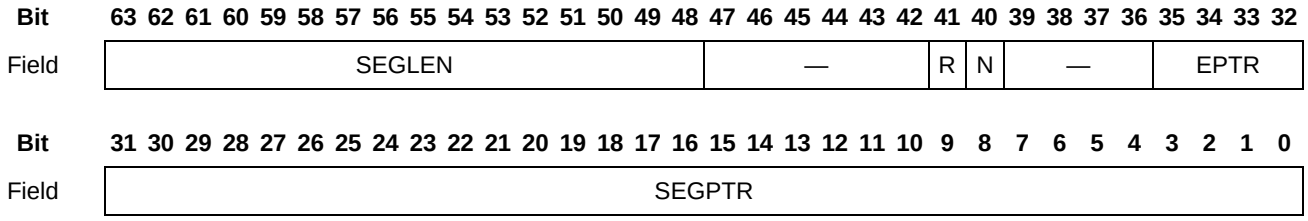

Figure 27-4. Link Table Entry

Whether the list of memory segments is in a single link table or split into several link tables, the last entry in the last link table is a regular entry with the R (return) bit set. The R bit signifies the end of link table operations so that the channel returns to the descriptor for its next pointer (if any).

For any sequence of parcels accessed by a link table or chain of link tables, the combined lengths of the parcels (the sum of their LENGTH and/or EXTENT fields) must equal the combined lengths of the link table memory segments (SEGLEN fields). Otherwise the channel sets the error state in the SGLM bit of the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202).

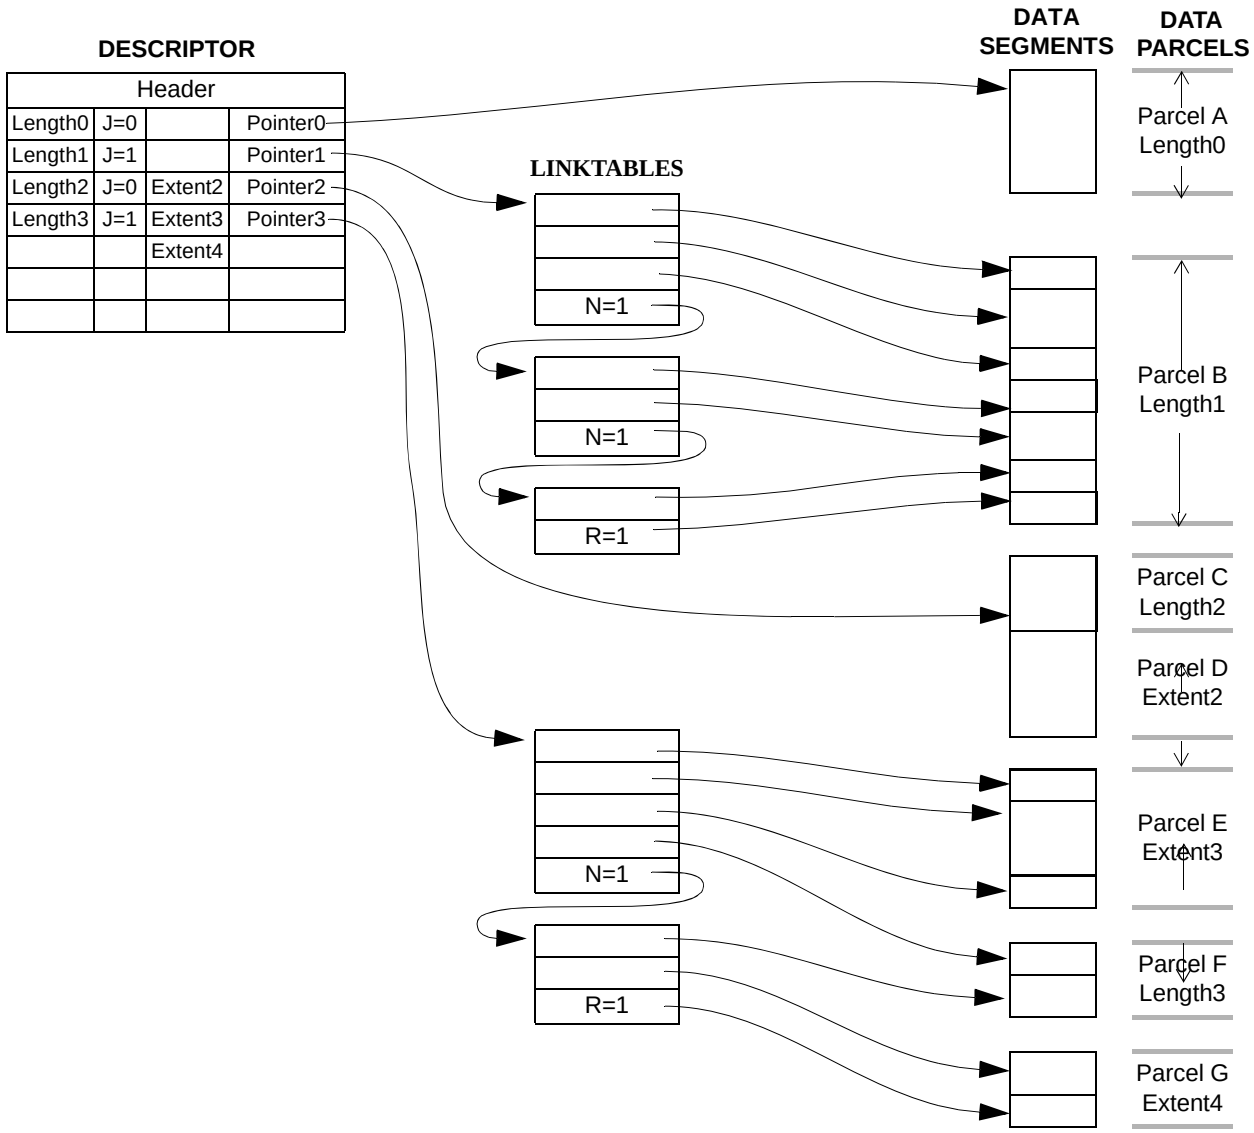

Figure 27-5. Descriptors, Link Tables, and Parcels

Figure 27-5 illustrates various ways that a descriptor can specify parcels:

- The first pointer in the descriptor specifies Parcel A using the simplest method. The pointer identifies the parcel directly through Pointer0 and Length0.
- The second pointer d uses a chain of link tables to specify Parcel B. Since J=1, Pointer1 is used as the address of a link table. The link table specifies several regular entries specifying data segments to be concatenated. The last entry of the link table is a next entry

indicating that the list continues in the next link table. The last entry in the last link table of the chain has the R bit set.

- The last pointers show how one pointer in a descriptor can specify multiple parcels. Pointer2 and Length2 specify Parcel C, then Parcel D follows immediately afterwards, with length specified by Extent2. Pointer3 is used for three parcels (E, F, and G) using link tables.

To demonstrate the use of a link table, assume that the current descriptor type requests the channel to read a parcel using Pointer3 and Extent3 fields, and assume that J3=1. Due to the J3 value, Pointer3 is not used as a data address but instead used as the address of a link table. The channel begins by reading the first four entries starting at Pointer3 into an internal gather table buffer. Using the first entry of the gather table buffer, the channel starts accessing the parcel by reading SEGLEN bytes beginning at SEGPTR. If the required parcel size (Extent3) is greater than this first SegLen, the channel moves on to the next entry of the gather table buffer, and reads SEGLEN bytes starting at SEGPTR. As long as there are more bytes to read in the parcel, the process continues. If the channel gather table buffer is exhausted, the channel reads the next four entries of the link table into its gather table buffer. If a gather table buffer entry is encountered in which the N bit is set, the channel uses the SEGPTR field in that word to find the next link table in the chain.

Now assume that the channel accesses its next parcel using Pointer3 again, this time with length given by Length3. In this case the channel continues to the next line of the link table, and begins reading the memory segment specified there. As before, the channel concatenates memory segments from as many link table entries as necessary to obtain the required number of bytes (Length3).

Similarly, the next parcel is obtained by using Pointer3 yet again, this time with length given by Extent4.

Assume that for the current descriptor type, the Extent4 parcel is the last one to accessed through Pointer3. Then the link table entry that supplies the last memory segment for Extent4 has the R bit set, signifying that this is the last entry in the chain of link tables.

27.6 Execution Units

Execution unit (EU) is the term used for a functional block that performs the mathematical manipulations required by protocols used in cryptographic processing. The EUs are compatible with IPSec, IKE, SSL/TLS, iSCSI, SRTP, and **IEEE** Std. 802.11i, WiMAX, 3G, A5/3 for GSM and EDGE, and GEA for GPRS, processing and can work together to perform high level cryptographic tasks.

The following execution units are used in the SEC:

- Public Key Execution Unit (PKEU)

- Data Encryption Standard Execution Unit (DEU)
- Advanced Encryption Standard Execution Unit (AESU) implementing the Rinjdael symmetric key cipher.
- Message Digest Execution Unit (MDEU)
- ARC Four Execution Unit (AFEU)
- Kasumi (F8/F9) Execution Unit (KEU)
- Cyclic Redundancy Check Unit (CRCU)
- SNOW3G Execution Unit (STEU)
- One private internal Random Number Generator Unit (RNGU)

Working together, the EUs can perform high-level cryptographic tasks, such as the IPSec Encapsulating Security Protocol (ESP) and digital signature. The following sections provide overview of the execution unit operations. Register details are given in the Programming Model at the end of the chapter (**Section 27.7**, *Programming Model*, on page 27-96). In general, direct access to the EU registers is only used for debugging operations.

The mapping each set of EU registers is similar and the location of registers within the memory map uses the same offsets from the specific EU register base address for each of the common EU registers. The EUs and the RNGU all include the following 64-bit registers:

- Mode Register
- Data Size Register
- Reset Control Register
- Status Register
- Interrupt Status Register
- Interrupt Mask Register

In addition to the basic registers, an EU also includes specific registers and data structures to support the individual computational requirements. The register and structure types can include:

- Input FIFOs and/or output FIFOs
- End_of_Message Registers
- Key registers and key memory
- Context registers and context memory and context memory pointers
- Special purpose registers for ABSize, EU-GO, IV, ICV, and data registers

Refer to the individual EU functional descriptions for a list the registers for that EU and to **Section 27.7**, *Programming Model*, on page 27-96 for a detailed description of each register and associated register fields.

27.6.1 Public Key Execution Unit (PKEU)

The public key execution unit (PKEU) is typically operated through channel-controlled access, which means that most reads and writes of PKEU registers are directed by the SEC channels. Driver software performs core processor-controlled register accesses only on a few registers for initial configuration and error handling.

The following subsections include general descriptions of the PKEU registers and structures. **Section 27.7**, *Programming Model*, on page 27-96 provides a detailed description of each register and associated register fields.

27.6.1.1 PKEU Mode Register

This register specifies the internal PKEU routine to execute. The Mode Register is cleared when the PKEU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated.

27.6.1.2 PKEU Key Size Register

The register reflects the number of significant bytes to use from PKEU Parameter Memory E in performing modular exponentiation or elliptic curve point multiplication. The range of values for this register when performing either modular exponentiation or elliptic curve point multiplication is from 1 to 512. Specifying a key size outside this range causes a key size error (KSE) in the PKEU Interrupt Status Register.

27.6.1.3 PKEU AB Size Register

This register represents the operand size for the specific operands whenever required. The AB size is in bits even though internally, the PKEU imposes 32-bit alignment. Any data beyond the number specified by the AB Size Register, either in A and B-ram (operands), is ignored. Because no error checking is performed, having an operand size greater than the prime modulus or the field size can result is a wrong result. It is assumed that operands are modulo reduced before being written into the PKEU. Therefore, the AB Size must be less than or equal to the Data Size for a correct result. If the AB Size Register is modified during processing, an error is generated.

27.6.1.4 PKEU Data Size Register

This register specifies, the size of the significant portion of the modulus or irreducible polynomial in bits. Any value written to this register that is a multiple of 32 bits (for example, 128 bits, 160 bits, and so on), is represented internally as the same value (128 bits, 160 bits, respectively). Any value written that is not a multiple of 32 bits (for example, 132 bits, 161 bits, and so on), is represented internally as the next larger 32-bit multiple (160 bits, 196 bits, and so on, respectively). This internal rounding up to the next 32-bit multiple is described for information only. The minimum size valid for all routines to operate properly is 33 bits

(internally 128 bits). The maximum size to operate properly is 2048 bits. A value in bits larger than 2048 results in a data size error.

An illegal data size error is generated as follows:

- All non ECC routines with a data size > 512 generate an illegal data size error.
- All ECC routines with a data size > 128 generate an illegal data size error.
- AB Size = 0 (either intentionally written or by ignoring and not writing at all) generates an illegal size error, except for routines that do not require an A or B operand such as the CLEAR_MEM routine.

27.6.1.5 PKEU Reset Control Register

This register contains three reset options specific to the PKEU.

27.6.1.6 PKEU Status Register

This register contains 6 fields that reflect the state of PKEU internal fields. The PKEU Status Register is read-only. Writing to this location result in an address error being reflected in the PKEU Interrupt Status Register.

27.6.1.7 PKEU Interrupt Status Register

This register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the PKEU Interrupt Mask Register is zero. If the PKEU Interrupt Status Register is non-zero, the PKEU halts and the PKEU error interrupt signal is asserted to the controller (see **Section 27.2.2**, *Controller Interrupts*). In addition, if the PKEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error then appears in the Channel Pointer Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller. If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the PKEU Reset Control Register.

27.6.1.8 PKEU Interrupt Mask Register

This register controls the result of detected errors. For a given error (as defined in Section 27.6.1.7, **PKEU Interrupt Status Register**), if the corresponding bit in this register is set, then the error is disabled; no error interrupt occurs and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the PKEU Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

27.6.1.9 PKEU End_of_Message Register

This register indicate the start of a new computation. Writing to this register causes the PKEU to execute the function requested by the ROUTINE field, per the contents of the parameter memories. This register has no data size, and during the write operation, the core processor data bus is not read. Hence, any data value is accepted.

27.6.1.10 PKEU Parameter Memories.

The PKEU uses four 4096-bit memories to receive and store operands for the arithmetic operations the PKEU performs. In addition, results are stored in one particular parameter memory. Data addressing within these memories is big-endian, that is, the most significant byte is stored in the lowest address.

- PKEU Parameter Memory A. This 4096-bit memory is used typically as an input parameter memory space. For modular arithmetic routines, this memory operates as one of the operands of the desired function. For elliptic curve routines, this memory is segmented into four 1024 bit memories, and is used to specify particular curve parameters and input values.
- PKEU Parameter Memory B. This 4096-bit memory is used typically as an input parameter memory space, as well as the result memory space. For modular arithmetic routines, this memory operates as one of the operands of the desired function, as well as the result memory space. For elliptic curve routines, this memory is segmented in to four 1024 bit memories, and is used to specify particular curve parameters and input values, as well as to store result values.
- PKEU Parameter Memory E. This 4096-bit memory is non-segmentable, and stores the exponent for modular exponentiation, or the multiplier k for elliptic curve point multiplication. This memory space is write only; a read of this memory space causes address error to be reflected in the PKEU Interrupt Status Register.
- PKEU Parameter Memory N. This 4096-bit memory is non-segmentable, and stores the modulus for modular arithmetic and F_p elliptic curve routines. For F_2m elliptic curve routines, this memory stores the irreducible polynomial.

27.6.1.11 PKEU Routines

Once a write to End_of_Message Register is issued, the EU checks the Mode Register and if appropriate, the Data Size and Key Size Registers for valid data. If a valid routine is requested (refer to **Section 27.7.7.1, *PKEU Mode Register (PKEUMR), on page 27-211*** for a list of valid routine values), it is performed.

Descriptions of the PKEU routines use the following notational conventions:

- All values are positive
- The modulus and elements of the prime field (F_p) are positive numbers

- The modulus and elements of the polynomial field (F_2m) are polynomials represented as bit strings, where the most-significant bit represents the highest-degree coefficient
- Significant bits of a value: Defined to be all the bits from the least significant bit up to the most significant 1 in the value. For example, the binary number 0b00010010 has 5 significant bits (0b10010).
- Significant bytes of a value: Defined to be all the bytes from the least significant byte up to the most significant non-zero byte in the value. For example, 0x00_00_02_A6_3F_00 has 4 significant bytes (0x02_A6_3F_00).
- A, B, E, N: 4096-bit values from the parameter memories (see **Section 27.6.1.10**). Unless otherwise noted, N is modulus, E is exponent or key, and A and B are other operands.
- X. Underscore denotes Montgomery format
- Data Size: Contents of the Data Size Register. Normally loaded with the number of significant *bits* in N.
- Key Size: Contents of the Key Size Register. Normally loaded with the number of significant *bytes* in E.
- Sz'(N): The value in the Data Size Register rounded up to the next multiple of 32. (This notation recognizes that Data Size is normally related to N, making Sz'(N) the number of significant bits in N, rounded up to the next multiple of 32.)
- Sz'(K): The value in the Key Size Register, times 8, rounded up to the next multiple of 32 (which is the number of bits specified by Key Size, rounded up to the next multiple of 32)

Additional notation for elliptic curve routines:

- A0, A1, A2, A3, B0, B1, B2, B3: For elliptic curve routines, 4096-bit memories A and B are each segmented into 1024-bit quantities: A = A3 • A2 • A1 • A0 and B = B3 • B2 • B1 • B0 (where • denotes concatenation).
- [X, Y] or [X, Y, Z]: coordinates of a point in two or three dimensions
- PK_BUILD: The 768-byte data structure constructed by the SPK_BUILD routine, which is the concatenation of six 1024-bit quantities: B1 • B0 • A3 • A2 • A1 • A0.

Almost all the PKEU routines require the user to supply a modulus input value. Cryptographic security depends strongly on the quality of the modulus chosen. To achieve the best security,

- In Diffie-Hellman, the modulus should be a large prime number.
- In prime field elliptic curve cryptography, the modulus should be a large prime number.
- In polynomial field elliptic curve cryptography, the modulus should be a bit string representing a large irreducible polynomial.
- in RSA, the modulus should be a product of two large prime numbers.

The Montgomery representation allows modular multiplications to take place without the costly trial division often associated with regular modular multiplication. In the Montgomery residue

number system, a number X is represented as X*R (mod N), where $R = 2^s$ and s is computed as D*U.

The block or unit size, U, is a system parameter usually defined by the multiplier data bus size. In this version of the PKEU, its value is 32, the multiplier operand size.

The digit size D represents the quotient of the size of the modulus N (in binary representation) divided by U plus one. In simpler terms, the $2^s = 2^{DU}$ is the first multiple of 2^U larger than N.

The following sections give a brief description of the function performed by each routine using the inputs, outputs, and requirements.

27.6.1.11.1 CLEARMEMORY: Clear Memory (0x01)

- Input: Data Size (Note: this register must be loaded, but the value is not used.)
- Output: A=0, B=0, E=0, N=0
- Requirements:
  - minimum Data Size = 33
  - maximum Data Size = 4096

27.6.1.11.2 MOD_EXP: Prime field (F_p) Exponential mod N and Deconvert From Montgomery Format (0x02)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - Data Size = the number of significant bits in N
  - $\underline{A}$ = field element in Montgomery format
  - E = Exponent
  - Key Size = the number of significant bytes in E
- Output: $B = \underline{A}^E \bmod N$, a field element, non-Montgomery format
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 4096 bits
  - E > 1
  - maximum key (exponent) size 256 bytes
  - (number of significant bits in $\underline{A}$) < (number of significant bits in N)

Note: The input data (base) to be exponentiated must be provided in the Montgomery format. That is, $\underline{A} = AR \pmod N$, where the computation of R (the Montgomery Constant) is described in **Section 27.6.1.11**. The result is returned in parameter memory B in normal integer (non-Montgomery) representation.

27.6.1.11.3 MOD_EXP_TEQ: Exponentiate mod N and Deconvert From Montgomery Format with Timing Equalization (0x1d)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the even modulus error bit in the PKEU Interrupt Status Register is set.)
  - A = a prime field element in Montgomery format
  - E = Exponent (normal integer representation)
- Output:
  - B = A^E mod N, a prime field element, normal integer (non-Montgomery) format
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 4096 bits
  - maximum key (exponent) size 256 bytes
  - (number of significant bits in A) ≤ (number of significant bits in N)

Note: The input data (base) to be exponentiated must be provided in the Montgomery format. That is, A = AR (mod N), where the computation of R (the Montgomery Constant) is described in **Section 27.6.1.11**. The result is returned in parameter memory B in normal integer (non-Montgomery) representation.

MOD_EXP_TEQ performs the same operation as MOD_EXP but with an added timing equalization security feature. That is, its computation run-time is independent from its exponent content and is always equal to a maximum value. Also, its power consumption pattern largely follows that of an exponent with all ones.

27.6.1.11.4 MOD_R2MODN: Prime Field (F_p) Compute Montgomery Converter Constant (0x03)

- Input:
  - N = modulus. For a mathematically meaningful result, N should be odd.
  - Data Size = the number of significant bits in N
- Output: B = R^2 mod N, where R = $2^{Sz'(N)}$
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 4096 bits

27.6.1.11.5 MOD_RRMODP: Prime Field (F_p) Compute Montgomery Converter Constant for Chinese Remainder Theorem (0x04)

- Input:
  - N = modulus, a prime number (modulus P or Q of CRT).
  - Data Size = the number of significant bits in N

- Key Size = number of bytes in the modulus product PQ of CRT. (Note: in this instance, Key Size is not loaded with a value related to E.)

- Output: $B = R_n R_p \bmod N$, where $R_p = 2^{Sz'(N)}$ and $R_n = 2^{Sz'(K)}$
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 1023 bits
  - minimum key size = 13 bytes
  - maximum key size = 512 bytes
  - key size > modulus size/8

27.6.1.11.6 EC_FP_AFF_PTMULT: Prime Field Elliptic Curve Scalar Point Multiply in Affine Coordinates (0x05)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - Data Size = the number of significant bits in N
  - E = scalar multiplier (key)
  - Key Size = the number of significant bytes in E
  - [A0, A1] = multiplicand, an input point in affine coordinates
  - A2 = 0x1 (a bit string representing field element 1)
  - A3 = elliptic curve a parameter
  - B0 = elliptic curve b parameter
  - B1 = R^2 mod N, computed as described in MOD_R2MODN (0x03)
  - B2 = ignored
  - B3 = ignored
- Output:
  - [B1, B2] = E × [A0, A1], where × denotes elliptic curve scalar point multiplication. B1 and B2 are in affine coordinates.
  - B0 = undefined
  - B3 = undefined
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 512 bits
  - Point coordinates A0, A1 and elliptic curve parameters A3, B0 are elements of the prime field and therefore are less than the modulus N.
  - E > 1
  - maximum key size = 512 bytes

27.6.1.11.7 EC_F2M_AFF_PTMULT: Polynomial Field Elliptic Curve Scalar Point Multiply in Affine Coordinates (0x06)

- Input:

- N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
- Data Size = the number of significant bits in N
- E = scalar multiplier (key)
- Key Size = the number of significant bytes in E
- [A0, A1] = multiplicand, an input point in affine coordinates
- A2 = 0x1 (a bit string representing field element 1)
- A3 = elliptic curve a parameter
- B0 = elliptic curve c parameter:

$$c = b^{(2^{m-2})} \bmod N, \quad \text{where } m = \text{the degree of polynomial } N$$

- B1 = R^2 mod N, computed as described in F2M_R2MODN (0x0D)
- B2 = ignored
- B3 = ignored

■ Output:

- [B1, B2] = E × [A0, A1], where × denotes elliptic curve scalar point multiplication. B1 and B2 are in affine coordinates.
- B0 = undefined
- B3 = undefined

■ Requirements:

- minimum modulus size = 33 bits
- maximum modulus size = 512 bits
- Point coordinates A0, A1 and elliptic curve parameters A3, B0 are elements of the polynomial field and therefore have fewer significant bits than the modulus N.
- E > 1
- maximum key size = 512 bytes

27.6.1.11.8 EC_FP_PROJ_PTMULT: Prime Field Elliptic Curve Scalar Point Multiply in Projective Coordinates (0x07)

■ Input:

- N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
- Data Size = the number of significant bits in N
- E = scalar multiplier (key)
- Key Size = the number of significant bytes in E
- [A0, A1, A2] = multiplicand, an input point in projective coordinates
- A3 = elliptic curve a parameter
- B0 = elliptic curve b parameter
- B1 = R^2 mod N, computed as described in MOD_R2MODN (0x03)
- B2 = ignored
- B3 = ignored

- Output:
  - [B1, B2, B3] = E × [A0, A1, A2], where × denotes elliptic curve scalar point multiplication. B1, B2, and B3 are in projective coordinates.
  - B0 = undefined
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 512 bits
  - Point coordinates A0, A1, A2, and elliptic curve parameters A3, B0 are elements of the prime field and therefore are less than the modulus N.
  - E > 1
  - maximum key size = 512 bytes

27.6.1.11.9 EC_F2M_PROJ_PTMULT: Polynomial Field Elliptic Curve Scalar Point Multiply in Projective Coordinates (0x08)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - Data Size = the number of significant bits in N
  - E = scalar multiplier (key)
  - Key Size = the number of significant bytes in E
  - [A0, A1, A2] = multiplicand, an input point in projective coordinates
  - A3 = elliptic curve a parameter
  - B0 = elliptic curve c parameter:

$$c = b^{(2^{m-2})} \bmod N, \quad \text{where } m = \text{the degree of polynomial } N$$

  - B1 = R^2 mod N, computed as described in F2M_R2MODN (0x0D)
  - B2 = ignored
  - B3 = ignored
- Output:
  - [B1, B2, B3] = E × [A0, A1, A2], where × denotes elliptic curve scalar point multiplication. B1, B2, and B3 are in projective coordinates.
  - B0 = undefined
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 512 bits
  - Point coordinates A0, A1, A2, and elliptic curve parameters A3, B0 are elements of the polynomial field and therefore have fewer significant bits than the modulus N.
  - E > 1
  - maximum key size = 512 bytes

27.6.1.11.10 EC_FP_ADD: Prime Field Elliptic Curve Point Add in Projective Coordinates (0x09)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - Data Size = the number of significant bits in N
  - [A0, A1, A2] = first addend in projective coordinates and Montgomery format
  - A3 = elliptic curve a parameter in Montgomery format
  - B0 = elliptic curve b parameter in Montgomery format
  - [B1, B2, B3] = second addend in projective coordinates and Montgomery format
- Output:
  - [B1, B2, B3] = [A0, A1, A2] + [B1, B2, B3], where + represents an elliptic curve point addition. Outputs B1, B2, and B3 are in projective coordinates and Montgomery format.
  - B0 = elliptic curve b parameter in Montgomery format
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 512 bits
  - Point coordinates A0, A1, A2, B1, B2, B3, and elliptic curve parameters A3, B0 are elements of the prime field and therefore are less than the modulus N.

27.6.1.11.11 EC_FP_DOUBLE: Prime Field Elliptic Curve Point Double in Projective Coordinates (0x0A)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - Data Size = the number of significant bits in N
  - A0 = ignored
  - A1 = ignored
  - A2 = ignored
  - A3 = elliptic curve a parameter in Montgomery format
  - B0 = elliptic curve b parameter in Montgomery format
  - [B1, B2, B3] = input point in projective coordinates and Montgomery format
- Output:
  - [B1, B2, B3] = [B1, B2, B3] + [B1, B2, B3], where + represents an elliptic curve point addition. Outputs B1, B2, and B3 are in projective coordinates and Montgomery format.
  - B0 = elliptic curve b parameter in Montgomery format
- Requirements:
  - minimum modulus size = 33 bits

- maximum modulus size = 512 bits
- Point coordinates B1, B2, B3, and elliptic curve parameters A3, B0 are elements of the prime field and therefore are less than the modulus N.

27.6.1.11.12 EC_F2M_ADD: Polynomial Field Elliptic Curve Point Add in Projective Coordinates (0x0B)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - Data Size = the number of significant bits in N
  - [A0, A1, A2] = first addend in projective coordinates and Montgomery format
  - A3 = elliptic curve a parameter in Montgomery format
  - B0 = elliptic curve b parameter in Montgomery format
  - [B1, B2, B3] = second addend in projective coordinates and Montgomery format
- Output:
  - [B1, B2, B3] = [A0, A1, A2] + [B1, B2, B3], where + represents an elliptic curve point addition. Outputs B1, B2, and B3 are in projective coordinates and Montgomery format.
  - B0 = elliptic curve b parameter in Montgomery format
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 512 bits
  - Point coordinates A0, A1, A2, B1, B2, B3, and elliptic curve parameters A3, B0 are elements of the polynomial field and therefore have fewer significant bits than the modulus N.

27.6.1.11.13 EC_F2M_DOUBLE: Polynomial Field Elliptic Curve Point Double in Projective Coordinates (0x0C)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - Data Size = the number of significant bits in N
  - A0 = ignored
  - A1 = ignored
  - A2 = ignored
  - A3 = elliptic curve a parameter in Montgomery format
  - B0 = elliptic curve b parameter in Montgomery format
  - [B1, B2, B3] = input point in projective coordinates and Montgomery format
- Output:

- [B1, B2, B3] = [B1, B2, B3] + [B1, B2, B3], where + represents an elliptic curve point addition. Outputs B1, B2, and B3 are in projective coordinates in Montgomery format.
- B0 = elliptic curve b parameter in Montgomery format

- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 512 bits
  - Point coordinates B1, B2, B3, and elliptic curve parameters A3, B0 are elements of the polynomial field and therefore have fewer significant bits than the modulus N.

27.6.1.11.14 F2M_R2: Polynomial Field (F_2m) Compute Montgomery Converter Constant (0x0D)

- Input:
  - N = modulus. For a mathematically meaningful result, N should be odd.
  - Data Size = the number of significant bits in N
- Output: $B = R^2 \bmod N$, where $R = 2^{Sz'(N)}$
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 4096 bits

27.6.1.11.15 F2M_INV: Polynomial Field (F_2m) Modular Inversion (0x0E)

- Input:
  - N = modulus
  - Data Size = the number of significant bits in N
  - A = a field element
- Output: $B = A^{-1} \bmod N$, a field element
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 4096 bits
  - A is a is an element of the polynomial field and therefore has fewer significant bits than the modulus N.

27.6.1.11.16 MOD_INV: Prime Field (F_p) Modular Inversion (0x0F)

- Input:
  - N = modulus
  - Data Size = the number of significant bits in N
  - A = a field element
- Output: $B = A^{-1} \bmod N$, a field element
- Requirements:
  - minimum modulus size = 33 bits

— maximum modulus size = 4097 bits
— A is a is an element of the prime field and therefore is less than the modulus N.

27.6.1.11.17 MOD_ADD: Prime Field (F_p) Modular Addition (0x10)

- Input:
  — N = modulus
  — Data Size = the number of significant bits in N
  — A = first addend, a field element
  — B = second addend, a field element
- Output: B = (A + B) mod N, a field element
- Requirements:
  — minimum modulus size = 33 bits
  — maximum modulus size = 4096 bits
  — A and B are elements of the prime field and are therefore less than the modulus N

27.6.1.11.18 MOD_RED: Prime Field (Fp) Modulo Reduction (0x12)

- Input:
  — N = any nonzero integer
  — E = any positive integer
- Output:
  — B = E mod N, a field element modulo reduced N
- Requirements:
  — N = nonzero value
  — maximum modulus size = 256 bytes
  — Exact data_size (N) and key_size (E) must be provided

Note: E and N can be of any size, and it is not required that E > N, but N must be non-zero. This routine is mainly provided to support DSA (Digital Signature Algorithm) type algorithms where for example a 1024 bit vector must be reduced with a 160 bit modulus. This routine computes the remainder of E divided by N.

27.6.1.11.19 MOD_SUB: Prime Field (F_p) Modular Subtraction (0x20)

- Input:
  — N = modulus
  — Data Size = the number of significant bits in N
  — A = minuend, a field element
  — B = subtrahend, a field element
- Output:
  — B = (A - B) mod N, a field element
- Requirements:
  — minimum modulus size = 33 bits

— maximum modulus size = 4096 bits
— A and B are elements of the prime field and are therefore less than the modulus N

27.6.1.11.20 MOD_MULT1_MONT: Prime Field (F_p) Montgomery Modular Multiplication (0x30)

- Input:
  — N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  — Data Size = the number of significant bits in N
  — A = multiplicand, a field element in Montgomery format
  — B = multiplier, a field element in Montgomery format
- Output:
  — B = (A x B) mod N, a field element in Montgomery format
  — minimum modulus size = 33 bits
  — maximum modulus size = 4096 bits
  — Inputs A and B are elements of the prime field and are therefore less than the modulus N

27.6.1.11.21 MOD_MULT2_DECONV: Prime Field (F_p) Montgomery Modular Multiplication and Deconvert From Montgomery Format (0x40)

- Input:
  — N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  — Data Size = the number of significant bits in N
  — A = multiplicand, a field element in Montgomery format
  — B = multiplier, a field element in Montgomery format
- Output:
  — B = (A x B) mod N, a field element, non-Montgomery format
- Requirements:
  — minimum modulus size = 33 bits
  — maximum modulus size = 4096 bits
  — Inputs A and B are elements of the prime field and are therefore less than the modulus N

27.6.1.11.22 F2M_ADD: Polynomial Field (F_2m) Modular Addition (0x50)

- Input:
  — N = modulus
  — Data Size = the number of significant bits in N
  — A = First addend, a field element
  — B = Second addend, a field element
- Output:

— B = A ⊕ B where ⊕ represents an exclusive-OR operation

- Requirements:
  - — minimum modulus size = 33 bits
  - — maximum modulus size = 4096 bits
  - — A and B are elements of the polynomial field and therefore have fewer significant bits than the modulus N.

27.6.1.11.23 F2M_MULT1_MONT: Polynomial Field (F_2m) Montgomery Modular Multiplication (0x60)

- Input:
  - — N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - — Data Size = the number of significant bits in N
  - — A = multiplicand, a field element in Montgomery format
  - — B = multiplier, a field element in Montgomery format
- Output: B = (A x B) mod N, a field element in Montgomery format
- Requirements:
  - — minimum modulus size = 33 bits
  - — maximum modulus size = 4096 bits
  - — A and B are elements of the polynomial field and therefore have fewer significant bits than the modulus N.

27.6.1.11.24 F2M_MULT2_DECONV: Polynomial Field (F_2m) Montgomery Modular Multiplication and Deconvert From Montgomery Format (0x70)

- Input:
  - — N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - — Data Size = the number of significant bits in N
  - — A = Multiplicand as a field element in Montgomery format
  - — B = Multiplier as a field element in Montgomery format
- Output: B = A x B mod N, a field element, non-Montgomery format
- Requirements:
  - — minimum modulus size = 33 bits
  - — maximum modulus size = 4096 bits
  - — A and B are elements of the polynomial field and therefore have fewer significant bits than the modulus N.

27.6.1.11.25 RSA_SSTEP: RSA Single Step Modular Exponentiation (0x80)

- Input:
  - — N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)

- Data Size = the number of significant bits in N
- A = a field element
- E = Exponent
- Key Size = the number of significant bytes in E

- Output: B = A^E mod N, a field element
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 4096 bits
  - E > 1
  - maximum key (exponent) size 256 bytes
  - A is an element of the field and is therefore less than the modulus N.

27.6.1.11.26 RSA_SSTEP_TEQ: RSA Single Step Modular Exponentiation with Timing Equalization (0x1e)

- Input:
  - N = modulus, an odd number (If an even number is supplied, the EVM—even modulus error bit in the PKEU Interrupt Status Register is set by the SEC.)
  - Data Size = the number of significant bits in N
  - A = a field element
  - E = Exponent
  - Key Size = the number of significant bytes in E
- Output:
  - B = A^E mod N, a field element
- Requirements:
  - minimum modulus size = 33 bits
  - maximum modulus size = 4096 bits
  - E > 1
  - maximum key (exponent) size 256 bytes

A is an element of the field and is therefore less than the modulus N.

RSA_SSTEP_TEQ performs the same operation as RSA but with an added timing equalization security feature. That is its computation run-time is independent from its exponent content and its is always equal to a maximum value. Also to a large extend its power consumption pattern follows that of an exponent with all ones.

27.6.1.11.27 SPK_BUILD: Build PK Data Structure (0xFF)

This routine must always precede any of eight elliptic curve routines, in order to prepare the data structure required by those routines.

- Input: A0, A1, A2, A3, B0, B1 = parameters required by the elliptic curve routines

- Output: PK_BUILD = B1 • B0 • A3 • A2 • A1 • A0, a structure of 6144 bits (768 bytes), (where • represents a concatenation of memory segments) In PK_BUILD, each segment is right-justified and zero-padded on the left to a total of 1024 bits
- Requirements: maximum size of each parameter = 1023 bits

27.6.2 Data Encryption Standard Execution Unit (DEU)

In typical operation, the DEU is used through channel-controlled access, which means that most reads and writes of DEU registers are directed by the SEC channels. Driver software performs core processor-controlled register accesses only on a few registers for initial configuration and error handling.

The following subsections include general descriptions of the DEU registers and structures. **Section 27.7**, *Programming Model*, on page 27-96 provides a detailed description of each register and associated register fields.

27.6.2.1 DEU Mode Register

The DEU Mode Register contains 3 bits used to program DEU operation. The Mode Register is cleared when the DEU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated.

27.6.2.2 DEU Key Size Register

The key size value indicates the number of bytes of key memory to use in encrypting or decrypting. If the DEU Mode Register is set for single DES, any value other than 8 bytes automatically generates a key size error in the DEU Interrupt Status Register. If the mode bit is set for triple DES, any value other than 16 bytes (112 bits for 2-key triple DES (K1 = K3)) or 24 bytes (168 bits for 3-key triple DES) generates an error. Triple DES always uses K1 to encrypt, K2 to decrypt, K3 to encrypt.

27.6.2.3 DEU Data Size Register

This register stores the number of bits in the final message and has an upper bound of 4096. Whatever number is written (and whatever truncated value is stored) must be a multiple of 64, except if OFB mode is selected. All data processed by the DEU must be a multiple of the DES algorithm block size of 64 bits; the DEU does not automatically pad messages out to 64-bit blocks. If a data size that is not a multiple of 64 bits is written, a data size error is generated. Only bits 7–0 are checked to determine if there is a data size error. Since all upper bits are ignored, the entire message length (in bits) can be written to this register. This register is cleared when the DEU is reset or reinitialized.

27.6.2.4 DEU Reset Control Register

This allows three levels reset of just DEU, as defined by the three self-clearing bits:

27.6.2.5 DEU Status Register

The Status Register contains 6 fields that reflect the state of DEU internal signals. The DEU Status Register is read-only. Writing to this location results in address error being reflected in the DEU Interrupt Status Register.

27.6.2.6 DEU Interrupt Status Register

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the DEU Interrupt Mask Register is zero (see **Section 27.6.2.7**, *DEU Interrupt Mask Register*).

If the DEU Interrupt Status Register is non-zero, the DEU halts and the DEU error interrupt signal is asserted to the controller (see **Section 27.2.2**, *Controller Interrupts*). In addition, if the DEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error then appears in the Channel Pointer Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the DEU Reset Control Register[RI] (see **Section 27.7.9.4**, *AESU Reset Control Register (AESURCR)*, on page 27-239).

27.6.2.7 DEU Interrupt Mask Register

The Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.6.2.6**, *DEU Interrupt Status Register*, on page 27-43), if the corresponding bit in this register is set, then the error is ignored; no bit is set in the DEU Interrupt Status Register, and no error interrupt occurs. If the corresponding bit is not set, then upon detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

27.6.2.8 DEU End_of_Message Register

Writing the end-of-message register is a handshake mechanism indicating the end of incoming data. DESA signals a done interrupt when the input FIFO becomes empty after the End-of-Message is issued. After the final message block is written to the input FIFO, the End_of_Message register must be written. The value in the Data Size Register is used to determine how many bits of the final message block (always 64) to process. Note that the End_of_Message register has no data size, and during the write operation, the core processor data bus is not read. Hence, any data value is accepted. Normally, a write operation with a zero data value is performed. Reading from this register is not meaningful: it always returns a zero value

and does not generate any error. Writing to this register is the trigger that causes the DEU to process the final block of a message, allowing it to issue a done interrupt.

27.6.2.9 DEU IV Register

For CBC mode, the initialization vector is written to and read from the DEU IV register. The value of this register changes as a result of the encryption process and reflects the context of DEU. Reading this memory location while the module is processing data generates an error interrupt.

27.6.2.10 DEU Key Registers

The DEU uses three write-only key registers, K1, K2, and K3, to perform encryption and decryption. In Single DES mode, only K1 is written and the value is simultaneously written to K3, auto-enabling the DEU for 112-bit Triple DES if the Key Size Register indicates 2-key 3DES is to be performed (key size = 16 bytes). To operate in 168-bit Triple DES, K1 must be written first, followed by the write of K2, then K3. Reading any of these memory locations generates an address error interrupt.

27.6.2.11 DEU FIFOs

The DEU uses an input FIFO/output FIFO pair to hold data before and after the encryption process. Normally, the channels control all access to these FIFOs. For core processor-controlled operation, a write to anywhere in the DEU FIFO address space enqueues data to the DEU input FIFO, and a read from anywhere in the DEU FIFO address space dequeues data from the DEU output FIFO.

Writes to the input FIFO go first to a staging register that can be written in byte, 4-byte, or 8-byte units. When all 8 bytes of the staging register are written, the entire 8 bytes is automatically enqueued into the FIFO. If any byte is written twice between enqueues, it causes an error interrupt of type AE from the EU. Since the DEU data length should always be a multiple of 8 bytes, the last write should complete the 8-byte set. However, if there is any partial data set in the staging register when the DEU End_of_Message Register is written, the partial data set is automatically padded with zeros to a full 8 bytes and enqueued to the input FIFO.

The output FIFO is readable in byte, 4-byte, or 8-byte units. When all 8 bytes of the header are read, that 8-byte set is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Overflows and underflow caused by reading or writing the DEU FIFOs are reflected in the DEU Interrupt Status Register.

27.6.3 Advanced Encryption Standard Execution Unit (AESU)

In typical operation, the AESU is used through channel-controlled access, which means that most reads and writes of AESU registers are directed by the SEC channels. Driver software performs core processor-controlled register accesses only on a few registers for initial configuration and error handling.

This EU includes an ICV checking feature, that is, it can generate an integrity check value (ICV) and compare it to another supplied ICV. The pass/fail result of this ICV check can be returned to the core processor either via interrupt by a writeback of EU status fields into core processor memory, but not by both methods at once.

To signal the ICV checking result by status writeback, turn on either the IWSE bit or AWSE bit in the Channel Configuration Register (see **Section 27.7.6.1**, *Channel Configuration Registers for Channels 1–4 (CCR[1–4])*, on page 27-199), and mask the ICE bit in the Interrupt Mask Register (**Section 27.6.3.7**, *AESU Interrupt Mask Register*, on page 27-47). In this case the normal done signalling (by interrupt or writeback) is undisturbed.

To signal the ICV checking result by interrupt, unmask the ICE bit in the Interrupt Mask Register and turn off the IWSE and AWSE bits in the Channel Configuration Register. If there is no ICV mismatch, then the normal done signalling (by interrupt or writeback) occurs. When there is an ICV mismatch, there is an error interrupt generated to the core processor, but no done interrupt or writeback.

The following subsections include general descriptions of the AESU registers and structures. **Section 27.7**, *Programming Model*, on page 27-96 provides a detailed description of each register and associated register fields.

27.6.3.1 AESU Mode Register

The AESU Mode Register contains 7 fields used to program the AESU. The Mode Register is cleared when the AESU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated.

In most networking applications, the decryption of an AES protected packet is performed as a single operation. However, if circumstances require that the decryption of a message be split across multiple descriptors, the AESU allows the user to save the decrypt key and the active AES context to memory for later reuse. This eliminates the internal AESU processing overhead associated with regenerating the decryption key schedule (~12 AESU clock cycles for the first block of data decrypted).

27.6.3.2 AESU Key Size Register

The AESU Key Size Register stores the number of bytes in the key (16, 24, or 32). Any key data beyond the number of bytes in the Key Size Register is ignored. This register is cleared when the

AESU is reset or reinitialized. If you specify a key size other than 16, 24, or 32 bytes, an illegal key size error is generated. If the Key Size Register is modified during processing, a context error is generated.

27.6.3.3 AESU Data Size Register

The AESU Data Size Register stores the number of bits in the final message block. Acceptable sizes vary depending on the AES mode selected. In ECB and CBC modes, the message processed by the AESU must be a multiple of 128 bits; the AESU does not automatically pad messages out to 128-bit blocks. In CCM and CTR modes, data size must be a multiple of 8 bits. In XOR mode the data size must be a multiple of 256 bits (32 bytes). If an improper data size is written, a data size error is generated. Only the lowest 3, 7, or 8 bits of the Data Size Register are checked to determine if there is a data size error. Since all upper bits are ignored, the entire message length (in bits) can be written to this register. This register is cleared when the AESU is reset or reinitialized. Writing to this register signals the AESU to start processing data from the input FIFO as soon as it is available. If the value of data size is modified during processing, a context error is generated.

27.6.3.4 AESU Reset Control Register

This register allows three levels reset of just AESU, as defined by the three self-clearing bits:

27.6.3.5 AESU Status Register

AESU Status Register is a read-only register that reflects the state of six status outputs. Writing to this location result in an address error being reflected in the AESU Interrupt Status Register.

27.6.3.6 AESU Interrupt Status Register

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the AESU Interrupt Mask Register is zero (see **Section 27.6.3.7**, *AESU Interrupt Mask Register*, on page 27-47).

If the AESU Interrupt Status Register is non-zero, the AESU halts and the AESU error interrupt signal is asserted to the controller (see **Section 27.2.2**, *Controller Interrupts*). In addition, if the AESU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error then appears in the Channel Pointer Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the AESU Reset Control Register [RI] bit.

27.6.3.7 AESU Interrupt Mask Register

The AESU Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.7.9.6**, *AESU Interrupt Status Register (AESUISR)*, on page 27-241), if the corresponding bit in this register is set, then the error is ignored; no error interrupt occurs and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

27.6.3.8 AESU End_of_Message Register

The AESU End_of_Message register indicates whether an AES operation is completed. After the final message block is written to the input FIFO, you must write to the End_of_Message register. The value in the Data Size Register is used to determine how many bits of the final message block (always 128) to process. Writing to this register causes the AESU to process the final block of a message, allowing it to signal a done interrupt. A read of this register always return a zero value.

27.6.3.9 AESU Context Registers

There are twelve 64-bit context data registers that allow the core processor to read/write the contents of the context used to process the message. The context must be written prior to the key data. If the Context Registers are written during message processing, a context error is generated. All Context Registers are cleared when a hard/soft reset or initialization is performed. If a message is processed through the AESU in two separate operations (for example, using two descriptors), then the context must be read out of the SEC at the end of the first operation and then restored at the beginning of the second operation.

Not all of the AESU context registers are used in every mode. However, context is always read and restored as a contiguous subset of the twelve context registers ending with the highest numbered register used in that cipher mode. The context registers are summarized by modes in **Table 27-2**, **Table 27-3**, and **Table 27-4**.

Table 27-2 summarizes the context registers used for confidentiality modes only.

Table 27-2. AESU Context Registers for Confidentiality Modes

Context Register (address offset)	Cipher Mode Providing Only Confidentiality			
	CBC/ CBC-RBP/ OFB/ CFB128 (Section 27.6.3.9.1)	CTR (Section 27.6.3.9.2)	SRT (Section 27.6.3.9.3	XTS (Section 27.6.3.9.4)
1 (0xC4100)	IV *		Counter *	I *
2 (0xC4108)				sector size *
3 (0xC4110)	—	—	Counter Modulus *	—
4 (0xC4118)			—	
5 (0xC4120)	—	Counter *	—	—
6 (0xC4128)				

Table 27-2. AESU Context Registers for Confidentiality Modes

Context Register (address offset)	Cipher Mode Providing Only Confidentiality			
	CBC/ CBC-RBP/ OFB/ CFB128 (Section 27.6.3.9.1)	CTR (Section 27.6.3.9.2)	SRT (Section 27.6.3.9.3	XTS (Section 27.6.3.9.4)
7 (0xC4130)	—	Counter Modulus Exponent *	—	—

Notes: **1.** Context Registers 8 through 12 are unused for these modes
2. * = Must be written at start of new message, except if zero.
3. —- = ignored.

Table 27-3 summarizes the different cipher modes that provide data integrity only.

Table 27-3. AESU Context Registers for Integrity Modes

Context Register (address offset)	Cipher Mode Providing Only Data Integrity		
	XCBC-MAC (Section 27.6.3.9.5)	GCM-GHASH (Section 27.6.3.9.6)	CMAC (Section 27.6.3.9.7)
1 (0xC4100)	Computed MAC	Computed MAC	Computed MAC
2 (0xC4108)			
3 (0xC4110)	Received MAC*	—	Received MAC*
4 (0xC4118)

6 (0xC4128)			
7 (0xC4130)	—	$len(AAD)^T$	Key 2
8 (0xC4138)		—	
9 (0xC4140)	—	H	Key 1**
10 (0xC4148)			
11 (0xC4150)	—	$len(AAD)^C$	—

Notes: **1.** Context register 12 is unused for these modes.
2. * Used only in ICV mode. Must be written at start of new message for ICV checking.
3. ^{T} = length of total data (in bits)
4. ** = Output only, not reloaded
5. ^{C} = length of data processed with current descriptor (in bits)
6. — = ignored

Table 27-4 summarizes the context registers used for confidentiality and integrity.

Table 27-4. AESU Context Registers for Modes Providing Confidentiality and Integrity

Context Register (address offset)	Cipher Mode Providing Confidentiality and Integrity	
	CCM (Section 27.6.3.9.8)	GCM (Section 27.6.3.9.9)
1 (0xC4100)	IV* / MAC	Computed MAC
2 (0xC4108)		
3 (0xC4110)	Encrypted MAC** / Decrypted MAC / Encrypted Counter	Received MAC
4 (0xC4118)		
5 (0xC4120)	Counter*	Counter
6 (0xC4128)		
7 (0xC4130)	Counter Modulus Exponent* (header size/ MAC size)***	$len(AAD)^T$
8 (0xC4138)	—	$len(IV)^T$
9 (0xC4140)	—	Y_0
10 (0xC4148)		
11 (0xC4150)	—	$len(AAD)^C$
12 (0xC4158)		$len(IV)^C$

Notes:
1. * = Must be written at start of new message, except if zero
2. ** = Must be written at start of new CCM decryption
3. *** = The Header and MAC Sizes are internally constructed by the AES engine; then, that information is included inside Context Register 7 for context switching purposes
4. ^{C} = length of data processed with current descriptor (in bits)
5. ^{T} = length of total data (in bits)
6. ^{ICV} = Needed only in ICV mode
7. — = Ignored

27.6.3.9.1 Context for CBC, CBC-RBP, OFB, and CFB128 Cipher Modes

Within the Context registers, for use in CBC, CBC-RBP, OFB, and CFB128 cipher modes, are two 64-bit context data registers that allow the core to read/write the contents of the initialization vector (IV):

- Context Register 1 holds the ***least*** significant bytes of the initialization vector (bytes 1–8).
- Context Register 2 holds the ***most*** significant bytes of the initialization vector (bytes 9–16).

The IV must be written prior to the message data. If the IV registers are written during message processing, or the mode is not set, a context error will be generated.

The IV registers may only be read after processing has completed, as indicated by the assertion of DI (done interrupt) in the AESU status register as shown in Section 27.7.9.5, **AESU Status Register (AESUSR)**". If the IV registers are read prior to assertion of Interrupt Done, an early read error will be generated.

27.6.3.9.2 Context for Counter (CTR) Cipher Mode

In counter cipher mode, a random 128-bit initial counter value is incremented modulo 2^M with each block processed. The running counter is encrypted and XORed with the plaintext to derive the ciphertext, or with the ciphertext to recover the plaintext. The modulus exponent M can be set between 8 and 128 in multiples of 8.

There are two options for loading CTR mode context. When using descriptor type 0001_0, AES-CTR context is loaded as shown in **Table 27-2**. The Context_IN length must be set to 56 B, and the context itself must be 32 B of zeroes (context registers 1–4), followed by the initial counter value (context registers 5–6), and finally, the modulus exponent M in context register 7. When using descriptor type 0000_0, 24 B of context can be loaded as shown for SRT, dispensing with the need for the initial zeroes.

27.6.3.9.3 Context for SRT Cipher Mode

As was noted for the AESU Mode Register, SRT is not a new AES cipher mode, it is an AESU method of performing AES-CTR cipher mode with reduced context loading overhead. This mode as originally developed for SRTP, but is also applicable to the use of AES-CTR for LTE EEA2. SRT cipher mode can be used with a descriptor type 0010_0 (SRTP). As with CTR cipher mode, a random 128-bit initial counter value is incremented modulo 2^M with each block processed. The running counter is encrypted and XORed with the plaintext to derive the ciphertext, or with the ciphertext to recover the plaintext. The modulus exponent M can be set between 8 and 128 in multiples of 8.

As shown in **Table 27-2**, in SRT mode, context registers 1–2 hold the initial counter value, and context register 3 holds the modulus exponent M.

Note: There are two methods of performing AES-CTR with reduced context loading. Either use descriptor type 0000_0 with the AES mode register set to CTR, or use descriptor type 0001_0 with the AES mode register set to SRT. These methods are completely equivalent for cipher only operations (no snooping for ICV generation). When performing AES-CTR in conjunction with HMAC-SHA-1, reduced context loading can only be achieved by using SRT.

27.6.3.9.4 Context and Operation for XTS Cipher Mode

IEEE P1619 describes XTS mode as a tweakable block cipher used for encryption of sector-based storage. The key material for XTS consists of a data encryption key (used by the AES block cipher) as well as a tweak key that is used to incorporate the logical position of the data block into the encryption. The key is parsed as a concatenation of two fields of equal size called Key1 and Key2 (16 or 32 bytes each).

A 256-bit or 512-bit key is associated with an ordered sequence of sectors, numbered consecutively. The sequence of sectors that are associated with the key is related to the scope of

that key. In order to encrypt or decrypt a sector, the sequence number of this sector within the scope of the key (I) must be known. Each 16-byte block within the sector has its own sequence number that gives the logical position of the data block inside the sector.

The tweak value (T) is computed based on both the sector number (I) and the 16-byte block number within the sector (j) as

T_0 = aes_encrypt(I, Key2);

T_j = $xtime^j(T_0)$;

The *xtime* function can be described mathematically as follows:

If L(127) = 0, the xtime(l) = L << 1; Else xtime(L) = (L << 1) XOR 0x87;

where L is a 128-bit vector and L[127] is its most significant bit. The irreducible polynomial $f = \alpha^{128} + \alpha^7 + \alpha^2 + \alpha + 1$ is used in the tweak calculation and can be represented as 0x87.

When the last block of the message is not a full 16-byte block, processing of the penultimate and the last block implements a borrowing mechanism whereby bits from the penultimate block ciphertext are appended to the last block plaintext to pad it out to a 16-byte boundary. This is described in detail in **IEEE** Std. P1619.

For sector byte sizes that are divisible by 16, XTS mode also supports processing of multiple sectors per session where the sector sequence number (I) is automatically incremented. When multiple sectors are decrypted, the tweak key (Key2) is expanded once for the initial tweak computation pertaining to the first sector; this expanded value is directly used for other sectors. In case that a message needs to be processed in multiple XTS sessions, message splitting must be on a sector boundary.

XTS cipher mode uses context register 1 for the index (I) and context register 2 for the sector size (see **Table 27-2**).

For core-controlled operation of the AESU in XTS cipher mode, the following steps must be performed:

1. Reset
2. Write the Mode Register to:
   a. Set Cipher Mode to XTS
   b. Specify encryption/decryption
3. Load Key
4. Load I into context register 1 and the sector size in bytes into context register 2. Note that I must be written as big-endian (LSB in the left-most bit positions), while sector size must be in little-endian format.

5. Set Key size
6. Set Data size
7. While available:
   a. Load plaintext (for encryption) or ciphertext (for decryption) blocks
   b. Unload ciphertext (for encryption) or plaintext (for decryption) blocks
8. Write to the End of Message register
9. Unload final ciphertext (for encryption) or plaintext (for decryption) blocks

27.6.3.9.5 Context and Operation for XCBC-MAC Cipher Mode

XCBC-MAC cipher mode is an authentication only mode of AES. Normal CBC-MAC runs AES in CBC cipher mode and assigns the final ciphertext result as the MAC. XCBC-MAC supports only 16-byte keys.

The AESU supports three mode options while operating in XCBC-MAC cipher mode. These options are controlled by the AUX bits in the AESU Mode Register. The encrypt/decrypt bit has no meaning in an XCBC-MAC operation and is ignored by the AESU. The AUX bits are as follows:

- *AUX0*. Controls whether the XCBC-MAC is completed with this descriptor, or whether this descriptor is only doing a portion of the total MAC generation, and context needs to be output so that it can be reloaded for subsequent operations.
- *AUX1*. Controls whether K1, K2, and K3 are initialized at the start of the descriptor, or whether previously initialized keys are reloaded.
- *AUX2*. Controls whether the AESU performs automatic checking of a received MAC against the newly calculated MAC.

For a descriptor that generates an XCBC-MAC over a full message, program AUX0 = 0, AUX1 = 0, and AUX2 = 0. The descriptor key length is loaded into the AESU Key Size Register, and the key itself is loaded into the AESU Key Registers IU and IL. The generated MAC is held in the AESU Context Registers 1 and 2 and output according to the ICV Output length and pointer in the descriptor.

For a descriptor that generates an XCBC-MAC over a full message and compares the calculated MAC with the MAC received with the message, program AUX0 = 0, AUX1 = 0, and AUX2 = 1. The descriptor key length is loaded into the AESU Key Size Register, and the key itself is loaded into the AESU Key Registers IU and IL. The generated MAC is held in AESU Context Registers 1 and 2 and is compared to the received MAC that the channel loads into AESU Context Registers 3 and 4 using the Extent field in the descriptor. Success or failure of the MAC comparison can be reported by an interrupt or through the ICCR1 bits in the modified descriptor header, if header writeback is enabled.

Sometimes a message cannot be processed by a single descriptor. All the data might not be present, or the message might be larger than a single XCBC-MAC descriptor can process (>64KB-1). In either case, this situation can be handled through combinations of AUX mode bits.

For the first descriptor that processes the initial portion of the message, program AUX0 = 1, AUX1 = 0, and AUX2 = 0. The descriptor key length is loaded into the AESU Key Size Register and the key itself is loaded into the AESU Key Registers 1U and 1L. The AESU generates K3, K2, and K1 and stores them, respectively, in AESU Context Registers 5-6, 7-8, and 9-10. When the first descriptor has consumed all of its message data, it outputs the contents of Context Registers 1–10 using the Context Out length (80B) and pointer.

There can be an unlimited number of intermediate descriptors that are neither the first nor last descriptor. Intermediate descriptors program AUX0 = 1, AUX1 = 1, and AUX2 = 0. The descriptor key length is set to 16B and the key pointer is set to the address of Key 1 (Context Registers 9–10) from the previous descriptor. This loads Key 1 into AESU Key Size Registers 1U and 1L. The descriptor Context In length is set to 64B, and the pointer is set to the address of Context Registers 1–8 from the previous descriptor.

When an intermediate descriptor has consumed all of its message data, it outputs the contents of Context Regs 1–10 using the Context Out length (80B) and pointer.

For the last descriptor that processes the final portion of the message, program AUX0 = 0, AUX1 = 1, and AUX2 = 0. The descriptor's key length is set to 16B and the key pointer is set to the address of Key 1 (Context Registers 9–10) from the previous descriptor. This loads Key 1 into AESU Key Size Registers 1U and 1L. The descriptor Context In length is set to 64B, and the pointer is set to the address of Context Registers 1–8 from the previous descriptor.

When the last descriptor has consumed all its message data, the generated MAC is held in AESU Context Regs 1–2 and output according to the ICV Out length and pointer in the descriptor. To compare the calculated MAC with the MAC received with the message, program AUX2 = 1 on the final descriptor. The generated MAC is held in AESU Context Regs 1–2, and is compared to the received MAC, which is input using the Extent field in the descriptor. The channel overwrites the context reload values in Context Regs 3–4 with the real received MAC.

27.6.3.9.6 Context and Operation for GCM-GHAS Cipher Mode

GCM-GHAH denotes the authentication part of GCM cipher mode and is described in **Section 27.6.3.9.9**, *Context and Operation for GCM Cipher Mode*, on page 27-58.

27.6.3.9.7 Context and Operation for CMAC (OMAC1) Cipher Mode

CMAC cipher mode is an authentication only mode of AES. CMAC can be specified using the following notation:

- E(K,L) denotes the AES-encrypt function;
- xtime(L) is defined as follows, where L is a 128-bit vector with L[127] as most significant bit:
  - If L[127]=0, then xtime(L)=L<<1 (where '<<' denotes bitwise left shift)
  - Else xtime(L) = (L<<1) XOR 0x87.

The AESU supports three mode options while operating in CMAC mode. These options are controlled by the AUX bits in the AESU Mode Register. The encrypt/decrypt bit has no meaning in a CMAC operation and is ignored by the AESU.

- *AUX0*. Controls whether the CMAC is completed with this descriptor or whether this descriptor is only doing a portion of the total MAC generation, and context needs to be output so that it can be reloaded for subsequent operations.
- *AUX1*. Controls whether K1 and K2 are initialized at the start of the descriptor or whether previously initialized keys are reloaded.
- *AUX2*. Controls whether the AESU must perform automatic checking of a received MAC against the newly calculated MAC.

For a descriptor that generates a CMAC over a full message, program AUX0 = 0, AUX1 = 0, and AUX2 = 0. The descriptor key length is loaded into the AESU Key Size Register, and the key itself is loaded into the AESU Key Registers. The generated MAC is held in AESU Context Registers 1–2, and output according to the ICV Out length and pointer in the descriptor.

Note: For some uses of CMAC, the message data itself can be modified to include packet specific context in the CMAC generation process. For instance, when using AES-CMAC for the LTE EIA2 algorithm, a 64b IV-like value is prepended to the PDCP header prior to calculating the MAC. The 64b value consists of COUNT (32b)||Bearer (5b)|| Direction (1b) || Zeroes (26b).

For a descriptor that generates a CMAC over a full message and compares the calculated MAC with the MAC received with the message, program AUX0 = 0, AUX1 = 0, and AUX2 = 1. The descriptor key length is loaded into the AESU Key Size Register, and the key itself is loaded into the AESU Key Registers. The generated CMAC is held in AESU Context Registers 1–2, and is compared to the received CMAC, which the channel loads into AESU Context Registers 3–4 using the Extent field in the descriptor. Success or failure of the MAC comparison can be reported by an interrupt or through the ICCR1 bits in the modified descriptor header if header writeback is enabled.

Sometimes a message cannot be processed by a single descriptor. All the data might not be present, or the message might be larger than a single CMAC descriptor can process (>64KB – 1). In either case, this situation can be handled through combinations of AUX mode bits.

For the first descriptor that processes the initial portion of the message, program AUX0 = 1, AUX1 = 0, and AUX2 = 0. The descriptor key length is loaded into the AESU Key Size Register, and the key itself is loaded into the AESU Key Registers. The AESU internally generates CMAC context and stores it respectively in AESU Context Registers 5–6. When the first descriptor has consumed all of its message data, it outputs the contents of Context Registers 1–6 using the Context Out length (48B) and pointer.

There can be an unlimited number of intermediate descriptors that are neither the first nor last descriptor. Intermediate descriptors program AUX0 = 1, AUX1 = 1, and AUX2 = 0. The descriptor key length is set to 0. The descriptor Context In length is set to 48B and the pointer is set to the address of Context Registers 1–6 from the previous descriptor.

When an intermediate descriptor has consumed all of its message data, it outputs the contents of Context Registers 1–6 using the Context Out length (48B) and pointer.

For the last descriptor that processes the final portion of the message, program AUX0 = 0, AUX1 = 1, and AUX2 = 0. The descriptor key length is set to 0. The descriptor Context In length is set to 48B, and the pointer is set to the address of Context Registers 1–6 from the previous descriptor.

When the last descriptor has consumed all of its message data, the generated CMAC is held in AESU Context Registers 1–2 and output according to the ICV Out length and pointer in the descriptor. To compare the calculated MAC with the MAC received with the message, program AUX2 = 1 on the final descriptor. The generated CMAC is held in AESU Context Regs 1–2, and is compared to the received CMAC, which is input using the Extent field in the descriptor. The channel overwrites the context reload values in Context Regs 3–4 with the real received MAC.

27.6.3.9.8 Context for CCM Cipher Mode

The SEC AESU can performing single pass encryption and MAC generation. The core processor is required to arrange the CCM context so that the context can be fetched as a contiguous string into the Context Registers prior to encryption/MAC generation or decryption/MAC validation. The Context Register contents for CCM mode is summarized in **Figure 27-6**.

		Context Registers						
		1	2	3	4	5	6	7
Encrypt (outbound)	Inputs	IV		0		Initial Counter		Counter Modulus Exponent
	Outputs	MAC	0	MIC	0			
Decrypt (inbound)	Inputs	IV		MIC	0	Initial Counter		Counter Modulus Exponent
	Outputs	Computed MAC	0	Decrypted MAC	0			

Figure 27-6. AESU CCM Context Registers

Note: AES-CCM mode does not support zero length AAD and zero length payload simultaneously. Either AAD length or payload length must be greater than zero.

The context for CCM encryption/MAC generation is:

- Reg 1–2 are session specific and hold the 128-bit Initialization Vector (from memory)
- Reg 3–4 contains 128 bits of zero padding
- Reg 5–6 are a session specific counter (Initial Counter Value) (from memory)
- Reg 7 has the Counter Modulus Exponent (msb to lsb). Should be fixed at 0x0000_0080.

Note: The counter modulus for CCM mode is currently defined as 2^{128} making the exponent 128. This value is made programmable in the SEC in case the final version of 802.11i uses a different counter modulus. Because this is a programmable field, it must be generated and stored along with other session specific information for loading into the AESU Context Register prior to CCM encryption.

- *CCM Encryption Processing*. With the session specific key and context, the AESU performs the following operations.

1. Initialize the IV, and encrypt with the symmetric key.
2. In CBC fashion, take the output of step 1, hash with the first block of plaintext, and encrypt with the symmetric key.
3. Continue as in step 2 until the final block of plaintext is processed. The result of the encryption of the final block of plaintext with the symmetric key is the MAC Tag. The

full 128bits of MAC data is written to Context Registers 1-2, for use in the next phase of CCM processing.

4. Once the MAC Tag is generated (step 3), the MAC tag, along with the plaintext is encrypted with the AESU operating in Counter mode.
5. The first item to be encrypted in Counter Mode is the counter (Initial Counter Value) from Context Registers 5–6. The counter is encrypted with the symmetric key, and the result is hashed with the MAC Tag (retrieved from Context Registers 1–2) to produce the MIC (encrypted MAC), which is then stored in Context Registers 3-4. At the completion of CCM encrypt processing, this MIC is output to memory (per the descriptor pointer) for the core processor to append to the **IEEE** 802.11i standard frame. Note: The MIC written out to memory by the AESU is the full 128 bits. The core processor must only append the most significant 64 bits to the frame as the MIC.
6. The counter value is incremented, and is then encrypted with the symmetric key. The result is then hashed with the first block of plaintext to produce the first block of cipher text. The ciphertext is placed in the AESU output FIFO.
7. The counter continues to be incremented, and encrypted with the symmetric key, with the result hashed with each successive block of plaintext, until all plaintext is converted to ciphertext. The SEC controller manages FIFO reads and writes, fetching plaintext and writing ciphertext per the pointers provided in the descriptor. When all ciphertext and the MIC is output, the CCM encrypt operation is complete.

- *CCM Decryption Processing*. The context for CCM decryption/MAC generation is:
  - Reg 1–2 is session specific and holds the 128 bit Initialization Vector (from memory)
  - Reg 3–4 holds the MIC (from the received frame) + 64 bits of zero padding
  - Reg 5–6 is a session specific counter (Initial Counter Value) (from memory)
  - Reg 7 holds the Counter Modulus Exponent (msb to lsb). Should be fixed at 0x0000_0080.

Note: The counter modulus for CCM mode is currently defined as 2^128, making the exponent 128. This value is made programmable in the SEC to in case the final version of 802.11i uses a different counter modulus. Because this is a programmable field, it must be generated and stored along with other session specific information for loading into the AESU Context Register prior to CCM decryption.

CCM decryption processing is the reverse of encryption. With the session specific key and context, the AESU performs the following operations.

1. Initializes the IV, and encrypts with the symmetric key. Simultaneously, the counter (Initial Counter Value) from Context Registers 5–6 is encrypted with the symmetric key. The result is hashed with the Encrypted MAC (from Context Register 3–4), and the

resulting Original MAC is written to Context Registers 3–4, overwriting the encrypted MAC.

Note: Strictly speaking, the Counter is encrypted with the symmetric key, however the AESU should be set for decrypt to perform the counter and CBC processes in the correct order.

2. The **IEEE** Std. 802.11 frame header is hashed with the encrypted IV. (The AESU automatically determines the header length.) Simultaneously, the counter is incremented, and is then encrypted with the symmetric key. The result is then hashed with the first block of ciphertext to produce the first block of plaintext. The plaintext is placed in the AESU output FIFO, while simultaneously, in CBC fashion, a copy of the first block of plaintext is hashed with the output of encryption of the **IEEE** Std. 802.11 frame header. The output is encrypted with the symmetric key.
3. As each ciphertext block is converted to plaintext, the plaintext is CBC encrypted. When the final plaintext block is processed, the CBC MAC (MAC Tag) is written to Context Registers 1–2. The first 64 bits of the MAC Tag are compared to the MAC Tag recovered in step 1.

Note: For both encrypt and decrypt operations, if the **IEEE** 802.11 frame is being processed as a whole (not split across multiple descriptors), the Initialize and Final MAC bits should be set in the AESU Mode Register.

27.6.3.9.9 Context and Operation for GCM Cipher Mode

Galois Counter Mode (GCM) uses AES Counter mode to achieve data confidentiality. Authentication is achieved by computing a GHASH Message Authentication Code (GMAC) through performing repetitive multiplication-accumulate functions in a Galois Field.

Normally, the IV (which is provided through the input FIFO) is 96 bits. If it is 96 bits, then the IV is padded with the value $(\{0\}^{31}1)$, where $(0)^{31}1$ is defined as a string of 31 bits of 0 followed by a single bit of 1. Otherwise, the IV is hashed using the GHASH (H, {}, IV) function, where H is defined as $E(\{0\}^{128}, K)$, E stands for encryption operation, and K represents the key used. The resulting value Y_0 (the padded IV or the GHASHed IV) is provided as the counter input to Counter Mode AES. The result of encrypting Y_0 is called $E(Y_0, K)$, and is used to generate the final MAC tag.

Data is encrypted or decrypted by XORing input data with the Pseudorandom Key Stream generated by Counter Mode AES, starting with the second PRK block. Initial counter value Y_0 is incremented modulo 2^{32}.

GCM cipher mode can be used to perform only the authentication part (GHASH (H, AAD, ciphertext)). To do this, set AUX0 and specify encryption operation. This special sub-mode is called GCM-GHASH in this document. The format of the context registers for GCM-GHASH mode is shown in **Table 27-10** on page 27-65. GCM cipher mode also has option of

automatically verifying that the received and computed MAC tags are identical. This cipher mode is called GCM w/ICV and can be specified by setting Mode Register bits 56, 57 and 62 to 1, and bit 61 to 0. GCM w/ICV context format is shown in **Table 27-9** on page 27-64.

Messages (IV+AAD+textdata) are fed in through the input FIFO, and are always processed in the following order: IV, AAD, textdata, followed by the final MAC computation (where “textdata” refers to plaintext or ciphertext to be operated on). The whole message, however, does not have to be processed in one GCM execution. It can be split and processed in multiple GCM runs separated by resets of the AESU block that is, in multiple descriptors. The boundaries can be set at the end of any full block (16 bytes) of the stream IV+AAD+textdata. Hence, any of the individual components (IV, AAD, or textdata) can be split into multiple descriptors. Refer to 27-5 for proper AUX mode specification in this case and to **Table 27-7** through **Table 27-10** for proper context formatting. It should be noted that in case of a late arrival of the MAC tag on the receiving side, the final MAC can be computed and verified against the received MAC in a separate descriptor after the rest of the message (IV+AAD+textdata) has already been processed.

For core-controlled operation of the AESU in GCM cipher mode, perform the following steps:

1. Reset.
2. Set Cipher Mode to GCM or GCM w/ICV and specify encrypt, decrypt in the Mode Register. To perform GCM-GHASH (only GHASH (H, AAD, ciphertext) is computed) set AUX0 and specify encrypt. Set AUX2 and AUX1 bits according to 27-5.
3. Load Key.
4. Load (Restore) Context as needed (see 27-7 to 27-10).
5. Set Key size.
6. Set the size of the computed/received MAC (8, 12 or 16 bytes, default is 16).
7. Set Data size.
8. While available:
   a. Load IV into the input FIFO (1 or multiple blocks up to 2^{64} bits in total).
   b. Load AAD into the input FIFO (0 or multiple blocks up to 2^{64} bits in total).
   c. Load plaintext (for encryption) or ciphertext (for decryption) blocks into the input FIFO.
   d. Unload ciphertext (for encryption) or plaintext (for decryption) blocks from the output FIFO.
9. Write to the End of Message register.
10. Unload final ciphertext (for encryption) or plaintext (for decryption) blocks.
11. Read (Save) context registers if another segment of the message will be processed later.
12. Read final GCM MAC from Context Registers 1–2, if AUX2 bit was set in Mode Register.
13. For GCM w/ICV, check ICCR bits in the AESU Status Register.

Table 27-5. GCM Cipher Mode Auxiliary Bit Definitions

Auxiliary Bit	Definitions	
	0	1
AUX2 (bit 58)	Do not compute MAC	Compute MAC
AUX1 (bit 59)	One of the following cases: • Descriptor contains the whole message (IV+AAD+textdata) • Descriptor contains the whole IV and no or part of AAD or textdata • Descriptor contains a non-final part of IV, AAD, textdata (IV, AAD or textdata split between descriptors) • Descriptor contains the final part of AAD or textdata but no MAC is computed	One of the following cases: • Descriptor contains the final part of IV (IV split between descriptors) - $len(IV)^T$ needed • Descriptor contains the final part of textdata and the final MAC is computed, that is, AUX2=1 (textdata split between descriptors) - $len(AAD)^T$, $len(textdata)^T$ needed • Descriptor contains the whole textdata but no or part of AAD and the final MAC is computed - $len(AAD)^T$, $len(textdata)^T$ needed • Descriptor contains the final part of AAD and the final MAC is computed - $len(AAD)^T$, $len(textdata)^T$ needed • Descriptor computes only MAC (based on restored context) but does not contain either IV, AAD or textdata – $len(AAD)^T$, $len(textdata)^T$ needed
AUX0 (bit 60) and Encrypt	—	GHASH-only mode
AUX0 (bit 60) and Decrypt	The key is to be unrolled	The key is already unrolled

AUX0 has different use depending on whether encryption or decryption is specified. For decryption, it determines whether the provided key should be first unrolled before processing starts, while in case of encryption it should generally be set to 0 unless GCM-GHASH cipher mode is desired. AUX2 bit determines whether the final MAC tag is to be computed or not. If AUX2 is set to 1, $E(K, Y_0)$ and the last iteration of the GHASH(H, AAD, ciphertext) is going to be performed and then XORed to give the MAC tag. Hence, if the message is split into multiple descriptors, only the last one should have AUX2=1 for proper MAC tag computation. AUX1 is used to resolve the issues related to the splitting of messages into multiple descriptors. **Table 27-5** shows the proper settings of AUX1 for several scenarios of message splitting. In general, whenever the final GHASH iteration needs to be computed (either for GHASH(H, {}, IV) or GHASH(H, AAD, ciphertext)), and the current length is not equal to total length for either IV, AAD, or textdata, AUX1 should be set to 1. Consequently, an AUX1 value of 1 also indicates that the context registers 9–10 need to provide the total length of IV, AAD, or textdata for this to be accomplished. **Table 27-6** describes how the context registers are used for GCM processing.

Table 27-6. Description of Context Register for GCM Processing

Registers	Description
1–2	Intermediate MAC value. This needs to be provided only when switching context during AAD and/or textdata processing (AAD+textdata stream split into multiple descriptors). On the output side, these registers contain either intermediate MAC tag in case of context switching (requires AUX2=0) or the final MAC tag at the end of processing if AUX2=1. If AUX2=0 on the last descriptor processing a particular message, these registers will contain partially computed GHASH(H, AAD, ciphertext) where the last GHASH iteration is not computed. In case of GCM w/ICV, the final MAC tag written here as the result of GCM processing will be truncated to 8, 12, or 16 (no truncation) bytes as defined in ICV Size register. Note, that any size from 1 to 16 bytes can be specified in ICV Size register but any value other than 8 or 12 will be defaulted to 16 bytes automatically.
3–4	Received MAC tag used only in case of inbound processing with GCM w/ICV. This can be a 8, 12 or 16-byte block as specified by writing to the ICV Size register.
5–6	Counter value Y_i is required only if restoring context to continue processing a message. Note that the same value read when saving context should be written to these registers when restoring context since it is automatically incremented after every processed block. In case of GCM-GHASH, these registers are not used.
7	Total length of AAD in bits. This is the total AAD length irrespective of whether AAD is split in multiple descriptors. It is required when AUX1=1 and the current descriptor processes the last segment of AAD or textdata. It is also required if the whole message is already processed and the current descriptor only computes the final MAC tag.
8	Total length of the plaintext/ciphertext or IV in bits. Required only when AUX1=1 (see 27-5). If the current descriptor processes the last segment of the IV then total IV length should be provided, otherwise total length of textdata should be provided.
9–10	Initial counter value Y_0. Normally, this value is a result of the IV stream processing and needs to be provided only if the message is split into multiple descriptors and for those descriptors that come after IV processing is complete. Otherwise, value provided here is ignored and overwritten with computed Y_0. In case of GCM-GHASH cipher mode setting, constant H from GHASH(H, AAD, ciphertext) should be provided in these registers. Note that this, in the general case, does not have to be equal to E(K, $\{0\}^{128}$) where K is a key as defined for GCM.
11	Length of AAD in bits. This pertains to the length of the AAD part processed in the current descriptor. If the current descriptor does not process AAD, 0 should be written. If AAD is not split into multiple descriptors, this field should contain the total AAD length. The value written here should be divisible by 128 for all AAD segments except for the last one that can be any number of bits. Note, however, that the actual AAD stream supplied to the AES engine through FIFOs has to be zero-padded to an integral number of 16-byte blocks.
12	Length of IV in bits or a part of it processed in the current descriptor. Similar remarks apply like in the case of AAD. This register is not used for GCM-GHASH.

Table 27-7 to **Table 27-10** describe the proper usage of context registers in case of encryption, decryption, GCM w/ICV and GCM-GHASH cipher mode settings. The context is in each case described in terms of the input context required for starting new GCM processing or continuation of processing after context switch, and in terms of the results (output) stored in context registers after GCM execution run is completed.

Table 27-7. GCM Encryption Context

Context Register	GCM Encrypt (outbound)				
	Mode Register (ECM = 10, AUX0 = 0, CM = 01, ED = 1)				
	AUX1 Value			AUX2 Value	
	Inputs			Outputs	
	AUX1 = 0	AUX1 = 1		AUX2 = 0	AUX2 = 1
		last AAD or textdata segment, or MAC only	last IV segment		
1	MAC (Computed)			—	MAC (Computed)
2					
3	—			—	
4					
5	Y_i (Counter)				
6					
7	—	len(AAD)^{T*}	—		
8	—	len(textdata)^{T*}	len(IV)^{T}		
9	Y_0 (Initial Counter)				
10					
11	len(AAD)^{C*}				
12	len(IV)^{C*}				

Notes:
1. * = Must be written at the start of a new message, except if zero
2. ^{C} = length of data processed with current descriptor (in bits)
3. ^{T} = length of total data (in bits)
4. — = ignored

2. ^{C} = length of data processed with current descriptor (in bits)
3. ^{T} = length of total data (in bits)
4. — = don't care

As an example, lets consider the case of GCM encrypt operation that generates the final MAC tag and where the whole message is small enough that it can be processed with one descriptor. The mode bits should be configured as ECM = 10, AUX[2–0] =100, CM = 01, and ED = 1. Only context registers 11–12 need to be written with the bit lengths of AAD and IV, respectively. The bit length of textdata should be written to the data size register up to the size of 2^{19} bits. IV, AAD, and textdata in that order should be sent through the input FIFO and the result (textdata) read from the output FIFO as available. At the end, the final MAC tag is read from the context registers 1–2.

27.6.3.10 AESU Key Registers

The AESU key registers hold from 16, 24, or 32 bytes of key data, with the first 8 bytes of key data written to key 1U. Any key data written to bytes beyond the value written to the Key Size Register is ignored. The Key Data Registers are cleared when the AESU is reset or reinitialized. If these registers are modified during message processing, a context error is generated.

27.6.3.11 AESU FIFOs

AESU uses an input FIFO/output FIFO pair to hold data before and after the encryption process. Normally, the channels control all access to these FIFOs. For core processor-controlled operation, a write to anywhere in the AESU FIFO address space enqueues data to the AESU input FIFO, and a read from anywhere in the AESU FIFO address space dequeues data from the AESU output FIFO.

Writes to the input FIFO go first to a staging register which can be written by byte, 4-byte, or 8-byte accesses. When all 8 bytes of the staging register are written, the entire 8 bytes is automatically enqueued into the FIFO. If any byte is written twice between enqueues, it causes an error interrupt of type AE from the EU. When writing the last portion of data, it is not necessary to write all 8 bytes. Any last bytes remaining in the staging register are automatically padded with zeros and forced into the input FIFO when the AESU End_of_message register is written.

The output FIFO is readable by byte, 4-byte, or 8-byte accesses. When all 8 bytes of the header are read, that 8 bytes is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Overflows and underflows caused by reading or writing the AESU FIFOs are reflected in the AESU Interrupt Status Register.

The AESU fetches data 128 bits at a time from the input FIFO. During processing, the input data is encrypted or decrypted with the key and initialization vector (CBC mode only) and the results are placed in the output FIFO. The output size is the same as the input size.

The input FIFO can be written any time the number of 8-byte sets currently in the input FIFO (as indicated by the IFL field of the AESU Status Register) is less than 32. There is no limit on the total number of bytes in a message. The number of bits in the final message block must be set in the Data Size Register.

The output FIFO can be read any time the OFR signal is asserted (as indicated in the AESU Status Register). This indicates that the number of bytes in the output FIFO is at or above the threshold specified in the Mode Register.

For AES-CCM mode, the input data stream to the input FIFO consists of the CCM Header, followed by the Additional Authenticated Data (AAD), followed by Plaintext if encrypting, or

Ciphertext if decrypting. This mode does not support zero length AAD and zero length payload. Note that AESU only supports 2 byte CCM headers and does not support extended CCM headers.

27.6.4 Message Digest Execution Unit (MDEU)

The MDEU computes a single message digest (or hash or integrity check) value of all the data presented on the input bus, using the MD5, SHA-1, SHA-224, SHA-256, SHA-384, and SHA-512 algorithms for bulk data hashing.

With any hash algorithm, the larger message is mapped onto a smaller output digest, so it is possible for two messages to produce the same digest. The hash digest lengths (128 bits or more) are sufficiently large, however, that such collisions are extremely rare. The security of the hash function is based on the difficulty of locating collisions. That is, it is computationally unfeasible to construct two distinct but similar messages that produce the same hash output. The MDEU is designed to support the following cryptographic algorithms:

- The MD5 generates a 128-bit hash, and the algorithm is specified in RFC 1321.
- SHA-1 is a 160-bit hash function, specified by the NIST FIPS 180-1 standard.
- SHA-224 is a 224-bit hash function, specified by the NIST FIPS 180-2 standard.
- SHA-256 is a 256-bit hash function that provides 256 bits of security against collision attacks, specified by the NIST FIPS 180-2 standard.
- SHA-384 is a 384-bit hash function, specified by the NIST FIPS 180-2 standard.
- SHA-512 is a 512-bit hash function, specified by the NIST FIPS 180-2 standard.
- The MDEU also supports HMAC computations, as specified by the NIST FIPS-198 standard.

If a digest is supplied to the MDEU, it can do a bitwise check of this supplied digest against the one computed by the MDEU (ICV checking). In a typical operation, the MDEU is used through channel-controlled access, which means that most reads and writes of MDEU registers are directed by the SEC channels. Driver software performs core processor-controlled register accesses only on a few registers for initial configuration and error handling.

The following subsections include a description of ICV checking functionality and general descriptions of the MDEU registers and structures. **Section 27.7**, *Programming Model*, on page 27-96 provides a detailed description of each register and associated register fields.

27.6.4.1 ICV Checking

This EU includes an ICV checking feature, that is, it can generate an ICV and compare it to another supplied ICV. The pass/fail result of this ICV check can be returned to the core processor either via interrupt by a writeback of EU status fields into core processor memory, but not by both methods at once.

To signal the ICV checking result by status writeback, turn on either the IWSE bit or AWSE bit in the Channel Configuration Register (see **Section 27.7.6.1**, *Channel Configuration Registers for Channels 1–4 (CCR[1–4])*, on page 27-199), and mask the ICE bit in the Interrupt Mask Register (**Section 27.6.4.8**, *MDEU Interrupt Mask Register*, on page 27-71). In this case the normal done signalling (by interrupt or writeback) is undisturbed.

To signal the ICV checking result by interrupt, unmask the ICE bit in the Interrupt Mask Register and turn off the IWSE and AWSE bits in the Channel Configuration Register. If there is no ICV mismatch, then the normal done signalling (by interrupt or writeback) occurs. When there is an ICV mismatch, there is an error interrupt to the core processor, but no done interrupt or writeback.

27.6.4.2 MDEU Mode Register

The MDEU Mode Register is used to program the function of the MDEU. For normal operation through a channel, the least significant byte of this register is specified through the MODE0 or MODE1 field of the descriptor header. The remaining bits are supplied by the channel and thus are not under direct user control.

The MDEU Mode Register has two bits used to define the register configurations:

- *MDEU_B bit.* Determines which of two sets of algorithms are available through the ALG bits. The two sets of algorithms are:
  - MDEU-A set (MD5, SHA-1, SHA-224, and SHA-256) selected when MDEU_B = 0.
  - MDEU-B set (SHA-224, SHA-256, SHA-384, and SHA-512) selected when MDEU_B = 1

  In channel-controlled operation, the channel supplies the MDEU_B mode bit value based on the EU_SEL field of the descriptor header:
  - MDEU-A is selected if EU_SEL = 0b0011.
  - MDEU-B is selected if EU_SEL = 0b1011

  See **Section 27.7.1.2**, *Descriptor Header*, on page 27-102 for details.
- *NEW bit*. Determines the configuration of the other mode register fields (see **Section 27.7.10.1**, *MDEU Mode Register (MDEUMR)*, on page 27-252 for alternate register fields). The new configuration (NEW=1) is used only by TLS/SSL descriptor types (1000_1, 1001_1). The old configuration (NEW=0) is used by all other descriptor types and is the almost the same as defined in the SEC 2.0 specification, except for the CICV and SMAC bits. When MDEU is configured by the Polychannel, the value of NEW is determined by the descriptor type field of the descriptor header. If the descriptor type field indicates an SSL/TLS type descriptor, the Polychannel sets the NEW bit; otherwise NEW is cleared.

The Mode Register is cleared when the MDEU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated.

The most common task likely to be executed via the MDEU is HMAC generation. HMACs are used to provide message integrity within a number of security protocols, including IPSec, and TLS. The SSL 3.0 protocol uses a slightly different SSL-MAC. If an HMAC or SSL-MAC is to be performed using a single descriptor (with the MDEU acting as sole or secondary EU), use the Mode Register bit settings listed in **Table 27-11**

Table 27-11. Mode Register—HMAC or SSL-MAC Generated by Single Descriptor

Bits	Field	Value	
		for HMAC	for SSL-MAC
56	CONT	0 (off)	0 (off)
58	SMAC	0(on)	1(on)
59	INIT	1(on)	1(on)
60	HMAC	1(on)	0(on)

To generate an HMAC for a message that is spread across a sequence of descriptors, use the Mode Register bit settings listed in **Table 27-12**.

Table 27-12. Mode Register—HMAC Generated Across a Sequence of Descriptors

Bits	Field	Value		
		First Descriptor	Middle Descriptor(s)	Final Descriptor
56	CONT	1 (on)	1 (on)	0 (off)
59	INIT	1 (on)	0 (off)	0 (off)
60	HMAC	1 (on)	0 (off)	1 (on)

All descriptors other than the final descriptor must output the intermediate message digest for the next descriptor to reload as MDEU context. SSL-MAC operations cannot be spread across a sequence of descriptors. Additional information on descriptors can be found in **Section 27.7.1.1**, *Descriptor Structure*, on page 27-100.

27.6.4.3 MDEU Key Size Register

The MDEU key size value indicates the number of bytes of key memory that should be used in HMAC generation. MDEU supports at one key block. MDEU generates a key size error if the value written to this register exceeds 64 bytes for MD5, SHA-1, SHA-224, or SHA-256, or if the value exceeds 128 bytes for SHA-384 or SHA-512.

27.6.4.4 MDEU Data Size Register

The MDEU Data Size Register indicates the number of bits of data to be processed. The Data Size field is a 21-bit signed number. Values written to this register are added to the current

register value. Multiple writes are allowed. The MDEU processes data when there is a positive value in this register and there is data available in the MDEU input FIFO. (Negative values can arise in inbound processing, when it is necessary to hold back data from the MDEU until the pad length is decrypted.). Because the MDEU does not support bit offsets, the least significant 3 bits must be written as 0 and are always read as zero. Furthermore, when the CONT bit of the MDEU Mode Register is high, the data size must be a multiple of the block size (that is, 512 bits for MD5, SHA-1, SHA-224, and SHA-256; 1024 bits for SHA-384 and SHA-512). Violating either of these conditions causes a data size error (the MDEUIDR[DSE] bit is set).

This register is cleared when the MDEU is reset or reinitialized. At the end of processing, its contents is decremented down to zero (unless there is an error interrupt).

Note: Writing to the Data Size Register allows the MDEU to enter auto-start mode. Therefore, the required Context Registers must be written prior to writing the data size.

27.6.4.5 MDEU Reset Control Register

This register allows three levels of reset just for the MDEU, as defined by the three self-clearing bits.

27.6.4.6 MDEU Status Register

This Status Register reflects the state of the MDEU internal signals. The majority of these internal signals reflect the state of low-level MDEU functions, such as data padding, key padding, and so forth, and are not important to the user, however the user should be aware that reads of this register, especially during processing, are likely to return non-zero values for many of the most significant bits. The four least-significant bit fields are most likely to be of interest to the user.

The MDEU Status Register is read-only. Writing to this location result in an address error being reflected in the MDEU Interrupt Status Register.

27.6.4.7 MDEU Interrupt Status Register

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the MDEU Interrupt Mask Register is zero (see **Section 27.7.10.7**, *MDEU Interrupt Mask Register (MDEUIMR)*, on page 27-260).

If the MDEU Interrupt Status Register is non-zero, the MDEU halts and the MDEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189). In addition, if the MDEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Pointer Register (see **Section 27.7.6.2**, *Channel*

Status Registers (CSR[1–4]), on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit in the MDEU Reset Control Register.

27.6.4.8 MDEU Interrupt Mask Register

The MDEU Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.7.10.6**, *MDEU Interrupt Status Register (MDEUISR)*, on page 27-258), if the corresponding bit in this register is set, then the error is disabled; no error interrupt occurs and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

27.6.4.9 MDEU ICV Size Register

The MDEU ICV size register stores the number of bytes of the ICV result to compare if the MDEU performs ICV comparison (see **Section 27.7.10.1**, *MDEU Mode Register (MDEUMR)*, on page 27-252). This register is cleared when the MDEU is reset or reinitialized.

27.6.4.10 MDEU End_of_Message Register

The End_of_Message Register in the MDEU indicates that an authentication operation is completed. After the final message block is written to the input FIFO, the End_of_Message Register must be written. The value in the Data Size Register is used to determine how many bits of the final message block (512) are processed. Note that this register has no data size, and during the write operation, the core processor data bus is not read. Hence, any data value is accepted. Normally, a write operation with a zero data value is performed. Reading from this register is not meaningful, but a zero value is always returned, and no error is generated. Writing to this register is merely a trigger causing the MDEU to process the final block of a message, allowing it to initiate a done interrupt.

27.6.4.11 MDEU Context Registers

For MDEU, context consists of the hash plus the message length count. Write access to this register block allows continuation of a previous hash. Reading these registers provides the resulting message digest or HMAC, along with an aggregate bit count.

Note: All SHA algorithms are big endian. MD5 is little endian. The MDEU module internally reverses the endianness of the five registers A, B, C, D, and E upon writing to or reading from the MDEU context if the MDEU Mode Register indicates MD5 is the hash of choice. Most other endian considerations are performed as 8-byte swaps. In

this case, 4-byte endianness swapping is performed within the A, B, C, D, and E fields as individual registers. Reading this memory location before the module is done generates an error interrupt.

After a power-on reset, all the MDEU Context Register values are cleared (0). The MDEU Context Registers are initialized if the INIT bit is set in the MDEU Mode Register. However, all registers are initialized, regardless of mode selected, but only the appropriate Context Register values are used in hash generation per the mode selected. Even though the user typically does not need to know about the MDEU Context Register initialization values; they are documented for completeness in the event that the user reads these registers using core processor-controlled access. MDEU resets via the MDEU Reset Control Register (**Section 27.6.4.5**, *MDEU Reset Control Register*, on page 27-70) or SEC global software reset (**Section 27.7.4.1**, *Master Control Register (MCR)*, on page 27-179) do not clear these registers.

27.6.4.12 MDEU Key Registers

The MDEU maintains sixteen 64-bit registers for writing an HMAC key. Only the first eight registers are used for MD-5, SHA-1, SHA-224, or SHA-256. The IPAD and OPAD operations are performed automatically on the key data when required.

Note: All SHA algorithms are big endian. MD5 is little endian. The MDEU module internally reverses the endianness of the key upon writing to or reading from the MDEU key registers if the MDEU Mode Register indicates MD5 is the hash of choice.

27.6.4.13 MDEU FIFOs

MDEU uses an input FIFO to hold data to be hashed (followed in some case by an ICV value for ICV checking). Normally, the channels control all access to this FIFO. For core processor-controlled operation, a write to anywhere in the MDEU FIFO address space enqueues data to the MDEU input FIFO, and a read from anywhere in this address space returns all zeros.

When the core processor writes to the MDEU FIFO (using core processor-controlled access), it can write to any FIFO address using byte, 4-byte, or 8-byte accesses. The MDEU assembles these bytes from left to right, that is, the first bytes written are placed in the most significant bit-positions. Whenever the MDEU accumulates 8 bytes, these 8 bytes are automatically enqueued into the FIFO, and any remaining bytes are left-justified in preparation for assembling the next 8 bytes. It is not necessary to fill all bytes of the final 8-byte set. Any remaining bytes in the staging register are automatically padded with zeros and forced into the input FIFO when the MDEU End_of_Message Register is written.

Overflows caused by writing the MDEU FIFO are reflected in the MDEU Interrupt Status Register.

27.6.5 ARC Four Execution Unit (AFEU)

In typical operation, the AFEU is used through channel-controlled access, which means that most reads and writes of AFEU registers are directed by the SEC channels. Driver software would perform core processor-controlled register accesses only on a few registers for initial configuration and error handling.

The following subsections include general descriptions of the AFEU registers and structures. **Section 27.7**, *Programming Model*, on page 27-96 provides a detailed description of each register and associated register fields.

27.6.5.1 AFEU Mode Register

The AFEU Mode Register contains three bits that are used to program the AFEU. The Mode Register is cleared when the AFEU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated.

27.6.5.1.1 Core Processor-Provided Context via Prevent Permute

In the default mode of operation, the core processor provides the key and key size to the AFEU. The initial memory values in the S-Box are permuted with the key to create new S-Box values, which are used to encrypt the plaintext.

If the ‘Prevent Permute’ mode bit is set, the AFEU does not require a key. Rather, the core processor writes the context to the AFEU and message processing occurs using the provided context. This mode is used to resume processing of a message using the already permuted S-Box. The context can be written through the FIFO if the ‘context source’ mode bit is set. The AFEU context is 259 bytes long, and must be in the format provided by the Dump Context function (see Section 27.6.5.1.2, **Dump Context**).

27.6.5.1.2 Dump Context

This mode can be independently specified in addition to core processor-provided context mode. In this mode, once message processing is complete and the output data is read, the AFEU makes the current context data available for reads via the output FIFO. The AFEU context is 259 bytes long.

Note: After the initial key permute to generate a context for an AFEU encrypted session, all subsequent messages reuses that context, such that it is loaded, modified during the encryption, and unloaded, similar to the use of a CBC initialization vector in DES operations. A new context is generated (via key permute) according to a re-keying interval specified by the security protocol. Context should never be loaded to encrypt a message if a key is loaded and permuted at the same time.

27.6.5.2 AFEU Key Size Register

The AFEU key size value indicates the number of bytes of key memory to use in performing S-box permutation. Any key data beyond the number of bytes in the Key Size Register is ignored. This register is cleared when the AFEU is reset or reinitialized. If the key size specified is less than 1 or greater than 16, a key size error is generated. If the Key Size Register is modified during processing, a context error is generated. Note: Although the AFEU supports key lengths as short as 1 byte, a 1-byte key offers little security. Most ARC-4 applications specify keys of 5–16 bytes.

Note: The device driver creates properly formatted descriptors for situations requiring a key permute prior to ciphering. When using core processor-controlled access (typically for debug), the user must set the AFEU Mode Register to perform ‘permute with key’, then write the key data to AFEU key registers, then write the key size to the Key Size Register. The AFEU starts permuting the memory with the contents of the key registers immediately after the key size is written.

27.6.5.3 AFEU Context/Data Size Register

The AFEU context/Data Size Register stores the number of bits in the final message with an upper bound of 4096. Whatever number is written (and whatever truncated value is stored) must be a multiple of 8. This value controls how much data is processed from the last block. The last message block must be a multiple of 8 from 8–64. If you write data size that is not a multiple of 8, a data size error is generated. Only the 3 lsbs are checked to determine if there is a data size error. Because all upper bits are ignored, the entire message length (in bits) can be written to this register.

The context/Data Size Register is also used to specify the context size, when context is used. The context size is fixed at 2072 bits (259 bytes). When loading context through the FIFO, all context data must be written prior to writing the context data size. The message data size must be written separately.

Note: When reloading an existing context using core processor-controlled access, the user must write the context to the input FIFO, then write the context size (always 2072 bits). The write of the context size indicates to the AFEU that all context is loaded. The user then writes the message data size to the context/Data Size Register. After this write, the user can begin writing message data to the FIFO.

Writing to this register causes the AFEU to start processing data from the input FIFO as soon as it is available. If the value of data size is modified during processing, a context error is generated.

This register is cleared when the AFEU is reset or reinitialized.

27.6.5.4 AFEU Reset Control Register

This register allows 3 levels of reset that effect the AFEU only, as defined by 3 self-clearing bits. The AFEU executes an internal reset sequence for hardware reset, software reset, or module initialization, which performs proper initialization of the S-Box. Use the RESET_DONE bit in the AFEU Status Register to determine when the reinitialization is complete.

27.6.5.5 AFEU Status Register

This Status Register reflects the state of AFEU internal signals. The AFEU Status Register is read-only. Writing to this location results in address error being reflected in the AFEU Interrupt Status Register.

27.6.5.6 AFEU Interrupt Status Register

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the AFEU Interrupt Mask Register is zero (see **Section 27.7.11.7**, *AFEU Interrupt Mask Register (AFEUIMR)*, on page 27-274).

If the AFEU Interrupt Status Register is non-zero, the AFEU halts and the AFEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189). In addition, if the AFEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Pointer Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the AFEU Reset Control Register.

27.6.5.7 AFEU Interrupt Mask Register

The Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.7.11.6**, *AFEU Interrupt Status Register (AFEUISR)*, on page 27-272), if the corresponding bit in this register is set, the error is disabled; no error interrupt occurs and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

27.6.5.8 AFEU End_of_Message Register

The End_of_Message Register in the AFEU is used to signal the AFEU that all processed data is written to the input FIFO. This allows the AFEU to do special processing when it reaches the last

block of data. Before this register is written, the AFEU does not process the last block of data in its input FIFO. After this register is written, the AFEU continues to do normal processing on all except the last block of data, and then goes on to process the last block using the value in the Data Size Register to determine how much of the block to process. The Data Size Register specifies the number of bits to process, which must be a multiple of 8 from 8–64. Once processing of the last block is completed, the AFEU issues a done interrupt. If the dump context bit in the AFEU Mode Register is set, the context is written to the output FIFO after the last message. A read of the AFEU End_of_Message Register always returns a zero value.

27.6.5.9 AFEU Context

This section provides additional information about the AFEU context memory and its related pointer register.

27.6.5.9.1 AFEU Context Memory

The S-Box memory consists of 256 bytes of SRAM, each readable and writable as part of a 64-bit set. Do not write the S-Box contents with data unless that data is previously read from the S-Box. Context data should only be written if the ‘prevent permutation’ mode bit in the AFEU Mode Register is set (see **Section 27.6.5.1**, *AFEU Mode Register*, on page 27-73). After context data, the context length must be written to the context/data length register (see **Section 27.7.11.3**, *AFEU Context/Data Size Register (AFEUCDSR)*, on page 27-269). After this, message data can be written. If the Context Registers are written during message processing or the ‘prevent permutation’ bit is not set, a context error is generated.

Valid context data can only be read after processing is done. Reading context data before the module is done generates an error interrupt.

Context data can be written and read either via the Context Registers or via the input and output FIFOs. The user specifies which through the CS bit of the AFEU Mode Register (see Section 27.6.5.1, **AFEU Mode Register**). See Section 27.6.5.11, **AFEU FIFOs** for more about addressing the FIFOs.

27.6.5.9.2 AFEU Context Memory Pointer Register

The context memory pointer register holds the internal context pointers that are updated with each byte of message processed. These pointers correspond to the values of I, J, and Sbox[I+1] in the ARC-4 algorithm. If this register is written during message processing, a context error is generated.

When performing ARC-4 operations, the user has the option of performing a new S-Box permutation per packet, or unloading the contents of the S-box (context) and reloading this context prior to processing of the next packet. The S-Box contents (256 bytes) plus the three bytes of the context memory pointers are unloaded and reloaded via the AFEU FIFOs.

AFEU Context consists of the contents of the S-Box, as well as three counter values, which indicate the next values to be used from the S-Box. Context must be loaded in the same order in which it was unloaded.

27.6.5.10 AFEU Key Registers

AFEU uses two write-only key registers to guide initial permutation of the AFEU S-Box, in conjunction with the AFEU Key Size Register. AFEU performs permutation starting with the first byte of key register 0, and uses as many bytes from the two key registers as necessary to complete the permutation. Reading either of these memory locations generates an address error interrupt.

27.6.5.11 AFEU FIFOs

AFEU uses an input FIFO/output FIFO pair to hold data before and after the encryption process. Normally, the channels control all access to these FIFOs. For core processor-controlled operation, a write to anywhere in the AFEU FIFO address space enqueues data to the AFEU input FIFO, and a read from anywhere in the AFEU FIFO address space dequeues data from the AFEU output FIFO.

In the special case where context is written through the input FIFO, the first write must be to range address 3_8E00 – 3_8E07. Context reads can be from any address in the FIFO address range.

Writes to the input FIFO go first to a staging register which can be written by byte, 4-byte, or 8-byte accesses). When all 8 bytes of the staging register are written, the entire 8 bytes is automatically enqueued into the FIFO. If any byte is written twice between enqueues, it causes an error interrupt of type AE from the EU. When writing the last portion of data, it is not necessary to write all 8 bytes. Any last bytes remaining in the staging register are automatically padded with zeros and forced into the input FIFO when the AFEU End_of_Message Register is written.

The output FIFO is readable by byte, 4-byte, or 8-byte accesses. When all 8 bytes of the header are read, that 8 bytes is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Overflows and underflow caused by reading or writing the AFEU FIFOs are reflected in the AFEU Interrupt Status Register.

27.6.6 Kasumi Execution Unit (KEU)

The Kasumi execution unit (KEU) is designed to support the F8 confidentiality function of the 3GPP, GSM A5/3, EDGE A5/3 and GPRS GEA3 algorithms and also the 3GPP F9 integrity function. This section contains details about the Kasumi Execution Unit (KEU), including modes of operation, status and control registers, and FIFOs.

In typical operation, the KEU is used through channel-controlled access, which means that most reads and writes of KEU registers are directed by the SEC channels. Driver software would perform core processor-controlled register accesses only on a few registers for initial configuration and error handling.

This EU includes an ICV checking feature, that is, it can generate an ICV and compare it to another supplied ICV. The pass/fail result of this ICV check can be returned to the core processor either via interrupt by a writeback of EU status fields into core processor memory, but not by both methods at once.

To signal the ICV checking result by status writeback, turn on either the IWSE bit or AWSE bit in the Channel Configuration Register (see **Section 27.7.6.1**, *Channel Configuration Registers for Channels 1–4 (CCR[1–4])*, on page 27-199), and mask the ICE bit in the Interrupt Mask Register (**Section 27.7.12.7**, *KEU Interrupt Mask Register (KEUIMR)*, on page 27-286). In this case the normal done signalling (by interrupt or writeback) is undisturbed.

To signal the ICV checking result by interrupt, unmask the ICE bit in the Interrupt Mask Register and turn off the IWSE and AWSE bits in the Channel Configuration Register. If there is no ICV mismatch, then the normal done signalling (by interrupt or writeback) occurs. When there is an ICV mismatch, e an error interrupt is generated to the core processor, but no done interrupt or writeback is issued.

The following subsections include general descriptions of the KEU registers and structures. **Section 27.7**, *Programming Model*, on page 27-96 provides a detailed description of each register and associated register fields.

27.6.6.1 KEU Mode Register

The KEU Mode Register contains several bits used to program the KEU. The Mode Register is cleared when the KEU is reset or reinitialized. Setting a reserved mode bit generates a data error. Setting both the GSM and EDGE bits to one generates a data error. If the KEU Mode Register is modified during processing, a context error is generated.

27.6.6.2 KEU Key Size Register

The KEU Key Size Register stores the number of bytes in the key. It should be set to 16 bytes. This register is cleared when the KEU is reset or reinitialized. If a specified key size does not match the selected algorithm(s), an illegal key size error is generated.

27.6.6.3 KEU Data Size Register

The KEU Data Size Register stores the number of bits to process in the final message set. Because Kasumi allows for bit level granularity for encryption/decryption, there are no illegal data sizes. The user must write the proper bit length of the message to notify the KEU of any padding performed by the core processor. This register is cleared when the KEU is reset or

reinitialized. Writing to this register signals the KEU to start processing data from the input FIFO as soon as it is available. If the value of data size is modified during processing, a context error is generated.

Example 27-1. F8 Function Example

If the 64-bit F8 keystream is ‘0x1234567890abcdef’and the Data Size Register contains 0x0a (10 = 1 byte + 2 bits), the final ten message bits is XORed with ten bits of keystream ‘0x120’. The PE (Process End of Message) mode bit must be set (see **Section 27.7.12.1**, *KEU Mode Register (KEUMR)*, on page 27-278). If PE is cleared (= 0), processing can not occur.

Example 27-2. 3GPP F9 Function Example

The final 64 bits of the message are padded as specified in the 3GPP F9 algorithm. The Process End of Message (PE) mode bit must be set. 3GPP F9 padding is automatically performed. The Communication Direction (CD) bits and ‘1’ are appended to the end of the message. The result is then zero-padded to 64 bits.

For example, if the last block is xF81A000000000000 (big endian) and data size contains 0x0F (15 bits = 1 byte + 7 bits), the most-significant 15 bits (underlined) of the last block (0xF81A = 1111_1000_0001_101) are padded left to right as follows:

1111_1000_0001_101$_1000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000

where ‘$’ is the value of the CD bits in the Mode Register. If PE is cleared (= 0), processing can not occur.

27.6.6.4 KEU Reset Control Register

The KEU Reset Control Register allows 3 levels reset of the KEU, as defined by the 3 self-clearing bits:

27.6.6.5 KEU Status Register

The KEU Status Register is a read-only register that reflects the state of six status outputs. Writing to this location results in an address error being reflected in the KEU Interrupt Status Register.

27.6.6.6 KEU Interrupt Status Register

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the KEU Interrupt Mask Register is zero (see **Section 27.7.12.7**, *KEU Interrupt Mask Register (KEUIMR)*, on page 27-286).

If the KEU Interrupt Status Register is non-zero, the KEU halts and the KEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189). In addition, if the KEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU

error bit is set in the Channel Pointer Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit in the KEU Reset Control Register.

27.6.6.7 KEU Interrupt Mask Register

The KEU Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.7.12.6**, *KEU Interrupt Status Register (KEUISR)*, on page 27-284), if the corresponding bit in this register is set, then the error is ignored; no error interrupt occurs and the KEU Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the KEU Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

27.6.6.8 KEU Data Out Register (F9 MAC)

Following a done interrupt, the read-only KEU data out register holds the F9 message authentication code. A 64-bit value is returned. This value can be truncated to 32 bits for some applications. Writing to this location results in an address error being reflected in the KEU Interrupt Status Register.

Note: According to the ETSI/SAGE 3GPP specification for F9 (version 1.2), only 32 bits of the final MAC are used. This is the lower 4 bytes of the KEU data out register.

27.6.6.9 KEU End_of_Message Register

The KEU End_of_Message Register signals the KEU that the final message block is written to the input FIFO. Writing to this register causes the KEU to process the final block of a message, allowing it to signal a done interrupt. When processing the last block, the value in the Data Size Register determines how many bits of the final message set (1–64) are processed. The value written to this register does not matter. A read of this register always returns a zero value.

27.6.6.10 KEU IV_1 Register

The KEU IV_1 register is a general purpose IV register used during the initialization phase of the F8 algorithms for 3GPP, GSM A5/3, EDGE A5/3, GPRS GEA3 and also for the F9 algorithm for 3GPP. The user must write the appropriate value as defined by the standards for each algorithm before a new message is started. Once the initialization phase is completed, the KEU IV_1 register is no longer used for the remainder of F8 or F9 processing. However, if 3GPP F9, is selected, because the KEU IV_1 register contains the direction bit as defined by the 3GPP standard, the KEU IV_1 register MUST be written back during context switches, to complete the generation of the 3GPP MAC.

Note: The user must ensure that fields of the IV_1 register are programmed correctly in accordance with the selected algorithm.

27.6.6.11 KEU ICV_In Register

If ICV checking is required, then the value to compare with the computed F9 MAC value must be written to the ICV_In register before data size is written.

27.6.6.12 KEU IV_2 Register (Fresh)

The fresh value in the KEU IV_2 register is used during the initialization phase of the 3GPP F9 algorithm. This value is ignored when the F8 algorithm is selected. The fresh value must be written before a new message to be processed with 3GPP F9 is started. Once the initialization phase is completed, the KEU IV_2 register is no longer used during message processing. You do not need to write the KEU IV_2 register during context switches.

27.6.6.13 KEU Context Data Registers

There are six 64-bit KEU context data registers that allow the core processor to read/write the contents of the context used to process the message. The KEU context data registers must be read when changing context and restored to their original values to resume processing an interrupted message. For F8 and 3GPP F9 modes, all six 64-bit KEU context data registers must be read to retrieve context, and all 6 must be written back to restore context. The context must be written prior to the key data. If the any of the KEU context data registers are written during message processing, a context error is generated. All KEU context data registers are cleared when a hard/soft reset or initialization is performed.

Note: In typical operation, a frame is received and processed in its entirety, with the KEU performing session specific initialization using the contexts of KEU IV_1 and IV_2 registers. The KEU context data and IV_1 registers should only be unloaded/reloaded when the processing of a frame is discontinued prior to completion, then processing is resumed.

27.6.6.14 KEU Key Data Registers_[1–2] (Confidentiality Key)

The first pair of KEU Key data registers together hold one 128-bit key used for F8 encryption/ decryption. KEU Key Data Register_1, (CK-high), holds the first 8 bytes (1–8). KEU Key Data Register_2, (CK-low), holds the second 8 bytes (9–16). The KEU Key Data Registers must be written before message processing begins. Writing a register while the block is processing data, generates a context error. Reading from either of these registers results in an address error being reflected in the KEU Interrupt Status Register.

27.6.6.15 KEU Key Data Registers _[3–4] (Integrity Key)

The second pair of KEU Key Data Registers together hold one 128-bit key that is used for F9 message authentication. KEU Key Data Register_3, (IK-high) holds the first 8 bytes (1–8). KEU Key Data Register_4, (IK-low), holds the second 8 bytes (9–16). The KEU Key Data Registers must be written before message processing begins. Writing a register while the block is processing data generates a context error.

If the ‘F9 only’ mode is set, the integrity key data can optionally be written to KEU Key Data Registers_[1–2]. This eliminates the need for the core processor to offset from the base key address to write to KEU Key Data Registers[3–4] while using the KEU exclusively for the F9 integrity function.

Reading from either of these registers results in an address error being reflected in the KEU Interrupt Status Register.

27.6.6.16 KEU FIFOs

KEU uses an input FIFO/output FIFO pair to hold data before and after the encryption process. Normally, the channels control all access to these FIFOs. For core processor-controlled operation, a write to anywhere in the KEU FIFO address space enqueues data to the KEU input FIFO, and a read from anywhere in the KEU FIFO address space dequeues data from the KEU output FIFO.

Writes to the input FIFO go first to a staging register which can be written by byte, 4 bytes, or 8 bytes. When all 8 bytes of the staging register are written, the entire 8 bytes are automatically enqueued into the FIFO. If any byte is written twice between enqueues, it causes an error interrupt of type AE from the EU. When writing the last portion of data, it is not necessary to write all 8 bytes. Any last bytes remaining in the staging register are automatically padded with zeros and forced into the input FIFO when the KEU End_of_Message Register is written.

The output FIFO is readable in byte, 4-byte, or 8-byte increments. When all 8 bytes of the header are read, that 8 bytes is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU. Overflows and underflows caused by reading or writing the KEU FIFOs are reflected in the KEU Interrupt Status Register.

The KEU fetches data 64 bits at a time from the KEU Input FIFO. During F8 processing, the input data is XORed with the generated keystream and the results are placed in the KEU Output FIFO. During F9 processing, the input data is hashed with the integrity key and the resulting MAC is placed in the KEU data out register. The output size is the same as the input size.

27.6.7 Cyclic Redundancy Check Unit (CRCU)

The CRCU computes a single 32-bit cyclic redundancy code (checksum) from all data presented on the input bus. The CRC algorithm treats a message stream of bits as coefficients of a massive polynomial and computes the remainder of the modulo two division by an order 32 divisor polynomial. The divisor polynomial is specific to the protocol and chosen to conform to certain mathematical properties to ensure that single bit errors can be detected. Cyclic redundancy codes are used to ensure data integrity over potentially unreliable channels. There are two major CRC protocol algorithms: CRC32 and CRC32C. **IEEE** Std. 802 defines the CRC32 algorithm, while iSCSI defines the CRC32C algorithm. Both protocols bit swap, byte swap, and then complement the calculated remainder to generate the checksum. The CRCU is designed to support the following check algorithms:

- CRC32 algorithm is specified in **IEEE** Std. 802.1.
- CRC32C algorithm is specified in RFC3385.
- Programmable polynomial mode with optional remainder bit mangling. This can be used to implement proprietary protocols.

The CRCU can perform ICV checking by computing a raw CRC across a message and previously-calculated CRC. Integrity is verified if the result matches the polynomial specific residue.

The following sections describe the CRCU modes of operation, status and control registers, and FIFOs. Most of the registers are not normally accessed by the core, but are documented primarily for debug purposes. In typical operation, the CRCU is used through channel-controlled access, which means that most reads and writes of CRCU registers are directed by the SEC channels. Driver software perform core-controlled register accesses only on a few registers for initial configuration and error handling. Detailed programming information is provided in **Section 27.7**.

27.6.7.1 ICV Checking

This EU includes an ICV checking feature, that is, it can verify a message/CRC pair by calculating a raw CRC and comparing it to the polynomial specific residue. The pass/fail result of this check can be returned to the core either via interrupt by a writeback of EU status fields into core memory, but not by both methods at once.

To signal the ICV checking result by status writeback, turn on either the IWSE bit or AWSE bit in the Channel Configuration Register (see **Section 27.7.6.1**), and mask the CICV Fail bit in the CRCU Interrupt/Error Mask Register (**Section 27.7.13.8**). For this case, the normal done signalling (by interrupt or writeback) is undisturbed.

To signal the ICV checking result by interrupt, unmask the CICVF bit in the CRCU Interrupt Mask Register and turn off the IWSE and AWSE bits in the Channel Configuration Register. If there is no CRC mismatch, then the normal done signalling (by interrupt or writeback) occurs.

When there is a CRC mismatch, an error interrupt is sent to the core, but no done interrupt or writeback.

27.6.7.2 CRCU Mode Register

The CRCU Mode Register programs the function of the CRCU and is generally the first register written. A context error is generated if this register is written after processing begins.

27.6.7.3 CRCU Key Size Register

The Key Size Register stores the number of valid bytes in the dynamic polynomial written to the Key Register. This value is reset to zero, and if a value other than zero, four, or eight is written to it, an illegal key size error is generated. It is not necessary to write to this register, because the polynomial size is clearly fixed by the algorithm. A context error is generated if this register is written after processing begins.

27.6.7.4 CRCU Data Size Register

The Data Size Register is written with the number of bits of data to process. Writing to this register puts the CRCU module into a busy state and starts data processing. This register can be written multiple times while data processing is in progress. The actual values written are ignored, although an error is generated if the value is not a multiple of 8 bits.

27.6.7.5 CRCU Reset Control Register

The Reset Control Register controls the reset/re-initialization of the block.

27.6.7.6 CRCU Control Register

The Control Register stores the static polynomial and residue used in custom CRC computations. The reset value of this register is the **IEEE** 802 standard CRC32 residue coefficient “r” and polynomial coefficient “g”. This register is static, in that it is only reset by performing a software reset, not by an EU reinitialization. This allows an application specific custom polynomial to be written to the register once and used many times. A context error is generated if this register is written after processing begins. A polynomial error is generated if a value is written to this register that does not have a one in g^0.

27.6.7.7 CRCU Status Register

The Status Register provides general information about the status of the CRCU. A read of the status register captures a snapshot of CRCU operating state at a particular moment in time. The three interrupt flags (error, done, and reset), provide visibility to the respective EU ports used to notify the core about the operation status. Writes to this register are ignored.

27.6.7.8 CRCU Interrupt/Error Status Register

The Interrupt/Error Status Register latches the source of various error interrupts. This register is both readable and writable, allowing the setting and/or clearing of the individual status bits. All status bits are maskable by setting the corresponding bit in the Interrupt/Error Mask Register. A status bit must be unmasked for it to be set. Individual status bits can be cleared by writing a zero to the respective bits. If these bits are masked, writing a one still clears them. The entire Interrupt/Error Status Register can be cleared, except for the Halt on Error bit, by resetting/reinitializing CRCU or by writing to the Clear IRQ bit in the Reset Control Register. The Halt on Error bit can only be cleared by resetting/reinitializing the CRCU. If an error occurs and is not masked, the error interrupt signal is asserted and the CRCU stops processing. If the error is masked, the interrupt is not asserted and the CRCU continues processing with likely bizarre results.

27.6.7.9 CRCU Interrupt/Error Mask Register

The Interrupt/Error Mask Register allows for individual error sources to be masked, thus preventing the error interrupt signal from being asserted. Error status is not captured for any error bits that are masked. Any core writes to a masked error bit result in clearing that error bit. Masking an error bit allows for a hardware error condition to occur potentially undetected. Therefore, use extreme care when masking errors because it can produce invalid results. Do not mask errors except for debug operation. This register can be reset by resetting the CRCU.

27.6.7.10 CRCU ICV Size Register

The ICV Size Register is 64-bit readable/writable for compatibility with the MDEU. Values written to this register are always ignored and a read of this register always returns zero. A context error is generated if this register is written after processing begins.

27.6.7.11 CRCU End of Message Register

The End of Message Register is used to indicate that all data is written to the CRCU. A write to this register is required to complete a CRC32 operation. The CRCU starts processing message data as soon as the Data Size Register is written and data becomes available in the FIFO, but it does not process a remaining partial word or perform an ICV check until a write to this register occurs. The value written is not used. Reading this register returns a zero.

27.6.7.12 CRCU Context Register

The Context Register can be written with an intermediate CRC result or desired initial state prior to processing any data. Once processing is complete, the CRC result is available from this register. Note that the CRC result is stored in the upper half of this register; the lower half is not used. The reset state of this register is all ones, because this allows the CRC32 algorithm to detect bit errors in the leading zeros of a message. A context error is generated if this register is written

after processing begins. An early read error is generated if this register is read while the EU is busy.

If the CRCU is in the default output mode (DOS and DOC bits are 0), this register holds the CRC remainder after it is bit swapped, byte swapped, and complemented. This sequence of operations is described in the protocol specifications and generates a result that can be written directly to the end of a frame or command. The result is shown in **Figure 27-7**.

Bit	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Value	x^{24}	x^{25}	x^{26}	x^{27}	x^{28}	x^{29}	x^{30}	x^{31}	x^{16}	x^{17}	x^{18}	x^{19}	x^{20}	x^{21}	x^{22}	x^{23}	x^{8}	x^{9}	x^{10}	x^{11}	x^{12}	x^{13}	x^{14}	x^{15}	x^{0}	x^{1}	x^{2}	x^{3}	x^{4}	x^{5}	x^{6}	x^{7}

Figure 27-7. CRCU Context Register Contents, Upper Half (Read—Default Mode)

If the CRCU is in the Disable Output Swap mode (DOS bit is 1), the Context Register holds the unswapped but complemented CRC remainder, as shown in **Figure 27-8**.

Bit	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Value	x^{31}	x^{30}	x^{29}	x^{28}	x^{27}	x^{26}	x^{25}	x^{24}	x^{23}	x^{22}	x^{21}	x^{20}	x^{19}	x^{18}	x^{17}	x^{16}	x^{15}	x^{14}	x^{13}	x^{12}	x^{11}	x^{10}	x^{9}	x^{8}	x^{7}	x^{6}	x^{5}	x^{4}	x^{3}	x^{2}	x^{1}	x^{0}

Figure 27-8. CRCU Context Register Contents, Upper Half (Read—DOS Mode)

If the CRCU is in the Disable Output Complement mode (DOC bit is 1), this register holds the uncomplemented but swapped CRC remainder, as shown in **Figure 27-9**.

Bit	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Value	x^{24}	x^{25}	x^{26}	x^{27}	x^{28}	x^{29}	x^{30}	x^{31}	x^{16}	x^{17}	x^{18}	x^{19}	x^{20}	x^{21}	x^{22}	x^{23}	x^{8}	x^{9}	x^{10}	x^{11}	x^{12}	x^{13}	x^{14}	x^{15}	x^{0}	x^{1}	x^{2}	x^{3}	x^{4}	x^{5}	x^{6}	x^{7}

Figure 27-9. CRCU Context Register Contents, Upper Half (Read—DOC Mode)

If the CRCU is in both Disable Output Complement mode (DOC bit is 1) and Disable Output Swap mode (DOS bit is 1), this register holds the uncomplemented and unswapped CRC remainder, as shown in **Figure 27-10**. This form is the one used internally to match against the polynomial specific residue when performing ICV checking. This form can also be written back to the CRCU after reset to continue a partial CRC operation.

Bit	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

Figure 27-10. CRCU Context Register Contents, Upper Half (Read—DOC and DOS Mode)

27.6.7.13 CRCU Key Register

The Key Register stores the polynomial and residue for the dynamic custom mode as set in the Mode Register (**Section 27.7.13.1**). The reset value of this register is all zeros with a one in bit position 0. This register is dynamic, in that it is reset by performing a reinitialize or a software reset. This allows a custom polynomial to be used for specific processing without changing the platform-specific static custom polynomial stored in the Control Register (**Section 27.6.7.6**). A residue does not need to be programmed unless ICV checking is being performed. A context

error is generated if this register is written after processing begins. A polynomial error is generated if a value is written to this register which does not have a one in bit g^0.

27.6.7.14 CRCU FIFO

Words written to this address range are pushed onto the CRCU input FIFO, thereby buffering them for processing. Partial words and misaligned data can be written to this address and it is automatically realigned based on a big-endian byte order.

27.6.8 SNOW3G Execution Unit (STEU)

The STEU is a functional block capable of encrypting/decrypting and/or performing integrity checks on 32-bit blocks of data using a 128-bit key. The STEU is designed to accelerate the 3G UEA2 and UIA1 algorithms and the LTE EEA1 and EIA1 algorithms.

The SEC EU Assignment Status Register shows which channels own which EUs at a particular moment in time. However, there is a missing value in the EU Assignment Register (EUASR) such that the STEU (Snow3G Execution Unit) field in the EUASR is not updated properly, and always reads back as 0xF. As a result, it is not possible to know which (if any) channel is using the STEU. When operating the SEC in descriptor mode, the user does not have any reason to care which channel owns the STEU at a particular moment in time. STEU descriptors can be dispatched to any channel, and the SEC controller ensures that all channels get access to the STEU.

The only conditions under which the EU Assignment Register is useful is when mixing descriptor based operations with direct access mode (slave mode) operations. Direct access mode operations involve software writing directly to EU registers, bypassing the channels entirely. This is not a recommended mode of operation, but if there is a compelling reason to use direct access mode for STEU operations, only use direct access mode. If not, software must ensure that all STEU descriptors have completed before performing an STEU direct access. The recommendation is to use descriptors for all STEU operations. If the alternative is required, use direct access mode for all STEU operations. Do not switch between the two modes.

The following sections describe the STEU modes of operation, status and control registers, and FIFOs. Most of the registers are not normally accessed by the core, but are documented primarily for debug purposes. In typical operation, the STEU is used through channel-controlled access, which means that most reads and writes of STEU registers are directed by the SEC channels. Driver software performs core-controlled register accesses only on a few registers for initial configuration and error handling. Detailed programming information is provided in **Section 27.7**.

27.6.8.1 ICV Checking

In F9 mode, this EU includes an ICV checking feature, that is, it can generate an ICV and compare it to another supplied ICV. The pass/fail result of this ICV check can be returned to the

core either via interrupt by a writeback of EU status fields into core memory, but not by both methods at once.

To signal the ICV checking result by status writeback, turn on either the IWSE bit or AWSE bit in the Channel Configuration Register (see **Section 27.7.6.1**), and mask the ICE bit in the Interrupt Mask Register (see **Section 27.7.14.7**). In the case of status writeback, the normal done signalling (by interrupt or writeback) is undisturbed.

To signal the ICV checking result by interrupt, unmask the ICE bit in the Interrupt Mask Register and turn off the IWSE and AWSE bits in the Channel Configuration Register. If there is no ICV mismatch, then the normal done signalling (by interrupt or writeback) occurs. When there is an ICV mismatch, an error interrupt is sent to the core, but no channel done interrupt or writeback is sent.

27.6.8.2 STEU Mode Register

The Mode register determines the mode of operation. If an undefined mode is set, an Illegal Mode Error is generated. If the mode is modified during message processing, a Context Error is generated.

27.6.8.3 STEU Key Size Register

The STEU Key Size register does not physically exist, because the key size is always 16 bytes for the SNOW3G algorithms. If an illegal key size is written, an Illegal Key Size Error is generated.

27.6.8.4 STEU Data Size Register

The Data Size Register holds the number of bits to process. This value must be set prior to loading message data and after the Mode Register is written. The STEU internally decrements this value while it processes the message. The Data Size Register can be read at any time to determine the number of bits left to process. The STEU continues to process data until the value in the Data Size register reaches zero. For the F9 mode, the data size must be divisible by 64 when the PE bit is cleared in the Mode Register. In other words, the message can be split for multi-session processing only on a 64-bit boundary. If this rule is violated, an Illegal Data Size Error is generated. If 0 is written to the Data Size register, followed by EOM, or only EOM is written, the STEU asserts the done interrupt which signals that processing is complete.

27.6.8.5 STEU Reset Control Register

The Reset Control register controls the type of reset. All bits are self-clearing. Reading from this register returns 0.

27.6.8.6 STEU Status Register

The Status Register is read-only and reflects the current state of the STEU.

27.6.8.7 STEU Interrupt Status Register

The Interrupt Status Register indicates which unmasked errors occurred and generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the STEU Interrupt Mask Register is zero. If the STEU Interrupt Status Register is non-zero, the STEU halts and the STEU error interrupt signal is asserted to the controller. In addition, if the STEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error then appears in the Channel Status Register and generates a channel error interrupt to the controller. To recover and start new processing after an error, the STEU must be reset (using the SR bit in the Reset Control Register, see **Section 27.7.14.4**).

27.6.8.8 STEU Interrupt Mask Register

The Interrupt Mask Register is used to disable an error indication by writing 1 to the corresponding bit. Disabling an error causes the STEU to ignore the error and continue processing. The error is not indicated in the Interrupt Status Register and the error interrupt signal is not asserted.

Extreme care should be taken when disabling errors because it can produce invalid results. For normal operation, do not disable errors. Errors should only be disabled during debug operation.

Note that processing halts if an internal error occurs, even if the Internal Error indicator in the Interrupt Status Register is masked. An internal error is indicated when the Status Register HALT bit is set accompanied by the absence of any asserted bits in the Interrupt Status Register.

27.6.8.9 STEU Data Out Register (F9 MAC)

The Data Out Register is physically the same as the STEU Context Register 1. The difference is that the Data Out Register can be read at any time, even during processing, while the Context Register 1 can only be read after processing is completed. Writing to the Data Out Register is ignored. Reading the register returns the contents of the Context Register 1, which is used for computation of the MAC. The MAC produced by F9 mode, when read after processing is completed, always has the upper 32 bits equal to 0x0.

27.6.8.10 STEU End of Message Register

The End of Message Register indicates that all of the message data is provided to the STEU. Once the End of Message Register is written, the STEU processes any remaining data in the input FIFO and generates the done interrupt. Reading this register returns all zeros.

27.6.8.11 STEU IV_1 Register

The IV_1 register is used during the initialization phase of both F8 confidentiality and F9 integrity algorithms. The IV_1 register must be written before processing of a new message

starts. Once the initialization phase is completed, the IV_1 register is no longer used in normal processing of F8 or F9 modes. Although generally this register is considered to be a context register, it does not need to be saved/restored during context switching in multi-session message processing. As with other context registers, any byte of this register can be enabled or disabled during accesses.

For f8 operations without hardware ICV checking, the IV_1 Register is the only register that must be loaded. Consequently, the Context In Length field in the STEU descriptor must be set to 8B.

For f9 operations with or without hardware ICV checking, the IV_1, ICV_In, and IV_2 registers must be loaded, and the Context In Length field in the STEU descriptor must be set to 24B. When hardware ICV checking is not enabled, the context must be constructed so that bytes 9–16 of the Context In are set to zero.

27.6.8.12 STEU ICV_In Register

If ICV checking is required, then the value to be compared with the computed f9 MAC value must be written to the ICV_In Register before Data Size is written. The 32-bit written ICV occupies the lower half of the ICV_In register, as shown in **Section 27.7.14.11**, *STEU ICV_In Register (STEUICVIR)*, on page 27-323.

Caution: *The LTE EIA1 and 3G UIA2 algorithms (based on Snow F9) produce an 8B MAC, however only the 4 MSBs of the MAC are transmitted with the PDU as the MAC-I. When operating in Snow F9 mode, the STEU is able to output the needed 4B of MAC, however its 4B MAC output is preceded by 4B of zeroes.*

Example 27-3. STEU ICV Checking

Assume that a given F9 calculation over a packet produces an 8B MAC of 0xABCDABCD_EEEEFFFF. The LTE EIA1 and 3G UIA2 algorithms transmit the packet with a MAC-I value of 0xABCDABCD. The STEU internally generates 0xABCDABCD_EEEEFFFF, but it outputs 0x00000000_ABCDABCD. If the descriptor ICV Out length is only set to 4B, only 0x00000000 is output, meaning the user is required to output all 8B of the generated ICV and only append the 4 LSBs to the packet as the MAC-I.

In the MSC8157E, any hardware comparison of a received MAC to a MAC-1 value fails. Therefore, never set CICV = 1 for a SNOW F9 operation. To make the comparison using software with CICV = 0, the user constructs a SNOW F9 descriptor to instruct the SEC to output the calculated F9 MAC so that the software can compare the calculated MAC with the received MAC-1 value. Refer to the *SEC 2/3x Descriptor Programmer's Guide* for details on constructing the descriptor.

27.6.8.13 STEU IV_2 Register (FRESH)

The STEU IV_2 Register hold input context during 3G UIA2 and LTE EIA1 operations. The format of the IV_2 register for each of the algorithms is as follows.

- UIA2: 4B of zeroes || 4B Fresh (4B)
- EIA1: 4B of zeroes || 5b Bearer || 27b zeroes

The specific value is used during the initialization phase of the f9 algorithm and is ignored when the f8 algorithm is selected. This register must be written before a new message to be processed with f9 is started. Once the initialization phase is completed, the IV_2 Register is no longer used during message processing. The IV_2 Register need not be saved/restored during context switches.

27.6.8.14 STEU Context Registers

There are four 64-bit STEU Context Registers (Context 1–Context 4) that are used in F9 processing. These allow the core to interrupt F9 message processing and to resume at a later time. The Context Registers must be read when changing context and restored to their original values prior to resuming processing of an interrupted message. If the any of the STEU Context Registers are written during message processing, a Context Error is generated. All STEU Context Registers are cleared when a hard/soft reset or initialization is performed.

27.6.8.15 STEU LFSR State Registers

The STEU LFSR State Registers are used to record LFSR state during F8 processing. These registers must saved/restored when switching context in F8 mode.

27.6.8.16 STEU FSM State Registers

The STEU FSM State Registers are used to record FSM state during F8 processing. These registers must be saved/restored when switching context in F8 mode. Note that the lower half of FSM State Register 2 is not used.

27.6.8.17 STEU Key Data Registers (Confidentiality Key)

The STEU Key Data Register 1 and Key Data Register 2 together hold one 128-bit key that is used for initialization. Key Data Register 1 holds the upper 8 bytes of key data while Key Data Register 2 holds the lower 8 bytes. The STEU Key Data Registers must be written before message processing begins. Writing to either of the Key Data Registers during processing results in a Context Error. Reading from either of the Key Data Registers always returns 0.

27.6.8.18 STEU FIFOs

STEU uses an input FIFO/output FIFO pair to hold data before and after processing. Normally, the channels control all access to these FIFOs. For core-controlled operation, a write to anywhere in the STEU FIFO address space enqueues data to the input FIFO, and a read from anywhere in the STEU FIFO address space dequeues data from the output FIFO.

Writes to the input FIFO go first to a staging register that can be written by byte, 4-byte, or 8-byte accesses. When all 8 bytes of the staging register are written, the entire 8 bytes is automatically enqueued into the FIFO. If any byte is written twice between enqueues, an Address Error results. When writing the last portion of data, it is not necessary to write all 8 bytes. Any remaining input bytes in the staging register are automatically padded with zeros and forced into the input FIFO when the STEU End of Message Register is written.

The output FIFO is readable by byte, 4-byte, or 8-byte accesses. When the first 8 bytes are read, that data is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, an Address Error results.

Overflows and underflows caused by reading or writing the STEU FIFOs are reflected in the STEU Interrupt Status Register.

The STEU fetches data 64 bits at a time from the input FIFO. During F8 processing, the input data is XORed with the generated keystream and the results are placed in the output FIFO. The output size is the same as the input size. During F9 processing, the input data is hashed with the integrity key and the resulting MAC is placed in the Data Out Register.

27.6.9 Random Number Generator (RNGU)

The RNGU is an execution unit capable of generating 64-bit random numbers. It combines a True Random Number Generator (TRNG) and a deterministic Pseudo-Random Number Generator (PRNG), based on SHA, as described in FIPS 186-2, Appendix 3.1. It is designed to comply with the FIPS-140 standard for randomness and non-determinism.

The RNGU consists of five major functional blocks:

- 64-bit slave bus interface, registers, and FIFO
- True Random Number Generator (ring oscillator, Linear Feedback Shift Registers (LFSRs), and Statistical Checker)
- Xseed Generator
- Pseudo-Random Number Generator (XKEY, SHA-1, FSM)
- Simultaneous Reseed LFSR

The states of the LFSRs in the TRNG are advanced at unknown frequency determined by the ring oscillator clock. The entropy generated by this structure is then added into the XKEY structure of the PRNG during seed generation. Seed generation takes approximately 2,000,000 cycles as 20,000 bits of entropy are sampled from the output of the LFSRs of the TRNG.

After the initial seeding, the RNGU turns off the TRNG and uses solely the PRNG to generate random data. After 1,000,000 times through the algorithm the RNGU is once again seeded. This second seed occurs the next time through the algorithm by using data from the Simultaneous Reseed LFSR to modify the algorithm. The data in the simultaneous reseed LFSR comes directly from the TRNG as well and was being generated during the first 20,000 times through the PRNG algorithm after the initial seed was completed.

Most of the registers described in this section are not normally accessed by the core processor. They are documented here mainly for debug purposes. During typical operation, the RNGU is used through channel-controlled access, which means that most reads and writes of RNGU registers are directed by the SEC channels. Driver software performs core-controlled register accesses only on a few registers for initial configuration and error handling.

The following subsections include general descriptions of the RNGU registers and structures. **Section 27.7**, *Programming Model*, on page 27-96 provides a detailed description of each register and associated register fields.

27.6.9.1 RNGU Mode Register

The RNGU Mode Register is a writable location but all mode bits are currently reserved. It is documented for the sake of consistency with the other EUs.

27.6.9.2 RNGU Data Size Register

The RNGU Data Size Register is used to tell the RNGU to begin generating random data. The actual contents of the Data Size Register do not affect the operation of the RNGU. After a reset and prior to the first write of data size, the RNGU builds entropy without pushing data onto the FIFO. Once the Data Size Register is written, the RNGU begins pushing data onto the FIFO. Eight bytes (64 bits) of data are pushed onto the FIFO every 112 cycles until the FIFO is full. The RNGU then attempts to keep the FIFO full.

27.6.9.3 RNGU Reset Control Register

This register contains three reset options specific to the RNGU: Reset interrupt, module initialization, and software reset. See **Section 27.7.15.3**, *RNGU Reset Control Register (RNGRCR)*, on page 27-335 for programming details.

27.6.9.4 RNGU Status Register

This RNGU Status Register contains five fields that reflect the state of the RNGU internal signals. The RNGU Status Register is read-only. Writing to this location results in an address error being reflected in the RNGU Interrupt Status Register. See **Section 27.7.15.4**, *RNGU Status Register (RNGSR)*, on page 27-336 for details.

27.6.9.5 RNGU Interrupt Status Register

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the RNGU Interrupt Mask Register is zero (see **Section 27.7.15.5**, *RNGU Interrupt Status Register (RNGISR)*, on page 27-337).

If the RNGU Interrupt Status Register is non-zero, the RNGU halts and the RNGU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189). In addition, if the RNGU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Pointer Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the RNGU Reset Control Register.

27.6.9.6 RNGU Interrupt Mask Register

The RNGU Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.7.15.5**, *RNGU Interrupt Status Register (RNGISR)*, on page 27-337), if the corresponding bit in this register is set, then the error is disabled; no error interrupt occurs and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

27.6.9.7 RNGU End_of_Message Register

The RNGU End_of_Message Register is a writable location can be used to start the RNGU to produce random numbers. A write of any value to this register will cause the RNGU to begin to produce random numbers in the FIFO. It is documented for the sake of consistency with the other EUs.

27.6.9.8 RNGU Entropy Registers

The RNGU allows the user to input Entropy into the PRNG algorithm to modify the randomness of the RNGU. This group of registers are write only and all writes to these registers are ignored when the RNGU is busy. However, when the RNGU is IDLE (FIFO is full or RNGU has not yet been started), all data written to these registers is used to modify the internal XKEY structure. These registers cannot be written back to back, there must be a clock cycle in between writes, so that the RNGU can process all 64-bits of data, as the RNGU processes only 32-bits per cycle.

27.6.9.9 RNGU FIFO

The RNGU uses an output FIFO to collect periodically sampled random 64-bit numbers, with the intent that random data is always available for reading. Normally, the channels control all access to this FIFO. For core processor-controlled operation, a read from anywhere in the RNGU FIFO address space dequeues data from the RNGU output FIFO.

The output FIFO is readable using byte, 4-byte, or 8-byte accesses. When all 8 bytes of the header are read, those 8 bytes are automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Underflows caused by reading or writing the RNGU output FIFO are reflected in the RNGU Interrupt Status Register. Also, a write to the RNGU output FIFO space is reflected as an addressing error in the RNGU Interrupt Status Register.

27.7 Programming Model

Note: To prevent stalling and enable the detection of stalled channels, ensure the following conditions:

- Ensure that software does not create SEC descriptors that request encryption or decryption of zero length data.
- Use the SEC crypto-channel watchdog timer to detect stalled channels. Enable the individual channel watchdog timer via the Channel Configuration Register CCRx[WGN] field. This is a one-time configuration. The timer stops when the channel completes a descriptor and restarts at zero each time the channel fetches a new descriptor. The default setting for the watchdog timer is 227 SEC clock cycles. If the timer expires, the channel generates an interrupt and the Channel Status Register shows the cause as a Watchdog Timeout (WDT). The channel stall is cleared by resetting the channel via CCR[R]. The offending EU is reset automatically by the channel.

The SEC uses the following structures and registers to configure and operate the security engine and the execution units:

- Descriptors and Link Tables
  - Descriptor structure, **page 27-100**
  - Descriptor header, **page 27-102**
  - Descriptor Pointers, **page 27-175**
  - Link tables, **page 27-177**

27.7.1 Descriptors and Link Tables

The following sections described the overall descriptor structure, the descriptor header, descriptor pointers, and the link table format.

27.7.1.1 Descriptor Structure

Bit	63 48	47	46 40	39 36	35 32	31 0
Header	Descriptor Control					Descriptor Feedback
Pointer 0	Length0	J0	Extent0	—	Eptr0	Pointer0
Pointer 1	Length1	J1	Extent1	—	Eptr1	Pointer1
Pointer 2	Length2	J2	Extent2	—	Eptr2	Pointer2
Pointer 3	Length3	J3	Extent3	—	Eptr3	Pointer3
Pointer 4	Length4	J4	Extent4	—	Eptr4	Pointer4
Pointer 5	Length5	J5	Extent5	—	Eptr5	Pointer5
Pointer 6	Length6	J6	Extent6	—	Eptr6	Pointer6

SEC descriptors are designed to support the cryptographic computation of a single packet using a single descriptor. They are conceptually similar to descriptors used by most devices with DMA capability. The descriptors have a fixed length of 64 bytes. A descriptor consists of one header (8 bytes) and seven pointers (each 8 bytes).

The upper half of the header is a Descriptor Control field, and the lower half is the Descriptor Feedback field. The Descriptor Control field of the header specifies the security operation to be performed, the execution unit(s) needed, and the modes for each execution unit. The pointers, all of which have the same format, contain pointer and length information for locating input or output parcels (such as keys, context, or text-data). The large number of pointers provided in the descriptor allows for multi-algorithm operations that require fetching of multiple keys, as well as fetch and return of contexts. Any pointer that is not needed can be given a length of zero.

SEC descriptors include scatter/gather capability, which means that each pointer in a descriptor can be either a direct pointer to a contiguous parcel of data, or can be a pointer to a link table which is a list of pointers and lengths used to assemble the parcel. When a link table is used to read input data, this is referred to as a gather operation; when used to write output data, it is referred to as a scatter operation.

27.7.1.2 Descriptor Header

Bit	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Field	OP_0												OP_1												DESC_TYPE					—	DIR	DN
	EU_SEL0				MODE0								EU_SEL1				MODE1															
Writeback	DONE												—																			

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	—																															
Writeback	—			ICCR0				—				ICCR1				—									ID_TAG							

The header specifies the security operation to perform, the execution unit(s) needed, and the modes for each execution unit. **Table 27-13** describes the fields that must be supplied to the SEC. The SEC device drivers allow the core processor to create proper headers for each cryptographic operation. SEC descriptor processing sometimes includes performing a writeback, that is, writing the original header back to system memory with certain fields modified. The modified fields are shown in the Writeback rows and described in **Table 27-14**.

Table 27-13. Header Bit Definitions

Bits	Name		Description	Settings
63–60	OP_0	EU_SEL0	**Primary EU Select** **Notes:** **1.** EU_SEL0 values of “No EU selected” or “Reserved” results in an “Unrecognized Header Error” condition during processing of the descriptor header. **2.** If EU_SEL1 is CRCU or MDEU, then EU_SEL0 must be DEU, AESU, AFEU, KEU, or STEU. All other values of EU_SEL0 result in an “Unrecognized header” error condition.	See **Table 27-15** for setting values.
59–52		MODE0	**Primary Mode** Mode data used to program the primary EU. The mode data is to the chosen EU. This field is passed directly to bits 7–0 of the Mode Register in the selected EU.	
51–48	OP_1	EU_SEL1	**Secondary EU Select** **Notes:** **1.** The only valid choices for EU_SEL1 are “No EU selected”, CRCU, or MDEU. Any other choice results in an “Unrecognized Header” error condition. **2.** If EU_SEL1 is CRCU or MDEU, then EU_SEL0 must be DEU, AESU, AFEU, KEU, or STEU. All other values of EU_SEL0 result in an “Unrecognized header” error condition.	See **Table 27-15** for setting values.
47–40		MODE1	**Secondary Mode** Mode data used to program the primary EU. The mode data is to the chosen EU. This field is passed directly to bits 7–0 of the Mode Register in the selected EU.	

Table 27-13. Header Bit Definitions (Continued)

Bits	Name	Description	Settings
39–35	DESC_TYPE	**Descriptor Type** Along with the DIR field, this determines the sequence of actions to be performed by the channel and selected EUs using the blocks of data listed in the rest of the descriptor. The determined attributes include: • the direction of data flow for each data block • which EU (primary or secondary) to access • what snooping options to use • and which internal EU addresses to access	See **Table 27-16** for valid settings. **Table 27-17** shows how the pointers should be used with the various descriptor types to load keys, context, and text-data into the Execution Units, and how the required outputs should be unloaded.
34	—	Reserved.	
33	DIR	**Direction: Direction of Overall Data Flow** Along with the DESC_TYPE field, this field helps determine the sequence of actions to be performed by the channel and selected EUs.	0 Outbound 1 Inbound
32	DN	**Done Notification** This enables done notification if the NT field is 1 in the Channel Configuration Register (see **Table 27-15**). The done notification can take the form of an interrupt, a writeback in the DONE field of this header (see **Table 27-16**), or both, depending upon the states of the Channel Done Interrupt Enable (CDIE) and Channel Done Writeback Enable (CDWE) bits in the Channel Configuration Register.	0 No done notification. 1 Signal DONE to the core processor on completion of this descriptor.
31–0	—	Reserved	

Table 27-14. Header Writeback Field Definitions

Bits	Name	Description	Settings
63–56	DONE	**DONE** When DONE writeback is used, then at the completion of descriptor processing this byte is written with the value 0xFF. To determine when done writeback is used, see the CDWE, NT, and CDIE fields in the Channel Configuration Register (**Section 27.7.6.1**, *Channel Configuration Registers for Channels 1–4 (CCR[1–4]),* on page 27-199).	
55–29	—	Reserved.	
28–27	ICCR0	**Integrity Check Comparison Result from Primary** These bits are supplied by the primary EU when descriptor processing is complete.	00 No integrity check comparison was performed. 01 The integrity check comparison passed. 10 The integrity check comparison failed. 11 Reserved
26–21	—	Reserved.	
20–19	ICCR1	**Integrity Check Comparison Result from Secondary** These bits are supplied by the secondary EU (if any) when descriptor processing is complete.	00 No integrity check comparison was performed. 01 The integrity check comparison passed. 10 The integrity check comparison failed. 11 Reserved.

Table 27-14. Header Writeback Field Definitions (Continued)

Bits	Name	Description	Settings
18–16	—	Reserved.	
15–0	ID_TAG	Identification Tag This value is copied from the ID_TAG field written by the host into the Fetch FIFO (see **Section 27.7.6.4**, *Channel Fetch FIFO (CFF)*).	

Table 27-15. EU_SEL0 and EU_SEL1 Values

Value (binary)	Selected EU
0000	No EU selected
0001	AFEU (not valid for EU_SEL1)
0010	DEU (not valid for EU_SEL1)
0011	MDEU-A
0100	RNGU (not valid for EU_SEL1)
0101	PKEU (not valid for EU_SEL1)
0110	AESU (not valid for EU_SEL1)
0111	KEU (not valid for EU_SEL1)
1000	CRCU
1001	STEU (not valid for EU_SEL1)
1010	Reserved
1011	MDEU-B
1100–1110	Reserved
1111	Reserved for header writeback

Note: MDEU has two different designators to refer to the same Message Digest Execution Unit. If MDEU-B is selected, then the Channel configures MDEU to perform SHA-224, SHA-256, SHA-384, and SHA-512. If MDEU-A is selected, then the Channel configures MDEU to perform SHA-160, SHA-224, SHA-256, or MD5. The channel uses the MODE0 (or MODE1) value to configure the MDEU Mode Register (MDEUMR) if it is selected by the descriptor and this automatically sets or clears the MDEUMR[MDEU_B] bit to select MDEU-A or MDEU-B.

27.7.1.2.1 Descriptor Types

Table 27-16 lists the available descriptors used by the SEC to identify the encryption operations to perform.

Table 27-16. Descriptor Types

Value (binary)	Descriptor Type	Notes
Descriptor Types (least significant bit must be 0)		
00000	aesu_ctr_nonsnoop	AESU-CTR non snooping operations.
00010	common_nonsnoop	Common, non snooping, non-PKEU, non-AFEU. For use with AES-CTR, you must prepend zeros to the AES-Context before loading the AES Context Registers.
00100	hmac_snoop_no_afeu	Snooping, HMAC, non-AFEU. For use with AES-CTR with HMAC, you must prepend zeros to the AES-Context before loading the AES Context Registers.
00110	—	Reserved
01000	—	Reserved
01010	common_nonsnoop_afeu	Common, non snooping, AFEU

Table 27-16. Descriptor Types (Continued)

Value (binary)	Descriptor Type	Notes
01100	—	Reserved
01110	—	Reserved
10000	pkeu_mm	PKEU-Montgomery Multiplication
10010	—	Reserved
10100	—	Reserved
10110	—	Reserved
11000	hmac_snoop_aesu_ctr	AESU CTR with HMAC snooping
11010	—	Reserved
11100	—	Reserved
11110	—	Reserved
Descriptor Types (least significant bit must be 1)		
00001	ipsec_esp	IPsec ESP mode encryption and hashing
00011	802.11i AES ccmp	CCMP encryption and hashing, suitable for 802.11i
00101	srtp	SRTP encryption and hashing
00111	pkeu_build	pkeu_build Elliptic Curve Cryptography
01011	pkeu_ptadd_dbl	pkeu_ptadd_dbl Elliptic Curve Cryptography
01101	—	Reserved
01111	—	Reserved
10001	tls_ssl_block	TLS/SSL generic block cipher
10011	tls_ssl_stream	TLS/SSL generic stream cipher
10101	raid_xor	XOR 3 sources together
10111	ipsec_aes_gcm	IPsec ESP mode using AES GCM encryption and hashing
11001	dbl_crc	Do two Cyclic Redundancy Check Operations
11011	—	Reserved
11101	—	Reserved
11111	—	Reserved

27.7.1.2.2 Descriptor Formats

Table 27-17 summarizes how the descriptors can be used.

Table 27-17. Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer 1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6

27.7.1.2.3 Descriptor Operations During Cryptographic Processing

The user should read and understand the following guidelines for correct use of the SEC in a particular application:

- The steps and diagrams in this document do not cover all the actions needed to implement a particular protocol, only those relevant to operations performed by the SEC. The INPUT and OUTPUT packet formats shown in the diagrams are typically not the complete packet formats handled by the protocol. Refer to the specific protocol for detailed information.
- In all cases that use two EUs, the cipher EU is set as the primary EU. The secondary EU may be MDEU for authentication, or CRCU for generating CRCs.
- The pointers obtained from descriptors are stored in the channel and are incremented as reads or writes take place. If the steps specify that a channel uses a pointer a second time (to access a second parcel), these accesses continue where the first operation left off. For example, the steps might call for reading E3 bytes starting at pointer P3 to obtain hash-only data. This leaves P3 at the *end* of the hash-only data. In a subsequent step, pointer P3 might be used again to read the main payload, with length given by L3, and then again to read a trailer, with length given by E4.
- Setting the J-bit enables the scatter/gather feature for all parcels accessed through the pointer in the same entry. If J<i> is false, then P<i> points directly to the parcel; if J<i> is true, P<i> is a pointer to a link table. If P<i> is used to access multiple parcels, then all of those accesses are affected by J<i>.
- If a length field is zero, the length field is not used. If an extent field is zero, then any reading or writing step that uses this extent field is skipped.
- Unless otherwise noted, any padding required by the authentication function is provided by the authentication EU.
- Where automatic ICV comparison is used, there is no need to output the new hash result. Software typically specifies a length of 0 to suppress the ICV output.

- Realignments performed by SEC are not detailed here. The general rule is that all data fed to any EUs input FIFO is realigned so that the FIFO obtains a sequence of completely filled words. In some cases the last word may be only partially filled.
- The terminology in the diagrams generally reflects that used in the protocol standards. Note that different protocols use different terms for similar quantities. For example:
  - Hash, MAC, HMAC, and ICV all refer to values used for authentication.
  - IV and context both refer to values that need to be loaded into a EU before it can process data.

Figure 27-11is a key to the packet pointer diagrams used to explain the individual descriptor types in the subsequent subsections. The diagram shows a flow of activity from top to bottom.

Input parcels, denoted by pointers (P), lengths (L), and extents (E), are shown at the top of the diagram, and output parcels are shown similarly at the bottom. These have the lightest shading (green). Where a length is given in the descriptor but there is no corresponding memory data, the shading is omitted (see E3 to the right). The green shaded areas depict the layout of data in memory if link tables are not in use.

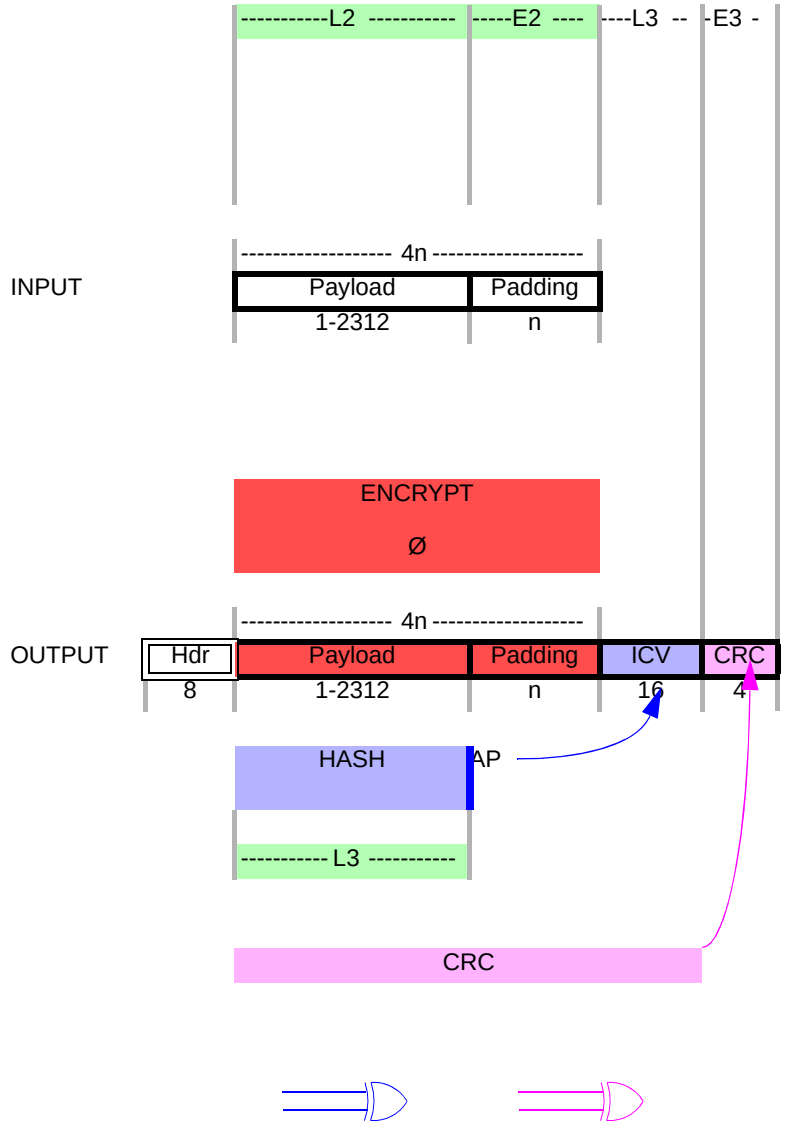
Relevant input data fields are shown with lengths labelled below them. Any additional restrictions on field sizes are shown above the fields. The following size designators are used:
B - bytes (the default for all lengths)
b - bits
n - any positive integer
4n - integer multiple of 4

An encryption or decryption process is denoted by a borderless rectangle of the darkest shading (red). Encrypted fields also have this shading.

A hashing process for authentication is denoted by a borderless rectangle of medium shading (blue). Authentication result fields also have this shading. A blue “AP” at the right end of a “HASH” rectangle means the EU provides autopadding to complete the last data block. A blue arrow shows where the authentication result is placed.

CRC operations are shown in the same way as hashing, but with magenta coloring.

A comparison between an integrity check field in a packet and a hash or CRC result is indicated by an XOR gate.



To provide additional information about the protocols, fields that are not encrypted or hashed are sometimes included in the diagrams. They are shown in white with a double border (see the “Hdr” field above).

Figure 27-11. Key to Packet Pointer Diagrams

27.7.1.2.4 Descriptor Types 0000_0: aesu_ctr_nonsnoop

Table 27-18. aesu_ctr Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
0000_0 aesu_ctr_ nonsnoop	Length	reserved	Cipher Context In	Cipher Key	Main Data In	Data Out	Cipher Context Out	reserved
	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved

Descriptor type aesu_ctr_nonsnoop is designed for use with AESU for Counter mode operation. For this descriptor type, the Channel accesses AESU Context Registers differently than most other descriptor types, permitting the transfer of a smaller AESU context when required. Descriptor type hmac_snoop_aesu_ctr (see Section 27.7.1.2.9) provides similar context access while snooping ciphertext to a secondary EU (either CRCU or MDEU).

Data Processing Steps for descriptor type aesu_ctr (as managed by the Channel):

1. AESU Mode, Key Size, Key, and Data Size registers are configured as appropriate.
2. Counter: driver builds Context in structure with initial counter value and counter modulus. Channel fetches this from address *P1* and writes into AESU Context registers.
3. Encrypt / Decrypt Input: *L3* bytes fetched from address *P3* and written to AESU input FIFO.
4. Output: *L4* bytes fetched from AESU output FIFO are written to address *P4.*
5. Counter out: *L5* bytes read from AESU context registers are written to address *P5.* This is useful should a subsequent descriptor need to start where this descriptor left off.

Table 27-19. Descriptor Control word examples for aesu_ctr

Control Word (32 bit hex)	Description
60600000	aesu_ctr nonsnoop outbound
606000002	aesu_ctr nonsnoop inbound

Pointer 6	--	J6	--	-	Eptr6	P6: --
	Length	J	Extent	--	Eptr	Pointer

Figure 27-12. aesu_ctr_nonsnoop Descriptor Format

27.7.1.2.5 Descriptor Type 0001_0: common_nonsnoop

common_nonsnoop is the descriptor type for performing most single-EU operations, to provide raw security functionality when a protocol-specific descriptor type is either undesirable or unavailable. For Public Key Operations, there are specific descriptor types (see Section 27.7.1.2.8 for regular modular math-type operations or Section 27.7.1.2.20 for elliptic curve-type operations). In addition, a specific descriptor type has been specified for AFEU (see Section 27.7.1.2.7).

Table 27-20. common_nonsnoop Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
0001_0 common_ nonsnoop for MDEU	Length	reserved	Context In	Key	Main Data In	ICV In	Context Out	reserved
	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved
0001_0 common_ nonsnoop for KEU f9, STEU f9, AES-XCBC , AES-CMAC	Length	reserved	Context In	Key	Main Data In	reserved	Context Out	ICV Out
	Extent	reserved	reserved	reserved	reserved	ICV In	reserved	reserved
0001_0 common_ nonsnoop for CRCU	Length	reserved	Context In	Key	Main Data In	reserved	Context Out	reserved
	Extent	reserved	reserved	reserved	reserved	ICV In	reserved	reserved
0001_0 common_ nonsnoop for other cases not listed above	Length	reserved	Context In	Key	Main Data In	Data Out	Context Out (incl. ICV Out)	reserved
	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved

Data Processing Steps (as managed by the Channel):

1. Setup: Mode, Key, Key Size and Data Size registers are configured as appropriate.
2. Data In: *L3* bytes are fetched from address *P3* and written into the selected EU input FIFO.
3. Data Out: If a symmetric cipher has been selected (or for RNG output data), read *L4* bytes from output FIFO and write to address *P4*.
4. Context Out: *L5* bytes read from Context registers are written to address *P5*. The definition of context depends on the execution unit; please see the section describing the Context registers for the selected execution unit for more information.
5. Integrity Check Value: In some execution units, the Integrity Check Value is part of context out. In others, it is separate.

— For AESU, KEU and STEU, *L6* bytes of ICV are read from the execution unit and written to address *P6*.
— For CRCU and MDEU, *L5* bytes of ICV are read from the execution unit and written to address *P5*.
  • For CRCU, the Context *is* the ICV.
  • For MDEU, the Context includes an additional 8-byte field. The ICV is the first N bytes in the Context, where N is dependent on which hash algorithm has been selected.

Figure 27-13. common_nonsnoop_no_afeu Descriptor Format

1. ICV Length and ICV Output address are used only when the execution unit provides the ICV result in a register other than a context register -- those are AESU and KFEU

Table 27-21 lists some selected functions that can be performed using the common-nonsnoop-no-afeu descriptor type, along with appropriate example Descriptor header control word values. It should be noted that this list is by no means exhaustive, and more control words can be constructed by varying the EU_MODE_0 field. For example, for descriptor triple-des-ecb encrypt, the control word is 0x20300010. In that control word, the field occupied by the value “2” identifies the Execution Unit desired, in this case DESU. The field occupied by the value “03” identifies the Mode that the channel will write into the execution unit as part of the execution unit configuration phase.

Table 27-21. Descriptor Control Word Examples For Common-nonsnoop-no-afeu Descriptors

Control Word (32 bit hex)	Description
20000012	des-ecb decrypt
20100010	des-ecb encrypt
20200012	triple-des-ecb decrypt

27.7.1.2.6 Descriptor Type 0010_0: hmac_snoop_no_afeu

Descriptor type hmac_snoop_no_afeu is designed for use when multi-processing is needed and a protocol-specific descriptor is either unavailable or undesirable. Despite the prefix “hmac”, the descriptor type can be used when either CRCU or MDEU is the secondary execution unit, and MDEU operation is not restricted to HMAC. The construction of this descriptor permits separate confidentiality and integrity keys, and also allows for a portion of data that is hashed (CRC’d) without being ciphered.

Table 27-22. Descriptor Format Summary for hmac_snoop_no_afeu

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
0010_0 hmac_snoop_no_afeu	Length	Hash Key	Hash-only Header	Cipher Key	Cipher Context In	Main Data In	Data Out	ICV Out
	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved

Data Processing Steps (as managed by the Channel):

1. Mode, Key Size, Key, and Data Size registers are configured as appropriate for primary execution unit.
2. Secondary EU Mode, Key Size, Key, and Data Size registers are configured as appropriate.
3. Hash-only Header: *L1* bytes fetched from address *P1* and written to secondary EU input FIFO.

4. Cipher Context: *L3* bytes are fetched from *P3* and written into the primary EU context registers
5. Main Data In: *L4* bytes fetched from address *P4* and written to primary EU input FIFO. If Descriptor header indicates outbound, this data is also written to secondary EU input FIFO.
6. Main Data out: *L5* bytes fetched from primary EU output FIFO are written to address *P5*. If Descriptor header indicates inbound, this data is also written into the secondary EU input FIFO.
7. ICV Out: *L6* bytes of hash / HMAC / CRC result fetched from secondary EU and written to address *P6*.

	0 15	16	17 23	24 27	28 31	32 63

	Length	**J**	**Extent**	**--**	**Eptr**	**Pointer**

Figure 27-14. Descriptor Format hmac_snoop_no_afeu

As an example, take the first control word listed in the table below: 0x20031c22. The two rightmost nibbles, “22”, indicate an inbound hmac_snoop_no_afeu descriptor without done notification. the two nibbles “1c” are written into MDEU mode register, which was selected on the basis of “3” appearing in the fourth nibble. The leftmost “2” indicates DESU for the primary execution unit, and the value “00” written into the DESU mode register.

27.7.1.2.7 Descriptor Type 0101_0: common_nonsnoop_afeu

Descriptor type common_nonsnoop_afeu differs from descriptor type common_nonsnoop_no_afeu only in how the channel moves data internally. More specifically, the channel writes data found at address *P1* into the AFEU input FIFO, and reads data to be written into address *P5* from the AFEU output FIFO.

Table 27-24. common_nonsnoop_afeu Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
0101_0 common_ nonsnoop_ afeu	Length	reserved	Context In (via In FIFO)	Cipher Key	Main Data In	Data Out	Context Out (via Out FIFO)	reserved
	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved

Data Processing Steps (as managed by the Channel):

1. Setup: Mode, Key, Key Size and Data Size registers are configured as appropriate.
2. Context In: *L1* bytes are fetched from address *P1* and written into the AFEU input FIFO.
3. Data In: *L3* bytes are fetched from address *P3* and written into the AFEU input FIFO.
4. Data Out: read *L4* bytes from output FIFO and write to address *P4*.
5. Context Out: *L5* bytes read from AFEU output FIFO are written to address *P5*. (Descriptor control word must select context out)

Table 27-25. Descriptor Control word examples for common_nonsnoop_afeu Descriptors

control word (32 bit hex)	Description
10000050	arc-four confidentiality
10200050	arc-four confidentiality with s-box context out
10500050	arc-four confidentiality with reuse of previous s-box context
10700050	arc-four confidentiality with s-box context in and out

27.7.1.2.8 Descriptor Type 1000_0: pkeu_mm

pkeu_mm descriptors are designed for efficient use of PKEU when performing RSA computations, or for the occasional elliptic curve field operation. For elliptic curve point operations, refer to Section 27.7.1.2.20.

Table 27-26. Descriptor Format Summary for pkeu_mm

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
1000_0 pkeu_mm	Length	“N” In	“B” In	“A” In	“E” In	“B” Out	reserved	reserved
	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved

Data Processing Steps (as managed by the Channel):

1. Setup: Mode, Key Size and Data Size registers are configured as appropriate.
2. Modulus: *L0* bytes of modulus are fetched from address *P0* and written into the PKEU "N" register. The byte found at address *P0* is the most significant byte of the modulus, and the byte found at address *(P0 + L0 - 1)* is the least significant byte of the modulus
3. Secondary Operand: *L1* bytes are fetched from address *P1* and written into the PKEU "B" register. This secondary operand is used for the more simple arithmetic operations supported by PKEU, such as modular multiplication.
4. Primary Operand: *L2* bytes are fetched from address *P2* and written into the PKEU "A" register. This primary operand is required for most operations. When computing modular exponentiation, the base is the primary operand.
5. Exponent: *L3* bytes are moved from address *P3* to the PKEU "E" register. For most operations, the exponent field is unused; it is the exponent for modular exponentiation. In addition, when computing R_nR_p mod P (conversion of modulus from N to P), this field is used to provide the *size* of the modulus N -- *L3* must be programmed with the size of the original modulus N. Because the original modulus N itself is not required, *P3* should be zero.
6. Result: *L4* bytes are read from the PKEU "B" register and written to address *P4*.

Table 27-27. Descriptor Control word examples for pkeu_mm Descriptors

control word (32 bit hex)	Description

27.7.1.2.9 Descriptor Type 1100_0: hmac_snoop_aesu_ctr

Table 27-28. hmac_snoop_aesu_ctr Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
1100_0 hmac_snoop_aesu_ctr	Length	Hash Key	Hash-only Header	AES Key	AES Context In	Main Data In	Data Out	ICV Out
	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved

Descriptor type hmac_snoop_aesu_ctr is designed for use with AESU for Counter mode operation. For hmac_snoop_aesu_ctr, the Channel accesses AESU Context Registers differently than most other descriptor types, permitting the transfer of a smaller AESU context when required. Descriptor type hmac_snoop_aesu_ctr provides for snooping ciphertext to a secondary EU (either CRCU or MDEU).

Data Processing Steps for descriptor type hmac_snoop_aesu_ctr (as managed by the Channel):

1. AESU Mode, Key Size, Key, and Data Size registers are configured as appropriate.
2. Secondary EU Mode, Key Size, Key, and Data Size registers are configured as appropriate.
3. Hash-only Header: *L1* bytes fetched from address *P1* and written to secondary EU input FIFO.
4. Counter: driver builds Context in structure with initial counter value and counter modulus. Channel fetches this from address *P3* and writes into AESU Context registers.

5. Encrypt / Decrypt Input: *L4* bytes fetched from address *P4* and written to AESU input FIFO. If Descriptor header indicates outbound, this data is also written to secondary EU input FIFO.
6. Output: *L5* bytes fetched from AESU output FIFO are written to address *P5*. If Descriptor header indicates inbound, this data is also written into the secondary EU input FIFO.
7. Hash / HMAC / CRC: *L6* bytes fetched from secondary EU and written to address *P6*.

27.7.1.2.10 Descriptor Type 0000_1: IPsec_ESP

The IPsec_ESP descriptor type is designed to efficiently process IPsec ESP packets. It is suitable for most IPsec packets, but not for AES-GCM packets. For AES-GCM IPsec packets, use descriptors shown in Section 27.7.1.2.28 on page 161.

Table 27-30. IPsec ESP Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
0000_1 ipsec_esp	Length	HMAC Key	Hash-only Header	Cipher IV In	Cipher Key	Main Data In	Data Out	Cipher IV Out
	Extent	reserved	reserved	reserved	reserved	ICV In	ICV Out	reserved

27.7.1.2.11 IPsec-ESP Outbound

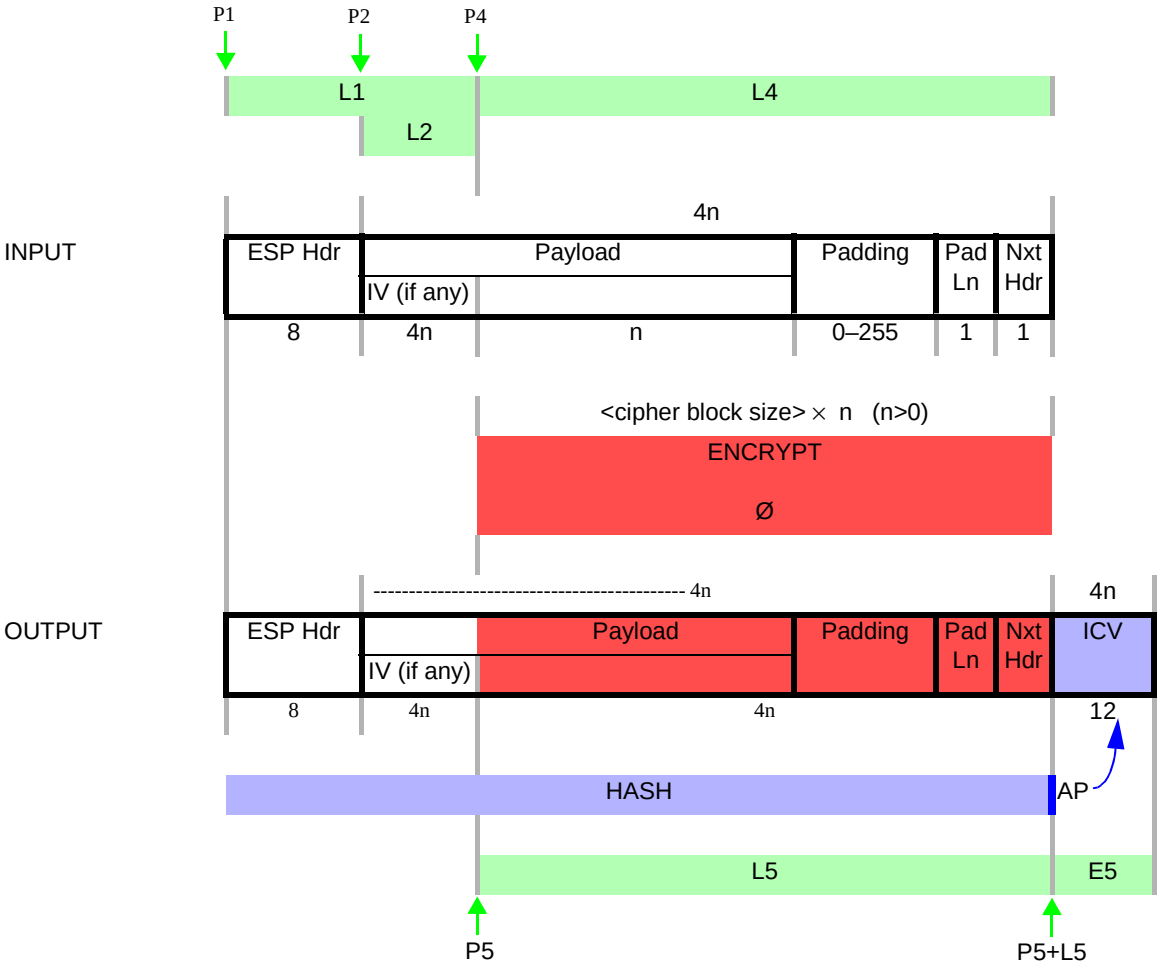

Figure 27-17. IPsec ESP Outbound Packet Pointer Diagram

Note: If the IV is in the packet (explicit IV), then the IV is the same as the last part of the hash-only header. In this case the L1 and L2 regions may overlap in memory, as shown above.

Data Processing Steps (as managed by the Channel):

1. Channel writes appropriate values to Mode Registers, Context, Key, Key Size and Data Size registers of selected Execution Units
2. Hash-only data (ESP HDR):
   - Starting at address *P1*, *L1* bytes fetched and fed to hashing EU input FIFO
   - SEC Channel computes hash-only datasize from *L1* and *L4*, and feeds to hashing EU Data Size register
3. Plaintext: Starting at *P4*, SEC fetches *L4* bytes and feeds them to the selected cipher EU input FIFO and to the selected hashing EU input FIFO.
4. Ciphertext: SEC fetches *L5* bytes from cipher EU output FIFO, and writes to *P5* and to hashing EU input FIFO.
5. ICV output: After the cipher EU has finished encryption, hashing EU finishes computation of the ICV in the MDEU. SEC obtains *E5* bytes of ICV from the hashing EU and writes to *P5*.

	0 15	16	17 23	24 27	28 31	32 63

Figure 27-18. IPsec ESP Outbound Descriptor Format

Below is a table containing selected Descriptor Header control words for descriptor type IPsec-ESP, outbound case. This is by no means an exhaustive list. Note that AES-GCM is not listed here because it is performed using the AES-GCM descriptor type (see Section 27.7.1.2.28).

Table 27-31. Descriptor Control word examples for IPsec ESP Outbound Descriptors

control word (32 bit hex)	Description
20531E08	DES-CBC / HMAC-MD5 Outbound
20512C08	DES-CBC / HMAC-SHA1 Outbound
20731E08	Triple-DES-CBC / HMAC-MD5 Outbound
20731C08	Triple-DES-CBC / HMAC-SHA1 Outbound
60331E08	AES-CBC / HMAC-MD5 Outbound
60331C08	AES-CBC / HMAC-SHA1 Outbound

27.7.1.2.12 IPsec-ESP Inbound

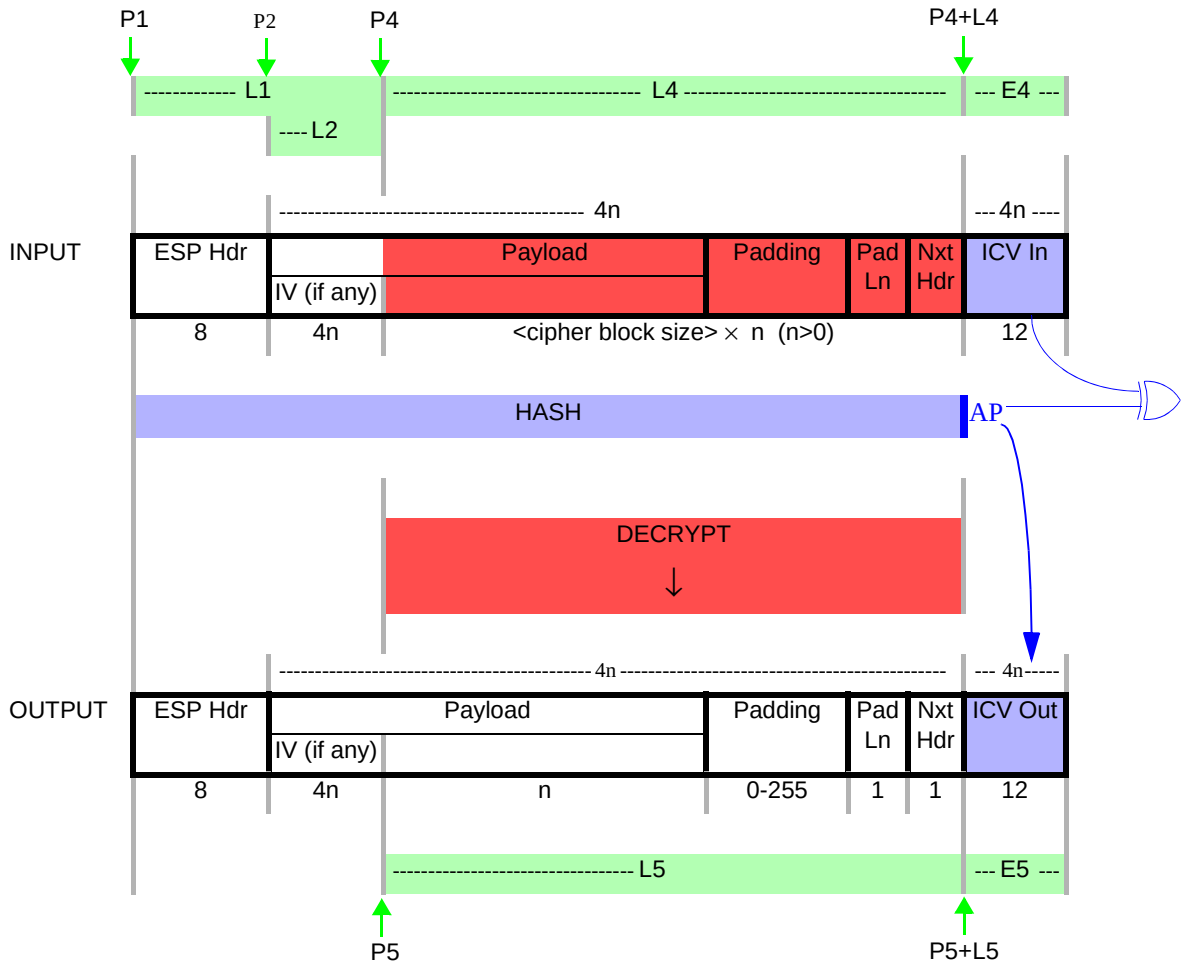

Figure 27-19. IPsec ESP Inbound Packet Pointer Diagram

Notes: **1.** If the IV is in the packet (explicit IV), then the IV is the same as the last part of the hash-only header. In this case the L1 and L2 regions may overlap in memory, as shown above.
2. When automatic ICV comparison is used, "ICV out" is typically not needed, so E5 may be set to 0.

Data Processing Steps (as managed by the Channel):

1. Hash-only: Starting at *P1*, read *L1* bytes and feed them to the MDEU.
2. Decrypt and hash: Starting at *P4*, read *L4* bytes and feed them to the cipher EU, with insnooping to the MDEU.
3. Output: Write *L5* bytes of cipher output data to *P5*.
4. ICV comparison: If ICV comparison is turned on, then continuing at *P4* read *E4* bytes and feed this "old ICV" to the MDEU. When the ICV computation in the MDEU is finished, compare the first *E4* bytes of MDEU output to the "old ICV", and send the pass/fail result back to the channel.

5. ICV output: Obtain *E5* bytes of ICV from the MDEU and write them continuing at *P5*.

	0 15	16	17 23	24 27	28 31	32 63
Header	Descriptor Control					Descriptor Feedback
Pointer 0	Hash Key Length	J0	--	-	Eptr0	P0: Address of Hash Key
Pointer 1	Hash-only Hdr Len	J1	--	-	Eptr1	P1: Address of Hash-only Header
Pointer 2	Cipher IV Length	J2	--	-	Eptr2	P2: Address of Cipher IV
Pointer 3	Cipher Key Length	J3	--	-	Eptr3	P3: Address of Cipher Key
Pointer 4	Plaintext Length	J4	ICV In Len	-	Eptr4	P4: Address of Plaintext • ICV In
Pointer 5	Ciphertext Length	J5	ICV Out Len	-	Eptr5	P5: Address of Ciphertext • ICV Out
Pointer 6	Cipher IV Length	J6	Extent6	-	Eptr6	P6: Address of Cipher IV Out
	Length	**J**	**Extent**	**--**	**Eptr**	**Pointer**

Figure 27-20. IPsec ESP Inbound Descriptor Format

Note: If automatic ICV comparison is used, there is no need to output the new ICV. To avoid writing out this ICV, set *E5* to zero. On the other hand, if automatic ICV comparison is not used, then the new ICV should be written out. In this case it will be placed after the decrypted data. If the packet is being decrypted in place (that is, if the same buffer is being used for packet data in and data out), then this would overwrite the original ICV, which would not be desirable, since the host needs to compare the old and new ICVs. The solution would be for the host to use the “scatter” capability to cause the new ICV to be written to some more convenient place.

Table 27-32 contains selected Descriptor Header control words for descriptor type IPsec-ESP, inbound case. This is by no means an exhaustive list. Note that AES-GCM is not listed here because it is performed using the AES-GCM descriptor type (see Section 27.7.1.2.28).

27.7.1.2.14 IEEE 802.11i Outbound

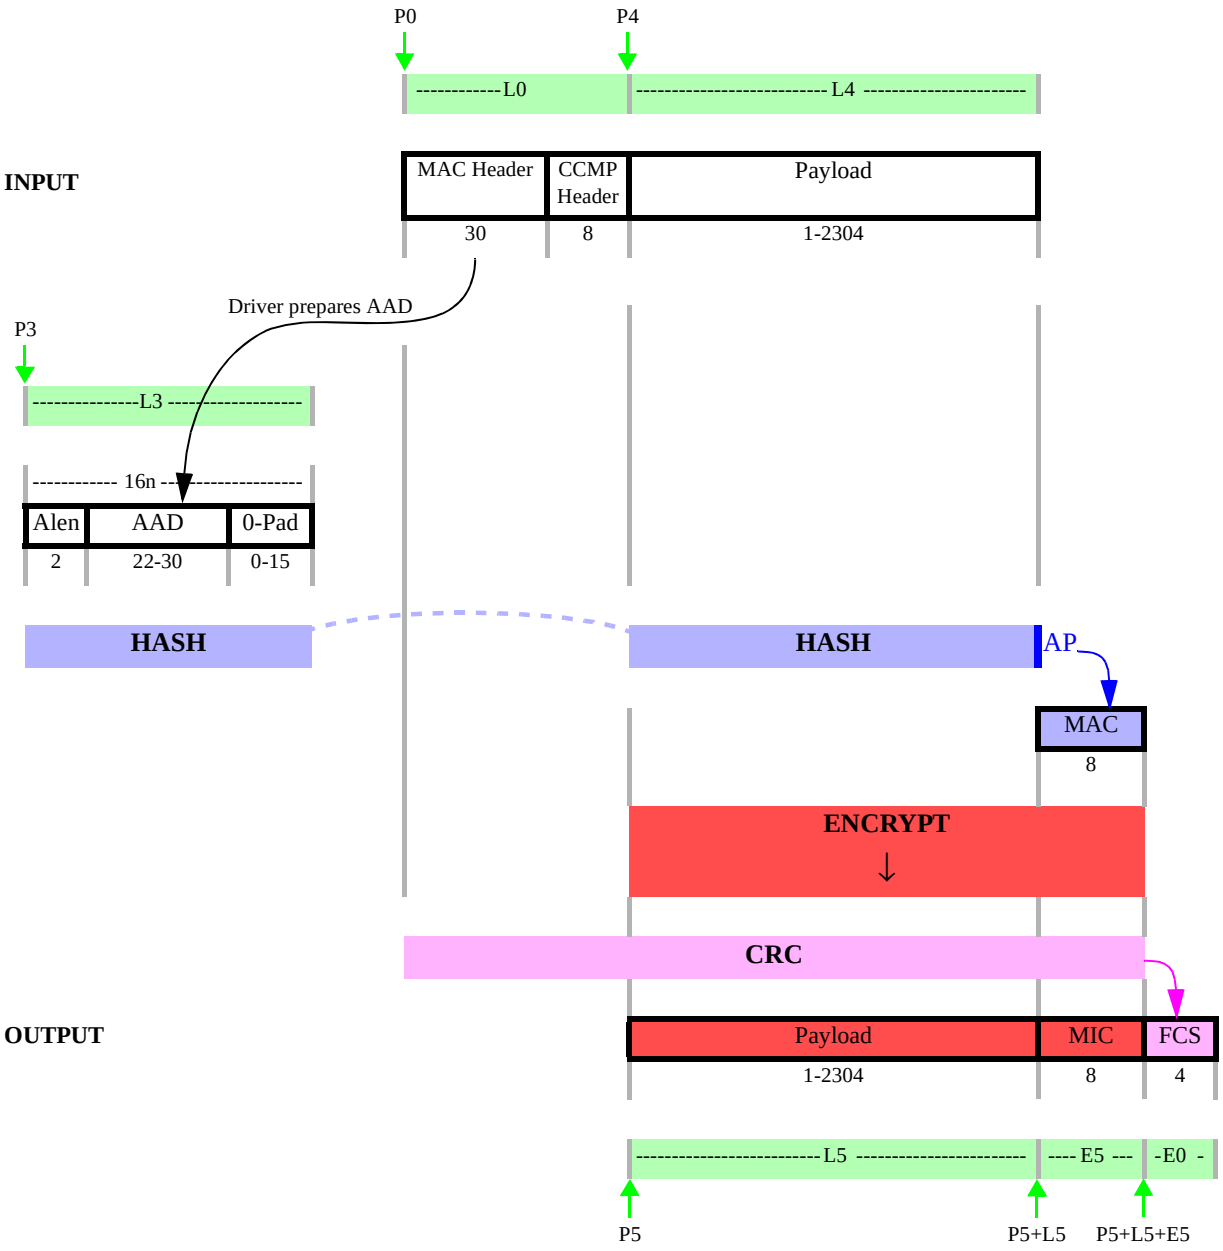

Figure 27-21. IEEE 802.11i (AES-CCM) Outbound Packet Pointer Diagram

Note: When implementing 802.11i CCMP, in preparation for authentication, the host must prepare the AAD field (additional authentication data) which is based on information in the MAC header. It must then add the Alen field (length of AAD), and zero-padding to make the hash-only length a multiple of 16B. The host must also supply the MAC Header and CCMP Header fields to accompany the encrypted output. 2.Hash autopadding is done with zeros.

	Length	**J**	**Extent**	**--**	**Eptr**	**Pointer**

Figure 27-22. IEEE 802.11 AES-CCMP Outbound Descriptor Format

Data Processing Steps (as managed by the Channel):

1. CRC Header: Starting at address *P0*, read *L0* bytes and send to CRCU input FIFO.
2. Hash-only: Set the AESU initialize bit. Starting at *P3*, read *L3* bytes and feed them to the AESU. The AESU automatically uses the *Alen* field to determine how much data is hash-only.
3. Encrypt and hash: Clear the AESU initialize bit. Starting at *P4*, read *L4* bytes, and feed them to the AESU. The AESU automatically does authentication and encryption on this region, and performs autopadding to complete the last block of data to the authentication function.
4. Output: Send *L5* bytes of cipher output data to *P5*. If CRCU is indicated in the descriptor header, this data is also sent to the CRCU input FIFO.
5. MIC output: Finish computation of the MAC in AESU, autopadding the data if necessary, and encrypt the result to form the MIC. Continuing at *P5*, write the MIC to memory. If CRCU is indicated in the descriptor header, the MIC is also sent to the CRCU input FIFO. The AESU also supplies the MIC as part of its Context output at *P6*.
6. CRCU: if CRCU is indicated by the descriptor header, get *E0* bytes of computed CRC from the CRCU, and write to memory continuing at *P5* (immediately after MIC).

Table 27-34. Descriptor Control word examples for CCMP Outbound Descriptors

control word (32 bit hex)	Description
6b100018	AES-CCM Outbound
6b180018	AES-CCM / CRC32-IEEE-802 Outbound

27.7.1.2.15 IEEE 802.11i Inbound

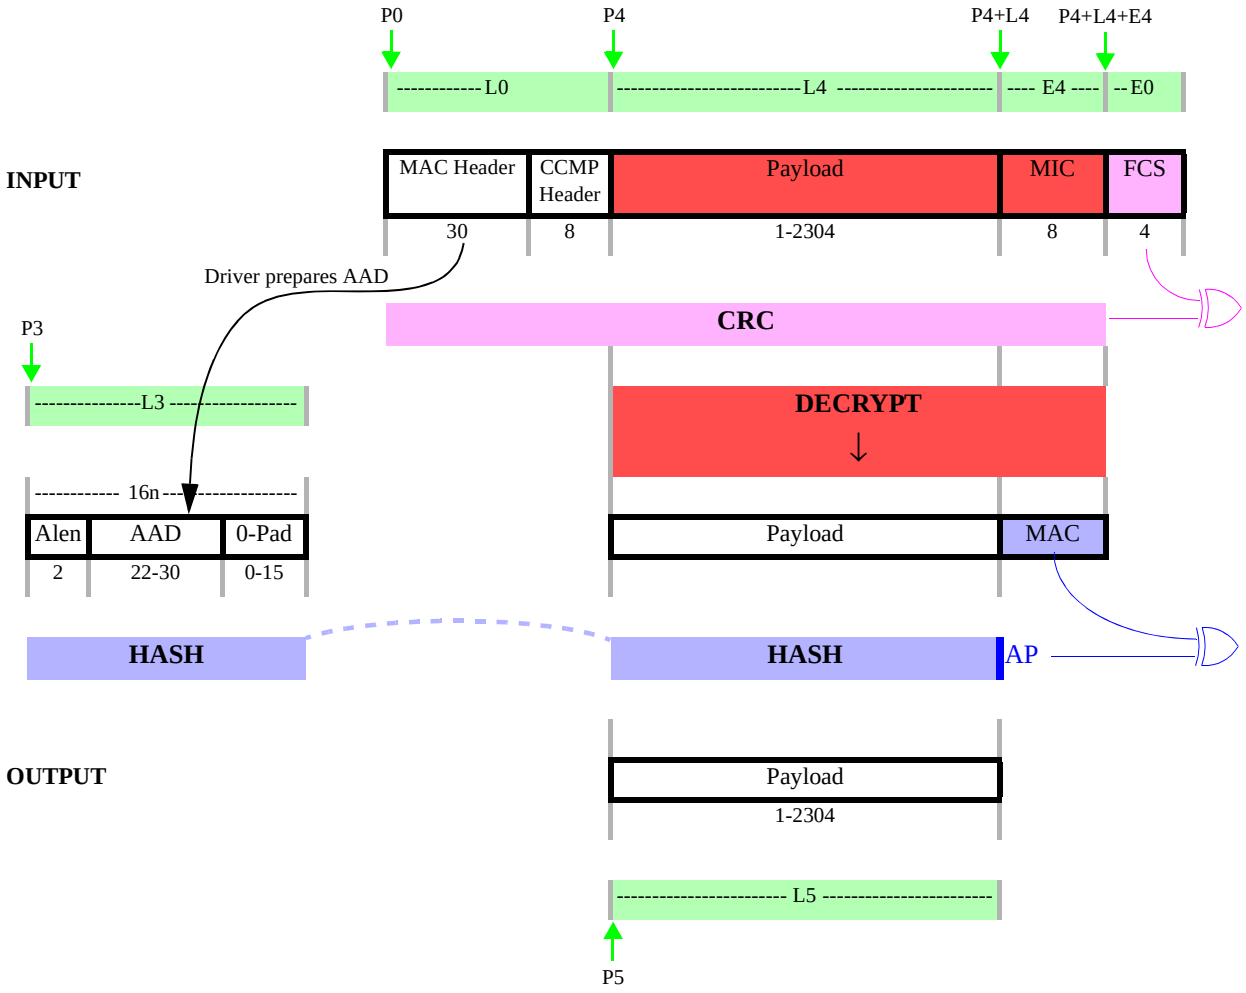

Figure 27-23. IEEE 802.11i (AES-CCM) Inbound Packet Pointer Diagram

Notes:
1. In preparation for authentication, the host must prepare the AAD field (additional authentication data) which is based on information in the MAC header. It must then add the Alen field (length of AAD), and zero-padding to make the hash-only length a multiple of 16B.
2. Hash autopadding is done with zeros.
3. When automatic ICV comparison is used, “Context out” is typically not needed, so L6 may be set to 0.

Data Processing Steps (as managed by the Channel):

1. CRC Header: Starting at address *P0*, read *L0* bytes and send to CRCU input FIFO.
2. Hash-only: Set the AESU initialize bit. Starting at *P3*, read *L3* bytes and feed them to the AESU (and the CRCU if the descriptor header specifies CRCU as a secondary EU). The AESU automatically uses the *Alen* field to determine how much data is hash-only.
3. Decrypt and hash: Clear the AESU initialize bit. Starting at *P4*, read *L4* bytes and feed them to the AESU (and the CRCU if the descriptor header specifies CRCU as a

secondary EU). The AESU automatically does authentication and decryption on this region, and performs autopadding to complete the last block for authentication.

4. MIC decryption: Continuing at *P4*, read *E4* bytes of old MIC and feed them to the AESU (and the CRCU if the descriptor header specifies CRCU as a secondary EU). The AESU decrypts this MIC to get the old MAC.
5. FCS: If *E0* is non-zero and the descriptor header specifies CRCU as a secondary EU, then continuing at *P4* read *E0* bytes of FCS and feed them to the CRCU input FIFO.
6. Output: Send *L5* bytes of cipher output data to *P5*.
7. ICV comparison: In the AESU, complete computation of the new MAC. If ICV comparison is turned on, compare the new MAC to the old MAC, and send the pass/fail result back to the channel.
8. FCS comparison: In the CRCU, complete computation of the CRC result. If CRC comparison is turned on, compare the computed CRC to the CRC residue.
9. ICV output: The computed MAC and decrypted MAC are part of the Context output at *P6*.

27.7.1.2.17 SRTP Outbound

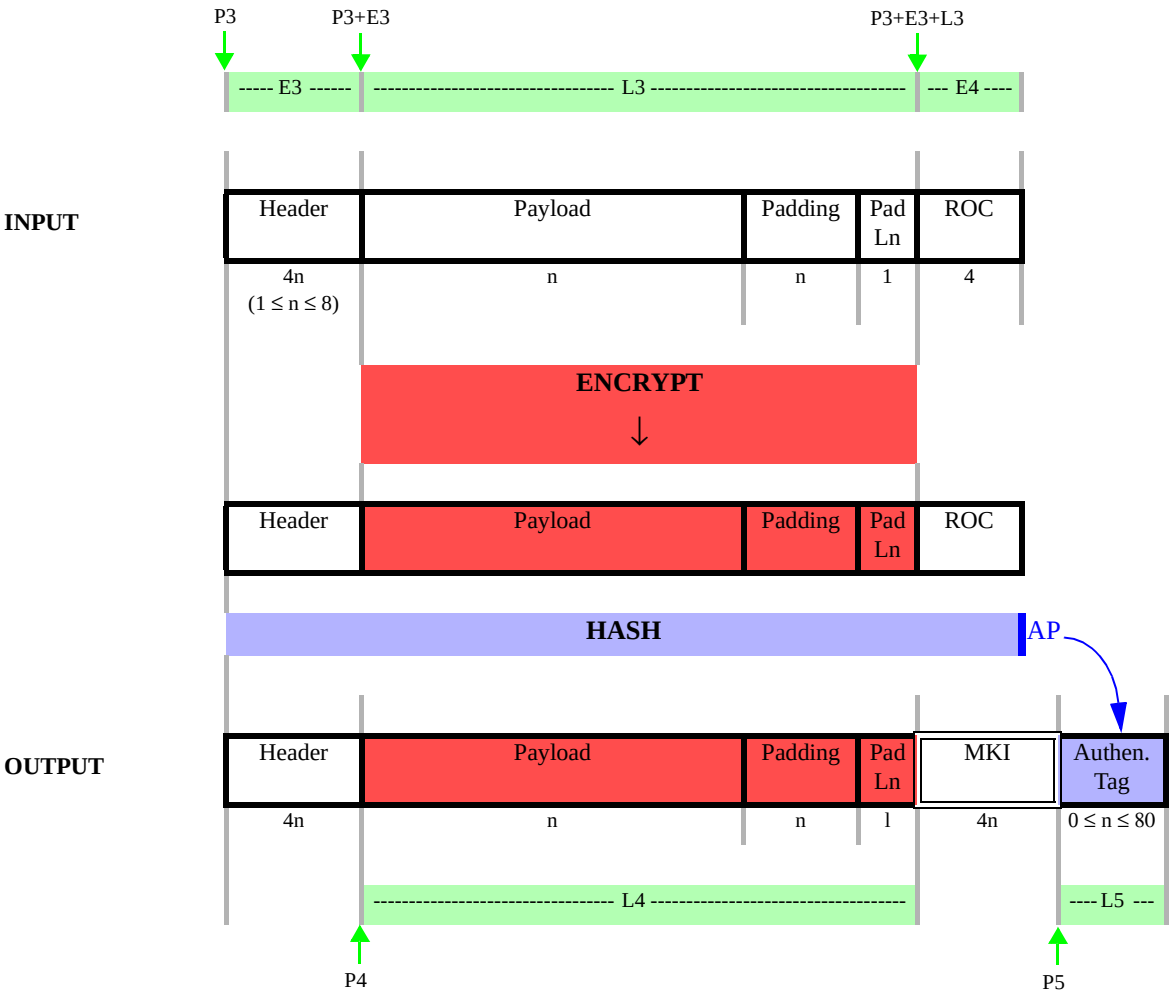

Figure 27-25. SRTP Outbound Packet Pointer Diagram

Data Processing Steps (as managed by the Channel):

1. Hash-only: Starting at *P3*, read *E3* bytes and feed them to the MDEU.
2. Encrypt and hash: Continuing at *P3*, read *L3* bytes and feed them to the cipher execution unit.
3. Output: Write *L4* bytes of cipher output to *P4*, with outsnooping to the MDEU.
4. Hash-only ROC: Continuing at *P3*, read *E4* bytes and feed them to the MDEU.
5. Authentication Tag output: Finish computation of the Authentication Tag in the MDEU. Obtain *L5* bytes of Authentication Tag from the MDEU and write them to *P5*.

Programming Notes:

- The ROC field must be contiguous with the Pad Ln field of the packet.

- Key length = 160b.

27.7.1.2.18 SRTP Inbound without ICV Compare

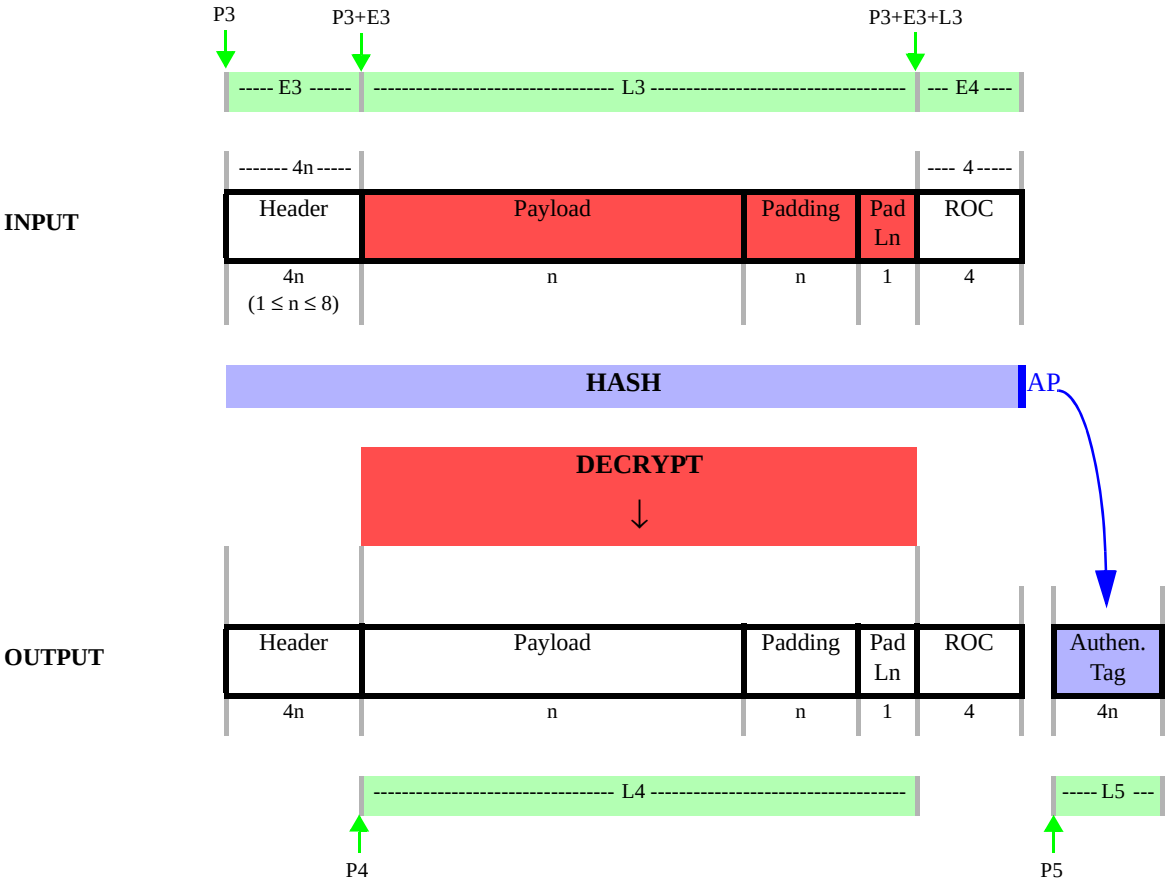

Figure 27-27. SRTP Inbound without ICV Compare Packet Pointer Diagram

Data Processing Steps (as managed by the Channel):

1. Hash-only: Starting at *P3*, read *E3* bytes and feed them to the MDEU.
2. Decrypt and hash: Continuing at *P3*, read *L3* bytes and feed them to the cipher EU, with insnooping to the MDEU.
3. Output: Write *L4* bytes of output data to *P4*.
4. Hash-only ROC: Continuing at *P3*, read *E4* bytes and feed them to the MDEU.
5. Authentication Tag: Finish computation of the Authentication Tag in the MDEU. Obtain *L5* bytes of Authentication Tag from the MDEU and write them to *P5*.

.

Programming Notes: See the notes for the outbound case.

27.7.1.2.19 SRTP Inbound with ICV Compare

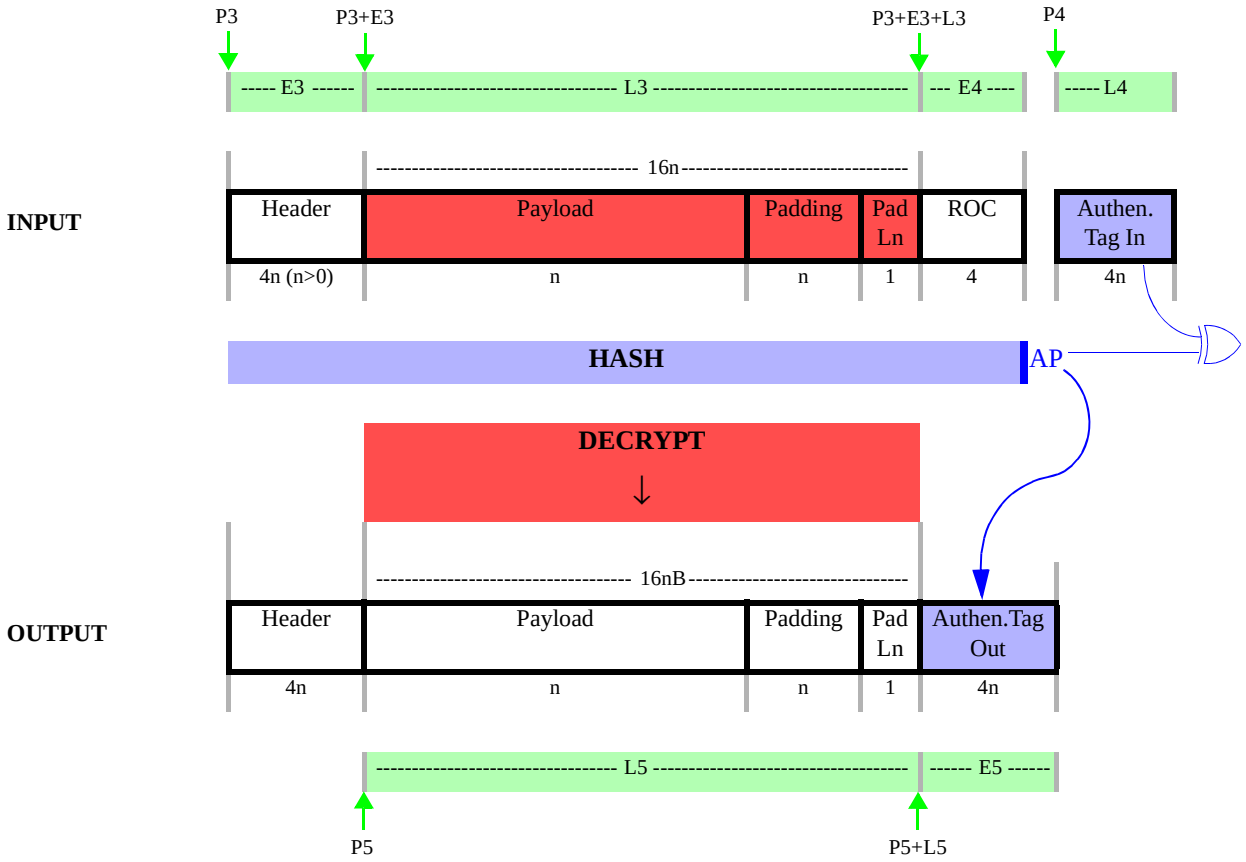

Figure 27-29. SRTP Inbound with ICV Compare Packet Pointer Diagram

Note: "Authentication tag out" is typically not needed, so E5 may be set to 0.

Data Processing Steps (as performed by the Channel):

1. Hash-only: Starting at *P3*, read *E3* bytes and feed them to the MDEU.
2. Decrypt and hash: Continuing at *P3*, read *L3* bytes and feed them to the cipher EU, with insnooping to the MDEU.
3. Output: Write *L5* bytes of output data to *P5*.
4. Hash-only ROC: Continuing at *P3*, read *E4* bytes and feed them to the MDEU.
5. ICV comparison: If ICV comparison is turned on, then starting at *P4* read *L4* bytes and feed this "old authentication tag" to the MDEU. When the ICV computation in the MDEU is finished, compare the first *L4* bytes of MDEU output to the "old authentication tag", and send the pass/fail result back to the channel.
6. ICV output: Obtain *E5* bytes of authentication tag from the MDEU and write them continuing at *P5*.

Table 27-39. Descriptor Control word examples for SRTP Inbound Descriptor with ICV Checking

control word (32 bit hex)	Description
64635C2A	AES-CTR / HMAC-SHA1 with ICV Check SRTP Inbound

27.7.1.2.20 Descriptor Types0011_1: pkeu_build, 0100_1: pkeu_ptmul, and 0101_1: pkeu_ptadd_dbl

These three descriptor types are defined for use with PKEU for elliptic curve cryptographic computations. pkeu_mm is summarized in 27-40 merely for comparative purposes.

Table 27-40. PKEU Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
1000_0	Length	“N” In	“B” In	“A” In	“E” In	“B” Out	reserved	reserved
pkeu_mm	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved
0011_1	Length	“A0” In	“A1” In	“A2” In	“A3” In	“B0” In	“B1” In	"Build" Out
pkeu_build	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved
0100_1	Length	“N” In	“E” In	“Build” In	“B1” Out	“B2” Out	“B3” Out	reserved
pkeu_ptmul	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved
0101_1	Length	“N” In	“Build” In	“B2” In	“B3” In	“B1” Out	“B2” Out	“B3” Out
pkeu_ptadd_dbl	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved

pkeu_build is a non-computational descriptor type defined for convenience in creating the parameter "Build" -- it simply takes the six parameters listed and creates a single 768-byte data structure to be loaded as a single structure in either the pkeu_ptmul or pkeu_ptadd_dbl descriptor. The same structure can easily be built by software or by using gather tables underneath either pkeu computational descriptor.

pkeu_build Data Processing Steps (as managed by the Channel):

1. Fetch *L0* bytes from address *P0* and write to PKEU "A0" register.
2. Fetch *L1* bytes from address *P1* and write to PKEU "A1" register.
3. Fetch *L2* bytes from address *P2* and write to PKEU "A2" register.
4. Fetch *L3* bytes from address *P3* and write to PKEU "A3" register.
5. Fetch *L4* bytes from address *P4* and write to PKEU "B0" register.
6. Fetch *L5* bytes from address *P5* and write to PKEU "B1" register.
7. Fetch *L6 bytes* from PKEU starting at register address "A0" and write to address *P6*. Note that for this to be useful, *L6* needs to specify at least 128 bytes for each non-zero-length segment in *L0* through *L4*. Further, any zero-length segments should be treated as non-zero for the sake of this computation. It is recommended that *L6* be 6*128 = 768 bytes.

Figure 27-31. Descriptor Format pkeu_build

pkeu_ptmul is used to perform elliptic curve point multiplication.

pkeu_ptmul Data Processing Steps (as managed by the Channel):

1. Fetch *L0* bytes of modulus / irreducible polynomial from address *P0* and write to PKEU "N" register.
2. Fetch *L1* bytes of point multiplier from address *P1* and write to the PKEU "E" register.
3. Fetch *L2* bytes containing up to 6 elliptic curve parameters (at 128 bytes each) from address *P2* and write to PKEU starting at address for register "A0". If *L2* is 768 bytes, this will completely cover PKEU registers A0, A1, A2, A3, B0, and B1.
4. After computation has completed, fetch *L3* bytes of elliptic curve result x_3 and write to address *P3*.
5. After computation has completed, fetch *L4* bytes of elliptic curve result y_3 and write to address *P4*.
6. After computation has completed, fetch *L5* bytes of elliptic curve result z_3 and write to address *P5* (note that z_3 is of interest only if projective coordinates were used.

	0 15	16	17 23	24 27	28 31	32 63

Figure 27-32. Descriptor Format pkeu_ptmul

pkeu_ptadd_dbl is used to perform either elliptic curve point addition or elliptic curve point doubling.

pkeu_ptadd_dbl Data Processing Steps (as managed by the Channel):

1. Fetch *L0* bytes of modulus / irreducible polynomial from address *P0* and write to PKEU "N" register.
2. Fetch *L1* bytes containing up to 6 elliptic curve parameters (at 128 bytes each) from address *P1* and write to PKEU starting at address for register "A0". If *L1* is 768 bytes, this will completely cover PKEU registers A0, A1, A2, A3, B0, and B1.
3. Fetch *L2* bytes from address *P2* and write to PKEU "B2" register.
4. Fetch *L3* bytes from address *P3* and write to PKEU "B3" register.

5. After computation has completed, fetch *L4* bytes of elliptic curve result x_3 and write to address *P4*.
6. After computation has completed, fetch *L5* bytes of elliptic curve result y_3 and write to address *P5*.
7. After computation has completed, fetch *L6* bytes of elliptic curve result z_3 and write to address *P6* (note that z_3 is of interest only if projective coordinates were used.

In 27-40 above, the identifiers listed are register names within PKEU. The table below is a cross-reference for *typical* use of those registers. For further information (such as exceptions to the table), see Section 27.6.1.11.

Table 27-42. Typical register usage for PKEU

PKEU Register	Typical EC Parameter	Description
A0	input: x_1 output: --	Input Point x coordinate
A1	input: y_1 output: --	Input point y coordinate
A2	input: z_1 output: --	Input Point z coordinate (byte string 0x01 if affine)
A3	input: a output: --	elliptic curve parameter "a"
B0	input: b / c output R^2 mod N	F_p: elliptic curve parameter "b" F_2m: elliptic curve parameter "c"; $= b^{(2^{m-2})} \bmod I$
B1	input (ptmul): R^2 mod N input (ptadd_dbl): x_2 output: x_3	input (ptmul): Montgomery conversion factor input (ptadd_dbl): second input point x coordinate output: Result point coordinate
B2	input (ptmul): -- input (ptadd_dbl): y_2 output: y_3	input (ptmul): unused input (ptadd_dbl): unused output: Result point coordinate
B3	input (ptmul): -- input (ptadd_dbl): z_2 output: z_3	input (ptmul): unused input (ptadd_dbl): second input point z coordinate output: Result point coordinate

For more information on PKEU operation and built in routines, see Section 27.6.1.11.

27.7.1.2.21 Descriptor Type 1000_1: tls_ssl_block

Table 27-43. tls_ssl_block Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
1000_1 outbound tls_ssl_block	Length	MAC Key	Cipher IV In	Cipher Key	Main Data In	reserved	Data Out	Cipher IV Out
	Extent	reserved	reserved	reserved	Hash-only Header	ICV Out	reserved	reserved
1000_1 inbound tls_ssl_block	Length	MAC Key	Cipher IV In	Cipher Key	reserved	Main Data In	Data Out	Cipher IV Out
	Extent	reserved	reserved	reserved	Hash-only Header	ICV In	ICV Out	reserved

Descriptor type TLS / SSL block is used for TLS or SSL packets when a block cipher is chosen. As can be seen by comparing the packet pointer diagrams in **Figure 27-34** and **Figure 27-35**, the usage of a block cipher requires the insertion of a special padding field. The requirements for processing this special padding field results in different descriptor types for TLS / SSL processing block ciphers versus stream ciphers.

27.7.1.2.22 TLS / SSL Block Cipher Outbound

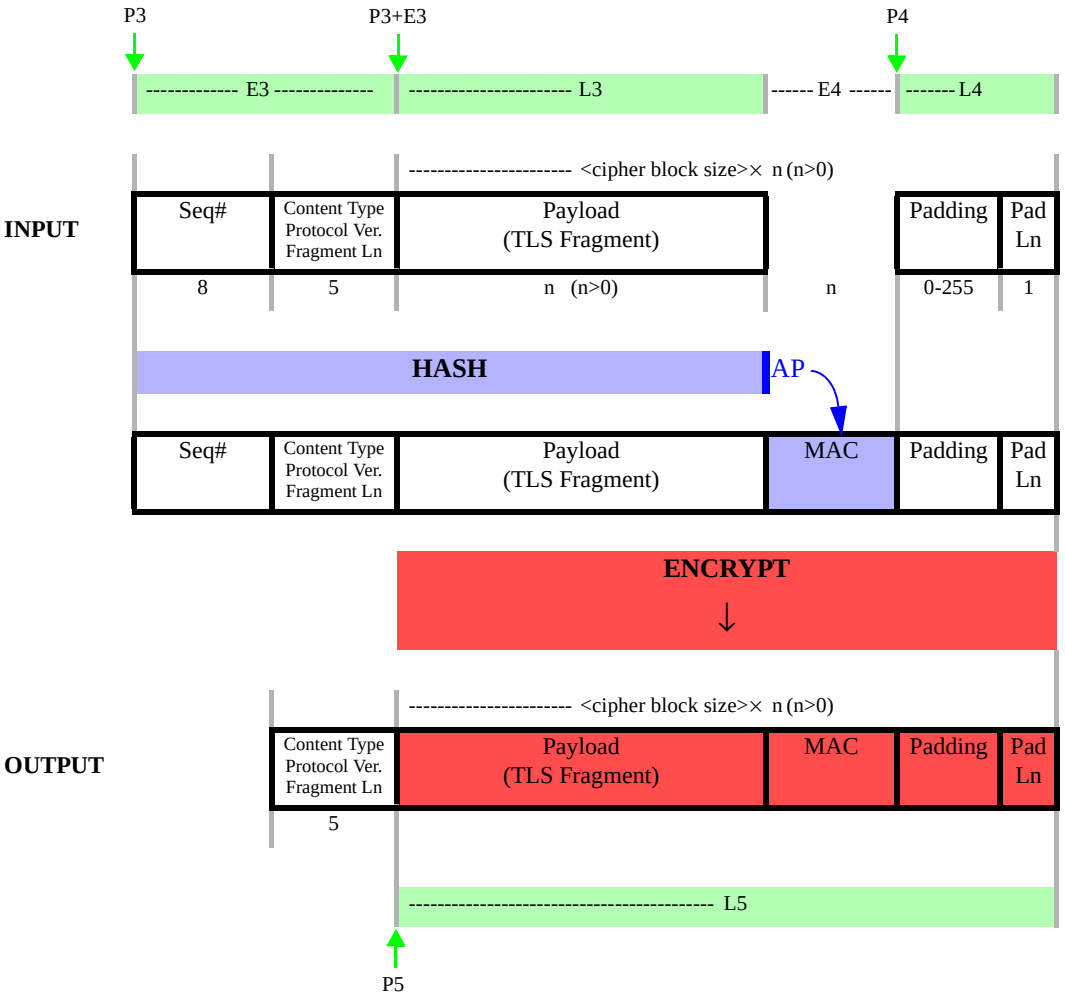

Figure 27-34. TLS / SSL Block Cipher Outbound Packet Pointer Diagram

Note: SSL has some different field lengths, but can be handled in the same manner.

Data Processing Steps (as managed by Channel)

1. Hash-only data: Starting at *P3*, read *E3* bytes and feed them to the MDEU.
2. Encrypt and hash: Continuing at *P3*, read *L3* bytes and feed them to the cipher EU, with insnooping to the MDEU.

	Length	**J**	**Extent**	**--**	**Eptr**	**Pointer**

Figure 27-37. TLS / SSL Block Cipher Inbound Descriptor Format

Data Processing Steps (as managed by the Channel):

1. Write initial_data_size to the MDEU byte_count, where:

   initial_data_size = E3 + L4 - (256 + E4) bytes

2. Hash-only: Starting at *P3*, read *E3* bytes and feed them to the MDEU. As the MDEU processes data, it decrements its byte_count. If the byte_count is zero or negative, processing stops.
3. Decrypt and hash: Starting at *P4*, read *L4* bytes and feed them to the cipher EU with outsnooping to the MDEU. As the MDEU processes data, it decrements its byte_count. If the byte_count is zero or negative, processing stops.
4. Output: Write output data to *P5*.
5. Decrypt and hash (continued): The MDEU intercepts the last byte written to its input FIFO, which is the decrypted pad length. The MDEU computes:

   remaining_bytes = 255 - pad_length

   and adds this to its byte count. The MDEU continues processing data from its input FIFO until its byte count reaches zero.
6. MAC comparison: In the MDEU, complete computation of the MAC. Compare the newly computed MAC to the next *E4* bytes from the MDEU input FIFO, and send the pass/fail result back to the channel. Clear the MDEU input FIFO.
7. MAC output: Obtain *E5* bytes of MAC from the MDEU and write them continuing at *P5*.

1001_1 inbound tls_ssl_ stream	Length	MAC Key	Cipher IV In	Cipher Key	reserved	Main Data In	Data Out	Cipher IV Out
	Extent	reserved	reserved	reserved	Hash-only Header	ICV In	ICV Out	reserved

27.7.1.2.25 TLS / SSL Stream Cipher Outbound

Descriptor type TLS / SSL Stream is used for TLS or SSL packets when a stream cipher is chosen. As can be seen by comparing the packet pointer diagrams in **Figure 27-34** and Figure 27-35, the usage of a block cipher requires the insertion of a special padding field. The lack of a padding field allows for optimizations that result in different descriptor types for TLS / SSL processing stream ciphers versus block ciphers.

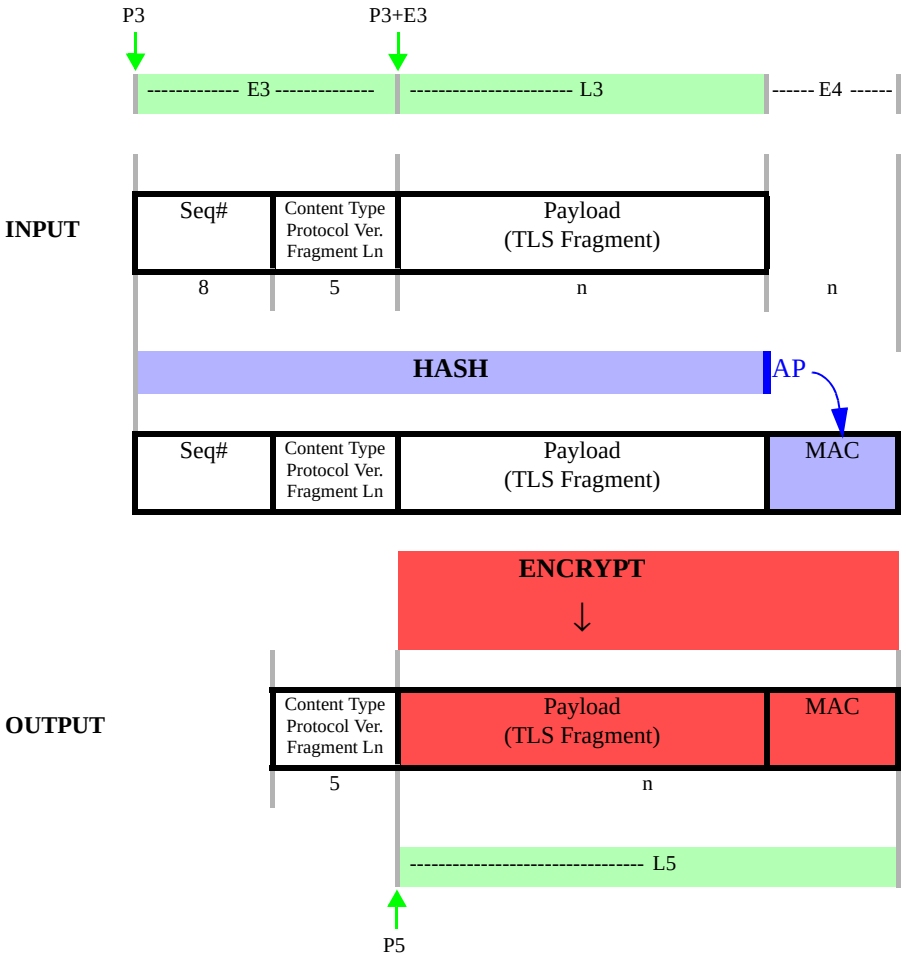

Figure 27-38. TLS / SSL Stream Cipher Outbound Packet Pointer Diagram

Note: SSL has some different field lengths, but can be handled in the same manner.

Data Processing Steps (as managed by the Channel); these are the same as the procedure for block cipher outbound except that there is no “encrypt only” padding at the end of the packet:

1. Hash-only: Starting at *P3*, read *E3* bytes and feed them to the MDEU.
2. Encrypt and hash: Continuing at *P3*, read *L3* bytes and feed them to the cipher EU, with insnooping to the MDEU.

27.7.1.2.26 TLS / SSL Stream Cipher Inbound

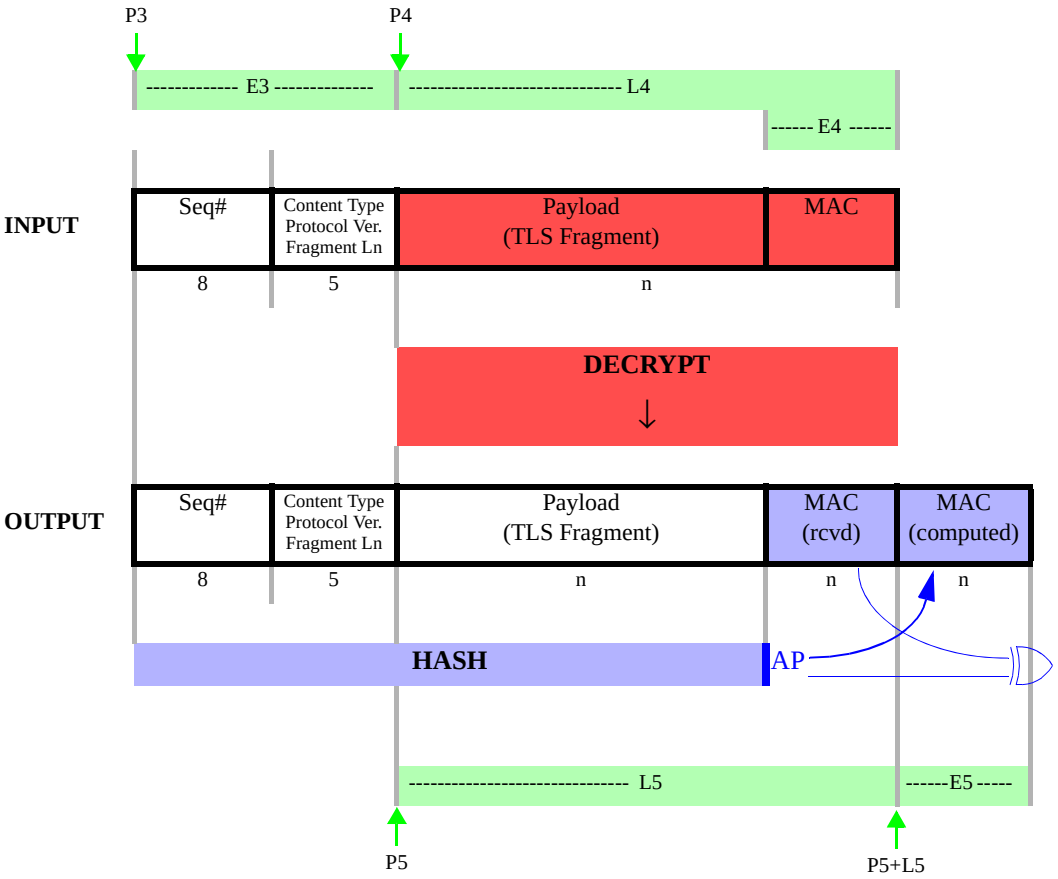

Figure 27-40. TLS / SSL Stream Cipher Inbound Packet Pointer Diagram

Notes: **1.** SSL has some different field lengths, but can be handled in the same manner.
2. When automatic ICV comparison is used, “MAC out” is typically not needed, so E5 may be set to 0.

Data Processing Steps (as managed by the Channel); note that these are very different from block cipher inbound:

1. Hash-only: Starting at *P3*, read *E3* bytes and feed them to the MDEU.
2. Decrypt and hash payload: Starting at *P4*, read *L4* bytes and feed them to the cipher EU, with outsnooping to the MDEU.
3. Output: Write output data to *P5*.
4. MAC comparison: In the MDEU, complete computation of the MAC. Compare the newly computed MAC to the last *E4* bytes from the MDEU input FIFO, and send the pass/fail result back to the channel. Clear the MDEU input FIFO.
5. MAC output: Obtain *E5* bytes of MAC from the MDEU and write them continuing at *P5*.

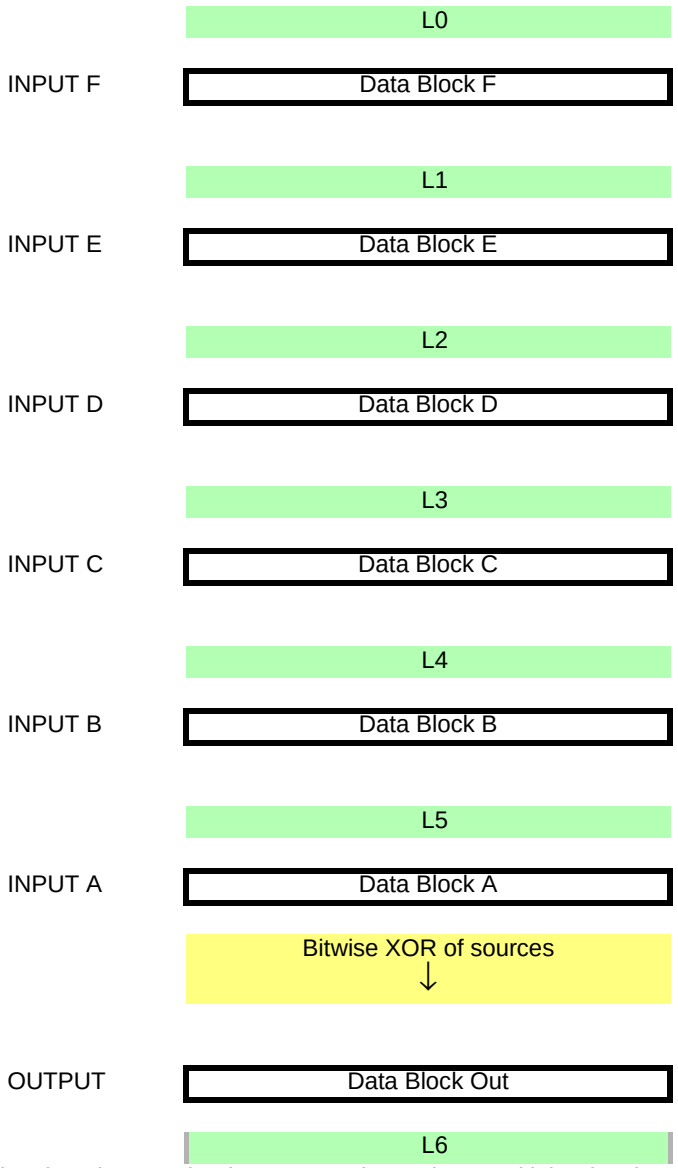
27.7.1.2.27 Descriptor Type 1010_1: raid_xor

The RAID-XOR descriptor type is designed for use when desired computation is an XOR of multiple sources into a single destination, such as for RAID level 5 data parity protection. Note that used pointers must be end-loaded for this descriptor type -- that is, all used pointer entries must be at the end and all unused pointers must be at the beginning of the descriptor. The channel will count the number of used pointers and write the appropriate value automatically into the SCM field of the AESU Mode register (**Figure 27-42**).

Table 27-49. Descriptor Format Summary for RAID-XOR

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
1010_1 raid_xor	Length	Source F Data In	Source E Data In	Source D Data In	Source C Data In	Source B Data In	Source A Data In	Data Out
	Extent	reserved	reserved	reserved	reserved	reserved	reserved	reserved

For this descriptor type, all lengths must be multiples of 32 bytes, and all J bits must be 0 (scatter-gather operation is not permitted for this descriptor type).



Notes: **1.** All data lengths must be the same and must be a multiple of 32 bytes.
2. Scatter/Gather is not allowed.

Figure 27-42. RAID-XOR Packet Pointer Diagram

	0 15	16	17 23	24 27	28 31	32 63
Header	Descriptor Control					Descriptor Feedback
Pointer 0	Data Block F Length	0	--	-	Eptr0	P0: Address of Data Block F
Pointer 1	Data Block E Length	0	--	-	Eptr1	P1: Address of Data Block E
Pointer 2	Data Block D Length	0	--	-	Eptr2	P2: Address of Data Block D
Pointer 3	Data Block C Length	0	--	-	Eptr3	P3: Address of Data Block C
Pointer 4	Data Block B Length	0	--	-	Eptr4	P4: Address of Data Block B
Pointer 5	Data Block A Length	0	--	-	Eptr5	P5: Address of Data Block A
Pointer 6	XOR Block Length	0	--	-	Eptr6	P6: Address of XOR Block Out
	Length	**J**[1]	**Extent**	**--**	**Eptr**	**Pointer**

Figure 27-43. RAID_XOR Descriptor Format

1. Jump bits are zero in the RAID_XOR descriptor format diagram because scatter and gather operation is not permitted.

Data Processing Steps (as managed by the Channel):

1. XOR: Read 32 bytes from *P5*, then *P4*, etcetera (for all consecutive non-zero pointers) and feed them to AESU. Continue reading 32-byte blocks in rotation from selected sources until *L0* bytes have been read from each.
2. Output: Write output data to *P6*.

Table 27-50. Descriptor Control word example for RAID-XOR Descriptors

control word (32 bit hex)	Description
6c6000a8	raid_xor

27.7.1.2.28 Descriptor Type 1011_1: aes_gcm

The AES_GCM descriptor type is overloaded to provide support for MACSec, IPsec, and any other AES-GCM needs. This descriptor is specific to the specific processing requirements of the AESU implementation of GCM.

Table 27-51. Descriptor Format Summary

Descriptor Type	field type	Pointer0	Pointer1	Pointer2	Pointer3	Pointer4	Pointer5	Pointer6
1011_1 ipsec_aes_gcm	Length	AES Context In	AAD In	Nonce Part 2 In	AES Key In	Main Data In	Data Out	Cipher Context Out
	Extent	reserved	reserved	reserved	Nonce Part 1 In	AES ICV In	AES ICV Out	CRC ICV In/Out

As can be seen by inspection of **Figure 27-46** versus **Figure 27-50**, the only difference between the two MACSec and IPsec descriptors is how the GCM-IV is provided to AESU. The Channel can handle any amount of GCM-IV that is provided as the last *E3* bytes of *P3*, and any amount of GCM-IV that is provided in *P2*. The portion of GCM-IV in *P3* is prepended to GCM-IV from *P2*. AES-GCM-IPsec descriptors are defined as AES-GCM descriptors with an E3 of 4. AES-GCM-MACSEC descriptors are defined as AES-GCM descriptors with an L2 of 0.

Table 27-52. Descriptor Control word examples for AES-GCM Outbound Descriptors

control word (32 bit hex)	Description
6a3000b8	aes gcm outbound
6a3800b8	aes gcm / crc-32 IEEE 802 outbound

	0 15	16	17 23	24 27	28 31	32 63
Header	Descriptor Control					Descriptor Feedback
Pointer 0	Context In Length	J0	--	-	Eptr0	P0: Address of AES-GCM Context
Pointer 1	GCM-AAD Length	J1	--	-	Eptr1	P1: Address of AES-GCM Additional Authen. Data
Pointer 2	Nonce Part 2 Length	J2	--	-	Eptr2	P2: Address of Part 2 of Nonce
Pointer 3	Key Length	J3	Nnc1 Ln	-	Eptr3	P3: Address of Cipher Key • Nonce Part 1 (Nnc1)
Pointer 4	Data In Length	J4	RICV Ln	-	Eptr4	P4: Address of Data In • Rcv ICV In • CRC In
Pointer 5	Data Out Length	J5	CICV Ln	-	Eptr5	P5: Address of Data Out • Comp ICV Out • CRC Out
Pointer 6	Cipher IV Length	J6	CRC Len	-	Eptr6	P6: Address of Cipher IV Out
	Length	**J**	**Extent**	**--**	**Eptr**	**Pointer**

Notes: **1.** Note that Rcv ICV In and CRC In are used only for inbound descriptor
2. Note that Comp ICV Out and CRC Out are used only for outbound descriptors

Figure 27-44. GCM General Descriptor Format

AES GCM Data Processing Steps[1] (as managed by the Channel):

1.this list of steps is true for General AES-GCM, for AES-GCM for MACSec, and AES-GCM for IPsec.

1. Channel prepares AESU Mode, Key Size, Key, Mac Size, and Data Size registers.
2. Channel fetches *E3* bytes from address *P3 + L3* and writes to AESU FIFO as first part of GCM-IV.
3. Channel fetches *L2* bytes from address *P2* and writes to AESU FIFO as remaining part of GCM-IV.
4. If *E3 + L2* is not a multiple of 16, the channel writes bytes of content zero to the AESU FIFO to pad the GCM-IV to a multiple of 16 bytes.[1]
5. Channel writes [*E3 + L2*] * 8 (length of IV in bits) to the AESU Context Registers len(IV)[c] field
6. Channel fetches *L1* bytes of AAD from address *P1* and writes to AESU FIFO (and the CRCU input FIFO if CRCU is specified in the header as a secondary EU)
7. If *L1* is not a multiple of 16, the channel writes bytes of content zero to the AESU FIFO (but not to the CRCU FIFO) to pad the AAD to a multiple of 16 bytes
8. Channel writes *L1* * 8 (length of AAD in bits) to the AESU Context Registers len(AAD)[c] field
9. If Pointer 4 specifies a receive ICV value, then it is written into the appropriate AESU Context registers.
10. *L4* bytes of Data In is fetched from address *P4* is written into the AESU input FIFO and to the CRCU input FIFO.
11. If *E6* is nonzero and the descriptor header specifies *inbound*, then write CRC to CRCU input FIFO.
12. Data Out is read from the AESU output FIFO and written to address *P5*.
13. If *E5* is nonzero, fetch the computed ICV and write to *P5 + L5*.
14. If *E6* is nonzero and the descriptor header specifies *outbound*, fetch the computed CRC and write to *P5 + L5 + E5*.

1.That the channel pads the GCM-IV and the AAD is pointed out only because the AESU section discusses the need for padding GCM-IV and AAD. Failure to note it here might leave the user with the mistaken belief that the padding is left to the host.

Table 27-53. Descriptor Control word examples for AES-GCM Inbound Descriptors

control word (32 bit hex)	Description
6a2000ba	aes gcm inbound
6a2800ba	aes gcm / crc-32 IEEE 802 inbound
6a2840ba	aes gcm / crc-32 IEEE 802 crc check inbound
6e2000ba	aes gcm icv check inbound
6e2800ba	aes gcm icv check / crc-32 IEEE 802 inbound
6e2840ba	aes gcm icv check / crc-32 IEEE 802 crc check inbound

Programming Notes:

1. CRC operations are optional.
2. The nonce, AAD, and payload are all sent to the AESU input FIFO. The channel pads the Nonce (GCM-IV) and AAD out to the next 16B word as written to AESU input FIFO, so that the AAD and payload start on a fresh block boundary.

27.7.1.2.29 AES_GCM Outbound for MACSec

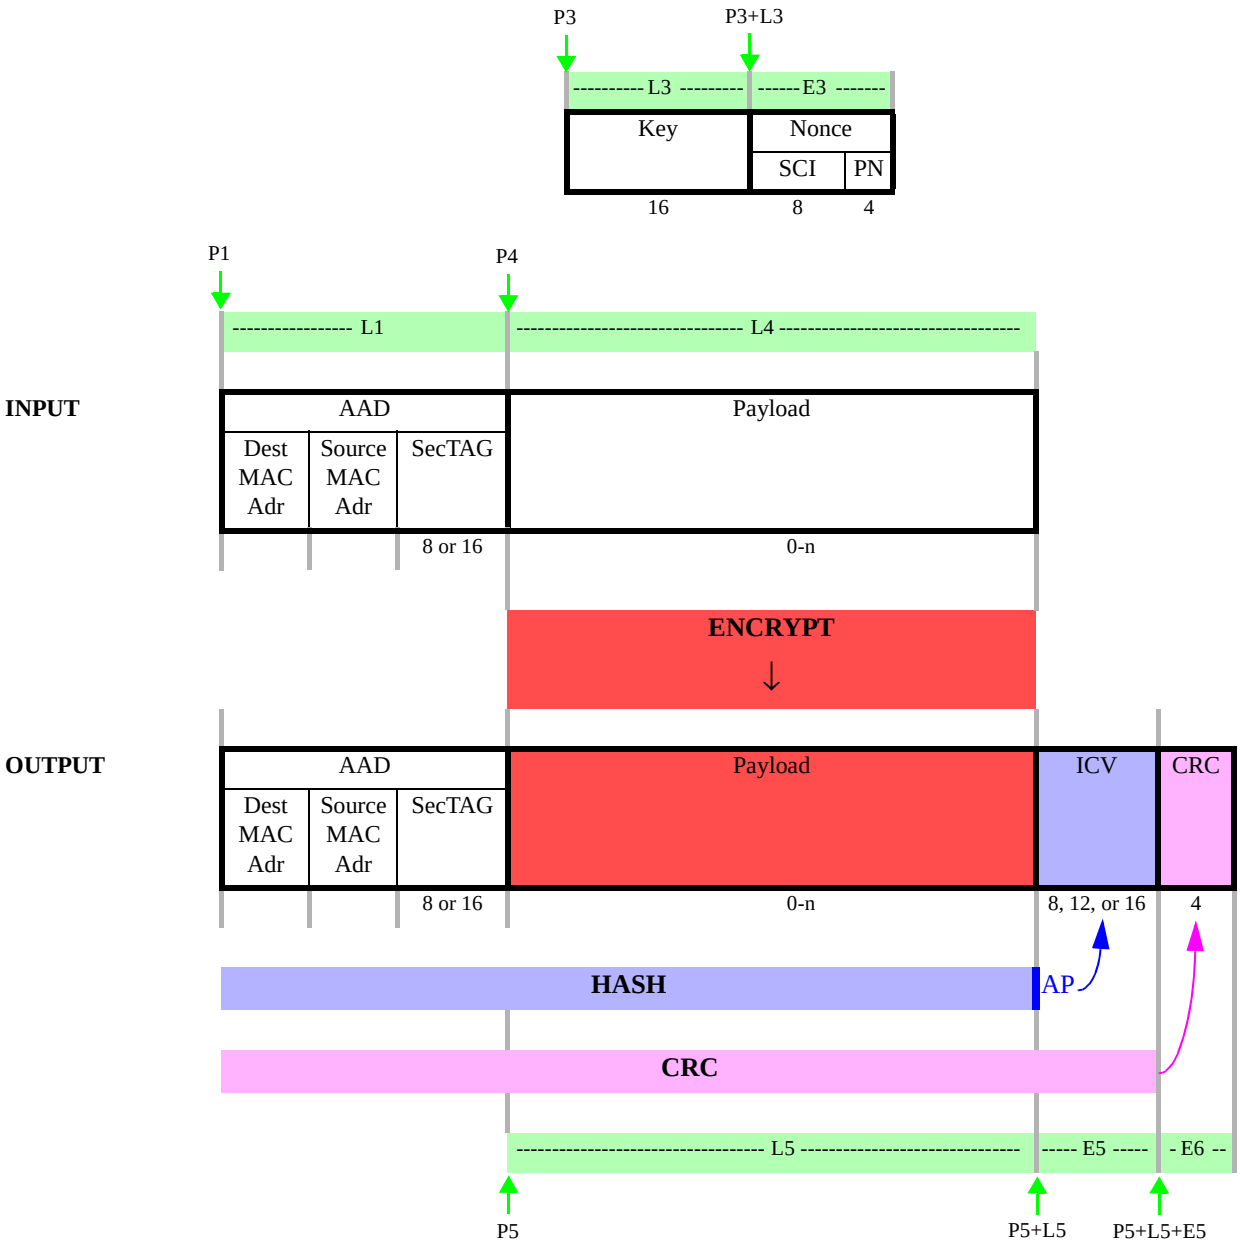


Figure 27-45. AES_GCM Outbound MACSec Packet Pointer Diagram

\Notes:

1. Driver must prepare AAD

	0 15	16	17 23	24 27	28 31	32 63

Figure 27-46. GCM MACSec Outbound Descriptor Format

27.7.1.2.30 AES_GCM Inbound for MACSec

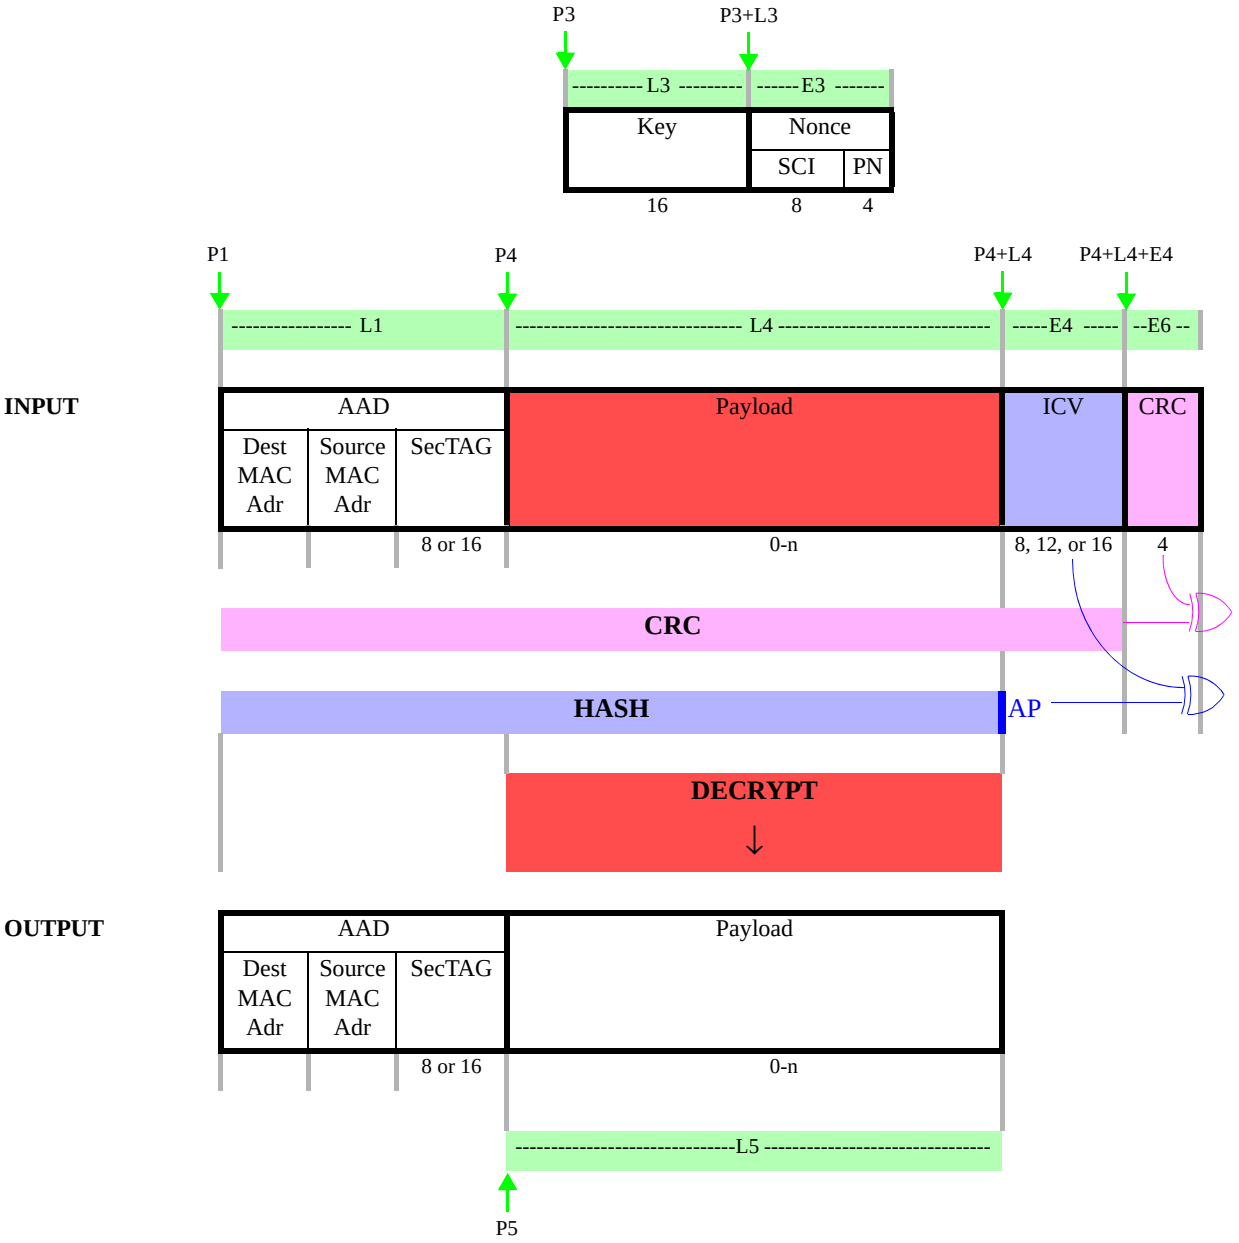

Figure 27-47. AES_GCM Inbound MACSec Packet Pointer Diagram

Notes:
1. CRC operations are optional. If CRC operation is used, then automatic CRC comparison must be activated. There is no CRC out.
2. When automatic ICV comparison is used for authentication, "ICV out" is typically not needed, so E5 may be set to 0.
3. The nonce, AAD, and payload are all sent to the AESU input FIFO. The Nonce and AAD must be padded out the next 16B word, so that the AAD and payload start on a fresh block boundary.

Figure 27-48. GCM MACSec Inbound Descriptor Format

27.7.1.2.31 AES_GCM Outbound for IPsec

To avoid a point of confusion, please note the term IV is overloaded for IPsec-AES-GCM. The IPsec-IV consists of SALT • GCM-IV. IPsec Salt for GCM comes from Key material, whereas IPsec-IV for GCM is transmitted (optionally) as part of the IPsec packet.

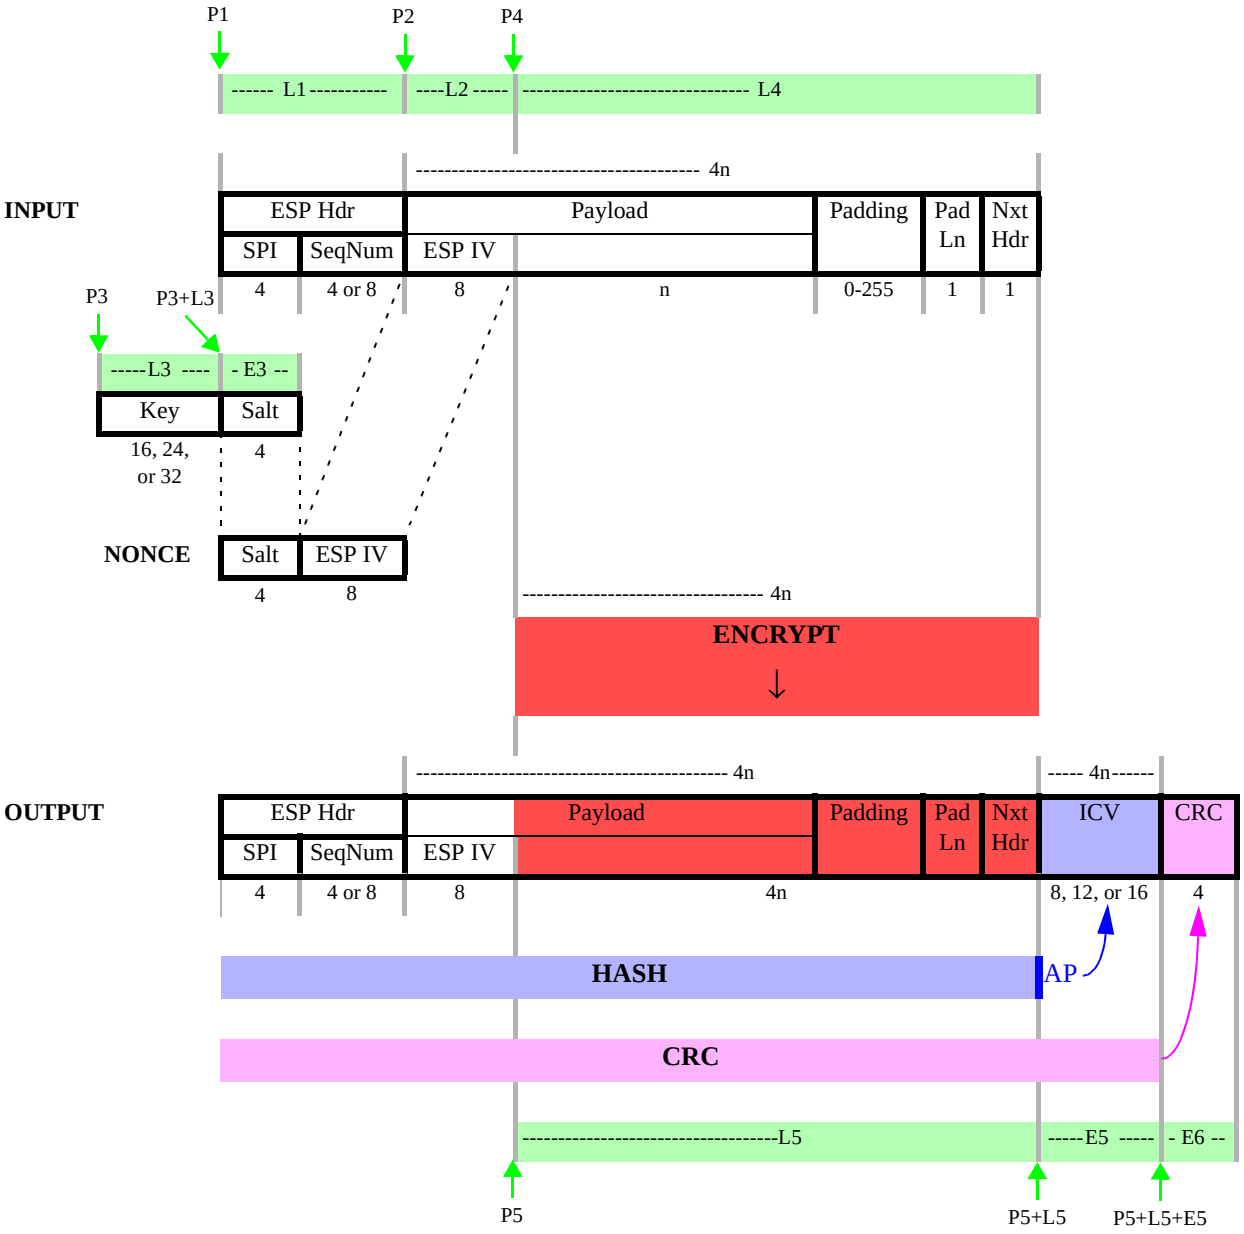

Figure 27-49. AES_GCM Outbound IPsec Packet Pointer Diagram

Notes: **1.** CRC operations are optional.
2. The nonce, AAD, and payload are all sent to the AESU input FIFO. The Nonce and AAD must be padded out the next 16B word, so that the AAD and payload start on a fresh block boundary.

27.7.1.2.35 iSCSI dbl_crc Inbound

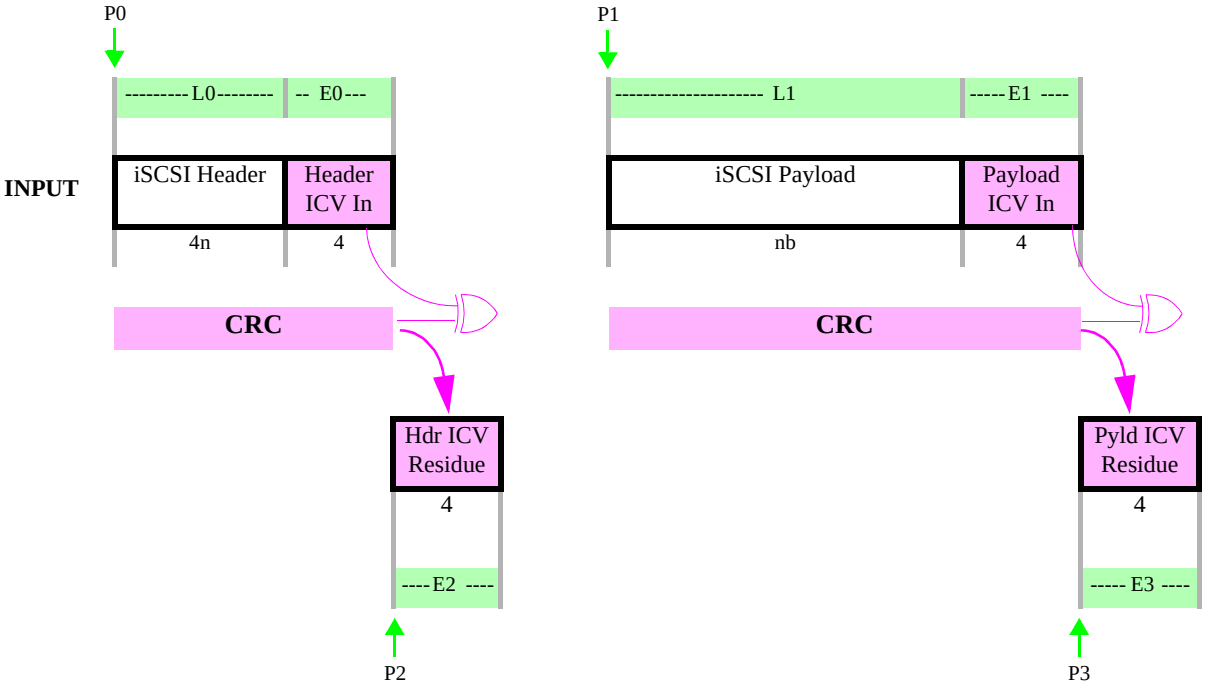

Figure 27-55. iSCSI dbl_crc Inbound Packet Pointer Diagram

Notes:

Notes: **1.** Typically, automatic ICV comparison would be used with this descriptor, so the “ICV out” values (see P2 and P3) are not needed. In this case, P2, E2, P3, and E3 may be set to 0.

2. Failed digest comparisons are indicated by the CICV interrupt from the EU (if this interrupt is enabled), and the ICCR0 and ICCR1 bits in header writeback (if writeback is enabled). ICCR0 gives the result of the payload ICV comparison and ICCR1 gives the result of the header ICV comparison.

27.7.2 Pointers

Bit	63 48	47	46 40	39 36	35 32	31 0
	LENGTH	J	EXTENT	—	EPTR	POINTER

The descriptor contains seven pointers that define where the SEC accesses its input and output data parcels in memory. The pointers are numbered from 0 to 6 as shown in **Section 27.7.1.1**. The channel determines how it uses each of the pointers based on the Descriptor Type and Direction fields in the header. The channel accesses the first data parcel by starting at a location given by a POINTER value, and accessing a number of bytes given by a LENGTH or EXTENT value. Subsequent data parcels can be accessed by starting where a previous data parcel ended, or by starting at a different POINTER location. The LENGTH or EXTENT used with any POINTER can be from the same pointer or from a different pointer in the same descriptor. Although the

EXTENT field exists in each pointer of the SEC descriptor, only the EXTENTs in pointers 3, 4, and 5 are currently used. If Extend Address Enable is set (1), then the four EPTR bits are concatenated with the POINTER field to form a 36-bit pointer address.

Table 27-57. Pointer Field Definitions

Bits	Name	Description	Settings
63–48	LENGTH	**Length** The use of this field depends on the Descriptor Type and Direction in the header. A value of zero causes the channel to skip this pointer.	A number of bytes in the range 0 to 65535.
47	J	**Jump** Determines whether to jump to a link table whenever the POINTER field in this same field is used.	0 The POINTER field points to data. 1 The POINTER field points to a link table, and scatter/gather is enabled.
46–40	EXTENT	**Extent** A number of bytes in the range 0 to 127. The use of this field depends on the Descriptor Type and Direction in the header.	
39–36	—	Reserved	
35–32	EPTR	**Extended Pointer** Concatenated as the top 4 bits of the pointer when EAE is high (see the EAE bit in **Table 27-1**).	
31–0	POINTER	**Pointer** A memory address.	

Examples of special cases include:

- Sometimes, a descriptor field does not apply for the requested service. With seven pointers, it is possible that not all these pointers are required to specify the input and output parameters. (Some operations, for example, do not require context.) Where a particular pointer is not used, all fields in that pointer should be cleared (0).
- Some descriptors involve more than seven parcels of input and output data. In these cases, it is necessary to use one POINTER field to address a sequence of data parcels.
- LENGTH and EXTENT fields normally specify the sizes of data parcels. Often, but not always, the size of a parcel located at the address contained in the matching POINTER field. Sometimes an EXTENT field will refer to data in a pointer not in the same pointer. For example, with the CCMP descriptor type, the length of the CRC check field appears in E0, but the field that is E0 bytes in length is referred to either by P4 or P5, depending on the direction bit in the Header Control Word. In some cases, however, the POINTER field is zero, and the LENGTH and/or EXTENT fields simply specify values to write to an EU.

- The J bit in each pointer is used to enable the scatter/gather feature. If a data parcel to be read or written by SEC is in one contiguous block of memory locations, then the scatter/gather feature is not needed. In this case, set the POINTER to point directly at the first byte of the parcel, and the J bit should be 0. On the other hand, if the data parcel is stored in several separate segments of memory, then the scatter/gather capability is needed to assemble or distribute the complete parcel. In this case, set the POINTER to point to a link table, and the J bit should be 1. For link table format, see **Section 27.7.3**, *Link Tables*, on page 27-177. Scatter/gather capability is available for all pointers of all descriptor types, with the exception that the raid-xor descriptor type does not allow scatter/gather.

27.7.3 Link Tables

Bit	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Field	SEGLEN																—						R	N	—				EPTR			

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	SEGPTR																															

Link tables implement scatter/gather capability. For gather operations, a link table specifies a list of memory segments that are to be concatenated in the process of assembling parcels. For scatter operations, a link table specifies a list of memory segments into which the output data should be written. Scatter or gather of a parcel may be specified by a single link table or by a chain of link tables that are linked together with pointers.

The link table or chain of link tables accessed through some descriptor POINTER must specify enough memory segments to hold precisely all the data that will be accessed through that pointer. In most cases, only a single parcel is accessed through a given POINTER, and the chain of link tables specifies just that parcel. In other cases, the descriptor POINTER is used multiple times to access a sequence of parcels, and the chain of link tables must supply data for the entire sequence.

A link table can contain any number of 64-bit entries. There are two kinds of entries, regular entries and next entries. Each regular entry specifies a memory segment by means of a 36-bit starting address (SEGPTR) and a 16-bit length (SEGLEN). A next entry is used at the end of a link table to specify that the list of memory segments is continued in another link table. In a next entry, the N bit is set, the SEGPTR field gives the address of the next link table, and the SEGLEN field must be 0. A chain of link tables can contain any number of link tables.

Whether the list of memory segments is in a single link table or split into several link tables, the last entry in the last link table is a regular entry with the R (return) bit set. The R bit signifies the end of link table operations so that the channel returns to the descriptor for its next pointer (if any).

Table 27-58 the components in a link table field.

Table 27-58. Link Table Field Definitions

Fields	Description	Settings
SEGLEN 63–48	**Segment Length** Indicates the number of bytes in the memory segment. **Notes:** **1.** See Section 27.7.6.2, **Channel Status Registers (CSR[1–4])**. **2.** When N = 1, must be 0.	N = 0 0 Error state in G_STATE (gather) or S_STATE (scatter). Any other value (1–65535) indicates the number of bytes in the memory segment. N = 1 0 Required value 1 Not valid.
— 47–42	Reserved	
R 41	**Return** Specifies whether this is the last data parcel. **Note:** If this entry does not specify the correct number of bytes to complete the last data parcel, a G_STATE or S_STATE error is set in the Channel Pointer Register (see Section 27.7.6.2).	N = 0 0 No special action. 1 Last entry in the chain of link tables. N = 1 All values ignored.
N 40	**Next** Indicates whether this is the last link table entry. The SEGPTR field holds the address of the next link table in the chain.	0 No special action. 1 Last 8-byte entry in the current link table.
— 39–36	Reserved	
EPTR 35–32	**Extended Pointer** Concatenated as the top 4 bits of the segment pointer when EAE is set (see the EAE bit in **Table 27-1**).	
SEGPTR 31–0	**Segment Pointer** A memory address.	

27.7.4 SEC Controller

The following sections describe the registers and structures used by the SEC Controller.

27.7.4.1 Master Control Register (MCR)

MCR — Master Control Register — Offset 0xC1030

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R/W															
Reset	0x0000															

Bits	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Field	RCA1	RCA2	RCA3	RCA4	—		PRIORITY		—						GIH	SWR
Reset	0x0000															
R/W	R/W															

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Field	CHN3_EU_PR_CNT								CHN4_EU_PR_CNT							
Type	R/W															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	CHN3_BUS_PR_CNT								CHN4_BUS_PR_CNT							
Type	R/W															
Reset	0x0000															

The MCR controls certain functions in the controller and provides a means for software to reset the SEC. **Table 27-59** describes the Master Control Register bit fields.

Table 27-59. Master Control Register Bit Field Descriptions

Bits	Reset	Description	Settings
— 63–48	0	Reserved. Write to zero for future compatibility.	
RCA1 47	0	**Remap Channel Address 1** Writing 1 to this bit remaps all Channel 1 core-accessible registers to an alternate 4KB address range. The channel done and error bits in the Interrupt Status Register cause the secondary interrupt to assert instead of the primary interrupt.	0 Channel 1 registers are accessible in the 0x11xx address range (default) 1 Channel 1 registers are accessible in the 0x01xx address range
RCA2 46	0	**Remap Channel Address 2** Writing 1 to this bit remaps all Channel 2 core-accessible registers to an alternate 4KB address range. The channel done and error bits in the Interrupt Status Register cause the secondary interrupt to assert instead of the primary interrupt.	0 Channel 2 registers are accessible in the 0x12xx address range (default) 1 Channel 2 registers are accessible in the 0x02xx address range

Table 27-59. Master Control Register Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
RCA3 45	0	**Remap Channel Address 3** Writing 1 to this bit remaps all Channel 3 core-accessible registers to an alternate 4KB address range. The channel done and error bits in the Interrupt Status Register cause the secondary interrupt to assert instead of the primary interrupt.	0 Channel 3 registers are accessible in the 0x13xx address range (default) 1 Channel 3 registers are accessible in the 0x03xx address range
RCA4 44	0	**Remap Channel Address 4** Writing 1 to this bit remaps all Channel 4 core-accessible registers to an alternate 4KB address range. The channel done and error bits in the Interrupt Status Register cause the secondary interrupt to assert instead of the primary interrupt.	0 Channel 4 registers are accessible in the 0x14xx address range (default) 1 Channel 4 registers are accessible in the 0x04xx address range
— 43–42	0	Reserved. Write to zero for future compatibility.	
PRIORITY 41–40	0	**Priority on Master Bus** The setting of these bits determines the transaction priority level the SEC asserts to the CLASS internal arbiter. The SEC does not dynamically alter its priority level based on system congestion or SEC utilization, however software can change the SEC priority level in realtime.	00 Lowest Priority (default) 01 Next Lowest Priority 10 Next Highest Priority 11 Highest Priority
— 39–34	0	Reserved. Write to zero for future compatibility.	
GIH 33	0	**Global Inhibit** Writing 1 to this bit defines external bus transfers to the master bus as non-snoopable and results in reducing the number of snoop bus requests generated by the external bridge.	0 External transfers snoopable (default) 1 External transfers are not snoopable.
SWR 32	0	**Software Reset** Writing 1 to this bit causes a global software reset. Upon completion of the reset, this bit is automatically cleared.	0 Do not reset 1 Global Reset
CHN3_EU_PR_CNT 31–24	0	**Channel 3 EU Priority Counter** This counter is used by the controller to determine when Channel 3 is denied access to a requested EU long enough to warrant immediate elevation to level 2 priority. **Note:** If set to zero and the CHN4_EU_PR_CTR is also set to zero, the controller assigns EUs on a purely round-robin basis. If either counter is zero and the other is non-zero, the zero is interpreted as 256.	
CHN4_EU_PR_CNT 23–17	0	**Channel 4 EU Priority Counter** This counter is used by the controller to determine when Channel 4 is denied access to a requested EU long enough to warrant immediate elevation to level 2 priority. **Note:** If set to zero and the CHN3_EU_PR_CTR is also set to zero, the controller assigns EUs on a purely round-robin basis. If either counter is zero and the other is non-zero, the zero is interpreted as 256.	

Table 27-59. Master Control Register Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
CHN3_BUS_PR_CNT 16–8	0	**Channel 3 Bus Priority Counter** This counter is used by the controller to determine when Channel 3 is denied access to the polychannel long enough to warrant immediate elevation to level 2 priority. **Note:** If set to zero and the CHN4_BUS_PR_CTR is also set to zero, the controller assigns polychannel access on a purely round-robin basis. If either counter is zero and the other is non-zero, the zero is interpreted as 256.	
CHN4_BUS_PR_CNT 7–0	0	**Channel 4 Bus Priority Counter** This counter is used by the controller to determine when Channel 4 is denied access to the polychannel long enough to warrant immediate elevation to level 2 priority. **Note:** If set to zero and the CHN3_BCUS_PR_CTR is also set to zero, the controller assigns polychannel access on a purely round-robin basis. If either counter is zero and the other is non-zero, the zero is interpreted as 256.	

27.7.4.2 Controller Identification Register (CIDR)

CIDR — Controller Identification Register — Offset 0xC1020

Bits	63 … 0
	ID
Type	R
Reset	0x0030030100000000

The read-only ID register contains the same value as the IP Block Revision Register (see **Section 27.7.4.3**, *Controller IP Block Revision Register (CIPBRR)*). In updating existing software, use of this address is likely to be most convenient, since it is the same address used for version information in previous SEC revisions.

27.7.4.3 Controller IP Block Revision Register (CIPBRR)

CIPBRR — Controller IP Block Revision Register — Offset 0xC1BF8

Bits	63–48	47–40	39–32	31–24	23–16	15–8	7–0
Field	IP_ID	IP_MJ	IP_MN	—	IP_INT	—	IP_CFG
Type	R						
Reset	0x0030	0x03	0x01	0x00	0x00	0x00	0x00

The read-only Controller IP Block Revision Register contains a 64-bit value that uniquely identifies the version of the SEC 3.1 block. **Table 27-60** describes the fields of the IP Block Revision Register.

Table 27-60. CIPBRR Bit Field Descriptions

Bits	Reset	Description	Settings
IP_ID 63–48	0x0030	**IP Block Identifier** Specifies the revision level of this IP block.	0x0030 fixed value.
IP_MJ 47–40	0x03	**IP Major Revision Number** Major revision level value.	0x03 fixed value.
IP_MN 39–32	0x01	**IP Minor Revision Number** Minor revision level value.	0x01 fixed value.
— 31–24	0	Reserved. Write to zero for future compatibility.	
IP_INT 23–16	0	**IP Integration Options**	0x00 fixed value.
— 15–8	0	Reserved. Write to zero for future compatibility.	
IP_CFG 7–0	0	**IP Block Configuration Options**	0x00 fixed value.

27.7.4.4 EU Assignment Status (EUASR)

EUASR — EU Assignment Status Register — Offset 0xC1028

Bits	63–60	59–56	55–52	51–48	47–44	43–40	39–36	35–32
Field	—	AFEU	—	MDEU	—	AESU	—	DEU
Type	R							
Reset	0xF	0x0	0xF	0x0	0xF	0x0	0xF	0x0

Bits	31–28	27–24	23–20	19–16	15–12	11–8	7–4	3–0
Field	—	—	CRCU	KEU	STEU	PKEU	—	RNGU
Type	R							
Reset	0xFF		0x0	0x0	0x0	0x0	0xF	0x0

The EUASR is used to check the assignment status of an EU to a particular channel. When an EU is already assigned, it is inaccessible to any other channel.

The SEC EU Assignment Status Register shows which channels own which EUs at a particular moment in time. However, there is a missing value in the EU Assignment Register (EUASR) such that the STEU (Snow3G Execution Unit) field in the EUASR is not updated properly, and always reads back as 0xF. As a result, it is not possible to know which (if any) channel is using the STEU. When operating the SEC in descriptor mode, the user does not have any reason to care which channel owns the STEU at a particular moment in time. STEU descriptors can be dispatched to any channel, and the SEC controller ensures that all channels get access to the STEU.

The only conditions under which the EU Assignment Register is useful is when mixing descriptor based operations with direct access mode (slave mode) operations. Direct access mode operations involve software writing directly to EU registers, bypassing the channels entirely. This is not a recommended mode of operation, but if there is a compelling reason to use direct access mode for STEU operations, only use direct access mode. If not, software must ensure that all STEU descriptors have completed before performing an STEU direct access. The recommendation is to use descriptors for all STEU operations. If the alternative is required, use direct access mode for all STEU operations. Do not switch between the two modes.

Table 27-61 describes the fields of the EUASR.

Table 27-61. EUASR Bit Field Descriptions

Bits	Reset	Description	Settings
— 63–60	0xF	Reserved. Write to 0xF for future compatibility.	
AFEU 59–56	0x0	**AFEU** Indicates the AFEU channel assignment.	See **Table 27-62**.
— 55–52	0xF	Reserved. Write to 0xF for future compatibility.	
MDEU 51–48	0x0	**MDEU** Indicates the MDEU channel assignment.	See **Table 27-62**.
— 47–44	0xF	Reserved. Write to 0xF for future compatibility.	

Table 27-61. EUASR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
AESU 43–40	0x0	**AESU** Indicates the AESU channel assignment.	See **Table 27-62**.
— 39–36	0xF	Reserved. Write to 0xF for future compatibility.	
DEU 35–32	0x0	**DEU** Indicates the DEU channel assignment.	See **Table 27-62**.
— 31–28	0xF	Reserved. Write to zero for future compatibility.	
— 27–24	0xF	Reserved. Write to zero for future compatibility.	
CRCU 23–20	0x0	**CRCU** Indicates the CRCU channel assignment.	See **Table 27-62**.
KEU 19–16	0x0	**KEU** Indicates the KEU channel assignment.	See **Table 27-62**.
STEU 15–12	0x0	**STEU** Indicates the STEU channel assignment.	See **Table 27-62**.
PKEU 11–8	0x00	**PKEU** Indicates the PKEU channel assignment.	See **Table 27-62**.
— 7–4	0	Reserved. Write to 0xF for future compatibility.	
RNGU 3–0	0x00	**RNGU** Indicates the RNGU channel assignment.	See **Table 27-62**.

Table 27-62. Channel Assignment Value

Value	Channel
0x0	No channel assigned
0x1	Channel 1
0x2	Channel 2
0x3	Channel 3
0x4	Channel 4
0x5–0xE	Undefined
0xF	Unavailable

27.7.4.5 Controller Interrupt Enable Register (CIER)

CIER — Controller Interrupt Enable Register — Offset 0xC1008

The SEC controller generates a single interrupt output from all possible interrupt sources. These sources can be individually enabled by the Interrupt Enable Register. If enabled, the interrupt source value, when active, is captured into the Interrupt Status Register. Each interrupt source is individually enabled by setting its corresponding bit. At reset, all bits are disabled. For normal operation, leave channel interrupts enabled, while disabling interrupts from the EUs. The channels generate the appropriate interrupts to the core processor. **Table 27-63** describes the register field names in the CIER.

Note: The recommended value for this register is 0x00310FFF00000000. Execution Unit interrupt bits are provided as a convenience during debug.

Table 27-63. CIER Bit Field Descriptions

Bits	Reset	Description	Settings
— 63–56	0	Reserved. Write to zero for future compatibility.

The CISR contains fields representing all possible sources of interrupts. The Interrupt Status Register is cleared either by a reset, or by writing the appropriate bits active in the CICR (see **Section 27.7.4.7**, *Controller Interrupt Clear Register (CICR)*, on page 27-192. The CISR bit fields are described in **Table 27-64**.

Table 27-64. CISR Bit Field Descriptions

Bits	Reset	Description	Settings
— 63–56	0	Reserved. Write to zero for future compatibility.	
FFE_CNT 55	0	**Fetch FIFO Enqueue Count Rollover** Indicates whether the Fetch FIFO enqueue counter has rolled over to zero.	0 Timer not rolled over. 1 Timer rolled over.
DF_CNT 54	0	**Descriptor Finished Count Rollover** Indicates whether the Descriptor Finished Counter rolled over to zero.	0 Counter not rolled over. 1 Counter rolled over.
DI_CNT 53	0	**Data In Count Rollover** Indicates whether the Data In Counter rolled over to zero.	0 Counter not rolled over. 1 Counter rolled over.
DO_CNT 52	0	**Data Out Count Rollover** Indicates whether the Data Out Counter rolled over to zero.	0 Counter not rolled over. 1 Counter rolled over.
— 51–49	0	Reserved. Write to zero for future compatibility.	

Table 27-64. CISR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
ITO 48	0	**Internal Time Out** Indicates whether an internal time-out has occurred, that is, whether a channel or EU has failed to respond to a slave read or write within 16 cycles, which only occurs in an impending hang condition. Assertion of this interrupt indicates the SEC Controller has completed the transaction, but the completed transaction does not result in a successful read or write. The interrupt advises the system that the slave transaction was unsuccessful.	0 No internal time-out. 1 An internal time-out was detected.
— 47–44	0	Reserved. Write to zero for future compatibility.	
DONE Overflow CH4–CH1 43–40	0	**DONE Overflow for Channels 4–1** For each channel, the bit indicates whether a DONE overflow condition occurred. A DONE overflow occurs when more than 15 Done interrupts are queued from the associated channel without an interrupt clear from the core processor.	0 No DONE overflow. 1 DONE overflow error.
CHN4 Err 39	0	**Channel 4 Error Interrupt** Indicates whether a Channel 4 error occurred. The Channel Status Register must be read to determine the exact cause of the error.	0 No error detected. 1 Error detected.
CHN4 Dn 38	0	**Channel 4 Done Interrupt** Indicates whether Channel 4 has completed its operation.	0 Not done. 1 Operation done.
CHN3 Err 37	0	**Channel 3 Error Interrupt** Indicates whether a Channel 3 error occurred. The Channel Status Register must be read to determine the exact cause of the error.	0 No error detected. 1 Error detected.
CHN3 Dn 36	0	**Channel 3 Done Interrupt** Indicates whether Channel 3 has completed its operation.	0 Not done. 1 Operation done.
CHN2 Err 35	0	**Channel 2 Error Interrupt** Indicates whether a Channel 2 error occurred. The Channel Status Register must be read to determine the exact cause of the error.	0 No error detected. 1 Error detected.
CHN2 Dn 34	0	**Channel 2 Done Interrupt** Indicates whether Channel 2 has completed its operation.	0 Not done. 1 Operation done.
CHN1 Err 33	0	**Channel 1 Error Interrupt** Indicates whether a Channel 1 error occurred. The Channel Status Register must be read to determine the exact cause of the error.	0 No error detected. 1 Error detected.
CHN1 Dn 32	0	**Channel 1 Done Interrupt** Indicates whether Channel 1 has completed its operation.	0 Not done. 1 Operation done.
— 31–28	0	Reserved. Write to zero for future compatibility.	
CRCU Err 27	0	**CRCU Error Interrupt** Indicates whether the CRCU generated an error.	0 No error detected. 1 Error detected.
CRCU Dn 26	0	**CRCU Done** Indicates whether the CRCU has completed its operation.	0 Not done. 1 Operation done.
KEU Err 25	0	**KEU Error Interrupt** Indicates whether the KEU generated an error.	0 No error detected. 1 Error detected.
KEU Dn 24	0	**KEU Done** Indicates whether the KEU has completed its operation.	0 Not done. 1 Operation done.
STEU Err 23	0	**STEU Error Interrupt** Indicates whether the STEU generated an error.	0 No error detected. 1 Error detected.

Table 27-64. CISR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
STEU Dn 22	0	**STEU Done** Indicates whether the STEU has completed its operation.	0 Not done. 1 Operation done.
PKEU Err 21	0	**PKEU Error Interrupt** Indicates whether the PKEU generated an error.	0 No error detected. 1 Error detected.
PKEU Dn 20	0	**PKEU Done** Indicates whether the PKEU has completed its operation.	0 Not done. 1 Operation done.
— 19–18	0	Reserved. Write to zero for future compatibility.	
RNGU Err 17	0	**RNGU Error Interrupt** Indicates whether the RNGU generated an error.	0 No error detected. 1 Error detected.
RNGU Dn 16	0	**RNGU Done** Indicates whether the RNGU has completed its operation.	0 Not done. 1 Operation done.
— 15–14	0	Reserved. Write to zero for future compatibility.	
AFEU Err 13	0	**AFEU Error Interrupt** Indicates whether the AFEU generated an error.	0 No error detected. 1 Error detected.
AFEU Dn 12	0	**AFEU Done** Indicates whether the AFEU has completed its operation.	0 Not done. 1 Operation done.
— 11–10	0	Reserved. Write to zero for future compatibility.	
MDEU Err 9	0	**MDEU Error Interrupt** Indicates whether the MDEU generated an error.	0 No error detected. 1 Error detected.
MDEU Dn 8	0	**MDEU Done** Indicates whether the MDEU has completed its operation.	0 Not done. 1 Operation done.
— 7–6	0	Reserved. Write to zero for future compatibility.	
AESU Err 5	0	**AESU Error Interrupt** Indicates whether the AESU generated an error.	0 No error detected. 1 Error detected.
AESU Dn 4	0	**AESU Done** Indicates whether the AESU has completed its operation.	0 Not done. 1 Operation done.
— 3–2	0	Reserved. Write to zero for future compatibility.	
DEU Err 1	0	**DEU Error Interrupt** Indicates whether the DEU generated an error.	0 No error detected. 1 Error detected.
DEU Dn 0	0	**DEU Done** Indicates whether the DEU has completed its operation.	0 Not done. 1 Operation done.

27.7.4.7 Controller Interrupt Clear Register (CICR)

CICR — Controller Interrupt Clear Register — Offset 0xC1018

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

The CICR provides a means of clearing the CISR. When a 1 is written to a bit in the CICR, the corresponding bit in the CISR is cleared, clearing the interrupt output pin $\overline{\text{IRQ}}$ (assuming the cleared bit in the CISR is the only interrupt source). If the input source to the CISR is a steady-state signal that remains active, the appropriate CISR bit, and subsequently $\overline{\text{IRQ}}$, is reasserted shortly thereafter. The bit fields are described in **Table 27-65**.

Note: When an ICR bit is written, it automatically clears itself one cycle later. It is not necessary to write a 0 to a bit position to which a 1 is written.

Interrupts are registered and sent based upon the conditions that cause them. If the cause of an interrupt is not removed, the interrupt returns a few cycles after it is cleared using the CICR.

Table 27-65. CICR Bit Field Descriptions

Bits	Reset	Description	Settings
— 63–56	0	Reserved. Write to zero for future compatibility.	
FFE_CNT 55	0	**Fetch FIFO Enqueue Count Rollover** Used to clear the fetch FIFO enqueue counter rollover status bit.	0 No action. 1 Clear status bit.
DF_CNT 54	0	**Descriptor Finished Count Rollover** Used to clear the descriptor finished counter rollover status bit.	0 No action. 1 Clear status bit.

Table 27-65. CICR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
DI_CNT 53	0	**Data In Count Rollover** Used to clear the data in counter rollover error status bit.	0 No action. 1 Clear status bit.
DO_CNT 52	0	**Data Out Count Rollover** Used to clear the data out counter rollover error status bit.	0 No action. 1 Clear status bit.
— 51–49	0	Reserved. Write to zero for future compatibility.	
ITO 48	0	**Internal Time Out** Used to clear the time-out error status bit.	0 No action. 1 Clear status bit.
— 47–44	0	Reserved. Write to zero for future compatibility.	
DONE Overflow CH4–CH1 43–40	0	**DONE Overflow for Channels 4–1** Used to clear the DONE overflow error status bit for each channel.	0 No action. 1 Clear status bit.
CHN4 Err 39	0	**Channel 4 Error Interrupt** Clears the Channel 4 error status bit	0 No action. 1 Clear status bit.
CHN4 Dn 38	0	**Channel 4 Done Interrupt** Clears the Channel 4 done status bit.	0 No action. 1 Clear status bit.
CHN3 Err 37	0	**Channel 3 Error Interrupt** Clears the Channel 3 error status bit	0 No action. 1 Clear status bit.
CHN3 Dn 36	0	**Channel 3 Done Interrupt** Clears the Channel 3 done status bit.	0 No action. 1 Clear status bit.
CHN2 Err 35	0	**Channel 2 Error Interrupt** Clears the Channel 2 error status bit.	0 No action. 1 Clear status bit.
CHN2 Dn 34	0	**Channel 2 Done Interrupt** Clears the Channel 2 done status bit	0 No action. 1 Clear status bit.
CHN1 Err 33	0	**Channel 1 Error Interrupt** Clears the Channel 1 error status bit.	0 No action. 1 Clear status bit.
CHN1 Dn 32	0	**Channel 1 Done Interrupt** Clears the Channel 1 done status bit.	0 No action. 1 Clear status bit.
— 31–28	0	Reserved. Write to zero for future compatibility.	
CRCU Err 27	0	**CRCU Error Interrupt** Clears the CRCU error status bit.	0 No action. 1 Clear status bit.
CRCU Dn 26	0	**CRCU Done** Clears the CRCU done status bit.	0 No action. 1 Clear status bit.
KEU Err 25	0	**KEU Error Interrupt** Clears the KEU error status bit.	0 No action. 1 Clear status bit.
KEU Dn 24	0	**KEU Done** Clears the KEU done status bit.	0 No action. 1 Clear status bit.
STEU Err 23	0	**STEU Error Interrupt** Clears the STEU error status bit.	0 No action. 1 Clear status bit.
STEU Dn 22	0	**STEU Done** Clears the STEU done status bit.	0 No action. 1 Clear status bit.
PKEU Err 21	0	**PKEU Error Interrupt** Clears the PKEU error status bit.	0 No action. 1 Clear status bit.
PKEU Dn 20	0	**PKEU Done** Clears the PKEU done status bit.	0 No action. 1 Clear status bit.

Table 27-65. CICR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
— 19–18	0	Reserved. Write to zero for future compatibility.	
RNGU Err 17	0	**RNGU Error Interrupt** Clears the RNGU error status bit.	0 No action. 1 Clear status bit.
RNGU Dn 16	0	**RNGU Done** Clears the RNGU done status bit.	0 No action. 1 Clear status bit.
— 15–14	0	Reserved. Write to zero for future compatibility.	
AFEU Err 13	0	**AFEU Error Interrupt** Clears the AFEU error status bit.	0 No action. 1 Clear status bit.
AFEU Dn 12	0	**AFEU Done** Clears the AFEU done status bit.	0 No action. 1 Clear status bit.
— 11–10	0	Reserved. Write to zero for future compatibility.	
MDEU Err 9	0	**MDEU Error Interrupt** Clears the MDEU error status bit.	0 No action. 1 Clear status bit.
MDEU Dn 8	0	**MDEU Done** Clears the MDEU done status bit.	0 No action. 1 Clear status bit.
— 7–6	0	Reserved. Write to zero for future compatibility.	
AESU Err 5	0	**AESU Error Interrupt** Clears the AESU error status bit.	0 No action. 1 Clear status bit.
AESU Dn 4	0	**AESU Done** Clears the AESU done status bit.	0 No action. 1 Clear status bit.
— 3–2	0	Reserved. Write to zero for future compatibility.	
DEU Err 1	0	**DEU Error Interrupt** Clears the DEU error status bit.	0 No action. 1 Clear status bit.
DEU Dn 0	0	**DEU Done** Clears the DEU done status bit.	0 No action. 1 Clear status bit.

27.7.5 Polychannel

The following sections describe the registers used by the Polychannel to manage the channel traffic.

27.7.5.1 Fetch FIFO Enqueue Counter (FFEC)

FFEC — Fetch FIFO Enqueue Counter — Offset 0xC1500

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R/W															
Reset	0x0000															

Bits	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Field	—															
Reset	0x0000															
R/W	R/W															

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Field	FETCH_FIFO_ENQ_CNT															
Type	R/W															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	FETCH_FIFO_ENQ_CNT															
Type	R/W															
Reset	0x0000															

The Fetch FIFO Enqueue Counter indicates the total number of descriptor addresses that are enqueued to the channel fetch FIFOs. If this counter is all 1s (0xFFFFFFFF), the next count causes it to roll over to all 0s and set the CISR[FFE_CNT] bit if it is enabled (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189).

27.7.5.2 Descriptor Finished Counter (DFC)

DFC — Descriptor Finished Counter — Offset 0xC1508

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R/W															
Reset	0x0000															

Bits	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Field	—															
Reset	0x0000															
R/W	R/W															

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Field	DESCR_FINISHED_CNT															
Type	R/W															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	DESCR_FINISHED_CNT															
Type	R/W															
Reset	0x0000															

The Descriptor Finished Counter indicates the total number of descriptors that successfully completed processing. It does not count descriptors that halt due to error. If this counter reaches all 1s (0xFFFFFFFF), the next count causes it to roll over to all 0s and set the CISR[DF_CNT] bit if it is enabled (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189).

27.7.5.3 Data Bytes In Counter (DBIC)

DBIC — Data Bytes In Counter — Offset 0xC1510

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	DATA_BYTES_IN_CNT															
Type	R/W															
Reset	0x0000															

Bits	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Field	DATA_BYTES_IN_CNT															
Reset	0x0000															
R/W	R/W															

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Field	DATA_BYTES_IN_CNT															
Type	R/W															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	DATA_BYTES_IN_CNT															
Type	R/W															
Reset	0x0000															

The DBIC indicates the total number of bytes written into a primary EU input FIFO. If other parcels, such as context or ICV, are placed in the input FIFO, they are not counted. For a secondary EU, data going only to the secondary EU (such as a hash-only region or authentication data) is counted. However, data is never counted twice by the same counter. If this counter reaches all 1s (0xFFFFFFFFFFFFFFFF), the next count causes it to roll over to all 0s and set the CISR[DI_CNT] if it is enabled. (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189).

If this counter is read by software in 32-bit increments, then the least significant 32 bits must be read first, followed by the most significant 32 bits. If this counter is written by software in 32-bit increments, then the most significant 32 bits must be written first, followed by the least significant 32 bits.

Note: 32 bit reads and writes must not be interleaved, that is, a read low-write low-read high-write high sequence is not allowed. These restrictions are required to maintain counter coherency.

27.7.5.4 Data Bytes Out Counter (DBOC)

DBOC — Data Bytes Out Counter — Offset 0xC1518

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	DATA_BYTES_OUT_CNT															
Type	R/W															
Reset	0x0000															

Bits	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32
Field	DATA_BYTES_OUT_CNT															
Reset	0x0000															
R/W	R/W															

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Field	DATA_BYTES_OUT_CNT															
Type	R/W															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	DATA_BYTES_OUT_CNT															
Type	R/W															
Reset	0x0000															

The DBOC indicates the total number of payload bytes read from a primary EU input FIFO. If other parcels, such as context or ICV, are read from the output FIFO, they are not counted. In no case is data ever counted twice by the same counter. If this counter reaches all 1s (0xFFFFFFFFFFFFFFFF), the next count causes it to roll over to all 0s and set the CISR[DO_CNT] if it is enabled. (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189).

If this counter is read by software in 32-bit increments, then the least significant 32 bits must be read first, followed by the most significant 32 bits. If this counter is written by software in 32-bit increments, then the most significant 32 bits must be written first, followed by the least significant 32 bits.

Note: 32 bit reads and writes must not be interleaved, that is, a read low-write low-read high-write high sequence is not allowed. These restrictions are required to maintain counter coherency.

27.7.6 Channel Registers and Structures

The following sections describe the registers and structures used by the four channels.

27.7.6.1 Channel Configuration Registers for Channels 1–4 (CCR[1–4])

CCR1 Channel Configuration Registers Offset 0xC1108 (0xC0108)
CCR2 Offset 0xC1208 (0xC0208)
CCR3 Offset 0xC1308 (0xC0308)
CCR4 Offset 0xC1408 (0xC0408)

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	—	FCC	WGN	PBS	—			BS	IWSE	—	EAE	CDWE	AWSE	NT	CDIE	—
Type	R/W															
Reset	0x0000															

Each CCR contains operational bits that permit configuration of the respective channel. The default address offset is used if the MCR[RCAn] bit is cleared (0) for the respective channel. The alternate address offset (shown in parentheses) is used if the MCR[RCAn] bit is set (1) for the respective channel. **Table 27-66** describes each field of the CCR.

Table 27-66. CCR Bit Field Descriptions

Bits	Reset	Description	Settings
— 63–35	0	Reserved. Write to zero for future compatibility.	
NPR 34	0	**No Pop Reset** Used to perform a partial reset that does not clear the lower half of the CCR or the Fetch FIFO. After the reset sequence completes, this bit automatically clears (0) and the channel resumes operation by re-fetching the previous descriptor. This permits debug of a descriptor in-place whithout having to rewrite the descriptor pointer into the Fetch FIFO. The following conditions apply: • If the NPR bit is set while the channel is requesting an EU assignment from the controller, the channel cancels its request. • If the NPR bit is set after the channel has reserved one or more EUs, the channel requests a write from the controller to set the software reset bit of each reserved EU. The channel then releases the EU(s).	0 No special action. 1 Causes the same channel reset actions as CON, but the Fetch FIFO is left unchanged.

Table 27-66. CCR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
CON 33	0	**Continue** Used to perform a soft reset that does not clear the Fetch FIFO or the lower half of the CCR. After the reset sequence completes, this bit automatically clears (0) and the channel resumes normal operation servicing the next descriptor pointer in the Fetch FIFO, if any is present. The following conditions apply: • If the CON bit is set whil the channel is requesting an EU from the controller, the channel cancels its request. • If the CON bit is set after the channel is assigned one or more EUs, the channel requests a write from the controller to set the software reset bit of each reserved EU. The channel then releases the EU(s).	0 No special action. 1 Partial reset.
R 32	0	**Reset Channel** Used to perform a soft reset of the channel. The details of the software reset actions depend upon what the channel is doing when the bit is set: • If the R bit is set while the channel is requesting an EU assignment from the controller, the channel cancels its request. • If the R bit is set after the channel is assigned to an EU, the channel requests a write from the controller to set the software reset bit of each reserved EU. The channel then releases the EU(s). AFter the reset sequence is complete, the channel returns to the idle state and the R bit automatically returns to 0 and the channel resumes normat operation.	0 No special action. 1 Initiates a soft reset of the channel, clearing all of its internal state.
— 31–15	0	Reserved. Write to zero for future compatibility.	
FCC 14	0	**Fast Clock Counting** This bit controls the changes the watchdog timer count rate.	0 Watchdog timer counts normally. 1 Watchdog timer uses an accelerated count to assist in functional testing.
WGN 13	0	**Watchdog Timer Go Now** Enables/disables the watchdog timer. **Note:** Always enable the timer to enable detection of stalled channels. This is a one-time configuration after device reset.	0 Watchdog timer disabled. 1 Watchdog timer enabled.
PBS 12	0	**Permit Byte Summing** This bit controls whether writes to the EU input FIFO and reads from the EU output FIFO are counted by the Data Byte Counters.	0 Bytes counted. 1 Bytes not counted.
— 11–9	0	Reserved. Write to zero for future compatibility.	
BS 8	0	**Burst Size** This bit determines the burst size used by the SEC to access long text-data parcels in main memory.	0 Burst size is 64 bytes. 1 Burst size is 128 bytes.
IWSE 7	0	**ICV Writeback Status Enable** If this bit is set and the descriptor calls for ICV comparison, then at completion of descriptor processing, the channel writes back to the descriptor header all the required writeback information: DONE, ICCR0, and ICCR1 fields.	0 No special action. 1 Write back the required data after processing if ICV comparison is required.
— 6	0	Reserved. Write to zero for future compatibility.	

Table 27-66. CCR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
EAE 5	0	**Extend Address Enable** Selects whether to use 32-bit or 36-bit addressing.	0 Channel address bus is 32 bits. 1 Channel address bus is 36 bits.
CDWE 4	0	**Channel Done Writeback Enable** Enables/disables writeback of the DONE field after descriptor processing is completed if the NT or DN bit is set in the descriptor header. When enabled, the core processor can poll the memory location of the original descriptor to determine if the processing for that descriptor is completed.	0 Channel Done writeback disabled. 1 Channel Done writeback enabled.
AWSE 3	0	**Always Writeback Status Enable** When set, enables the channel after completing descriptor processing to writeback all the writeback information: DONE, ICCR0, and ICCR1 fields. When set, this field overrides IWSE, which then has no effect.	0 No special action. 1 Always writeback DONE, ICCR0, and ICCR1 fields after descriptor processing.
NT 2	0	**Notification Type** Selects when the channel generates notification. Channel notification can take the form of an interrupt, modified header writeback, or both, depending on the settings of CDIE and CDWE.	0 Global. The channel generates a done notification (if enabled) at the end of each descriptor. 1 Selected. The channel generates channel done notification (if enabled) at the end of a descriptor only when the DN bit in the descriptor header is set.
CDIE 1	0	**Channel Done Interrupt Enable** When set, enables the generation of a channel done interrupt. Depending on the setting of the NT and DN bits, the channel sends an interrupt to the core processor at the end of every descriptor processing or at the end of descriptors for which the DN bit in the header is set. See **Section 27.4.4**, *Channel Interrupts,* on page 27-20 for details.	0 No action. 1 Clear status bit.
— 0	0	Reserved. Write to zero for future compatibility.	

Note: The done interrupt, done writeback, and status writeback does not occur if an EU produces and error interrupt to the channel. In particular, if the ICV check error interrupt is enabled in the EU (see the ICE bit in the EU Interrupt Mask Register), and the ICV check finds a mismatch, then it generates an error interrupt, but no done interrupt and no writebacks.

Various fields in this table are used together with the Descriptor Header Control Word (the upper 32 bits of the Descriptor Header, see **Section 27.7.1.2**) to determine writeback options (see **Table 27-67**) and done interrupt options (see **Table 27-68**).

Table 27-67. Writeback Options

CCR Field				Descriptor Header	Writeback Action for a Descriptor Completing Without Error
AWSE	**CDWE**	**IWSE**	**NT**	**DN**	
1	x	x	x	x	write back Header fields DONE, ICCR0, ICCR1
0	1	x	1	0	no write back performed
0	1	x	1	1	write back Header field DONE

Table 27-67. Writeback Options (Continued)

CCR Field				Descriptor Header	Writeback Action for a Descriptor Completing Without Error
AWSE	CDWE	IWSE	NT	DN	
0	1	x	0	x	write back Header field DONE
0	x	1	x	x	if the descriptor header indicated ICV checking in AESU, CRCU, KEU, STEU, or MDEU, then write back Header fields DONE, ICCR0, and ICCR1.

Table 27-68. Done Interrupt Options

CCR		Descriptor Header	Done Interrupt action by Channel to Controller for a Descriptor completing without error
NT	CDIE	DN	
x	0	x	never assert done interrupt
0	1	x	assert done interrupt
1	1	0	never assert done interrupt
1	1	1	assert done interrupt

27.7.6.2 Channel Status Registers (CSR[1–4])

CSR1 Channel Status Registers Offset 0xC1110 (0xC0110)
CSR2 Offset 0xC1210 (0xC0210)
CSR3 Offset 0xC1310 (0xC0310)
CSR4 Offset 0xC1410 (0xC0410)

This register contains status fields and counters that provide status information regarding the channel processing of the current descriptor. Bits 15–4 are error statuses. When a channel error

interrupt is generated, bits in this range that are set indicate the source of the error. The default address offset is used if the MCR[RCAn] bit is cleared (0) for the respective channel. The alternate address offset (shown in parentheses) is used if the MCR[RCAn] bit is set (1) for the respective channel. **Table 27-69** describes the CSR fields.

Table 27-69. CSR Bit Field Descriptions

Bits	Reset	Description	Settings
— 63	0	Reserved. Write to zero for future compatibility.	
GET_ STATE 62–56	0	**Get State Machine State** Reflects the state of the Get State Machine when it last went to sleep. For debug purposes only.	
— 55	0	Reserved. Write to zero for future compatibility.	
PUT_STATE 54–48	0	**Put State Machine State** Reflects the state of the Put State Machine when it last went to sleep. For debug purposes only.	
— 47–41	0	Reserved. Write to zero for future compatibility.	
MAIN_STATE 40–32	0	**Main State Machine State** Reflects the state of the Main State Machine when it last went to sleep. For debug purposes only.	
— 31–29	0	Reserved. Write to zero for future compatibility.	
FF_LEVEL 28–24	0	**Fetch FIFO Level** This 5-bit counter indicates how many pointers are currently stored in the Fetch FIFO.	
— 23–20	0	Reserved. Write to zero for future compatibility.	
PRD 19	0	**Primary Reset Done** Reflects the state of the reset done signal from the assigned primary EU.	0 Assigned primary EU reset done signal inactive. 1 Assigned primary EU reset done signal active. Reset sequence complete and EU is ready to accept data.
SRD 18	0	**Secondary Reset Done** Reflects the state of the reset done signal from the assigned secondary EU.	0 Assigned secondary EU reset done signal inactive. 1 Assigned secondary EU reset done signal active. Reset sequence complete and EU is ready to accept data.
PD 17	0	**Primary EU Done** Reflects the state of the done interrupt from the assigned primary EU.	0 Assigned primary EU done interrupt inactive. 1 Assigned primary EU done interrupt active. EU processing complete and EU is ready to provide output data.

Table 27-69. CSR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
SD 16	0	**Secondary EU Done** Reflects the state of the done interrupt from the assigned secondary EU.	0 Assigned secondary EU done interrupt inactive. 1 Assigned secondary EU done interrupt active. EU processing complete and EU is ready to provide output data.
DOF 15	0	**Double Fetch FIFO Write Overflow Error** Set when the channel fetch FIFO is full, SOF is set, and another write is made to the fetch FIFO. When this bit is set, the channel stops and activates an error interrupt. The channel does not start again until a continue or reset is generated via the CCR. You can clear this bit by writing a 1 to this bit.	0 No error detected. 1 Error detected.
SOF 14	0	**Single Fetch FIFO Write Overflow Error** Set when the channel fetch FIFO is full and another write is made to the fetch FIFO. The channel sets this bit and activates an error interrupt. The channel continues processing, but the descriptor pointer is lost. The core processor must clear this bit by writing a 1 to it.	0 No error detected. 1 Error detected.
MDTE 13	0	**Master Data Transfer Error** Set when the channel receives an error from the master bus interface. If the SEC is the bus master and detects the error, the controller passes the error to the channel in use. The channel halts and activates an interrupt. The channel can only be restarted by writing a 1 to the CON or R bit in the CCR, or resetting the whole SEC.	0 No error detected. 1 Error detected.
— 12–11	0	Reserved. Write to zero for future compatibility.	
IDH 10	0	**Illegal Descriptor Header** Possible causes of this error include: • Invalid primary EU indicated by the op_0 field. • Invalid secondary EU indicated by the op_1 field. • Descriptor type field in descriptor header indicates secondary EU transaction when not in snoop mode.	0 No error detected. 1 Error detected.
— 9	0	Reserved. Write to zero for future compatibility.	
EUE 8	0	**EU Error** Set when an EU assigned to this channel generates an error interrupt. The error can also be reflected in the CISR. **Note:** This bit can only be cleared by clearing the error interrupt source in the assigned EU that caused it to set.	0 No error detected. 1 Error detected.
WDT 7	0	**Watchdog Timeout** Set when the main state machine stays asleep too long. The timer runs only after EUs have been reserved, and does not run if the primary EU is the RNGU or PKEU. The timeout interval is controlled by the FCC field of the Channel Configuration Register. The channel stops when this bit is set and restarts when this bit is cleared.	0 No error detected. 1 Error detected.
SGLM 6	0	**Scatter/Gather Length Mismatch** Set when the total data size covered by a gather link table does not match the total data size from the main descriptor. The channel stops when this bit is set and restarts when this bit is cleared.	0 No error detected. 1 Error detected.

Table 27-69. CSR Bit Field Descriptions (Continued)

Bits	Reset	Description	Settings
RSI 5	0	**Raid Size Incorrect** Set when the channel receives a descriptor of type RAID_XOR with data sizes that are not permitted.	0 No error detected. 1 Error detected.
RSG 4	0	**Raid Scatter Gather Error** Set when the channel receives a descriptor of type RAID_XOR along with a set j bit. **Note:** Use of scatter/gather cannot be used with RAID_XOR type descriptors.	0 No error detected. 1 Error detected.
— 3–0	0	Reserved. Write to zero for future compatibility.

Reset	This register is not reset.															

The CDPR contains the address of the descriptor that the channel is currently processing. The default address offset is used if the MCR[RCAn] bit is cleared (0) for the respective channel. The alternate address offset (shown in parentheses) is used if the MCR[RCAn] bit is set (1) for the respective channel. The bits in the CDPR perform the functions described in **Table 27-72**.

Table 27-72. CDPR Bit Field Descriptions

Bits	Reset	Description
— 63–36	0	Reserved. Write to zero for future compatibility.

Table 27-72. CDPR Bit Field Descriptions (Continued)

Bits	Reset	Description
EPTR 35–32	0	**Extended Pointer** Concatenated as the upper 4 bits of the pointer address when extended mode is selected (EAE is high—see **Table 27-66** for details).
CUR_DES_PTR_ADRS 31–0	0	**Current Descriptor Pointer Address** Pointer to the system memory location of the current descriptor. This field reflects the starting location in system memory of the descriptor currently loaded into the DB. This value is updated whenever the channel requests a fetch of a descriptor from the controller. The value from the Fetch FIFO is transferred to the current descriptor pointer register immediately after the fetch is completed. This address is used as the destination for writeback of the modified header, if header writeback notification is enabled.

27.7.6.4 Channel Fetch FIFO (CFF)

CFF1	Channel Fetch FIFOs	Offset 0xC1148 (0xC0148)
CFF2		Offset 0xC1248 (0xC0248)

Type	W															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	FETCH_ADR															
Type	W															
Reset	0x0000															

Each channel contains a FIFO to store a queue of descriptor pointers starting with the address of the first byte of descriptors to process. Typically, the core processor creates a descriptor in memory containing all relevant mode and location information for the SEC and then launches the descriptor by writing its address to the SEC Fetch FIFO. The Fetch FIFO can hold up to 24 descriptor pointers at a time. When the end of the current descriptor is reached, the descriptor pointed to by the next location in the Fetch FIFO is read to launch the next descriptor. The Fetch Address is written into the FIFO only if the write includes the least significant byte. If extended addressing mode is selected (the EAE bit is high—see **Table 27-66** for details), then the Extended Fetch Address must be written before or concurrent with the Fetch Address. Specifying a FETCH_ADRS of 0 causes the channel to generate an error and stop. The default address offset is used if the MCR[RCAn] bit is cleared (0) for the respective channel. The alternate address offset (shown in parentheses) is used if the MCR[RCAn] bit is set (1) for the respective channel. The bits in the CFF perform the functions described in **Table 27-72**.

Table 27-73. CFF Bit Field Descriptions

Bits	Reset	Description
— 63–36	0	Reserved. Write to zero for future compatibility.
EPTR 35–32	0	**Extended Pointer** Concatenated as the upper 4 bits of the fetch address when extended mode is selected (EAE is high—see **Table 27-66** for details).
FETCH_ADR 31–0	0	**Fetch Address** Pointer to the memory location for the descriptor that the core processor wants the SEC to fetch.

27.7.6.5 Channel Descriptor Buffer (DB)

The descriptor buffer (DB) consists of eight 8-byte registers (DB[0–7]) and contains the current descriptor being processed by the channel. These registers are read-only because the descriptor is always fetched from system memory.

	0 15	16	17 23	24 27	28 31	32 63
DB0	Header					Reserved
DB1	Length0	J0	Extent0	—	Eptr0	Pointer0
DB2	Length1	J1	Extent1	—	Eptr1	Pointer1
DB3	Length2	J2	Extent2	—	Eptr2	Pointer2
DB4	Length3	J3	Extent3	—	Eptr3	Pointer3
DB5	Length4	J4	Extent4	—	Eptr4	Pointer4
DB6	Length5	J5	Extent5	—	Eptr5	Pointer5
DB7	Length6	J6	Extent6	—	Eptr6	Pointer6

Figure 27-57. Descriptor Format

For more information about the fields in a descriptor, see **Section 27.7.1.1**, *Descriptor Structure*, on page 27-100.

Note: The DBs are located at the following locations:

Channel 1: Offsets: 0xC1180–0xC11BF (0xC0180–0xC01BF)
Channel 2: Offsets 0xC1280–0xC12BF (0xC0280–0xC02BF)
Channel 3: Offsets 0xC1380–0xC13BF (0xC0380–0xC03BF)
Channel 4: Offsets 0xC1480–0xC14BF (0xC0480–0xC04BF)

The default address offset is used if the MCR[RCAn] bit is cleared (0) for the respective channel. The alternate address offset (shown in parentheses) is used if the MCR[RCAn] bit is set (1) for the respective channel.

27.7.7 PKEU Registers

27.7.7.1 PKEU Mode Register (PKEUMR)

PKEUMR PKEU Mode Register Offset 0xCC000

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R/W

Field	—								ROUTINE							
Type	R/W															
Reset	0x0000															

PKEUMR specifies the internal PKEU routine to execute. PKEUMR is cleared when the PKEU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated. **Table 27-74** describes the PKEUMR fields.

Table 27-74. PKEUMR Field Descriptions

Name	Reset	Description	Settings
— 63–8	0	Reserved. Write to zero for future compatibility.	
ROUTINE 7–0	0	**Routine** Specifies the PKEU routine to run.	See **Table 27-79** for values. See **Section 27.6.1.11**, *PKEU Routines,* on page 27-28 for details.

Table 27-75. ROUTINE Value Definitions

ROUTINE Value	Name	Description
0x00	Reserved	
0x01	CLEARMEMORY	Clear memory
0x02	MOD_EXP	FP: Exponential mod N and deconvert from Montgomery format
0x03	MOD_R2MODN	FP: Compute Montgomery converter (R^2 mod N)
0x04	MOD_RRMODP	FP: Compute Montgomery converter for Chinese Remainder Theorem (R_nR_p mod N)
0x05	EC_FP_AFF_PTMULT	FP EC: Multiply scalar times point in affine coordinates

Table 27-75. ROUTINE Value Definitions (Continued)

ROUTINE Value	Name	Description
0x06	EC_F2M_AFF_PTMULT	F2m EC: Multiply scalar times point in affine coordinates
0x07	EC_FP_PROJ_PTMULT	FP EC: Multiply scalar times point in projective coordinates
0x08	EC_F2M_PROJ_PTMULT	F2m EC: Multiply scalar times point in projective coordinates
0x09	EC_FP_ADD	FP EC: Add two points in projective coordinates
0x0A	EC_FP_DOUBLE	FP EC: Double a point in projective coordinates
0x0B	EC_F2M_ADD	F2m EC: Add two points in projective coordinates
0x0C	EC_F2M_DOUBLE	F2m EC: Double a point in projective coordinates
0x0D	F2M_R2	F2m: Compute Montgomery converter (R^2 mod N)
0x0E	F2M_INV	F2m: Invert mod N
0x0F	MOD_INV	FP: Invert mod N
0x10	MOD_ADD	FP: Add mod N
0x20	MOD_SUB	FP: Subtract mod N
0x30	MOD_MULT1_MONT	FP: Multiply mod N in Montgomery format
0x40	MOD_MULT2_DECONV	FP: Multiply mod N and deconvert from Montgomery format
0x50	F2M_ADD	F2m: Add mod N
0x60	F2M_MULT1_MONT	F2m: Multiply mod N in Montgomery format
0x70	F2M_MULT2_DECONV	F2m: Multiply mod N and deconvert from Montgomery format
0x80	RSA_SSTEP	FP: Exponentiate mod N (combines MOD_R2MODN, POLY_F2M_MULT1_MONT, and MOD_EXP)
0x1D	MOD_EXP_TEQ	FP: Exponentiate mod N and deconvert from Montgomery format with timing equalization
0x1E	RSA_SSTEP_TEQ	FP: Exponentiate mod N with timing equalization (combines MOD_R2MODN, EC_F2M_MULT1_MONT, and MOD_EXP_TEQ)
0xFF	SPK_BUILD	Build PK data structure (data structure used by all elliptic curve routines)

27.7.7.2 PKEU Key Size Register (PKEUKSR)

PKEUKSR PKEU Key Size Register Offset 0xCC008

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R/W

Field	—				Key Size											
Type	R/W															
Reset	0x0000															

The Key Size Register reflects the number of significant bytes to use from PKEU Parameter Memory E in performing modular exponentiation or elliptic curve point multiplication. The range of values for this register, when performing either modular exponentiation or elliptic curve point multiplication, is from 1 to 256. Specifying a key size outside of this range causes a key size error (KSE) in the PKEU Interrupt Status Register.

Table 27-76. PKEUKSR Field Descriptions

Name	Reset	Description	Settings
— 63–12	0	Reserved. Write to zero for future compatibility.	
Key Size 11–0	0	**Key Size** Specifies the size in bytes of the PKEU parameter memory E to use for modulator exponentiation or elliptic curve point multiplication.	1–256 **Note:** Any other value causes a KSE in the PKEUISR.

27.7.7.3 PKEU AB Size Register (PKEUABSR)

PKEUABSR — PKEU AB Size Register — Offset 0xCC040

Type	R/W															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	—				AB Size											
Type	R/W															
Reset	0x0000															

The AB Size register represents the operand size for the specific operands whenever it is required. The unit of the value written into the AB Size is in bits, even though internally the PKEU imposes a 32-bit alignment. Any data beyond the number of bits in the AB Size register, either in A and B-RAM (operands) is ignored. No error checking is performed whether the operand sizes are greater than the prime modulus or the field size and this can result is a wrong result. In other words, it is assumed that operands are modulo reduced before being written into the PKEU. Hence, the AB Size must be less than or equal to Data Size for a correct result. If the AB Size register is modified during processing, an error is generated.

Table 27-77. PKEUABSR Field Descriptions

Name	Reset	Description
— 63–12	0	Reserved. Write to zero for future compatibility.
AB Size 11–0	0	**AB Size** Specifies the maximum size in bits of data to use in the A- and B-RAM.

27.7.7.4 PKEU Data Size Register (PKEUDSR)

PKEUDSR PKEU Data Size Register Offset 0xCC010

Field	—				Data Size											
Type	R/W															
Reset	0x0000															

The PKEU Data Size Register specifies the size of the significant portion of the modulus or irreducible polynomial in bits. Any value written to this register that is a multiple of 32 bits (for example, 128 bits, 160 bits, and so on) is represented internally as the same value (128 bits, 160 bits, respectively). Any value written that is not a multiple of 32 bits (for example, 132 bits, 161 bits, and so on), is represented internally as the next larger 32-bit multiple (160 bits, 196 bits, respectively). This internal rounding up to the next 32-bit multiple is described for information only. The minimum size valid for all routines to operate properly is 33 bits (internally 128 bits). The maximum size to operate properly is 2048 bits. A value in bits larger than 2048 result in a data size error.

An illegal data size error is generated as follows:

- All non-ECC routines with a data size > 512 generate an illegal data size error.
- All ECC routines with a data size > 128 generate an illegal data size error.

An AB Size = 0 (either intentionally written, or by ignoring and not writing at all) generates an illegal size error, except for routines that do not require an A or B operand such as the CLEAR_MEM routine.

Table 27-78. PKEUDSR Field Descriptions

Name	Reset	Description
— 63–12	0	Reserved. Write to zero for future compatibility.
Data Size 11–0	0	**Data Size** Specifies the maximum size in bits of data used internally. The value must range between 97–2048. Any other value generates a data size error.

27.7.7.5 PKEU Reset Control Register (PKEURCR)

PKEURCR — PKEU Reset Control Register — Offset 0xCC018

Reset	0x0000															

This register contains three reset options specific to the PKEU.

Table 27-79. PKEURCR Field Descriptions

Name	Reset	Description	Settings
— 63–3	0	Reserved. Write to zero for future compatibility.	
RI 2	0	**Reset Interrupt** Setting this bit causes PKEU interrupts signalling done and error to reset. It further resets the state of the PKEU Interrupt Status Register.	0 No reset. 1 Reset interrupt logic.
MI 1	0	**Module Initialization** Setting this reinitializes the PKEU to accept another request without forcing the Interrupt Mask Register to change.This module initialization includes execution of an initialization routine, completion of which is indicated by the RD bit in the PKEUSR (see **Section 27.7.7.6**, *PKEU Status Register (PKEUSR),* on page 27-217).	0 No reset 1 Reset most of PKEU
SR 0	0	**Software Reset** Setting this bit is functionally equivalent to a hardware reset (asserting the $\overline{\text{HRESET}}$ pin), but the reset is restricted to the PKEU. When SR is cleared, the PKEU enters a routine to perform proper initialization of the parameter memories. The PKEUSR[RD] indicates when the initialization routine is complete (see **Section 27.7.7.6**, *PKEU Status Register (PKEUSR),* on page 27-217).	0 No reset 1 Full PKEU reset.

27.7.7.6 PKEU Status Register (PKEUSR)

PKEUSR — PKEU Status Register — Offset 0xCC028

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the PKEU Interrupt Mask Register is zero (see **Section 27.6.1.8**, *PKEU Interrupt Mask Register*, on page 27-27).

If the PKEU Interrupt Status Register is non-zero, the PKEU halts and the PKEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189). In addition, if the PKEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4]),* on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the PKEU Reset Control Register. The definition of each bit in the PKEU Interrupt Status Register is shown in **Table 27-81**.

Table 27-81. PKEUISR Field Descriptions

Name	Reset	Description	Settings
— 63–15	0	Reserved. Write to zero for future compatibility.	
EVM 14	0	**Even Modulus Error** When set, indicates that an even modulus was supplied for a PK operation that requires an odd modulus.	0 No even modulus error detected. 1 Even modulus error.
INV 13	0	**Inversion Error** When set, indicates that the inversion routine has a zero operand.	0 No inversion error detected. 1 Inversion error.
IE 12	0	**Internal Error** An internal processing error was detected while the PKEU was operating. **Note:** This bit is set any time an enabled error condition occurs and can only be cleared by setting the corresponding bit in the Interrupt Mask Register or by resetting the PKEU.	0 No internal error detected. 1 Internal error.
BE 11	0	**Boot Error** When set, indicates either a boot (reset) sequence or that RAM locations are not reset correctly.	0 No boot error detected. 1 Boot error.
CE 10	0	**Context Error** A PKEU key register, the Key Size Register, the Data Size Register, or the Mode Register was modified while the PKEU was operating.	0 No error detected. 1 Context error.
KSE 9	0	**Key Size Error** A value outside the bounds 1–256 bytes was written to the PKEU Key Size Register.	0 No error detected. 1 Key size error.
DSE 8	0	**Data Size Error** A value outside the range 97–2048 bits was written to the PKEU Data Size Register.	0 No error detected. 1 Data size error.
ME 7	0	**Mode Error** An illegal value was detected in the Mode Register. **Note:** Writing to reserved bits in the Mode Register is the most likely source of this error	0 No error detected. 1 Mode error.
AE 6	0	**Address Error** An illegal read or write address was detected within the PKEU address space.	0 No address error detected. 1 Address error detected.
— 5–0	0	Reserved. Write to zero for future compatibility.	

27.7.7.8 PKEU Interrupt Mask Register (PKEUIMR)

PKEUIMR — PKEU Interrupt Mask Register — Offset 0xCC038

The PKEU Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.6.1.7**, *PKEU Interrupt Status Register*, on page 27-27), if the corresponding bit in this register is set, then the error is disabled; no error interrupt occurs, and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then, upon detection of an error, the PKEU Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

The End_of_message Register in the PKEU is used to indicate the start of a new computation. Writing to this register causes the PKEU to execute the function requested by the ROUTINE field, per the contents of the parameter memories listed below. This register has no data size, and during the write operation, the core processor data bus is not read. Hence, any data value is accepted. Normally, a write operation with a zero data value is performed. Reading from this register is not meaningful, but a zero value is always returned, and no error is generated.

27.7.7.10 PKEU Parameter Memories

The PKEU uses four 4096-bit memories to receive and store operands for the arithmetic operations the PKEU is asked to perform. In addition, results are stored in one particular parameter memory. Data addressing within these memories is big-endian, that is, the most significant byte is stored in the lowest address.

27.7.7.10.1 PKEU Parameter Memory A

This 4096 bit memory is used typically as an input parameter memory space. For modular arithmetic routines, this memory operates as one of the operands of the desired function. For

elliptic curve routines, this memory is segmented into four 1024 bit memories, and is used to specify particular curve parameters and input values. The PKEU Parameter Memory A region comprises offset 0xC200 to 0xC27F.

27.7.7.10.2 PKEU Parameter Memory B

This 4096 bit memory is used typically as an input parameter memory space, as well as the result memory space. For modular arithmetic routines, this memory operates as one of the operands of the desired function, as well as the result memory space. For elliptic curve routines, this memory is segmented in to four 1024 bit memories, and is used to specify particular curve parameters and input values, as well as to store result values. The PKEU Parameter Memory B region comprises offset 0xC400 to 0xC47F.

27.7.7.10.3 PKEU Parameter Memory E

This 4096 bit memory is non-segmentable, and specifies the exponent for modular exponentiation, or the multiplier k for elliptic curve point multiplication. This memory space is write only; a read of this memory space causes an address error to be reflected in the PKEU Interrupt Status Register. The PKEU Parameter Memory E region comprises offset 0xCA00 to 0xCBFF.

27.7.7.10.4 PKEU Parameter Memory N

This 4096 bit memory is non-segmentable, and stores the modulus for modular arithmetic and F_p elliptic curve routines. For F_2m elliptic curve routines, this memory stores the irreducible polynomial. The PKEU Parameter Memory N region comprises offset 0xC800 to 0xC9FF.

27.7.8 DEU Registers

27.7.8.1 DEU Mode Register (DEUMR)

DEUMR — DEU Mode Register — Offset 0xC2000

This value indicates the number of bytes of key memory to use in encrypting or decrypting. If the DEU Mode Register is set for single DES, any value other than 8 bytes automatically generates a key size error in the DEU Interrupt Status Register. If the mode bit is set for triple DES, any value other than 16 bytes (112 bits for 2-key triple DES (K1=K3) or 24 bytes (168 bits for 3-key triple DES) generates an error. Triple DES always uses K1 to encrypt, K2 to decrypt, K3 to encrypt.

Table 27-84. PKEUKSR Field Descriptions

Name	Reset	Description	Settings
— 63–12	0	Reserved. Write to zero for future compatibility.	
Key Size 11–0	0	**Key Size** Specifies the size in bytes of the key memory to use for encrypitng or decrypting.	0x08 8 bytes (only legal value for single DES) 0x10 16 bytes (for 2-key 3DES, K1 = K3) 0x18 24 bytes (for 3-key 3DES) **Note:** Any other value causes a KSE in the DEUISR.

27.7.8.3 DEU Data Size Register (DEUDSR)

DEUDSR — DEU Data Size Register — Offset 0xC2010

Reset	0x0000															

This register stores the number of bits in the final message with an upper bound of 4096. Whatever number is written (and whatever truncated value is stored) must be a multiple of 64. All data to be processed by the DEU must be a multiple of the DES algorithm block size of 64 bits; the DEU does not automatically pad messages out to 64-bit blocks. If a data size that is not a multiple of 64 bits is written, a data size error is generated. Only the least significant 6 bits are checked to determine if there is a data size error. Since all upper bits are ignored, the entire message length (in bits) can be written to this register. This register is cleared when the DEU is reset or reinitialized.

Table 27-85. DEUDSR Field Descriptions

Name	Reset	Description
— 63–12	0	Reserved. Write to zero for future compatibility.
Data Size 11–0	0	**Data Size** Specifies the maximum size in bits of data used internally. The value must range between 97–2048. Any other value generates a data size error.

27.7.8.4 DEU Reset Control Register (DEURCR)

DEURCR — DEU Reset Control Register — Offset 0xC2018

This register allows three levels reset for the DEU, as defined by the three self-clearing bits described in **Table 27-86**.

Table 27-86. DEURCR Field Descriptions

Name	Reset	Description	Settings
— 63–3	0	Reserved. Write to zero for future compatibility.	
RI 2	0	**Reset Interrupt** Setting this bit causes DEU interrupts signalling done and error to reset. It further resets the state of the DEU Interrupt Status Register.	0 No reset. 1 Reset interrupt logic.
MI 1	0	**Module Initialization** Setting this bit perform like a software reset except that the Interrupt Mask Register remains unchanged. The module initialization includes execution of an initialization routine, completion of which is indicated by the RD bit in the DEUSR (see **Section 27.7.8.5**, *DEU Status Register (DEUSR),* on page 27-227).	0 No reset 1 Reset most of DEU.
SR 0	0	**Software Reset** Setting this bit is functionally equivalent to a hardware reset (asserting the $\overline{\text{HRESET}}$ pin), but the reset is restricted to the DEU. All registers and internal states are returned to the defined reset state. When SR is cleared, the DEU enters a routine to perform proper initialization of the parameter memories. The DEUSR[RD] indicates when the initialization routine is complete (see **Section 27.7.8.5**, *DEU Status Register (DEUSR),* on page 27-227).	0 No reset 1 Full DEU reset.

27.7.8.5 DEU Status Register (DEUSR)

This Status Register contains 6 fields that reflect the state of DEU internal signals. The DEU Status Register is read-only. Writing to this location results in an address error being reflected in the DEU Interrupt Status Register (DEUISR).

Table 27-87. DEUSR Field Descriptions

Name	Reset	Description	Settings
— 63–24	0	Reserved. Write to zero for future compatibility.	
OFL 23–16	0	**Output FIFO Length** Indicates the number of 8-byte sets currently in the output FIFO.	
IFL 15–8	0	**Input FIFO Length** Indicates the number of 8-byte sets currently in the input FIFO.	
— 7–6	0	Reserved. Write to zero for future compatibility.	
HALT 5	0	**Halt** Indicates whether the DEU is halted due to an error. **Note:** Because the error causing the DEU to stop operating can be masked before reaching the Interrupt Status Register, the DEU Interrupt Status Register is used to provide a second source of information regarding errors that prevent normal operation.	0 DEU not halted 1 DEU halted
— 4–3	0	Reserved. Write to zero for future compatibility.	
EI 2	0	**Error Interrupt** This status bit reflects the state of the error interrupt signal, as sampled by the controller Interrupt Status Register (**Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189).	0 DEU is not signaling error 1 DEU is signaling error

Table 27-87. DEUSR Field Descriptions (Continued)

Name	Reset	Description	Settings
DI 1	0	**Done Interrupt** This status bit reflects the state of the done interrupt signal as sampled by the controller Interrupt Status Register (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189)	0 DEU is not signalling done. 1 DEU is signalling done.
RD 0	0	**Reset Done** This status bit, when high, indicates that the DEU has completed its reset sequence, as reflected in the signal sampled by the appropriate channel. **Note:** The reset value of RD is 0, but it typically switches to 1 by the time a user checks the register, indicating the EU is ready for operation.	0 Reset in progress. 1 Reset done.

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the DEU Interrupt Mask Register is zero (see **Section 27.6.2.7**, *DEU Interrupt Mask Register*, on page 27-43). If the DEU Interrupt Status Register is non-zero, the DEU halts and the DEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189). In addition, if the DEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the DEU Reset Control Register (see **Section 27.7.8.4**, *DEU Reset Control Register (DEURCR)*, on page 27-226). The definition of each bit in the DEU Interrupt Status Register is listed in **Table 27-88**.

Table 27-88. DEUISR Field Descriptions

Name	Reset	Description	Settings
— 63–14	0	Reserved. Write to zero for future compatibility.	
KPE 13	0	**Key Parity Error** If set, defined parity bits in the keys written to the key registers do not reflect odd parity correctly. **Note:** Key register 2 and key register 3 are checked for parity only if the appropriate DEU Mode Register bit indicates triple DES. Also, key register 3 is checked only if key size reg = 24. Key register 2 is checked only if key size reg = 16 or 24.	0 No key parity error detected. 1 Key parity error.
IE 12	0	**Internal Error** Indicates whether an internal processing error was detected while the DEU was processing.	0 No internal error detected. 1 Internal error.
ERE 11	0	**Early Read Error** Indicates whether the DEU IV register was read while the DEU was performing encryption.	0 No early read error detected. 1 Early read error.
CE 10	0	**Context Error** If set, indicates that DEU key register, the Key Size Register, Data Size Register, Mode Register, or IV register was modified while DEU was performing encryption.	0 No context error detected. 1 Context error.
KSE 9	0	**Key Size Error** IF set, indicates that an inappropriate value (8 being appropriate for single DES, and 16 and 24 being appropriate for triple DES) was written to the DEU Key Size Register.	0 No key size error detected. 1 Key size error.
DSE 8	0	**Data Size Error** If set, a value was written to the DEU Data Size Register that is not a multiple of 64 bits.	0 No data size error detected. 1 Data size error.
ME 7	0	**Mode Error** If set, an illegal value was detected in the Mode Register.	0 No mode error detected. 1 Mode error.
AE 6	0	**Address Error** If set, an illegal read or write address was detected within the DEU address space.	0 No address error detected. 1 Address error detected.
OFE 5	0	**Output FIFO Error** If set, the DEU output FIFO was detected non-empty upon write of DEU Data Size Register.	0 No output FIFO error detected. 1 Output FIFO error.
IFE 4	0	**Input FIFO Error** If set, the DEU input FIFO was detected non-empty upon generation of a done interrupt.	0 No input FIFO error detected. 1 Input FIFO error.

Table 27-88. DEUISR Field Descriptions (Continued)

Name	Reset	Description	Settings
IFU 3	1	**Input FIFO Underflow** If set, the DEU input FIFO was read while empty.	0 No input FIFO underflow error detected. 1 Input FIFO underflow error.
IFO 2	0	**Input FIFO Overflow** If set, the DEU input FIFO was pushed while full. **Note:** When operated through channel-controlled access, the SEC implements flow control, and FIFO size is not a limit to data input. When operated through core processor-controlled access, the DEU cannot accept FIFO inputs larger than 256 bytes without overflowing.	0 No input FIFO overflow error detected. 1 Input FIFO overflow error.
OFU 1	0	**Output FIFO Underflow** If set, the DEU output FIFO was read while empty.	0 No output FIFO underflow error detected. 1 Output FIFO underflow error.
OFO 0	0	**Output FIFO Overflow** If set, the DEU output FIFO was pushed while full.	0 No output FIFO overflow error detected. 1 Output FIFO overflow error.

27.7.8.7 DEU Interrupt Mask Register (DEUIMR)

DEUIMR — DEU Interrupt Mask Register — Offset 0xC2038

The Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.6.2.6**, *DEU Interrupt Status Register*, on page 27-43), if the corresponding bit in this register is set, then the error is ignored; no bit is set in the DEU Interrupt Status Register, and no error interrupt occurs. If the corresponding bit is not set, then upon detection of an error, the

Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

Writing the end-of-message register is a handshake mechanism signalling that no more data is written to the input FIFO. DESA signals a done interrupt once the input FIFO is detected empty any time following the write to End-Of-Message. After the final message block is written to the input FIFO, the End_of_Message Register must be written. The value in the Data Size Register is used to determine how many bits of the final message block (always 64) is processed. Note that the end_of_ register has no data size, and during the write operation, the core processor data bus is not read. Hence, any data value is accepted. Normally, a write operation with a zero data value is performed. Reading from this register is not meaningful, but a zero value is always returned and no error is generated. Writing to this register is merely a trigger causing the DEU to process the final block of a message, allowing it to signal done interrupt.

27.7.8.9 DEU IV Register (DEUIVR)

For CBC mode, the initialization vector is written to and read from the DEU IV register. The value of this register changes as a result of the encryption process and reflects the context of DEU. Reading this memory location while the module is processing data generates an error interrupt.

Note: The DEUIVR is located at offset 0xC2100.

27.7.8.10 DEU Key Registers (DEUKR[1–3])

The DEU uses three write-only key registers, K1, K2, and K3, to perform encryption and decryption. In Single DES mode, only K1 can be written. The value written to K1 is simultaneously written to K3, auto-enabling the DEU for 112-bit Triple DES if the Key Size Register indicates 2 key 3DES is to be performed (key size = 16 bytes). To operate in 168-bit Triple DES, K1 must be written first, followed by the write of K2, then K3.

Note: The DEU key registers are located at the following offsets:
DEUKR1 = Offset 0xC2400.
DEUKR2 = Offset 0xC2408
DEUKR3 = Offset 0xC2410
The Reading any of these memory locations generates an address error interrupt.

27.7.8.11 DEU FIFOs

DEU uses an input FIFO/output FIFO pair to hold data before and after the encryption process. Normally, the channels control all access to these FIFOs. For core processor-controlled operation, a write to anywhere in the DEU FIFO address space enqueues data to the DEU input FIFO, and a read from anywhere in the DEU FIFO address space dequeues data from the DEU output FIFO.

Writes to the input FIFO go first to a staging register which can be written by byte, 4 bytes, or 8 bytes. When all 8 bytes of the staging register are written, the entire 8-byte set is automatically enqueued into the FIFO. If any byte is written twice between enqueues, it causes an error interrupt of type AE from the EU. Since the DEU data length should always be a multiple of 8 bytes, the last write should complete the 8-byte set. However, if there is any partial data set in the staging register when the DEU End_of_Message Register is written, the partial data is automatically padded with zeros to a full 8 bytes and enqueued to the input FIFO.

The output FIFO is readable by byte, 4-byte, or 8-byte accesses. When all 8 bytes of the header are read, that set is automatically dequeued from the FIFO so that the next 8 bytes (if any) become available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Overflows and underflow caused by reading or writing the DEU FIFOs are reflected in the DEU Interrupt Status Register.

Note: The DEU FIFOs occupy a memory space in the range defined by offsets 0xC2800–0xC2FFF

27.7.9 AESU Registers

27.7.9.1 AESU Mode Register (AESUMR)

AESUMR — AESU Mode Register — Offset 0xC4000

The AESU Mode Register contains 7 bit fields used to program the AESU. The Mode Register is cleared when the AESU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated. **Table 27-90** describes AESU Mode Register fields.

Note: The lowest 8 bits in this register are controlled by the MODE0 field in the descriptor header.

Table 27-90. AESUMR Field Descriptions

Name	Reset	Description	Settings
— 63–14	0	Reserved. Write to zero for future compatibility.	
SCM 13–11	0	**Sub-Cipher Mode** Specifies the number of sources to be XORd together for specific cipher modes.	*XOR Cipher Mode*: 1–6 are valid. All other values reserved. *Other cipher modes*: 0 is valid. All other values reserved.
— 10–8	0	Reserved. Write to zero for future compatibility.	
ECM 7–6	0	**Extend Cipher Mode** Used in combination with the CM field to define the AES operating mode.	See **Table 27-91** for details.

Table 27-90. AESUMR Field Descriptions (Continued)

Name	Reset	Description	Settings
AUX2 5	0	**AUX2 Mode** The definition depends on the value of the four CM and ECM bits: • ECM = 1x and CM = 0x. Finalize MAC for CCM and GCM modes. • ECM = 10 or 01 and CM = 10. Use ICV bit value. • ECM = 00 and CM = 01. Enable RBP.	*If ECM = 1x and CM = 0x*: 0 Do not generate final MAC tag. 1 Generate final MAC tag after CCM/GCM processing is complete. For GCM, if message processing is split into multiple descriptions, AUX1 must equal 1 when AUX2 = 1. *If ECM = 10 or 01 and CM = 10*: 0 XCBC-MAC or CMAC cipher mode if ICV = 0. 1 XCBC-MAC with ICV or CMAC with ICV cipher mode if ICV = 1. *If ECM = 00 and CM = 01*: 0 CBC cipher mode. 1 CBC-RBP cipher mode.
AUX1 4	0	**AUX1 Mode** The definition depends on the value of the four CM and ECM bits: • ECM = 10 and CM = 00. Initialize CCM. • ECM = 10 and CM = 01. Generate final GHASH bit. Enables completion of GHASH computation by signaling that the last iteration of GHASH should be performed. This last iteration performs XOR of the current (intermediate) GHASH result with the concatenation of AAD and ciphertext bit lengths in case of GHASH(H, AAD, ciphertext) or with the concatenation of 064 and the bit length of IV in case of GHASH(H, {}, IV). As an exception, clear this bit if the whole message (IV+AAD+textdata) together with the generation of the final MAC is processed with one descriptor because in that case the generation of final GHASH is implied. Whenever AUX1 = 1 in GCM cipher mode, the total bit lengths of AAD, textdata or IV, must be provided in AESU Context Registers 9–10. • ECM = 10 and CM = 10. Use Context for XCBC-MAC derived keys. • ECM = 01 and CM = 10. Use Context for CMAC derived keys.	*If ECM = 10 and CM = 00*: 0 Do not initialize; context loaded by core processor. 1 Initialize new message with nonce/initialization vector. *If ECM = 10 and CM = 01*: 0 Do not perform the laster iteration in GHASH(H,AAD,ciphertext) or GHASH(H,{},IV) unless the message is processed and the final MAC computed in 1 descriptor. 1 Generate the final result of GHASH(H, AAD, ciphertext) or GHASH(H, {}, IV). Setting this bit implies that the message processing is split into multiple descriptors. *If ECM = 10 and CM = 10*: 0 Compute K1=E(K,16(01)), K2=E(K,16(02)), K3=E(K,(03)) and write K1 to Context Registers 3–4, K2 to Context Registers 5–6, and K3 to Context Registers 7–8. 1 Load keys: K1=[Key Data Registers 1–2], K2=[Key Data Registers 5–6], K3=[Key Data Registers 7–8]. *If ECM = 01 and CM = 10*: 0 Compute E(K,0^{128}) and write it to Context Registers 3–4. 1 Load E(K,0^{128}) and preserve it in Context Registers 3–4.

Table 27-90. AESUMR Field Descriptions (Continued)

Name	Reset	Description	Settings
AUX0 3	0	**AUX0 Mode** The definition depends on the value of the four CM and ECM bits and the ED bit: • ED = 1 and ECM = 10 and CM = 01. Specifies GHASH mode. • ED = 1 and ECM = 10 or 01 and CM = 10. Specifies XCBC-MAC or CMAC Cipher mode.	*If ED = 1 and ECM = 10 and CM = 01*: 0 Perform GCM encryption. 1 Compute GHASH(H, AAD, ciphertext). *If ED = 1 and ECM = 10 or 01 and CM = 10*: 0 Generate final MAC tag; that is, XOR the final data block with K2/K3 (XCBC-MAC) or K1/K2 (CMAC) before encryption. 1 Do not generate final MAC tag before encryption to allow the message processing to be interrupted on the block boundary and later continue after a context switch.
CM 2–1	0	**Cipher Mode** Used in combination with the ECM field to define the AES operating mode.	See **Table 27-91** for details.
ED 0	0	**Encryption/Decryption** Specifies whether to encrypt or decrypt the data. **Note:** This bit is ignored in CTR, SRT, CMAC, and XCBC-MAC Cipher Modes.	0 Perform decryption. 1 Perform encryption.

Table 27-91. AES Cipher Modes

Mode	ECM	AUX2	CM
ECB	00	x	00
CBC	00	0	01
CBC-RBP	00	1	01
OFB	00	x	10
CTR	00	x	11
XTS	01	x	01
CMAC	01	0	10
CMAC with ICV	01	1	10
SRT	01	x	11
CCM	10	1	00
GCM	10	1	01
XCBC-MAC	10	0	10
XCBC-MAC with ICV	10	1	10
CFB128	10	x	11
CCM with ICV	11	1	00
GCM with ICV	11	1	01
XOR	11	x	11
Reserved	all others		

Notes: **1.** x indicates the value can be 1 or 0.
2. SRT is not a new AES mode, it is an AESU method of performing AES-CTR mode with reduced context loading overhead specifically for performing SRTP. It should be used with descriptor type 0010_0 srtp. See **Section 27.6.3.9.3**, *Context for SRT Cipher Mode,* on page 27-50 for more information on how SRT mode reduces context loading overhead.

27.7.9.2 AESU Key Size Register (AESUKSR)

AESUKSR — AESU Key Size Register — Offset 0xC4008

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—

Reset	0x0000															

The AESU Key Size Register stores the number of bytes in the key (16, 24, 32). Any key data beyond the number of bytes in the Key Size Register is ignored. This register is cleared when the AESU is reset or reinitialized. If a key size other than 16, 24, or 32 bytes is specified, an illegal key size error is generated. If the Key Size Register is modified during processing, a context error is generated.

Table 27-92. AESUKSR Field Descriptions

Name	Reset	Description	Settings

Reset	0x0000															

The AESU Data Size Register stores the number of bits of plaintext/ciphertext in the current descriptor. The number of Data Size Register bits used by the SEC, and the acceptable values for these bits, vary depending on the AES cipher mode selected. This register is cleared when the AESU is reset or reinitialized. Writing to this register signals the AESU to start processing data from the input FIFO as soon as it is available. If the value of data size is modified during processing, a context error is generated.

Table 27-93. AEUDSR Field Descriptions

Name	Reset	Description
— 63–19	0	Reserved. Write to zero for future compatibility.
Data Size 18–0	0	**Data Size** Stores the number of bits in the final message block. The required value is mode dependent. See **Table 27-94** for a list of bits used by selected cipher mode. **Note:** An improper data size sets AESUISR[DSE] to indicate a data size error. Modification of the data size during processing results in the setting of AESUISR[CE] bit to indicate a context error. AES-CCM mode does not support zero length AAD and zero length payload.

Table 27-94. Use of Data Size Register

AESU Cipher Mode	Register bits Used (others ignored)	Legal Values in Bits
ECB, CBC	lowest 7 bits	must be a multiple of 128
CCM		must be a multiple of 8
OFB, CMAC, CTR, SRT, CBC-RBP, XCBC-MAC, CFB128	all bits	
XTS		must be multiple of 8, minimum of 128
GCM		any value
XOR		must be a multiple of 256

27.7.9.4 AESU Reset Control Register (AESURCR)

AESURCR — AESU Reset Control Register — Offset 0xC4018

This register allows three levels reset of just AESU, as defined by the three self-clearing bits:

Table 27-95. AESURCR Field Descriptions

Name	Reset	Description	Settings
— 63–3	0	Reserved. Write to zero for future compatibility.	
RI 2	0	**Reset Interrupt** Setting this bit causes AESU interrupts signaling done and error to reset. It further resets the state of the AESU Interrupt Status Register (AESUISR).	0 No reset. 1 Reset interrupt logic.
MI 1	0	**Module Initialization** Setting this bit perform like a software reset except that the Interrupt Mask Register remains unchanged. The module initialization includes execution of an initialization routine, completion of which is indicated by the RD bit in the AESUSR (see **Section 27.7.9.5**, *AESU Status Register (AESUSR),* on page 27-240).	0 No reset 1 Reset most of AESU
SR 0	0	**Software Reset** Setting this bit is functionally equivalent to a hardware reset (asserting the $\overline{\text{HRESET}}$ pin), but the reset is restricted to the AESU. All registers and internal states are returned to the defined reset state. When SR is cleared, the AESU enters a routine to perform proper initialization of the parameter memories. The AESUSR[RD] indicates when the initialization routine is complete (see **Section 27.7.9.5**, *AESU Status Register (AESUSR),* on page 27-240).	0 No reset 1 Full AESU reset.

27.7.9.5 AESU Status Register (AESUSR)

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the AESU Interrupt Mask Register is zero (see **Section 27.6.3.7**, *AESU Interrupt Mask Register*, on page 27-47). If the AESU Interrupt Status Register is non-zero, the AESU halts and the AESU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189). In addition, if the AESU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4]),* on page 27-202) and generates a channel error interrupt to the

controller. If the Interrupt Status Register is written from the core processor, 1s in the written value are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the AESU Reset Control Register (AESURCR). The definition of each bit in the AESU Interrupt Status Register is listed in **Table 27-97**.

Table 27-97. AESUISR Field Descriptions

Name	Reset	Description	Settings
— 63–15	0	Reserved. Write to zero for future compatibility.	
ICE 14	0	**Integrity Check Error** If set, indicates that an ICV check was performed and that the supplied ICV did not match the value computed by the AESU.	0 No error detected. 1 Integrity check error.
— 13	0	Reserved. Write to zero for future compatibility.	
IE 12	0	**Internal Error** Indicates whether an internal processing error was detected while the AESU was processing. **Note:** This bit is set any time an enabled error condition occurs. It can only be cleared by setting the corresponding bit in the AESUIMR or by resetting the AESU.	0 No internal error detected. 1 Internal error.
ERE 11	0	**Early Read Error** Indicates whether the AESU IV register was read while the AESU was processing.	0 No early read error detected. 1 Early read error.
CE 10	0	**Context Error** If set, indicates that AESU key register, the Key Size Register, Data Size Register, Mode Register, or IV register was modified while the AESU was processing.	0 No context error detected. 1 Context error.
KSE 9	0	**Key Size Error** IF set, indicates that an inappropriate value (not 16, 24, or 32) was written to the AESU Key Size Register.	0 No key size error detected. 1 Key size error.
DSE 8	0	**Data Size Error** If set, an improper value was written to the AESU Data Size Register. See **Section 27.6.3.3**, *AESU Data Size Register,* on page 27-46 for details.	0 No data size error detected. 1 Data size error.
ME 7	0	**Mode Error** If set, indicates that invalid data was written to a register or that a reserved mode bit was set.	0 Valid data. 1 Reserved or invalid mode selected.
AE 6	0	**Address Error** If set, an illegal read or write address was detected within the AESU address space.	0 No address error detected. 1 Address error detected.
OFE 5	0	**Output FIFO Error** If set, the AESU output FIFO was detected non-empty upon write of AESU Data Size Register.	0 No output FIFO error detected. 1 Output FIFO non-empty error.
IFE 4	0	**Input FIFO Error** If set, the DEU input FIFO was detected non-empty upon generation of a done interrupt.	0 No input FIFO error detected. 1 Input FIFO non-empty error.

Table 27-97. AESUISR Field Descriptions (Continued)

Name	Reset	Description	Settings
— 3	0	Reserved. Write to zero for future compatibility.	
IFO 2	0	**Input FIFO Overflow** If set, the AESU input FIFO was pushed while full. **Note:** When operated through channel-controlled access, the SEC implements flow control, and FIFO size is not a limit to data input. When operated through core processor-controlled access, the AESU cannot accept FIFO inputs larger than 256 bytes without overflowing.	0 No input FIFO overflow error detected. 1 Input FIFO overflow error.
OFU 1	0	**Output FIFO Underflow** If set, the AESU output FIFO was read while empty.	0 No output FIFO underflow error detected. 1 Output FIFO underflow error.
— 0	0	Reserved. Write to zero for future compatibility.	

27.7.9.7 AESU Interrupt Mask Register (AESUIMR)

The AESU Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.6.3.6**, *AESU Interrupt Status Register*, on page 27-46), if the corresponding bit in this register is set, then the error is ignored; no error interrupt occurs and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon

detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing

Table 27-98. AESUIMR Field Descriptions

Field	—									ICV_Size						
Type	R/W															
Reset	0x0000															

The AESU ICV size register is used in AES hashing modes CMAC, GCM, and XCBC-MAC to specify the number of significant bytes in the received MAC tag supplied in Context Registers 3–4 (GCM w/ICV). AES truncates the computed MAC in Context Registers 1–2 to the same number of significant bytes and write zeros in the remaining positions. Note that the received MAC can be padded to the full 16 bytes with any value (that is. not necessarily zeros) when written into Context Registers 3-4. Acceptable values for ICV size are 8, 12, and 16 bytes. All other sizes are interpreted as 16. CCM with ICV does not use the ICV Size Register.

27.7.9.9 AESU End_of_Message Register (AESUEOMR)

AESUEOMR — AESU End_of_ Message Register — Offset 0xC4050

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Reset	0x0000															

The AESU End_of_Message Register is used to indicate that an AES operation can be completed. After the final message block is written to the input FIFO, the End_of_Message Register must be written. The value in the Data Size Register is used to determine how many bits of the final message block (always 128) to process. Writing to this register causes the AESU to process the final block of a message, allowing it to signal a done interrupt. A read of this register always returns a zero value.

27.7.9.10 AESU Context Registers (AESUCR[1–12])

AESUCR[1–12] AESU Context Registers 1–12 Offset 0xC4100 + x*11

Reset	0x0000															

There are twelve 64-bit context data registers that allow the core processor to read/write the contents of the context used to process the message. The context must be written prior to the key data. If the Context Registers are written during message processing, a context error is generated. All Context Registers are cleared when a hard or soft reset or initialization is performed.

The Context Registers must be read when changing context and restored to their original values to resume processing an interrupted message. The actual number of context registers used in an operation is protocol specific and can range from 2 to 12, However, even though the protocol does not use lower numbered registers, all of the context registers up to the highest number used must be read to retrieve context and all s must be written back to restore context. For example, CTR mode uses only Context Register 5–7 to hold the Counter and Counter Modulus Exponent. So, effectively, the user must read the four empty place holder Context Registers 1–4 in addition to the three Context Registers that are used. The contents of the empty Context Registers need not be preserved, but when restoring the CTR mode context, the empty registers must be filled with 32 bytes of zeros before writing the saved Counter and Counter Modulus Exponent.

Context should be loaded starting with the lower bytes in the lowest 64-bit Context Register.

The context registers are summarized by modes in **Table 27-99**, **Table 27-100**, and **Table 27-100**.

Table 27-99. AESU Context Registers for Confidentiality Modes

Context Register (address offset)	Cipher Mode Providing Only Confidentiality			
	CBC/ CBC-RBP/ OFB/ CFB128 (Section 27.6.3.9.1)	CTR (Section 27.6.3.9.2)	SRT (Section 27.6.3.9.3	XTS (Section 27.6.3.9.4)
1 (0xC4100)	IV *		Counter *	I *
2 (0xC4108)				sector size *
3 (0xC4110)	—	—	Counter Modulus *	—

Type	R/W															
Reset	0x0000															

The AESU key registers are organized as an 8-byte upper half following by an 8-byte lower half. They hold 16, 24, or 32 bytes of key data, with the first 8 bytes of key data written to KEY 1U. Any key data written to bytes beyond the value written to the Key Size Register are ignored. The Key Data Registers are cleared when the AESU is reset or reinitialized. If these registers are modified during message processing, a context error is generated.

27.7.9.12 AESU FIFOs

AESU uses an input FIFO/output FIFO pair to hold data before and after the encryption process. Normally, the channels control all access to these FIFOs. For core processor-controlled operation, a write to anywhere in the AESU FIFO address space enqueues data to the AESU input FIFO, and a read from anywhere in the AESU FIFO address space dequeues data from the AESU output FIFO.

Writes to the input FIFO go first to a staging register which can be written by byte, 4 bytes, or 8 bytes. When all 8 bytes of the staging register are written, the entire set is automatically enqueued into the FIFO. If any byte is written twice between enqueues, it causes an error interrupt of type AE from the EU. When writing the last portion of data, it is not necessary to write all 8 bytes. Any last bytes remaining in the staging register are automatically padded with zeros and forced into the input FIFO when the AESU End_of_Message Register is written.

The output FIFO is readable by byte, 4-byte, or 8-byte accesses. When all 8 bytes of the header are read, that 8-bytes is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Overflows and underflows caused by reading or writing the AESU FIFOs are reflected in the AESU Interrupt Status Register.

The AESU fetches data 128 bits at a time from the input FIFO. During processing, the input data is encrypted or decrypted with the key and initialization vector (CBC mode only) and the results are placed in the output FIFO. The output size is the same as the input size.

The input FIFO can be written any time the number of 8-byte sets currently in the input FIFO (as indicated by the IFL field of the AESU Status Register) is less than 32. There is no limit on the total number of bytes in a message. The number of bits in the final message block must be set in the Data Size Register.

The output FIFO can be read any time the OFR signal is asserted (as indicated in the AESU Status Register). The result indicates that the number of bytes in the output FIFO is at or above the threshold specified in the Mode Register.

For AES-CCM mode, the input data stream to the input FIFO consists of the CCM Header, followed by the Additional Authenticated Data (AAD), followed by Plaintext if encrypting, or Ciphertext if decrypting. This mode does not support zero length AAD and zero length payload. Note that AESU only supports 2 byte CCM headers and does not support extended CCM headers.

Note: The AESU FIFOs occupy a memory space in the range defined by offsets 0xC4800–0xC4FFF

27.7.10 MDEU Registers

The MDEU Mode Register is used to program the function of the MDEU. The least significant 8 bits of this register are specified by the user through the MODE0 or MODE1 field of the descriptor header. The remaining bits are supplied by the channel and thus are not under direct user control. The MDEU Mode Register has two configurations, determined by the value of the

NEW bit. The new configuration (NEW = 1) is used only by TLS/SSL descriptor types (1000_1, 1001_1). The old configuration (NEW = 0) is used by all other descriptor types. The old configuration is the same as the one used in SEC 2.0, except for the CICV and SMAC bits. The Mode Register is cleared when the MDEU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated. **Table 27-102** describes MDEU Mode Register fields.

Table 27-102. MDEUMR Field Descriptions

Name	Reset	Description	Settings
— 63–13	0	Reserved. Write to zero for future compatibility.	
MDEU_B 12	0	**MDEU_B Alternate Algorithms** Selects which algorithms are enabled by the ALG bits.	0 MDEU-A group (SHA-1, SHA-256, MD5, and SHA-224) 1 MDEU-B group (SHA-384, SHA-256, SHA-512, and SHA-224)
— 11	0	Reserved. Write to zero for future compatibility.	
STIB 10	0	**SSL/TLS Inbound Block Cipher (New mode only)** When this bit is set, upon receiving End_of_message, the MDEU performs a calculation involving the last valid byte of data written into its input FIFO (which is Pad Length) to compute a final data size. The MDEU then processes the amount of data specified by this data size, and completes the message digest.	0 Normal operation. 1 Special operation for SSL/TLS inbound, block cipher only.
NEW 9	0	**New Mode** Determines which format the MDEU Mode Register uses.	0 Old configuration. 1 New configuration.
— 8	0	Reserved. Write to zero for future compatibility.	
CONT 7	0	**Continue** Most operations require this bit to be cleared. It is set only when the data to be hashed is spread across multiple descriptors.	0 Do auto padding and complete the message digest. Used when the entire hash is performed with one descriptor, or on the last of a sequence of descriptors. 1 This hash is continued in a subsequent descriptor. Do not autopad and do not complete the message digest.
CICV 6	0	**Compare Integrity Check Values** Indicates whether to do an ICV check. The number of bytes to be compared is given by the ICV Size Register. This is only applicable to descriptor types that provide for reading in an ICV value.	0 Normal operation; no ICV comparison. 1 After the message digest (ICV) is computed, compare it to the data in the MDEU input FIFO. If the ICVs do not match, send an error interrupt to the channel.
SMAC 5	0	**SSL MAC Operation** Specifies whether to perform an SSL3.0 MAC operation. This requires a key and key length. **Note:** If this bit is set, HMAC should be 0.	0 Normal operation. 1 Perform.an SSL3.0 MAC operation
INIT 4	0	**Initialization** Indicates whether to initialize the MDEU. If initialization is not done, the registers must be loaded from a hash context pointer in the descriptor. When the data to be hashed is spread across multiple descriptors, this bit must be 0 on all but the first descriptor.	0 Do not initialize digest registers. 1 Do an algorithm-specific initialization of the digest registers.

Table 27-102. MDEUMR Field Descriptions (Continued)

Name	Reset	Description	Settings
HMAC 3	0	**HMAC Operation** Selects whether to perform an HMAC operation. The HMAC operation requires a key and a key length. If this bit is set, then SMAC should be cleared (0).	0 Normal operation. 1 Perform.an HMAC operation.
PD/EALG 2	0	**Padding** For Old configurations (NEW = 0), the value of this bit must be programmed to be the inverse of the CONT bit. **EALG** For New configurations (NEW = 1), this bit is an additional extension bit for the ALG field.	*For PD, New = 0*: 0 This hash is continued in a subsequent descriptor. Do not autopad and do not complete the message digest. 1 Do auto padding and complete the message digest. Used when the entire hash is performed with one descriptor, or on the last of a sequence of descriptors. *For EALG, New = 1:* 0 Only valid value. 1 Reserved.
ALG 1–0	0	**Message Algorithm** Selects the message algorithm to use.	00 SHA-160 algorithm (full name for SHA-1). 01 SHA-256 algorithm. 10 MD5 algorithm. 11 SHA-224 algorithm.

27.7.10.2 MDEU Key Size Register (MDEUKSR)

MDEUKSR — MDEU Key Size Register — Offset 0xC6008

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R/W															
Reset	0x0000

Field	—								Key Size							
Type	R/W															
Reset	0x0000															

The MDEU Key Size Register value indicates the number of bytes of key memory that should be used in HMAC generation. MDEU supports at most one block of key. MDEU generates a key size error if the value written to this register exceeds 64 bytes for MD5, SHA-1, SHA-224, or SHA-256, or if the value exceeds 128 bytes for SHA-384 or SHA-512.

27.7.10.3 MDEU Data Size Register (MDEUDSR)

MDEUDSR — MDEU Data Size Register — Offset 0xC6010

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R/W

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Field	—											Data Size				
Type	R/W															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	Data Size															
Type	R/W															
Reset	0x0000															

The MDEU Data Size Register indicates the number of bits of data to be processed. The Data Size field is a 21-bit signed number. Values written to this register are added to the current register value. Multiple writes are allowed. The MDEU processes data when there is a positive value in this register and there is data available in the MDEU input FIFO. (Negative values can arise in inbound processing, when it is necessary to hold back data from the MDEU until the pad length is decrypted.). Because the MDEU does not support bit offsets, the least significant 3 bits must be written as 0 and are always read as zero. Furthermore, when the CONT bit of the MDEU Mode Register is high, the data size must be a multiple of the block size (that is, 512 bits for MD5, SHA-1, SHA-224, and SHA-256; 1024 bits for SHA-384 and SHA-512). Violating either of these conditions causes a data size error (the MDEUIDR[DSE] bit is set).

This register is cleared when the MDEU is reset or reinitialized. At the end of processing, its contents are decremented down to zero (unless there is an error interrupt).

Note: Writing to the Data Size Register allows the MDEU to enter auto-start mode. Therefore, always write the required Context Registers prior to writing the data size.

27.7.10.4 MDEU Reset Control Register (MDEURCR)

MDEURCR — MDEU Reset Control Register — Offset 0xC6018

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Field	—										HALT	ICCR		EI	DI	RD
Type	R															
Reset	0x0000															

The MDEUSR reflects the state of the MDEU internal signals. The majority of these internal signals reflect the state of low-level MDEU functions, such as data padding, key padding, and so forth., and are not important to the user, however the user should be aware that reads of this register especially during processing are likely to return non-zero values for many of the most significant 58 bits. The MDEUSR is read-only. Writing to this location results in an address error being reflected in the MDEU Interrupt Status Register (MDEUISR).

Table 27-104. MDEUSR Field Descriptions

Name	Reset	Description	Settings
— 63–6	0	Reserved. Write to zero for future compatibility.	
HALT 5	0	**Halt** Indicates whether the MDEU is halted due to an error. **Note:** Because the error causing the MDEU to stop operating can be masked before reaching the Interrupt Status Register, the MDEUISR is used to provide a second source of information regarding errors that prevent normal operation.	0 MDEU not halted 1 MDEU halted
ICCR 4–3	0	**Integrity Check Comparison Result** A passed or failed result is generated only if ICV comparison is enabled.	00 No integrity check performed. 01 Integrity check comparison passed. 10 Integrity check comparison failed. 11 Reserved.
EI 2	0	**Error Interrupt** This status bit reflects the state of the error interrupt signal, as sampled by the controller Interrupt Status Register (**Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189).	0 MDEU is not signaling error 1 MDEU is signaling error

Table 27-104. MDEUSR Field Descriptions (Continued)

Name	Reset	Description	Settings
DI 1	0	**Done Interrupt** This status bit reflects the state of the done interrupt signal as sampled by the controller Interrupt Status Register (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189)	0 MDEU is not signalling done. 1 MDEU is signalling done.
RD 0	0	**Reset Done** This status bit, when high, indicates that the MDEU has completed its reset sequence. **Note:** The reset value of RD is 0, but it typically switches to 1 by the time a user checks the register, indicating the EU is ready for operation.	0 Reset in progress. 1 Reset done.

27.7.10.6 MDEU Interrupt Status Register (MDEUISR)

Field	—		ICE	—	IE	ERE	CE	KSE	DSE	ME	AE	—		IFO	—	
Type	R															
Reset	0x0000															

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the MDEU Interrupt Mask Register is zero (see **Section 27.7.11.7**, *AFEU Interrupt Mask Register (AFEUIMR),* on page 27-274).

If the MDEU Interrupt Status Register is non-zero, the MDEU halts and the MDEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189). In addition, if the MDEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4]),* on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s that are written in the value are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the MDEU Reset Control Register (MDEURCR[RI]). The definition of each bit in the MDEUISR is listed in **Table 27-105**.

Table 27-105. MDEUISR Field Descriptions

Name	Reset	Description	Settings
— 63–14	0	Reserved. Write to zero for future compatibility.	
ICE 13	0	**Integrity Check Error** If set, indicates that an ICV check was performed and that the supplied ICV did not match the value computed by the MDEU.	0 No error detected. 1 Integrity check error.
— 12	0	Reserved. Write to zero for future compatibility.	
IE 11	0	**Internal Error** Indicates whether the MDEU is locked and requires a reset before use. **Note:** This bit is set any time an enabled error condition occurs. It can only be cleared by resetting the MDEU.	0 No internal error detected. 1 Internal error.
ERE 10	0	**Early Read Error** Indicates whether the MDEU context was read before the MDEU completed the hashing operation.	0 No early read error detected. 1 Early read error.
CE 9	0	**Context Error** If set, indicates that MDEU key register, Key Size Register, or Data Size Register was modified while the MDEU was performing its hashing operation.	0 No context error detected. 1 Context error.
KSE 8	0	**Key Size Error** If set, indicates an error due to one of the following two causes: • A value greater than 64 bytes was written to the MDEU Key Size Register. • In either an HMAC or SMAC operation, the key size was not written prior to writing the data size or receiving a CHA_GO command.	0 No key size error detected. 1 Key size error.
DSE 7	0	**Data Size Error** If set, indicates that data with a size not a multiple of the block size (512 or 1024 depending on protocol) was found when the MDEUMR[CONT} bit was cleared (0).	0 No data size error detected. 1 Data size error.
ME 6	0	**Mode Error** If set, indicates one of the following conditions: • A reserved bit in the MDEUMR is set. • The ALG field of the MDEUMR contains an illegal value.	0 No error detected. 1 Mode error.
AE 5	0	**Address Error** If set, an illegal read or write address was detected within the MDEU address space.	0 No address error detected. 1 Address error detected.
— 4–3	0	Reserved. Write to zero for future compatibility.	

Table 27-105. MDEUISR Field Descriptions (Continued)

Name	Reset	Description	Settings
IFO 2	0	**Input FIFO Overflow** If set, the MDEU input FIFO was pushed while full. **Note:** When operated through channel-controlled access, the SEC implements flow control, and FIFO size is not a limit to data input. When operated through core processor-controlled access, the MDEU cannot accept FIFO inputs larger than 256 bytes without overflowing.	0 No input FIFO overflow error detected. 1 Input FIFO overflow error.
— 1–0	0	Reserved. Write to zero for future compatibility.	

27.7.10.7 MDEU Interrupt Mask Register (MDEUIMR)

MDEUIMR — MDEU Interrupt Mask Register — Offset 0xC6038

Reset	0x1000															

The MDEU Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.6.4.7**, *MDEU Interrupt Status Register*, on page 27-70), if the corresponding bit in this register is set, then the error is disabled; no error interrupt occurs and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then

upon detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

Table 27-106. MDEUIMR Field Descriptions

Type	W															
Reset	0x0000															

The End_of_message Register in the MDEU is used to indicate an authentication operation can be completed. After the final message block is written to the input FIFO, the End_of_Message Register must be written. The value in the Data Size Register is used to determine how many bits of the final message block (always 512) are processed. Note that this register has no data size, and during the write operation, the core processor data bus is not read. Hence, any data value is accepted. Normally, a write operation with a zero data value is performed. Reading from this register is not meaningful, but a zero value is always returned, and no error is generated. Writing to this register is merely a trigger causing the MDEU to process the final block of a message, allowing it to signal done interrupt.

27.7.10.10 MDEU Context Registers (MDEUCR)

For MDEU, context consists of the hash plus the message length count. Write access to this register block allows continuation of a previous hash. Reading these registers provides the resulting message digest or HMAC along with an aggregate bit count.

Note: All SHA algorithms are big endian. MD5 is little endian. The MDEU module internally reverses the endianness of the five registers A, B, C, D, and E upon writing to or reading from the MDEU context if the MDEU Mode Register indicates MD5 is the hash of choice. Most other endian considerations are performed as 8-byte swaps. In this case, 4-byte endianness swapping is performed within the A, B, C, D, and E fields as individual registers. Reading this memory location while the module is not done generates an error interrupt.

After a power-on reset, all the MDEU Context Register values are cleared (0). The MDEU Context Registers are initialized if the INIT bit is set in the MDEU Mode Register. However, all registers are initialized, regardless of mode selected, but only the appropriate Context Register values are used in hash generation per the mode selected. Even though the user typically does not need to know about the MDEU Context Register initialization values; they are documented for completeness in the event that the user reads these registers using core processor-controlled access. MDEU resets via the MDEU Reset Control Register (**Section 27.6.4.5**, *MDEU Reset Control Register*, on page 27-70) or SEC global software reset (**Section 27.7.4.1**, *Master Control Register (MCR)*, on page 27-179) do not clear these registers. **Figure 27-58** shows the memory map and register contents for the various hash modes. If SHA-384 or SHA-512 is selected, then each of the registers A, B, C, D, E, F, G, and H is 64-bits, instead of the 32 bit-width used with the other hash algorithms. As a result, the base address for each context register is shifted to adjust for the difference in register size.

Figure 27-58. MDEU Context Register Map

27.7.10.11 MDEU Key Registers (MDEUKR[1–8])

The MDEU maintains sixteen 64-bit registers for writing an HMAC key. Only the first eight registers are used for MD-5, SHA-1, SHA-224, or SHA-256. The IPAD and OPAD operations are performed automatically on the key data when required.

Note: All SHA algorithms are big endian. MD5 is little endian. The MDEU module internally reverses the endianness of the key upon writing to or reading from the MDEU key registers if the MDEU Mode Register indicates MD5 is the hash of choice.

Note: The MDEU key registers are located in a range defined by offsets 0xC6400–0xC647F.

27.7.10.12 MDEU Input FIFO

MDEU uses an input FIFO to hold data to be hashed (followed in some case by an ICV value for ICV checking). Normally, the channels control all access to this FIFO. For core processor-controlled operation, a write to anywhere in the MDEU FIFO address space enqueues data to the MDEU input FIFO, and a read from anywhere in this address space returns all zeros.

When the core processor writes to the MDEU FIFO (using core processor-controlled access), it can write to any FIFO address using byte, 4-byte, or 8-byte accesses. The MDEU assembles these bytes from left to right, that is, the first bytes written are placed in the most significant bit-positions. Whenever the MDEU accumulates 8 bytes, these 8 bytes are automatically enqueued into the FIFO, and any remaining bytes are left-justified in preparation for assembling the next 8 bytes. It is not necessary to fill all bytes of the final 8-byte set. Any remaining bytes in the staging register are automatically padded with zeros and forced into the input FIFO when the MDEU End_of_Message Register is written.

Overflows caused by writing the MDEU FIFO are reflected in the MDEU Interrupt Status Register.

Note: The MDEU input FIFO is located in a range defined by offsets 0xC6800–0xC6FFF.

27.7.11 AFEU Registers

27.7.11.1 AFEU Mode Register (AFEUMR)

AFEUMR — AFEU Mode Register — Offset 0xC8000

The AFEU Mode Register (AFEUMR) contains three bits used to program the AFEU. The Mode Register is cleared when the AFEU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the Mode Register is modified during processing, a context error is generated. **Table 27-107** describes AFEU Mode Register fields.

Table 27-107. AFEUMR Field Descriptions

Name	Reset	Description	Settings
— 63–3	0	Reserved. Write to zero for future compatibility.	
CS 2	0	**Context Source** If set, causes the context to be moved from the input FIFO into the S-box prior to starting encryption/decryption. Otherwise, context should be directly written to the Context Registers or context should be generated automatically via key permutation. The CS value is only checked if the PP bit is set.	0 Context not from FIFO. 1 Context from input FIFO.
DC 1	0	**Dump Context** If set, causes the context to be moved from the S-box to the output FIFO following assertion of the AFEU done interrupt.	0 Do not dump context. 1 After cipher, dump context.
PP 0	0	**Prevent Permute** Normally, AFEU receives a key and uses that information to randomize the S-box. If reusing a context from a previous descriptor, set this bit to prevent the AFEU from reperforming this permutation step.	0 Perform S-Box permutation. 1 Do not permute.

27.7.11.2 AFEU Key Size Register (AFEUKSR)

AFEUKSR — AFEU Key Size Register — Offset 0xC8008

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R/W

Field	—				Key Size											
Type	R/W															
Reset	0x0000															

The value in the AFEU Key Size Register (AFEUKSR) indicates the number of bytes of key memory that should be used in performing S-box permutation. Any key data beyond the number of bytes in the Key Size Register is ignored. This register is cleared when the AFEU is reset or reinitialized. If the key size specified is less than 1 or greater than 16, a key size error is generated. If the Key Size Register is modified during processing, a context error is generated.

Note: Although the AFEU supports key lengths as short as 1 byte, a 1-byte key offers little security. Most ARC-4 applications specify keys of 5–16 bytes.

The device driver creates properly formatted descriptors for situations requiring a key permute prior to ciphering. When using core processor-controlled access (typically for debug), the user must perform the following sequence:

1. Configure the AFEU Mode Register to perform a permute with key
2. Write the key data to AFEU key registers
3. Write the key size to the Key Size Register.

The AFEU starts permuting the memory with the contents of the key registers immediately after the key size is written.

27.7.11.3 AFEU Context/Data Size Register (AFEUCDSR)

AEFUCDSR AEFU Context Data Size Register Offset 0xC8010

Type	R/W															
Reset	0x0000															

The AFEU Context/Data Size Register (AFEUCDSR) stores the number of bits in the final message, with an upper bound of 4096. Whatever number is written (and whatever truncated value is stored) must be a multiple of 8. This value controls how much data is processed from the last block. The last message block must be a multiple of 8 in the range from 8–64. If a data size that is not a multiple of 8 bits is written, a data size error is generated. Only the least significant 3 bits are checked to determine if there is a data size error. Since all upper bits are ignored, the entire message length (in bits) can be written to this register.

The AFEUCDSR is also used to specify the context size when context is used. The context size is fixed at 2072 bits (259 bytes). When loading context through the FIFO, all context data must be written prior to writing the context data size. The message data size must be written separately.

Note: When reloading an existing context using core processor-controlled access, the user must write the context to the input FIFO, then write the context size (always 2072 bits). The write of the context size indicates to the AFEU that all context is loaded. The user then writes the message data size to the AFEUCDSR. After this write, the user can begin writing message data to the FIFO.

Writing to this register signals the AFEU to start processing data from the input FIFO as soon as it is available. If the value of data size is modified during processing, a context error is generated. This register is cleared when the AFEU is reset or reinitialized.

27.7.11.4 AFEU Reset Control Register (AFEURCR)

AFEURCR — AFEU Reset Control Register — Offset 0xC8018

The AFEU Reset Control Register (AFEURCR) allows 3 levels reset that affect the AFEU only as defined by 3 self-clearing bits. The AFEU executes an internal reset sequence (for hardware reset, SW_RESET, or Module Initialization) that performs proper initialization of the S-Box. To determine when this is complete, observe the AFEUSR[RD] bit (see **Section 27.7.11.5**, *AFEU Status Register (AFEUSR)*, on page 27-271).

Table 27-108. AFEURCR Field Descriptions

Name	Reset	Description	Settings
— 63–3	0	Reserved. Write to zero for future compatibility.	
RI 2	0	**Reset Interrupt** Setting this bit causes AFEU interrupts signalling done and error to reset. It further resets the state of the AFEU Interrupt Status Register.	0 No reset. 1 Reset interrupt logic.
MI 1	0	**Module Initialization** Module initialization is almost the same as a software reset except that the Interrupt Mask Register remains unchanged.	0 No reset 1 Reset most of AFEU.
SR 0	0	**Software Reset** Setting this bit is functionally equivalent to a hardware reset (asserting the $\overline{\text{HRESET}}$ pin), but the reset is restricted to the AFEU. When SR clears, the AFEU enters a routine to perform a proper initialization of the S-Box.	0 No reset 1 Full AFEU reset.

27.7.11.5 AFEU Status Register (AFEUSR)

AFEUSR — AFEU Status Register — Offset 0xC8028

The AFEU Interrupt Status Register (AFEUISR) indicates the unmasked errors that have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the AFEU Interrupt Mask Register is zero (see **Section 27.6.5.7**, *AFEU Interrupt Mask Register*, on page 27-75).

If the AFEU Interrupt Status Register is non-zero, the AFEU halts and the AFEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189). In addition, if the AFEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4]),* on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the AFEU Reset Control Register. The definition of each bit field in the AFEUISR is listed in **Table 27-110**.

Table 27-110. AFEUISR Field Descriptions

Name	Reset	Description	Settings
— 63–13	0	Reserved. Write to zero for future compatibility.	
IE 12	0	**Internal Error** Indicates whether an internal processing error was detected while the AFEU was performing encryption.	0 No internal error detected. 1 Internal error.
ERE 11	0	**Early Read Error** Indicates whether the AFEU context memory or control was read while the AFEU was performing encryption.	0 No early read error detected. 1 Early read error.
CE 10	0	**Context Error** If set, indicates that AESU key register, the Key Size Register, Data Size Register, Mode Register, or IV register was modified while the AESU was processing.	0 No context error detected. 1 Context error.
KSE 9	0	**Key Size Error** IF set, indicates that a value outside the range 1–16 bytes written to the AFEU Key Size Register.	0 No key size error detected. 1 Key size error.
DSE 8	0	**Data Size Error** If set, indicates that a value not a multiple of 8 bits was written to the AFEU Data Size Register.	0 No data size error detected. 1 Data size error.
ME 7	0	**Mode Error** If set, indicates that an illegal value was detected in the Mode Register, likely caused by writing to a reserved bit in that register.	0 Valid data. 1 Reserved or invalid mode selected.
AE 6	0	**Address Error** If set, an illegal read or write address was detected within the AFEU address space.	0 No address error detected. 1 Address error detected.
OFE 5	0	**Output FIFO Error** If set, the AFEU output FIFO was detected non-empty upon write of AFEU Data Size Register.	0 No output FIFO error detected. 1 Output FIFO non-empty error.
IFE 4	0	**Input FIFO Error** If set, the AFUE input FIFO was detected non-empty upon generation of a done interrupt.	0 No input FIFO error detected. 1 Input FIFO non-empty error.
— 3	0	Reserved. Write to zero for future compatibility.	

Table 27-110. AFEUISR Field Descriptions (Continued)

Name	Reset	Description	Settings
IFO 2	0	**Input FIFO Overflow** If set, the AFEU input FIFO was pushed while full. **Note:** When operated through channel-controlled access, the SEC implements flow control, and FIFO size is not a limit to data input. When operated through core processor-controlled access, the AFEU cannot accept FIFO inputs larger than 256 bytes without overflowing.	0 No input FIFO overflow error detected. 1 Input FIFO overflow error.
OFU 1	0	**Output FIFO Underflow** If set, the AFEU output FIFO was read while empty.	0 No output FIFO underflow error detected. 1 Output FIFO underflow error.
— 0	0	Reserved. Write to zero for future compatibility.	

27.7.11.7 AFEU Interrupt Mask Register (AFEUIMR)

AFEUIMR — AFEU Interrupt Mask Register — Offset 0xC8038

The AFEU Interrupt Mask Register (AFEUIMR) controls the result of detected errors. For a given error (as defined in **Section 27.6.5.6**, *AFEU Interrupt Status Register*, on page 27-75), if the corresponding bit in this register is set, the error is disabled; no error interrupt occurs and the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then

upon detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing.

Table 27-111. AFEUIMR Field Descriptions

Name	Reset	Description	Settings

The AFEU End_of_Message Register (AFEUEOMR) is used to signal the AFEU that all data to process is written to the input FIFO. This allows the AFEU to do special processing when it reaches the last block of data. Before this register is written, the AFEU does not process the last block of data in its input FIFO. After this register is written, the AFEU continues normal processing on all but the last block of data, then goes on to processes the last block, using the value in the Data Size Register to determine how much of the block to process. The Data Size Register specifies the number of bits to process, which is a multiple of 8 from 8–64. Once processing of the last block is completed, the AFEU signals done interrupt. If the AFEUMR[DC] bit is set, the context is written to the output FIFO following the last 8 message bytes. A read of the AFEUEOMR always returns a zero value.

27.7.11.9 AFEU Context Memory

The S-Box memory consists of 256 bytes of SRAM, each readable and writable as part of a 64-bit set. The S-Box contents should not be written with data unless that data was previously read from the S-Box. Context data should only be written if the AFEUMR[PP] bit is set (see **Section 27.7.11.1**, *AFEU Mode Register (AFEUMR)*, on page 27-267). After context data is written, the context length must be written to the context/data length register (see **Section 27.7.11.3**, *AFEU Context/Data Size Register (AFEUCDSR)*, on page 27-269). Then, message data can be written. If the Context Registers are written during message processing or the AFEUMR[PP] bit is not set, a context error is generated. Reading context data before the module is done generates an error interrupt. Context data can be written and read either via the Context Registers or via the input and output FIFOs. The user specifies the location through the

AFEUMR[CS] bit (see **Section 27.6.5.1**, *AFEU Mode Register*, on page 27-73). See **Section 27.7.11.12**, *AFEU FIFOs*, on page 27-277 for details about AFEU FIFO addressing.

Note: The AFEU Context Memory is in the range defined by offsets 0xC8100–0xC81FF.

27.7.11.10 AFEU Context Memory Pointer Register (AFEUCMPR)

The context memory pointer register holds the internal context pointers that are updated with each byte of message processed. These pointers correspond to the values of I, J, and Sbox[I+1] in the ARC-4 algorithm. If this register is written during message processing, a context error is generated. When performing ARC-4 operations, the user has the option of performing a new S-Box permutation per packet, or unloading the contents of the S-box (context) and reloading this context prior to processing of the next packet. The S-Box contents (256 bytes) plus the three bytes of the context memory pointers are unloaded and reloaded via the AFEU FIFOs. AFEU Context consists of the contents of the S-Box, as well as three counter values, which indicate the next values to be used from the S-Box. Context must be loaded in the same order in which it was unloaded.

Note: The AFEUCMPR is located at offset 0xC8200.

27.7.11.11 AFEU Key Registers (AFEUKR[1–2])

AFEU uses two write-only key registers to guide initial permutation of the AFEU S-Box, in conjunction with the AFEU Key Size Register. AFEU performs permutation starting with the first byte of key register 0, and uses as many bytes from the two key registers as necessary to complete the permutation. Reading either of these memory locations generates an address error interrupt.

Note: The AFEU key registers are located at the following offsets:
AESUKR1 = Offset 0xC8400.
AESUKR2 = Offset 0xC8408.

27.7.11.12 AFEU FIFOs

AFEU uses an input FIFO/output FIFO pair to hold data before and after the encryption process. Normally, the channels control all access to these FIFOs. For core processor-controlled operation, a write to anywhere in the AFEU FIFO address space enqueues data to the AFEU input FIFO, and a read from anywhere in the AFEU FIFO address space dequeues data from the AFEU output FIFO.

Note: The AFEU FIFOs reside in the range defined by offsets 0xC8800–0xC8FFF. In the special case where context is written through the input FIFO, the first write must be to address offset range 0xC8E00–0xC8E07. Context reads can be from any address in the FIFO address range.

Writes to the input FIFO go first to a staging register and can be written using byte, 4-byte, or 8-byte accesses. When all 8 bytes of the staging register are written, the entire 8 bytes are automatically enqueued into the FIFO. If any byte is written twice between enqueues, it causes an error interrupt of type AE from the EU. When writing the last portion of data, it is not necessary to write all 8 bytes. Any last bytes remaining in the staging register are automatically padded with zeros and forced into the input FIFO when the AFEUEOMR is written.

The output FIFO is readable using byte, 4-byte, or 8-byte accesses. When all 8 bytes of the header are read, that 8 bytes is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Overflows and underflow caused by reading or writing the AFEU FIFOs are reflected in the AFEUISR.

27.7.12 KEU Registers

27.7.12.1 KEU Mode Register (KEUMR)

KEUMR — KEU Mode Register — Offset 0xCE000

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—

Field	—								GSM	CICV	EDGE	PE	INT	—	ALG	
Type	R/W															
Reset	0x0000															

The KEU Mode Register (KEUMR) contains several bits used to program the KEU. The Mode Register is cleared when the KEU is reset or reinitialized. Setting a reserved mode bit generates a data error. Setting both the GSM and EDGE bits to one generates a data error. If the KEU Mode

Register is modified during processing, a context error is generated. **Table 27-112** describes the KEU Mode Register bit fields.

Table 27-112. KEUMR Field Descriptions

Name	Reset	Description	Settings
— 63–8	0	Reserved. Write to zero for future compatibility.	
GSM 7	0	**Select GSM A5/3 Blocks** GSM A5/3 requires that two 114-bit blocks be produced for every 4.615 mS slot. If GSM = 1, the first read of the output FIFO retrieves the first 64-bits of block 1. The second read of the output FIFO retrieves the next 50-bits of block 1 (the remaining bits of this 64 bits are set to zero). The third read of the output Fifo retrieves the first 64-bits of block 2, and a fourth read of the output FIFO retrieves the next 50-bits of block 2 (the remaining bits of this 64 bits are set to zero). If GSM = 0, 228 contiguous bits can be read with successive reads of the output FIFO. In this case, the core application is responsible for handling the A5/3 block formatting. **Note:** If GSM = 1 and EDGE = 1, an error interrupt is generated.	0 GSM A5/3 blocks not selected 1 GSM A5/3 blocks selected
CICV 6	0	**Compare Integrity Check Values** If set, selects integrity check comparison. If the ICVs do not match, an error interrupt is sent to the channel. This field is valid only when the ALG field is set to a function that uses F9.	0 Normal operation; no ICV comparison. 1 After the ICV is computed, compare it to the data in the KEU ICV_In register.
EDGE 5	0	**Select EDGE A5/3 Blocks** EDGE A5/3 requires that two 348-bit blocks be produced for every 4.615 mS slot. If EDGE = 1, the first five reads of the output FIFO retrieve the first 320-bits of block 1. The sixth read of the output FIFO retrieves the final 28-bits of block 1 (the remaining bits of the sixth 64-bit set are set to zero). The next five reads of the output FIFO retrieve the first 320-bits of block 2. The following read of the output FIFO retrieves the final 28-bits of block 2 (the remaining bits of this 64-bit set are set to zero). If EDGE = 0, 696 contiguous bits can be read with successive reads of the output FIFO. In this case the core application is responsible for handling the A5/3 block formatting. **Note:** If EDGE = 1 and GSM = 1, an error interrupt is generated.	0 EDGE A5/3 blocks not selected 1 EDGE A5/3 blocks selected
PE 4	0	**Process End_of_Message** Enables final processing of last message block fir F9 only. **Note:** The PE bit should be set for F9 operations if the 3G frame (or message) is processed as a whole (not split across multiple descriptors). If the frame is processed across multiple descriptors, this bit should only be set on the descriptor performing F9 processing on the final message block.	0 Prevent final block processing (message incomplete) 1 Enable final block processing (message complete)

Table 27-112. KEUMR Field Descriptions (Continued)

Name	Reset	Description	Settings
INT 3	0	**Initialization** Enables initialization for a new message. **Note:** Set this bit for F8 or F9 operations if the 3G frame (or message) is being processed through a single descriptor. If the frame is split across multiple descriptors, this bit should only be set in the descriptor that processes the first block of the message.	0 Prevent Initialization 1 Enable Initialization
— 2	0	Reserved. Write to zero for future compatibility.	
ALG 1–0	0	**Algorithm Selection** Specifies the functions to perform.	00 Perform F8 function only 01 reserved 10 Perform F9 function only 11 reserved

27.7.12.2 KEU Key Size Register (KEUKSR)

KEUKSR — KEU Key Size Register — Offset 0xCE008

Field	—				Data Size											
Type	R/W															
Reset	0x0000															

The KEU Data Size Register (KEUDSR) stores the number of bits to process in the final 8 message bytes. Because Kasumi allows for bit level granularity for encryption/decryption, there are no illegal data sizes. The proper bit length of the message must be written to notify the KEU of any padding performed by the core. This register is cleared when the KEU is reset or reinitialized. Writing to this register signals the KEU to start processing data from the input FIFO as soon as it is available. If the value of data size is modified during processing, a context error is generated.

27.7.12.4 KEU Reset Control Register (KEURCR)

KEURCR — KEU Reset Control Register — Offset 0xCE018

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the KEU Interrupt Mask Register is zero (see **Section 27.6.6.7**, *KEU Interrupt Mask Register*, on page 27-80).

If the KEU Interrupt Status Register is non-zero, the KEU halts and the KEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189). In addition, if the KEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU

error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the KEURCR[RI] bit (see **Section 27.7.12.4**, *KEU Reset Control Register (KEURCR)*, on page 27-282).

The definition of each bit in the KEU Interrupt Status Register is listed in **Table 27-115**.

Table 27-115. KEUISR Field Descriptions

Name	Reset	Description	Settings
— 63–15	0	Reserved. Write to zero for future compatibility.	
ICE 14	0	**Integrity Check Error** If set, indicates that an ICV check was performed on an F9 result and that the supplied ICV did not match the value computed by the KEU.	0 No error detected. 1 Integrity check error.
— 13	0	Reserved. Write to zero for future compatibility.	
IE 12	0	**Internal Error** Indicates whether an internal processing error was detected while the KEU was processing. **Note:** This bit is set any time an enabled error condition occurs. It can only be cleared by setting the corresponding bit in the KEUIMR or by resetting the KEU.	0 No internal error detected. 1 Internal error.
ERE 11	0	**Early Read Error** Indicates whether a KEU context or IV register was read while the KEU was processing.	0 No early read error detected. 1 Early read error.
CE 10	0	**Context Error** If set, indicates that KEU key register, the Key Size Register, Data Size Register, Mode Register, or IV register was modified while the KEU was processing.	0 No context error detected. 1 Context error.
KSE 9	0	**Key Size Error** IF set, indicates that an inappropriate value (not 16 or 32) was written to the KEU Key Size Register.	0 No key size error detected. 1 Key size error.
DSE 8	0	**Data Size Error** If set, a value greater than 64 bits was written to the KEU Data Size Register.	0 No data size error detected. 1 Data size error.
DE 7	0	**Data Error** If set, indicates that invalid data was written to a register or that a reserved mode bit was set.	0 Valid data. 1 Reserved or invalid mode selected.
AE 6	0	**Address Error** If set, an illegal read or write address was detected within the KEU address space.	0 No address error detected. 1 Address error detected.
OFE 5	0	**Output FIFO Error** If set, the KEU output FIFO was detected non-empty upon write of KEU Data Size Register.	0 No output FIFO error detected. 1 Output FIFO non-empty error.

Table 27-115. KEUISR Field Descriptions (Continued)

Name	Reset	Description	Settings
IFE 4	0	**Input FIFO Error** If set, the KEU input FIFO was detected non-empty upon generation of a done interrupt.	0 No input FIFO error detected. 1 Input FIFO non-empty error.

The KEU Interrupt Mask register controls the result of detected errors. For a given error (as defined in **Section 27.6.6.6**, *KEU Interrupt Status Register*, on page 27-79), if the corresponding bit in this register is set, then the error is ignored; no error interrupt occurs and the KEU Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the KEU Interrupt Status Register is updated to reflect the error, causing

assertion of the error interrupt signal, and causing the module to halt processing. The definition of each bit in the KEU Interrupt Mask Register is listed in **Table 27-116**.

Table 27-116. KEUIMR Field Descriptions

Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	KEU Data Out (F9 MAC)															
Type	R															
Reset	0x0000															

Following a done interrupt, the read-only KEUDOR holds the F9 message authentication code. A 64-bit value is returned. This value can be truncated to 32 bits for some applications. Writing to this location results in an address error being reflected in the KEUISR.

Note: According to the ETSI/SAGE 3GPP specification for F9 (version 1.2), only 32 bits of the final MAC are used. This is the lower 4 bytes of the KEUDOR.

27.7.12.9 KEU End_of_Message Register (KEUEOMR)

KEUEOMR — KEU End_of_ Message Register — Offset 0xCE050

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Field	—															
Type	W															
Reset	0x0000															

The KEU End_of_Message Register (KEUEOMR) is used to signal to the KEU that the final message block is written to the input FIFO. Writing to this register causes the KEU to process the final block of a message, allowing it to signal a done interrupt. When processing the last block, the value in the Data Size Register determines how many bits of the final message word (1–64) are processed. The value written to this register has no significance. A read of this register always returns a zero value.

27.7.12.10 KEU IV1 Register (KEUIV1R)

KEUIV1R — KEU IV1 Register — Offset 0xCE100

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	CE															
Type	R/W															
Reset	0x0000															

KEU IV1R is a general-purpose IV register used during the initialization phase of F8 algorithms for 3GPP, GSM A5/3, EDGE A5/3, and GPRS GEA3 and for the F9 algorithm for 3GPP. The appropriate value, as defined by the standards for each algorithm, must be written before a new message is started. Once the initialization phase is completed, the KEU IV1 register is not used for the remainder of F8 or F9 processing. However, if 3GPP F9 is selected, the KEU IV_1 register MUST be written back during context switches to complete the generation of the 3GPP MAC, because the KEU IV_1 register contains the Direction bit as defined by the 3GPP standard.

Table 27-117. KEUIV1R Field Descriptions

Name	Reset	Description	Settings for Protocol			
			3GPP	GSM-A5/3	EDGE-A5/3	GPRS-GEA3
CE 63–48	0	**CE Value** Specifies the CE variable value.	0x0000	0x0000	0x0000	0x0000
CA 47–41	0	**CA Value** Specifies the CA variable value.	00000000	00001111	11110000	11111111
— 40–39	0	Reserved. Write to zero for future compatibility.				
CD 38	0	**CD Value** Specifies the CD variable value.	Direction bit	0	0	0
CB 37–32	0	**CB Value** Specifies the CB variable value.	Bearer	00000	00000	00000
CC 31–0	0	**CC Value** Specifies the CC variable value.	Count	Count	0000000000|| Count	Frame-dependent value (32 bits)

Note: The user must ensure that fields of the KEUIV1 register are programmed correctly in accordance with the selected algorithm.

27.7.12.11 KEU ICV_In Register (KEUICVIR)

KEUICVIR — KEU ICV_In Register — Offset 0xCE108

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	ICV_In															
Type	R															
Reset	0x0000															

Bits	47	46	45	44	43	42	41	40	39	38	37	36	35	34	33	32

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	—															
Type	R/W															
Reset	0x0000															

The KEUIV2R hold the FRESH value that is used during the initialization phase of the 3GPP F9 algorithm. This value is ignored when the F8 algorithm is selected. The FRESH value must be written before starting a new message to be processed with 3GPP F9. Once the initialization phase is completed, KEUIV2R is not used during message processing. KEUIV2R does not need to be written during context switches. FRESH is a 32-bit value that occupies the upper half of the register.

27.7.12.13 KEU Context 1–6 Registers (KEUCR[1–6])

KEUCR1	KEU Context Registers	Offset 0xCE118
KEUCR2		Offset 0xCE120

Field	Context															
Type	R/W															
Reset	0x0000															

There are six 64-bit KEU context data registers that allow the core to read/write the contents of the context used to process the message. The KEUCDRs must be read when changing context and restored to their original values to resume processing an interrupted message. For F8 and 3GPP F9 modes, all 6 64-bit KEUCDRs must be read to retrieve context, and all 6 must be written back to restore context. The context must be written prior to the key data. If the any of the KEU context data registers are written during message processing, a context error is generated. All KEUCDRs are cleared when a hard/soft reset or initialization is performed.

Note: In typical operation, a frame is received and processed in its entirety, with the KEU performing session specific initialization using the contexts of KEU IV_1 and IV_2 registers. The KEU Context Data and IV_1 registers should only be unloaded/reloaded when the processing of a frame is discontinued prior to completion, then processing is resumed.

27.7.12.14 KEU Key Data Registers 1–2 (KEUKDR[1–2])

KEUKDR1 KEU Key Data Registers 1–2 Offset 0xCE400
KEUKDR2 Offset 0xCE408

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	CK															
Type	W

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	CK															
Type	W															
Reset	0x0000															

The first two KEU Key Data Registers together hold one 128-bit key that is used for F8 encryption/decryption. KEUKDR1 (CK-high) holds the first 8 bytes (1–8). KEUKDR2 (CK-low) holds the second 8 bytes (9–16). The KEU Key Data Registers must be written before message processing begins and cannot be written while the block is processing data, or a context error occurs. Reading from either of these registers results in an address error being reflected in the KEUISR.

27.7.12.15 KEU Key Data Registers 3–4 (KEUKDR[3–4])

KEUKDR3 KEU Key Data Registers 3–4 Offset 0xCE410
KEUKDR4 Offset 0xCE418

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	IK															
Type	W															
Reset	0x0000															

The KEUKDR[3–4] together hold one 128-bit key used for F9 message authentication. KEUKDR3 (IK-high) holds the first 8 bytes (1–8). KEUKDR4 (IK-low) holds the second 8 bytes (9–16). The KEU Key Data Registers must be written before message processing begins and cannot be written while the block is processing data, or a context error occurs.

If the ‘F9 only’ mode is set, the integrity key data can be optionally written to KEUKDR[1–2]. This eliminates the need for the core to offset from the base key address to write to KEUKDR[3–4] while using the KEU exclusively for the F9 integrity function. Reading from either of these registers results in an address error being reflected in the KEUISR.

27.7.12.16 KEU Input FIFO/Output FIFO

The KEU uses an input FIFO/output FIFO pair to hold data before and after the encryption process. Normally, the channels control all access to these FIFOs. For core-controlled operation, a write to anywhere in the KEU FIFO address space enqueues data to the KEU input FIFO, and a read from anywhere in the KEU FIFO address space dequeues data from the KEU output FIFO.

Writes to the input FIFO go first to a staging register which can be written by byte, 4-byte, or 8-byte accesses. When all 8 bytes of the staging register are written, the entire 8-bytes is automatically enqueued into the FIFO. If any byte is written twice between enqueues, it causes an error interrupt of type AE from the EU. When writing the last portion of data, it is not necessary to write all 8 bytes. Any last bytes remaining in the staging register are automatically padded with zeros and forced into the input FIFO when the KEU End_of_Message Register is written.

The output FIFO is readable by byte, 4-byte, or 8-byte accesses. When all 8 bytes of the header are read, that 8 bytes is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Overflows and underflows caused by reading or writing the KEU FIFOs are reflected in the KEU Interrupt Status Register.

The KEU fetches data 64 bits at a time from the KEU Input FIFO. During F8 processing, the input data is XORed with the generated keystream and the results are placed in the KEU Output FIFO. During F9 processing, the input data is hashed with the integrity key and the resulting MAC is placed in the KEU data out register. The output size is the same as the input size.

Note: The KEU input FIFO and output FIFO are located at offset 0xCE800–0xCEFFF.

27.7.13 CRCU Registers

27.7.13.1 CRCU Mode Register (CRCUMR)

CRCUMR — CRCU Mode Register — Offset 0xCF000

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Type	R/W															
Reset	0x0000															

The CRCU Mode Register (CRCUMR) contains several bits used to program the CRCU and is generally the first register written. The Mode Register is cleared when the CRCU is reset or reinitialized. Setting a reserved mode bit generates a data error. If the CRCU Mode Register is

modified during processing, a context error is generated. **Table 27-118** describes the CRCU Mode Register bit fields.

Table 27-118. CRCUMR Field Descriptions

Name	Reset	Description	Settings
— 63–7	0	Reserved. Write to zero for future compatibility.	
CICV 6	0	**Compare Integrity Check Values** If set, selects integrity check comparison, which compares the CRC calculated across the message and received ICV against the stored residue. The comparison is performed prior to the bit manipulations controlled by the DOS and DOC bits.	0 Comparison disabled. 1 Enable ICV check.
— 5	0	Reserved. Write to zero for future compatibility.	
DOC 4	0	**Disable Output Complement** The normal processing includes complementing the CRC result.	0 Normal operation. CRC result is complemented. 1 Disable output complement.
DOS 3	0	**Disable Output Swap** The normal processing includes a bit swap and byte swap of the result CRC.	0 Normal operation. CRC result is bit-swapped and byte-swapped. 1 Disable output swapping.
DIS 2	0	**Disable Input Swap** The normal processing includes a bit swap and byte swap of the input data.	0 Normal operation. Input data is bit-swapped and byte-swapped. 1 Disable input swapping.
ALG 1–0	0	**Algorithm Selection** Specifies the CRC algorithm for the CRCU.	00 **IEEE** Std. 802 mode. The CRC32 algorithm is performed using the polynomial 0x04C11DB7 and the residue 0xC704DD7B is used for ICV checking. 01 iSCSI mode. The CRC32 algorithm is performed using the polynomial 0x1EDC6F41 and the residue 0x1C29D19ED is used for ICV checking. 10 Static custom mode. The CRC remainder is computed using the Control Register bits 31–0 as the polynomial and the bits 63–32 as the residue. 11 Dynamic custom mode. The CRC remainder is computed using the Key Register bits 31–0 as the polynomial and bits 63–32 as the residue.

27.7.13.2 CRCU Key Size Register (CRCUKSR)

CRCUKSR — CRCU Key Size Register — Offset 0xCF008

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	—				Key Size											
Type	R/W															
Reset	0x0000															

The CRCU Key Size Register (CRCUKSR) stores the number of bytes in the dynamic polynomial written to the CRCU Key Register (see **Section 27.7.13.12**). This register is cleared when the CRCU is reset or reinitialized. If a key size other than zero, four, or eight is written to it, an illegal key size error is generated. Because the polynomial size is clearly defined by the selected algorithm, it is not necessary to write to this register. A context error is generated if this register is written after processing begins.

27.7.13.3 CRCU Data Size Register (CRCUDSR)

CRCUDSR CRCU Data Size Register Offset 0xCF010

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—

Reset	0x0000															

The CRCU Reset Control Register (CRCURCR) controls the reset/reinitialization of the block:

Table 27-119. CRCURCR Field Descriptions

Name	Reset	Description	Settings
— 63–3	0	Reserved. Write to zero for future compatibility.	
RI 2	0	**Reset Interrupts** Setting this bit causes CRCU interrupts signalling done and error to reset. It further resets the CRCU Interrupt Status Register (CRCUISR).	0 Do not reset. 1 Reset interrupt logic.
MI 1	0	**Module Initialization** Module initialization is almost the same as a software reset except that the CRCU Interrupt Mask Register remains unchanged. Completion of the initialization is indicated by the CRCUSR[RD] bit (see **Section 27.7.13.6**, *CRCU Status Register (CRCUSR),* on page 27-302).	0 Do not initialize. 1 Initialize CRCU.
SR 0	0	**Software Reset** Setting this bit is functionally equivalent to a hardware reset (asserting the $\overline{\text{HRESET}}$ pin), but the reset is restricted to the CRCU. When the bit clears, the CRCU enters a routine that initializes the parameter memories. Completion of the initialization is indicated by the CRCUSR[RD] bit (see **Section 27.7.13.6**, *CRCU Status Register (CRCUSR),* on page 27-302).	0 Do not reset. 1 Full CRCU reset.

The Control Register stores the static polynomial and residue used in custom CRC computations. This register is static, in that it is reset by performing a software reset, not by an EU reinitialize. This allows a platform-specific custom polynomial to be written to the register once and used many times. A context error is generated if this register is written after processing begins. A polynomial error is generated if a value is written to this register which does not have a one in bit g^0.

Note: The default reset value is the **IEEE** 802 standard CRC32 residue coefficient r and polynomial coefficient g.

Table 27-120 indicates the bit position of each of the coefficients.

Table 27-120. CRCUCR Field Descriptions

Name	Reset	Description
r^{31}–r^0 63–32	1	**Residue Coefficient Bit Positions 31–0**
g^{31}–g^0 31–0	1	**Polynomial Coefficient Bit Positions 31–0** **Note:** The value of g^0 must be 1.

The CRCU Status Register (CRCUSR) is a read-only register that provides general information about the status of the CRCU. Writing to this location is ignored.

Table 27-121. CRCUSR Field Descriptions

Name	Reset	Description	Settings
— 63–16	0	Reserved. Write to zero for future compatibility.	
IFL 15–8	1	**Input FIFO Length** The number of 8-byte sets currently in the input FIFO.	
— 7–6	0	Reserved. Write to zero for future compatibility.	
HALT 5	0	**Halt** Indicates whether the CRCU is halted due to an error. **Note:** Because the error causing the CRCU to stop operating can be masked before reaching the Interrupt Status Register, the CRCU Interrupt Status Register is used to provide a second source of information regarding errors that prevent normal operation.	0 CRCU not halted 1 CRCU halted (must be reset/reinitialized)
ICCR 4–3	0	**Integrity Check Comparison Result** A passed or failed result is generated only if ICV checking is enabled and the selected algorithm is F9.	00 No integrity check performed. 01 Integrity check comparison passed. 10 Integrity check comparison failed. 11 Reserved.
EI 2	0	**Error Interrupt** This status bit reflects the state of the error interrupt signal, as sampled by the controller Interrupt Status Register (**Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189).	0 CRCU is not signaling error 1 CRCU is signaling error

Table 27-121. CRCUSR Field Descriptions (Continued)

Name	Reset	Description	Settings
DI 1	0	**Done Interrupt** This status bit reflects the state of the done interrupt signal, as sampled by the controller Interrupt Status Register (**Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189).	0 CRCU is not signaling done 1 CRCU is signaling done
RD 0	0	**Reset Done** This status bit, when high, indicates that the RNGU has completed its reset sequence. **Note:** The reset value of RD is 0, but it typically switches to 1 by the time a user checks the register, indicating the EU is ready for operation.	0 Reset in progress. 1 Reset done.

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the CRCU Interrupt Mask Register is zero (see **Section 27.7.13.8**, *CRCU Interrupt/Error Mask Register (CRCUIMR)*, on page 27-305).

If the CRCU Interrupt Status Register is non-zero, the CRCU halts and the CRCU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189). In addition, if the CRCU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller.

If the Interrupt Status Register is written from the core, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the Interrupt Mask Register. All other bits are cleared. All bits in this register except the IE bit can also be cleared by setting the CRCURCR[RI] bit (see **Section 27.7.13.4**, *CRCU Reset Control Register (CRCURCR)*, on page 27-300). The IE bit can only be cleared by resetting/initializing the CRCU.

The definition of each bit in the CRCU Interrupt Status Register is listed in **Table 27-122**.

Table 27-122. CRCUISR Field Descriptions

Name	Reset	Description	Settings
— 63–15	0	Reserved. Write to zero for future compatibility.	
ICE 14	0	**Integrity Check Error** If set, indicates that an ICV check was performed on an F9 result and that the supplied ICV did not match the value computed by the CRCU.	0 No error detected. 1 Integrity check error.
PE 13	0	**Polynomial Error** If set, indicates that an invalid polynomial was written to the CRCU Key Register or the CRCU Control Register.	0 No error detected. 1 Invalid polynomial error.
IE 12	0	**Internal Error** Indicates whether an internal processing error was detected while the CRCU was processing. **Note:** This bit is set any time an enabled error condition occurs. It can only be cleared by setting the corresponding bit in the CRCUIMR or by resetting the CRCU.	0 No internal error detected. 1 Internal error.
ERE 11	0	**Early Read Error** Indicates whether a CRCU context or IV register was read while the CRCU was processing.	0 No early read error detected. 1 Early read error.
CE 10	0	**Context Error** If set, indicates that the CRCU key register, the key size register, data size register, mode register, or IV register was modified while the CRCU was processing.	0 No context error detected. 1 Context error.
KSE 9	0	**Key Size Error** If set, indicates that an inappropriate value (not 16 or 32) was written to the CRCU Key Size Register.	0 No key size error detected. 1 Key size error.
DSE 8	0	**Data Size Error** If set, indicates one of the following three conditions: • A value that was not a multiple of 8 bits was written to the CRCU data size register • Data was written to the CRCU end-of-message register before writing to the CRCU data size register. • Data was written to the CRCU input FIFO before writing to the CRCU data size register.	0 No data size error detected. 1 Data size error.

Table 27-122. CRCUISR Field Descriptions (Continued)

Name	Reset	Description	Settings
DE 7	0	**Data Error** If set, indicates that invalid data was written to a register or that a reserved mode bit was set.	0 Valid data. 1 Reserved or invalid mode selected.
AE 6	0	**Address Error** If set, an illegal read or write address was detected within the CRCU address space.	0 No address error detected. 1 Address error detected.
— 5–3	0	Reserved. Write to zero for future compatibility.	
IFO 2	0	**Input FIFO Overflow** If set, the CRCUU input FIFO was pushed while full.	0 No input FIFO overflow error detected. 1 Input FIFO overflow error.
— 1–0	0	Reserved. Write to zero for future compatibility.

The CRCU Interrupt Mask register controls the result of detected errors. For a given error (as defined in **Section 27.7.13.7**, *CRCU Interrupt/Error Status Register (CRCUISR)*, on page 27-303), if the corresponding bit in this register is set, then the error is ignored; no error interrupt occurs and the CRCU Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the CRCU Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the

module to halt processing. The definition of each bit in the CRCU Interrupt Mask Register is listed in **Table 27-123**.

Table 27-123. CRCUIMR Field Descriptions

The CRCU End_of_Message Register (CRCUEOMR) is used to signal to the CRCU that the final message block is written to the CRCU. A write to this register is required to complete a CRC32 operation. The CRCU starts processing message data as soon as the CRCU data size register is written and data becomes available in the input FIFO, but it does not process a remaining partial word or perform an ICV check until a write to this register occurs. The written value is not used. Reading this register always returns 0.

27.7.13.11 CRCU Context Register (CRCUCXR)

CRCUCXR — CRCU Context Register — Offset 0xCF100

The CRCU context register contains the CRC result when processing is complete. The result is stored in the upper half of the register and the lower half is not used. The register can be written with an intermediate CRC result or desired initial state prior to processing any data. The reset state for the processing field is all 1s because this allows the CRC32 algorithm to detect bit errors in the leading zeros of a message. A context error is generated if this register is written after processing begins. An early read error is generated if this register is read while the module is busy. Actual manipulation of the data is determined by settings in the CRCU Mode Register (see **Section 27.7.13.1**)

Table 27-124. CRCUCXR Field Descriptions

The Key Register stores the polynomial and residue for the dynamic custom mode if selected by the CRCU Mode Register (see **Section 27.7.13.1**). This register is dynamic, in that it is reset by performing a reinitialize or a software reset. This allows a custom polynomial to be used for specific processing without changing the platform-specific static custom polynomial stored in the CRC Control Register (see **Section 27.7.13.5**). A residue does not need to be programmed unless ICV checking is being performed. A context error is generated if this register is written after processing begins. A polynomial error is generated if a value is written to this register which does not have a one in bit g^0. **Table 27-125** indicates the bit position of each of the coefficients.

Table 27-125. CRCUKR Field Descriptions

Name	Reset	Description
r^{31}–r^0 63–32	0	**Residue Bit Positions 31–0**
g^{31}–g^0 31–0	1	**Polynomial Bit Positions 31–0** **Note:** The value of g^0 must be 1.

27.7.13.13 CRCU Input FIFO

Words written to this address range are pushed onto the CRCU input FIFO, thereby buffering them for processing. Partial words and misaligned data can be written to this address and it is automatically realigned based on a big endian byte order.

The CRCU input FIFO is located at offset 0xCF800–0xCFFFF.

27.7.14 STEU Registers

27.7.14.1 STEU Mode Register (STEUMR)

STEUMR — STEU Mode Register — Offset 0xCD000

Field	—									CICV	—	PE	INT	ALG		
Type	R/W															
Reset	0x0000															

The STEU Mode Register (STEUMR) contains several bits used to program the STEU. The Mode Register is cleared when the STEU is reset or reinitialized. Selecting an undefined mode generates an illegal mode error. If the STEU Mode Register is modified during processing, a context error is generated. **Table 27-112** describes the STEU Mode Register bit fields.

Table 27-126. STEUMR Field Descriptions

Name	Reset	Description	Settings
— 63–7	0	Reserved. Write to zero for future compatibility.	
CICV 6	0	**Compare Integrity Check Values** If set, selects integrity check comparison. If the ICVs do not match, an error interrupt is sent to the channel. This field is valid only when the ALG field is set to a function that uses F9.	0 Normal operation; no ICV comparison. 1 After the ICV is computed, compare it to the data in the STEU ICV_In register.
— 5	0	Reserved. Write to zero for future compatibility.	
PE 4	0	**Process End_of_Message** Enables final processing of last message block for F9 only. **Note:** The PE bit should be set for F9 operations if the 3G frame (or message) is processed as a whole (not split across multiple descriptors). If the frame is processed across multiple descriptors, this bit should only be set on the descriptor performing F9 processing on the final message block.	0 Prevent final block processing (message incomplete) 1 Enable final block processing (message complete)

Table 27-126. STEUMR Field Descriptions (Continued)

Name	Reset	Description	Settings
INT 3	0	**Initialization** Enables initialization for a new message. **Note:** Set this bit for F8 or F9 operations if the 3G frame (or message) is being processed through a single descriptor. If the frame is split across multiple descriptors, this bit should only be set in the descriptor that processes the first block of the message.	0 Prevent Initialization 1 Enable Initialization
ALG 2–0	0	**Algorithm Selection** Specifies the functions to perform. Entry of any of the reserved modes generates an illegal mode error.	001 Perform F8 function only 010 Perform F9 function only All other values are reserved.

27.7.14.2 STEU Key Size Register (STEUKSR)

STEUKSR — STEU Key Size Register — Offset 0xCD008

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Field	Data Size in bits															
Type	R/W															
Reset	0x0000															

The STEU Data Size Register (STEUDSR) stores the number of bits to process. This value must be written prior to loading message data and after the STEU mode register is written. The STEU decrements the value in this register as it processes the message. The STEUDSR can be read at any time to determine the number of bits remaining to be processed. The STEU continues to process data until the value in the STEUDSR reaches 0. For F9 mode, the data size must be divisible by 64 when the STEUMR[PE] bit is set (see **Section 27.7.14.1**). Therefore, for multi-session processing, the message can only be split on 64-bit boundaries. Violating this rule generates an illegal data size error. If a 0 is written to the STEUDSR followed by a write to the STEUEOMR (see **Section 27.7.14.9**) or if the write to STEUEOMR occurs without writing the the STEUDSR, the STEU asserts a done interrupt signalling that processing is complete.

27.7.14.4 STEU Reset Control Register (STEURCR)

STEURCR — STEU Reset Control Register — Offset 0xCD018

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Field	—													CLI	RI	SR
Type	R/W															
Reset	0x0000															

The STEU Reset Control Register (STEURCR) determines the type of STEU reset as defined by the 3 self-clearing bits: Reading this register returns a 0.

Table 27-127. STEURCR Field Descriptions

Name	Reset	Description	Settings
— 63–3	0	Reserved. Write to zero for future compatibility.	
CLI 2	0	**Clear Interrupts** Setting this bit causes STEU interrupts clears the errors in the STEU Error Status Register and deasserts the error and done interrupt signals. The reset done signal is deasserted for one cycle following a CLI reset. This bit is self-clearing and also clears the EOM register and the ICV Error/Pass bits of the Status Register.	0 Do not clear interrupts/errors. 1 Clear interrupts/ errors.
RI 1	0	**Reinitialization** Setting this bit clears all registers except the Error Status Register. The bit is self-clearing and asserts the reset done interrupt when initialization is complete. Completion of the reinitialization is indicated by the STEUSR[RD] bit (see **Section 27.7.14.5**, *STEU Status Register (STEUSR),* on page 27-315).	0 No initialization. 1 Initialize STEU.
SR 0	0	**Software Reset** Setting this bit is functionally equivalent to a hardware reset (asserting the $\overline{\text{HRESET}}$ pin), but the reset is restricted to the STEU. The bit is self-clearing and asserts the reset done interrupt when initialization is complete. Completion of the reinitialization is indicated by the STEUSR[RD] bit (see **Section 27.7.14.5**, *STEU Status Register (STEUSR),* on page 27-315).	0 Normal operation. 1 Full STEU reset.

Type	R															
Reset	0x0000															

The STEU Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the STEU Interrupt Mask Register is zero (see **Section 27.7.14.7**, *STEU Interrupt Mask Register (STEUIMR),* on page 27-318).

If the STEU Interrupt Status Register is non-zero, the STEU halts and the STEU error interrupt signal is asserted to the controller (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189). In addition, if the STEU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4]),* on page 27-202) and generates a channel error interrupt to the controller.

To recover and start new processing after an error, the STEU must be reset (using the STEURCR[SR], see **Section 27.7.14.4**).

The definition of each bit in the STEU Interrupt Status Register is listed in **Table 27-115**.

Table 27-129. STEUISR Field Descriptions

Name	Reset	Description	Settings
— 63–15	0	Reserved. Write to zero for future compatibility.	
ICE 14	0	**Integrity Check Error** If set, indicates that an ICV check was performed on an F9 result and that the supplied ICV did not match the value computed by the STEU.	0 No error detected. 1 Integrity check error.
IM 13	0	**Illegal Mode Error** If set, indicates that an invalid value was written to the MODE field of the STEU Mode Register.	0 No error detected. 1 Illegal mode error.
IE 12	0	**Internal Error** Indicates whether an internal processing error was detected while the STEU was processing. **Note:** This bit is set any time an enabled error condition occurs. It can only be cleared by resetting the STEU.	0 No internal error detected. 1 Internal error.
ERE 11	0	**Early Read Error** Indicates whether a STEU context or LFSR/FSM State Register was read while the STEU was processing.	0 No early read error detected. 1 Early read error.
CE 10	0	**Context Error** If set, indicates that STEU Mode Register, Key Data Register, Data Size Register, or a Context Register was modified while the STEU was processing.	0 No context error detected. 1 Context error.
KSE 9	0	**Key Size Error** IF set, indicates that an illegal key size was written to the STEU Key Size Register.	0 No key size error detected. 1 Key size error.
DSE 8	0	**Data Size Error** If set, F9 mode selected and the PE bit in the Mode register is 0 and the data size is not a multiple of 64	0 No data size error detected. 1 Data size error.
— 7	0	Reserved. Write to zero for future compatibility.	
AE 6	0	**Address Error** If set, an illegal read or write address was detected within the STEU address space. **Note:** This error results from an access to an undefined address, or a write to the Status Register, or an illegal byte enable configuration for the accessed address. All STEU registers below offset 0x100 must be accessed as a whole (8 bytes) or in halves (lower 4 bytes or upper 4 bytes). All STEU registers above and including offset 0x100 can be accessed with any combination of byte enables.	0 No address error detected. 1 Address error detected.
OFE 5	0	**Output FIFO Error** If set, the STEU output FIFO was detected non-empty upon write of STEU Data Size Register.	0 No output FIFO error detected. 1 Output FIFO non-empty error.

Table 27-129. STEUISR Field Descriptions (Continued)

Name	Reset	Description	Settings
IFE 4	0	**Input FIFO Error** If set, the STEU input FIFO was detected non-empty upon generation of a done interrupt.	0 No input FIFO error detected. 1 Input FIFO non-empty error.
IFU 3	0	**EOM Before Input FIFO Write End Error** If set, the EOM was issued before all data is written to the STEU input FIFO.	0 No error detected. 1 Not all data written to the input FIFO.
IFO 2	0	**Input FIFO Overflow** If set, the STEU input FIFO was pushed while full.	0 No input FIFO overflow error detected. 1 Input FIFO overflow error.
OFU 1	0	**Output FIFO Underflow** If set, the STEU output FIFO was read while empty.	0 No output FIFO underflow error detected. 1 Output FIFO underflow error.
— 0	0	Reserved. Write to zero for future compatibility.	

27.7.14.7 STEU Interrupt Mask Register (STEUIMR)

STEUIMR — STEU Interrupt Mask Register — Offset 0xCD038

The STEU Interrupt Mask register controls the result of detected errors. For a given error (as defined in **Section 27.7.14.6**, *STEU Interrupt Status Register (STEUISR)*, on page 27-316), if the corresponding bit in this register is set, then the error is ignored; no error interrupt occurs and the STEU Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then upon detection of an error, the STEU Interrupt Status Register is updated to reflect the

error, causing assertion of the error interrupt signal, and causing the module to halt processing. The definition of each bit in the STEU Interrupt Mask Register is listed in **Table 27-116**.

Table 27-130. STEUIMR Field Descriptions

Name	Reset	Description	Settings
— 63–15	0	Reserved. Write to zero for future compatibility.

Type	R															
Reset	0x0000															

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Field	STEU Data Out (F9 MAC)															
Type	R															
Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	STEU Data Out (F9 MAC)															
Type	R															
Reset	0x0000															

STEUDOR is physically the same as the STEU Context Register 1, except that the STEUDOR can be read at any time, even during processing, while the context register can only be read after processing is complete. A write to the STEUDOR is ignored. Reading STEUDOR returns the contents of STEU Context Register 1 which is used to compute the MAC produced by F9 mode. Following a done interrupt, the read-only STEUDOR holds the F9 message authentication code. A 64-bit value is returned. If this register is read after processing is complete, the upper 32 bits are always equal to 0.

27.7.14.9 STEU End_of_Message Register (STEUEOMR)

STEUEOMR — STEU End_of_ Message Register — Offset 0xCD050

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	W

Field	—															
Type	W															
Reset	0x0000															

The STEU End_of_Message Register (STEUEOMR) is used to signal to the STEU that the final message block is written to the input FIFO. Writing to this register causes the STEU to process the remaining data in the input FIFO and generate a done interrupt. The value written to this register has no significance. A read of this register always returns a zero value.

27.7.14.10 STEU IV1 Register (STEUIV1R)

STEUIV1R STEU IV1 Register Offset 0xCD100

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	CC															
Type	R/W

Field	—															
Type	R/W															
Reset	0x0000															

STEU IV1R is used during the initialization phase of both F8 confidentiality and F9 integrity algorithms. STEU IV1R must be written before processing of a new message begins. Once the initialization phase is completed, STEU IV1R is no longer used in normal processing of F8 or F9 modes.

Although this register is generally considered to be a context register, it does not need to be saved/restored during context switching in multi-session message processing. As with context registers, any byte of this register can be enabled or disabled during accesses.

Table 27-131. STEUIV1R Field Descriptions

Name	Reset	Description	Settings
CC 63–32	0	**Frame Independent Input Count** Stores the input count.	
CB 31–27	0	**Bearer Identity** Specifies the bearer identity.	
CD 26	0	**Direction** Specifies the message direction.	0 Inbound, decrypt 1 Outbound, encrypt
— 25–0	0	Reserved. Write to zero for future compatibility.	

Note: The user must ensure that fields of the STEUIV1 register are programmed correctly in accordance with the selected algorithm.

27.7.14.11 STEU ICV_In Register (STEUICVIR)

STEUICVIR — STEU ICV_In Register — Offset 0xCD108

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48
Field	—															
Type	R

There are four 64-bit STEU context data registers that are used in F9 processing. These allow the core to interrupt F9 message processing and to resume at a later time. The Context Registers must be read when changing context and restored to their original values prior to resuming processing of an interrupted message. If the any of the STEU Context Registers is written during message processing, a Context Error is generated. All STEU Context Registers are cleared when a hard/soft reset or initialization is performed.

27.7.14.17 STEU LFSR State Registers 0–7 (STEULFSRSR[0–7])

The STEU Key Data Registers together hold one 128-bit key that is used for initialization. STEUKDR1 (KEY-H) holds the upper 8 bytes of key data. STEUKDR2 (KEY-L) holds the lower 8 bytes. The STEU Key Data Registers must be written before message processing begins and cannot be written while the block is processing data, or a context error occurs. Reading from either of these registers always returns 0.

27.7.14.21 STEU Input FIFO/Output FIFO

STEU uses an input FIFO/output FIFO pair to hold data before and after processing. Normally, the channels control all access to these FIFOs. For core-controlled operation, a write to any area in the STEU FIFO address space enqueues data to the input FIFO, and a read from any area in the STEU FIFO address space dequeues data from the output FIFO.

Writes to the input FIFO go first to a staging register that supports 8-bit, 32-bit, or 64-bit accesses. When all 8 bytes of the staging register are written, the entire 8 bytes is automatically enqueued into the FIFO. If any byte is written twice between enqueues, an Address Error results. When writing the last portion of data, it is not necessary to write all 8 bytes. Any remaining input bytes in the staging register are automatically padded with zeros and forced into the input FIFO when the STEU End of Message Register is written.

The output FIFO supports 8-bit, 32-bit, or 64-bit read accesses. When all 8 bytes of the head 64-bit access are read, that 64-bit access is automatically dequeued from the FIFO so that the next 64 bits (if any) becomes available for reading. If any byte is read twice between dequeues, an Address Error results.

Overflows and underflows caused by reading or writing the STEU FIFOs are reflected in the STEU Interrupt Status Register. The STEU fetches data 64 bits at a time from the input FIFO. During F8 processing, the input data is XORed with the generated keystream and the results are placed in the output FIFO. The output size is the same as the input size. During F9 processing, the input data is hashed with the integrity key and the resulting MAC is placed in the Data Out Register.

The STEU input FIFO and output FIFO are located at offset 0xCD800–0xCDFFF.

27.7.15 RNGU Registers

27.7.15.1 RNGU Mode Register (RNGMR)

RNGMR — RNGU Mode Register — Offset 0xCA000

Reset	0x0000															

The RNGU Data Size Register is used to tell the RNGU to begin generating random data. The actual content of the Data Size Register does not affect the operation of the RNGU. After a reset and prior to the first write of data size, the RNGU builds entropy without pushing data onto the FIFO. Once the Data Size Register is written, the RNGU begins pushing data onto the FIFO. Eight bytes (64 bits) of data is pushed onto the FIFO every 112 cycles until the FIFO is full. The RNGU then attempts to keep the FIFO full.

27.7.15.3 RNGU Reset Control Register (RNGRCR)

RNGRCR — RNGU Reset Control Register — Offset 0xCA018

Type	R/W															
Reset	0x0000															

The RNGRCR contains three reset options specific to the RNGU. 27-132 describes RNGRCR fields.

Table 27-132. RNGRCR Field Descriptions

Name	Reset	Description	Settings
— 63–3	0	Reserved. Write to zero for future compatibility.	
RI 2	0	**Reset Interrupt** Setting this bit causes RNGU interrupts signalling done and error to reset. It further resets the state of the RNGU Interrupt Status Register.	0 No reset. 1 Reset interrupt logic.
MI 1	0	**Module Initialization** Setting this reinitializes the RNGU to accept another request without forcing the internal control machines and the output FIFO to reset, which would invalidate stored random numbers or require reinvocation of a warm-up period. Module initialization is almost the same as a software reset except that the Interrupt Mask Register remains unchanged.	0 No reset 1 Reset most of RNGU
SR 0	0	**Software Reset** Setting this bit is functionally equivalent to a hardware reset (asserting the $\overline{\text{HRESET}}$ pin), but the reset is restricted to the RNGU. All registers and internal states are returned to the defined reset state.	0 No reset 1 Full RNGU reset.

27.7.15.4 RNGU Status Register (RNGSR)

RNGSR — RNGU Status Register — Offset 0xCA028

Bits	63	62	61	60	59	58	57	56	55	54	53	52	51	50	49	48

Reset	0x0000															

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	—										HALT	—		EI	DI	RD
Type	R															
Reset	0x0000															

This RNGSR contains 5 fields that reflect the state of the RNGU internal signals. The RNGSR is read-only. Writing to this location results in an address error being reflected in the RNGISR. **Table 27-133** describes RNGSR fields.

Table 27-133. RNGSR Field Descriptions

Name	Reset	Description	Settings
— 63–24	0	Reserved. Write to zero for future compatibility.	
OFL 23–16	1	**Output FIFO Length** The number of 8-byte sets currently in the output FIFO.	
— 15–6	0	Reserved. Write to zero for future compatibility.	
HALT 5	0	**Halt** Indicates whether the RNGU is halted due to an error. **Note:** Because the error causing the RNGU to stop operating can be masked before reaching the Interrupt Status Register, the RNGU Interrupt Status Register is used to provide a second source of information regarding errors that prevent normal operation.	0 RNGU not halted 1 RNGU halted
— 4–3	0	Reserved. Write to zero for future compatibility.	
EI 2	0	**Error Interrupt** This status bit reflects the state of the error interrupt signal, as sampled by the controller Interrupt Status Register (**Section 27.7.4.6**, *Controller Interrupt Status Register (CISR),* on page 27-189).	0 RNGU is not signaling error 1 RNGU is signaling error

Table 27-133. RNGSR Field Descriptions (Continued)

Name	Reset	Description	Settings
DI 1	0	**Done Interrupt** This status bit, when high, reflects the state of the done interrupt signal as sampled by the Controller Interrupt Status Register (see **Section 27.7.4.6**, *Controller Interrupt Status Register (CISR)*, on page 27-189 for details).	0 No done interrupt. 1 RNGU signalling done.
RD 0	0	**Reset Done** This status bit, when high, indicates that the RNGU has completed its reset sequence. **Note:** The reset value of RD is 0, but it typically switches to 1 by the time a user checks the register, indicating the EU is ready for operation.	0 Reset in progress. 1 Reset done.

27.7.15.5 RNGU Interrupt Status Register (RNGISR)

RNGISR — RNGU Interrupt Status Register — Offset 0xCA030

The Interrupt Status Register indicates which unmasked errors have occurred and have generated error interrupts to the channel. Each bit in this register can only be set if the corresponding bit of the RNGU Interrupt Mask Register is zero (see **Section 27.6.9.6**, *RNGU Interrupt Mask Register*, on page 27-95). If the RNGU Interrupt Status Register is non-zero, the RNGU halts and the RNGU error interrupt signal is asserted to the controller (see **Section 27.6.9.5**, *RNGU Interrupt Status Register*, on page 27-94). In addition, if the RNGU is being operated through channel-controlled access, then an interrupt signal is generated to the channel to which this EU is assigned. The EU error bit is set in the Channel Status Register (see **Section 27.7.6.2**, *Channel Status Registers (CSR[1–4])*, on page 27-202) and generates a channel error interrupt to the controller. If the Interrupt Status Register is written from the core processor, 1s in the value written are recorded in the Interrupt Status Register if the corresponding bit is unmasked in the

Interrupt Mask Register. All other bits are cleared. This register can also be cleared by setting the RI bit of the RNGU Reset Control Register. **Table 27-134** describes RNGISR fields.

Table 27-134. RNGISR Field Descriptions

Name	Reset	Description	Settings
— 63–13	0	Reserved. Write to zero for future compatibility.	
IE 12	1	**Internal Error** An internal processing error was detected while generating random numbers.	0 No internal error detected. 1 Internal error.
— 11–8	0	Reserved. Write to zero for future compatibility.	
ME 7	0	**Mode Error** An illegal value was detected in the Mode Register.	0 Valid data. 1 Invalid data error.
AE 6	0	**Address Error** An illegal read or write address was detected within the RNGU address space.	0 No address error detected. 1 Address error detected.
— 5–2	0	Reserved. Write to zero for future compatibility.	
OFU 1	0	**Output FIFO Underflow** RNGU Output FIFO was read while empty.	0 No output FIFO underflow error detected. 1 Output FIFO underflow error detected.
— 0	0	Reserved. Write to zero for future compatibility.	

27.7.15.6 RNGU Interrupt Mask Register (RNGIMR)

RNGIMR — RNGU Interrupt Mask Register — Offset 0xCA038

The RNGU Interrupt Mask Register controls the result of detected errors. For a given error (as defined in **Section 27.6.9.5**, *RNGU Interrupt Status Register*, on page 27-94), if the corresponding bit in this register is set, then the error is disabled; no error interrupt occurs, and

the Interrupt Status Register is not updated to reflect the error. If the corresponding bit is not set, then, upon detection of an error, the Interrupt Status Register is updated to reflect the error, causing assertion of the error interrupt signal, and causing the module to halt processing. **Table 27-135** describes RNGU Interrupt Status Register fields.

Table 27-135. RNGIMR Field Descriptions

Name	Reset	Description	Settings
— 63–13	0	Reserved. Write to zero for future compatibility.

The RNGU End_of_message is a writable location but serves no function in the RNGU. It is documented for the sake of consistency with the other EUs.

27.7.15.8 RNGU Entropy Registers 0–7 (RNGER[0–7])

The RNGU allows the user to input Entropy into the PRNG algorithm to modify the randomness of the RNGU. This group of registers are write only and all writes to these registers are ignored when the RNGU is busy. However, when the RNGU is IDLE (FIFO is full or RNGU has not yet been started), all data written to these registers is used to modify the internal XKEY structure. These registers cannot be written back to back, there must be a clock cycle in between writes, so that the RNGU can process all 64-bits of data, because the RNGU processes only 32-bits per cycle. The eight 8-byte Entropy Registers 0–7 are located from offset 0xCA400 to 0xCA43F.

27.7.15.9 RNGU Output FIFO

RNGU uses an output FIFO to collect periodically sampled random 64-bit-words, with the intent that random data always be available for reading. Normally, the channels control all access to this FIFO.

Note: For core processor-controlled operation, a read from anywhere in the RNGU FIFO address space dequeues data from the RNGU output FIFO. Such reads should be performed on an 8-byte basis regardless of the number of random number bits required. Partial reads by the core processor can leave the RNGU FIFO in a state that results in a channel error.

The output FIFO is readable by byte, 4-byte, or 8-byte accesses. When the first 8 bytes are read, that 8 bytes is automatically dequeued from the FIFO so that the next 8 bytes (if any) becomes available for reading. If any byte is read twice between dequeues, it causes an error interrupt of type AE from the EU.

Underflows caused by reading or writing the RNGU output FIFO are reflected in the RNGU Interrupt Status Register. Also, a write to the RNGU output FIFO space is reflected as an addressing error in the RNGU Interrupt Status Register.

Note: The RNGU output FIFO is located at offset 0xCA800–0xCAFFF.
